Junos® OS MPLS Applications Feature Guide

The information in this document is current as of the date on the title page.

YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at https://support.juniper.net/support/eula/. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

About the Documentation

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at https://www.juniper.net/documentation/.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at https://www.juniper.net/books.

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

   For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

   ```
   system {
     scripts {
       commit {
         file ex-script.xsl;
       }
     }
   }
   interfaces {
     fxp0 {
       disable;
       unit 0 {
         family inet {
           address 10.0.0.1/24;
         }
       }
     }
   }
   ```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

   ```
   [edit]
   user@host# load merge /var/tmp/ex-script.conf
   load complete
   ```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

   For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

   ```
   commit {
     file ex-script-snippet.xsl; }
   ```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see CLI Explorer.

Documentation Conventions

Table 1 on page lv defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page lvi defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the **configure** command: user@host> **configure**
`Fixed-width text like this`	Represents output that appears on the terminal screen.	`user@host>` **show chassis alarms** `No alarms currently active`
Italic text like this	• Introduces or emphasizes important new terms. • Identifies guide names. • Identifies RFC and Internet draft titles.	• A policy *term* is a named structure that defines match conditions and actions. • *Junos OS CLI User Guide* • RFC 1997, *BGP Communities Attribute*
Italic text like this	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# **set system domain-name** *domain-name*
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	• To configure a stub area, include the **stub** statement at the **[edit protocols ospf area area-id]** hierarchy level. • The console port is labeled **CONSOLE**.
< > (angle brackets)	Encloses optional keywords or variables.	**stub <default-metric** ***metric*****>;**
| (pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	**broadcast | multicast** **(*string1* | *string2* | *string3*)**
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	**rsvp { # Required for dynamic MPLS only**
[ ] (square brackets)	Encloses a variable for which you can substitute one or more values.	**community name members [** ***community-ids*** **]**

Indention and braces ({ })	Identifies a level in the configuration hierarchy.	[edit]
		routing-options {
		  static {
		  route default {
		  nexthop *address*;
		  retain;
		  }
		  }
		}

; (semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

Table 2: Text and Syntax Conventions (continued)

Convention	Description	Examples
GUI Conventions		
Bold text like this	Represents graphical user interface (GUI) items you click or select.	• In the Logical Interfaces box, select **All Interfaces**. • To cancel the configuration, click **Cancel**.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select **Protocols>Ospf**.

Documentation Feedback

We encourage you to provide feedback so that we can improve our documentation. You can use either of the following methods:

- Online feedback system—Click TechLibrary Feedback, on the lower right of any page on the Juniper Networks TechLibrary site, and do one of the following:

  - Click the thumbs-up icon if the information on the page was helpful to you.
  - Click the thumbs-down icon if the information on the page was not helpful to you or if you have suggestions for improvement, and use the pop-up form to provide feedback.

- E-mail—Send your comments to **techpubs-comments@juniper.net**. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at https://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf.
- Product warranties—For product warranty information, visit https://www.juniper.net/support/warranty/.

- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: https://www.juniper.net/customers/support/
- Search for known bugs: https://prsearch.juniper.net/
- Find product documentation: https://www.juniper.net/documentation/
- Find solutions and answer questions using our Knowledge Base: https://kb.juniper.net/
- Download the latest versions of software and review release notes: https://www.juniper.net/customers/csc/software/
- Search technical bulletins for relevant hardware and software notifications: https://kb.juniper.net/InfoCenter/
- Join and participate in the Juniper Networks Community Forum: https://www.juniper.net/company/communities/
- Open a case online in the CSC Case Management tool: https://www.juniper.net/cm/

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: https://entitlementsearch.juniper.net/entitlementsearch/

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at https://www.juniper.net/cm/.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see https://www.juniper.net/support/requesting-support.html.

PART 1

MPLS Overview

CHAPTER 1

Introduction to MPLS

MPLS Overview

Multiprotocol Label Switching (MPLS) is a protocol that uses labels to route packets instead of using IP addresses. In a traditional network, each switch performs an IP routing lookup, determines a next-hop based on its routing table, and then forwards a packet to that next-hop. With MPLS, only the first device does a routing lookup, and, instead of finding the next-hop, finds the ultimate destination along with a path to that destination. The path of an MPLS packet is called a label-switched path (LSP).

MPLS applies one or more labels to a packet so it can follow the LSP to the destination. Each switch pops off its label and sends the packet to the next switch label in the sequence.

The Junos OS includes everything you need to configure MPLS. You do not need to install any additional programs or protocols. MPLS is supported on switches with a subset of the commands supported on routers. The Junos MPLS-configured switches can interact with each other and with Junos MPLS-configured routers.

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

This topic describes:

Why Use MPLS?

MPLS reduces the use of the forwarding table by using labels instead of the forwarding table. The size of forwarding tables on a switch are limited by silicon and using exact matching for forwarding to destination devices is cheaper than buying more sophisticated hardware. In addition, MPLS allows you to control where and how traffic is routed on your network – this is called traffic engineering.

Some reasons to use MPLS instead of another switching solution are:

- MPLS can connect different technologies that would not otherwise be compatible---service providers have this compatibility issue when connecting clients with different autonomous systems in their networks. In addition, MPLS has a feature called Fast Reroute that provides alternate backups for paths – this prevents network degradation in case of a switch failure.
- · Other IP-based encapsulations such as Generic Route Encapsulation (GRE) or Virtual Extensible Local Area Networks (VXLAN) support only two levels of hierarchy, one for the transport tunnel and one piece of metadata. Using virtual servers means that you need multiple hierarchy levels. For example, one label is needed for top-of-rack (ToR), one label for the egress port that identifies the server, and one for the virtual server.

Why Not Use MPLS?

There are no protocols to auto-discover MPLS enabled nodes. MPLS protocol just exchanges label values for an LSP. They do not create the LSPs.

You must build the MPLS mesh, switch by switch. We recommend using scripts for this repetitive process.

MPLS hides suboptimal topologies from BGP where multiple exits may exist for the same route.

Large LSPs are limited by the circuits they traverse. You can work around this by creating multiple, parallel LSPs.

How Do I Configure MPLS?

There are three types of switches you must set up for MPLS:

- Label Edge Router/Switch (LER) or ingress node to the MPLS network. This switch encapsulates the packets.
- Label Switching Routers/Switches (LSR). One or more switches that transfer MPLS packets in the MPLS network.
- Egress router/switch is the final MPLS device that removes the last label before packets leave the MPLS network.

Service providers (SP) use the term provider router (P) for a backbone router/switch doing label switching only. The customer-facing router at the SP is called a provider edge router (PE). Each customer needs a customer edge router (CE) to communicate with the PE. Customer facing routers typically can terminate IP addresses, L3VPNs, L2VPNs/pseudowires, and VPLS before packets are transferred to the CE.

Configure the MPLS LER (Ingress) Switch and the Egress Switch

To configure MPLS, you must first create one or more named paths on the ingress and egress routers. For each path, you can specify some or all transit routers in the path, or you can leave it empty. See “Configuring the Ingress and Egress Router Addresses for

LSPs" on page 412 and "Configuring the Connection Between Ingress and Egress Routers" on page 419.

Configure LSRs for MPLS

Configure one or more MPLS LSRs by following these steps:

1. Configure interfaces on each switch to transmit and receive MPLS packets using the usual interface command with MPLS appended. For example:

```
[edit interfaces ge-0/0/0 unit 0] family mpls;
```

2. Add those same interfaces under [edit protocols mpls]. For example:

```
[edit protocols mpls]
  interface ge-0/0/0;
```

3. Configure the interfaces on each switch to handle MPLS labels with a protocol. For example, for LDP:

```
[edit protocols ldp]
  Interface ge-0/0/0.0;
```

To watch a demo of these configurations, see https://www.youtube.com/watch?v=xegWBCUJ4tE.

What Does the MPLS Protocol Do?

Multiprotocol Label Switching (MPLS) is an Internet Engineering Task Force (IETF)-specified framework that provides for the designation, routing, forwarding and switching of traffic flows through the network. In addition, MPLS:

- Specifies mechanisms to manage traffic flows of various granularities, such as flows between different hardware, machines, or even flows between different applications.
- Remains independent of the layer-2 and layer-3 protocols.
- Provides a means to map IP addresses to simple, fixed-length labels used by different packet-forwarding and packet-switching technologies.
- Interfaces to existing routing protocols, such as Resource ReSerVation Protocol (RSVP) and Open Shortest PathFirst (OSPF).
- Supports IP, ATM, and Frame Relay layer-2 protocols.
- Uses these additional technologies:
  - FRR: MPLS Fast Reroute improves convergence during a failure by mapping out alternate LSPs in advance.
  - Link Protection/ Next-hop backup: A bypass LSP is created for every possible link failure.

- Node Protection/ Next-hop backup: A bypass LSP is created for every possible switch (node) failure.
- VPLS: Creates Ethernet multipoint switching service over MPLS and emulates functions of an L2 switch.
- L3VPN: IP-based VPN customers get individual virtual routing domains.

How Does MPLS Interface to Other Protocols?

Some of the protocols that work with MPLS are:

- RSVP-TE: Resource Reservation Protocol - Traffic Engineering reserves bandwidth for LSPs.
- LDP: Label Distribution Protocol is the defacto protocol used for distribution of MPLS packets and is usually configured to tunnel inside RSVP-TE.
- IGP: Interior Gateway Protocol is a routing protocol. Edge routers (PE-routers) run BGP between themselves to exchange external (customer) prefixes. Edge and core (P) routers run IGP (usually OSPF or IS-IS) to find optimum path toward BGP next hops. P- and PE-routers use LDP to exchange labels for known IP prefixes (including BGP next hops). LDP indirectly builds end-to-end LSPs across the network core.
- BGP: Border Gateway Protocol (BGP) is allows policy-based routing to take place, using TCP as its transport protocol on port 179 to establish connections. The Junos OS routing protocol software includes BGP version 4. You do not configure BGP---configuring interfaces with MPLS and LDP/RSVP establishes the labels and the ability to transmit packets. BGP automatically determines the routes packets take.
- OSPF and ISIS: These protocols are used for routing between the MPLS PE and CE. Open Shortest Path First (OSPF) is perhaps the most widely used interior gateway protocol (IGP) in large enterprise networks. IS-IS, another link-state dynamic routing protocol, is more common in large service provider networks. Assuming you're running L3VPN to your customers, on the SP edge between the PE and the CE you can run any protocol that your platform supports as a VRF aware instance.

If I Have Used Cisco MPLS, What Do I Need to Know?

Cisco Networks and Juniper Networks use different MPLS terminology.

What Cisco Calls:	Juniper Calls:
affinities	admin-groups
autoroute announce	TE shortcuts
forwarding adjacency	LSP-advertise
tunnel	LSP
make-before-break	adaptive

What Cisco Calls:	Juniper Calls:
application-window	adjust-interval
shared risk link groups	fate-sharing

MPLS Overview for ACX Series Universal Metro Routers

Multiprotocol Label Switching (MPLS) provides a mechanism for engineering network traffic patterns that is independent of routing tables by assigning short labels to network packets, which describe how to forward them through the network. MPLS is independent of any routing protocol and can be used for unicast packets. On the ACX Series routers, the following MPLS features are supported:

- The configuration of a label-switching router (LSR) for processing of label-switched packets and forwarding of packets based on their labels.
- The configuration of an ingress label edge router (LER) where IP packets are encapsulated within MPLS packets and forwarded to the MPLS domain, and as an egress LER where MPLS packets are decapsulated and the IP packets contained within the MPLS packets are forwarded using information in the IP forwarding table. Configuring MPLS on the LER is the same as configuring an LSR.
- Uniform and pipe mode configuration providing different types of visibility in the MPLS network. Uniform mode makes all the nodes that a label-switched path (LSP) traverses visible to nodes outside the LSP tunnel. Uniform mode is the default. Pipe mode makes only the LSP ingress and egress points visible to nodes outside the LSP tunnel. Pipe mode acts like a circuit and must be enabled with the global **no-propagate-ttl** statement at the [**edit protocols mpls**] hierarchy level on each router that is in the path of the LSP. The **no-propagate-ttl** statement disables time-to-live (TTL) propagation at the router level and affects all RSVP-signalled or LDP-signalled LSPs. Only the global configuration of TTL propagation is supported.
- Exception packet handling of IP packets not processed by the normal packet flow through the Packet Forwarding Engine. The following types of exception packet handling are supported:
  - Router alert
  - Time-to-live (TTL) expiry value
  - Virtual circuit connection verification (VCCV)

- LSP hot standby for secondary paths configuration to maintain a path in a hot-standby state enabling swift cut over to the secondary path when downstream routers on the current active path indicate connectivity problems.
- Redundancy for a label-switched path (LSP) path with the configuration of fast reroute.
- Configuration of link protection to ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails.

MPLS for EX Series Switches Overview

You can configure Junos OS MPLS on Juniper Networks EX Series Ethernet Switches to increase transport efficiency in the network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

NOTE: MPLS configurations on EX Series switches are compatible with configurations on other Juniper Networks devices that support MPLS and MPLS-based circuit cross-connect (CCC). MPLS features available on the switches depend upon which switch you are using. For information about the software features on the EX Series switches, see Feature Explorer.

NOTE: MPLS configurations on the switches do not support:

- Q-in-Q tunneling

This topic describes:

- Benefits of MPLS on page 9
- Additional Benefits of MPLS and Traffic Engineering on page 10

Benefits of MPLS

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

Additional Benefits of MPLS and Traffic Engineering

MPLS is the packet-forwarding component of the Junos OS traffic engineering architecture. Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide efficient use of available aggregate bandwidth and long-haul fiber by ensuring that certain subsets of the network are not overutilized while other subsets of the network along potential alternate paths are underutilized.
- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservice Internet.

MPLS Applications

In the Junos OS implementation of MPLS, establishing an LSP installs on the ingress router a host route (a 32-bit mask) toward the egress router. The address of the host route is the destination address of the LSP. By default, the route has a preference value of 7, a value that is higher than all routes except direct interface and static routes. The 32-bit mask ensures that the route is more specific (that is, a longer match) than all other subnet routes. The host routes can be used to traffic-engineer BGP destinations only, or both IGP and BGP destinations.

This section discusses the following topics:

- Selecting a Forwarding LSP Next Hop on page 407

Link-Layer Support in MPLS

MPLS supports the following link-layer protocols, which are all supported in the Junos OS MPLS implementation:

- Point-to-Point Protocol (PPP)—Protocol ID 0x0281, Network Control Protocol (NCP) protocol ID 0x8281.
- Ethernet/Cisco High-level Data Link Control (HDLC)—Ethernet type 0x8847.
- Asynchronous Transfer Mode (ATM)—Subnetwork attachment point encoded (SNAP-encoded) Ethernet type 0x8847. Support is included for both point-to-point mode or nonbroadcast multiaccess (NBMA) mode. Support is not included for encoding MPLS labels as part of ATM virtual path identifier/virtual circuit identifier (VPI/VCI).
- Frame Relay—SNAP-encoded, Ethernet type 0x8847. Support is not included for encoding MPLS labels as part of Frame Relay data-link connection identifier (DLCI).
- Generic routing encapsulation (GRE) tunnel—Ethernet type 0x8847.

Supported MPLS Scaling Values

This topic lists the MPLS scaling values supported on the QFX Series and EX4600 switches.

Table 3 on page 11 lists the MPLS scaling values supported on the QFX3500, QFX5100, QFX5110, QFX5120, QFX5200, QFX5210, aEX4600, and EX4650 switches.

Table 3: MPLS Scaling Values for QFX3500, QFX5100, QFX5110, QFX5120, QFX5200, QFX5210,EX4600, and EX4650 Switches

Feature	QFX3500	QFX5100, EX4600	QFX5120, EX4650	QFX5110	QFX5200	QFX5210
Maximum number of MPLS labels in a packet's label stack (push, pop, and swap operations)	3 labels (push) 2 labels (pop) 1 label (swap)	3 labels (push) 2 labels (pop) 1 label (swap)	3 labels (push) 2 labels (pop) 1 label (swap)	3 labels (push) 2 labels (pop) 1 label (swap)	3 labels (push) 2 labels (pop) 1 label (swap)	3 labels (push) 2 labels (pop) 1 label (swap)
Maximum number of MPLS labels (provider switches)	4096	16,384	32,768	32,768	16,384	32,768

Table 3: MPLS Scaling Values for QFX3500, QFX5100, QFX5110, QFX5120, QFX5200, QFX5210,EX4600, and EX4650 Switches (continued)

Feature	QFX3500	QFX5100, EX4600	QFX5120, EX4650	QFX5110	QFX5200	QFX5210
Maximum number of tunnel initiators (combination of routes and LSPs)	Ingress LSPs: 1024 Transit LSPs: 4000	Ingress LSPs: 1024 Transit LSPs: 16,384	Ingress LSPs: 8192 Transit LSPs: 15000 Egress LSPs: 8192	Ingress LSPs: 5000 Transit LSPs: 16,384 Egress LSPs: 5000	Ingress LSPs: 2048 Transit LSPs: 15,900 Egress LSPs: 2048	Ingress LSPs: 4096 Transit LSPs: 16,384 Egress LSPs: 4096
Maximum number of unique next hops (Egress provider edge (PE) switches)	1024	1024	8192	5000	2048	4096
Maximum number of MPLS firewall filters	768	1536	1536(ingress) 2046(egress)	6143 (ingress) 1022 (egress)	768 (ingress) 1024 (egress)	768 (ingress) 1024 (egress)

Supported MPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for MPLS and traffic engineering.

- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3031, *Multiprotocol Label Switching Architecture*
- RFC 3032, *MPLS Label Stack Encoding*
- RFC 3140, *Per Hop Behavior Identification Codes*
- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*

  Only E-LSPs are supported.

- RFC 3443, *Time To Live (TTL) Processing in Multi-Protocol Label Switching (MPLS) Networks*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*

  Node protection in facility backup is not supported.
- RFC 4124, *Protocol Extensions for Support of Diffserv-aware MPLS Traffic Engineering*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*
- RFC 4385, *Pseudowire Emulation Edge-to-Edge (PWE3) Control Word for Use over an MPLS PSN*.

  Supported on MX Series routers with the Channelized OC3/STM1 (Multi-Rate) Circuit Emulation MIC with SFP.
- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*
- RFC 4950, *ICMP Extensions for Multiprotocol Label Switching*
- RFC 5317, *Joint Working Team (JWT) Report on MPLS Architectural Considerations for a Transport Profile*
- RFC 5586, *MPLS Generic Associated Channel*
- RFC 5654, *Requirements of an MPLS Transport Profile*

  The following capabilities are supported in the Junos OS implementation of MPLS Transport Profile (MPLS-TP):

  - MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
  - Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.
- RFC 5712, *MPLS Traffic Engineering Soft Preemption*
- RFC 5718, *An In-Band Data Communication Network For the MPLS Transport Profile*
- RFC 5860, *Requirements for Operations, Administration, and Maintenance (OAM) in MPLS Transport Networks*
- RFC 5884, *Bidirectional Forwarding Detection (BFD) for MPLS Label Switched Paths (LSPs)*
- RFC 5921, *A Framework for MPLS in Transport Networks*
- RFC 5950, *Network Management Framework for MPLS-based Transport Networks*
- RFC 5951, *Network Management Requirements for MPLS-based Transport Networks*
- RFC 5960, *MPLS Transport Profile Data Plane Architecture*

- RFC 6215, *MPLS Transport Profile User-to-Network and Network-to-Network Interfaces*
- RFC 6291, *Guidelines for the Use of the "OAM" Acronym in the IETF*.
- RFC 6370, *MPLS Transport Profile (MPLS-TP) Identifiers*
- RFC 6371, *Operations, Administration, and Maintenance Framework for MPLS-Based Transport Networks*.
- RFC 6372, *MPLS Transport Profile (MPLS-TP) Survivability Framework*
- RFC 6373, *MPLS-TP Control Plane Framework*
- RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*

  Only Point-to-Multipoint LSPs are supported.
- RFC 6424, *Mechanism for Performing Label Switched Path Ping (LSP Ping) over MPLS Tunnels*
- RFC 6425, *Detecting Data-Plane Failures in Point-to-Multipoint MPLS - Extensions to LSP Ping*
- RFC 6426, *MPLS On-Demand Connectivity Verification and Route Tracing*
- RFC 6428, *Proactive Connectivity Verification, Continuity Check, and Remote Defect Indication for the MPLS Transport Profile*
- RFC 6510, *Resource Reservation Protocol (RSVP) Message Formats for Label Switched Path (LSP) Attributes Objects*
- Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*

The following RFCs and Internet drafts do not define standards, but provide information about MPLS, traffic engineering, and related technologies. The IETF classifies them variously as "Experimental," "Historic," or "Informational."

- RFC 2547, *BGP/MPLS VPNs*
- RFC 2702, *Requirements for Traffic Engineering Over MPLS*
- RFC 2917, *A Core MPLS IP VPN Architecture*
- RFC 3063, *MPLS Loop Prevention Mechanism*
- RFC 3208, *PGM Reliable Transport Protocol Specification*

  Only the network element is supported.
- RFC 3469, *Framework for Multi-Protocol Label Switching (MPLS)-based Recovery*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

  Junos OS differs from the Internet draft in the following ways:

  - A packet with a sequence number of 0 is treated as out of sequence.
  - Any packet that does not have the next incremental sequence number is considered out of sequence.
  - When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.

- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*
- Internet draft draft-raggarwa-mpls-p2mp-te-02.txt, *Establishing Point to Multipoint MPLS TE LSPs*

  The features discussed in the indicated sections of the draft are not supported:

  - Nonadjacent signaling for branch LSPs (section 7.1)
  - Make-before-break and fast reroute (section 9)
  - LSP hierarchy using point-to-point LSPs (section 10)

IP and MPLS Packets on Aggregated Interfaces

You can send IP and MPLS packets over aggregated interfaces. To the IP or MPLS session, there is a single LSP composed of the aggregated interfaces. Packets sent to an LSP that is part of an aggregated interface are redistributed over the aggregated member interfaces.

Sending IP and MPLS packets over aggregated interfaces has the following benefits:

- Bandwidth aggregation—You can increase the number of MPLS packet flows sent over each connection. In MPLS, a set of packets sharing the same label is considered a part of the same flow.
- Link redundancy—If a link or a line card failure affects an aggregate member link, the traffic flowing across that link is immediately forwarded across one of the remaining links.

The Junos OS supports aggregated SONET and Ethernet interfaces.

Note that the Junos implementation of IP and MPLS over aggregated interfaces (aggregated Ethernet devices only) complies with IEEE 802.3ad.

For information about how to configure aggregated Ethernet or aggregated SONET interfaces, see *Ethernet Interfaces Feature Guide for Routing Devices* and *Configuring Aggregated SONET/SDH Interfaces*.

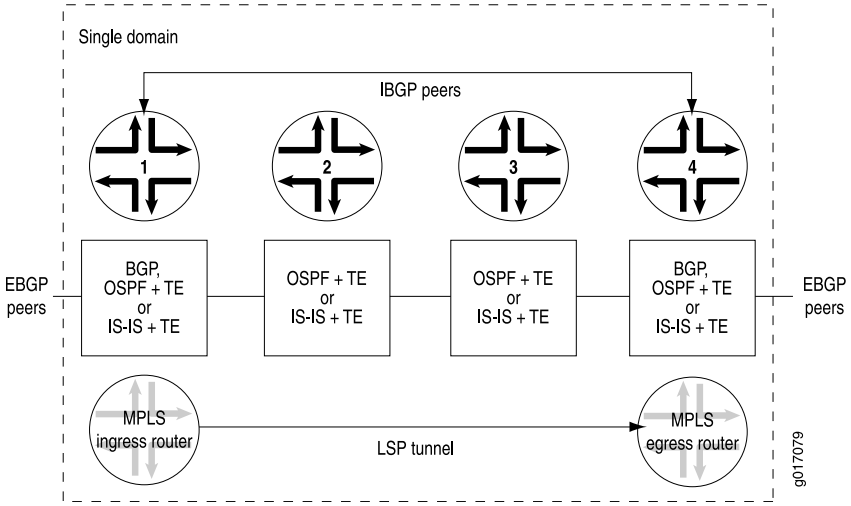
BGP Destinations

You can configure MPLS to control the paths that traffic takes to destinations outside an AS.

Both IBGP and EBGP take advantage of the LSP host routes without requiring extra configuration. BGP compares the BGP next-hop address with the LSP host route. If a match is found, the packets for the BGP route are label-switched over the LSP. If multiple BGP routes share the same next-hop address, all the BGP routes are mapped to the same LSP route, regardless of which BGP peer the routes are learned from. If the BGP next-hop address does not match an LSP host route, BGP routes continue to be forwarded based on the IGP routes within the routing domain. In general, when both an LSP route and an IGP route exist for the same BGP next-hop address, the one with the lowest preference is chosen.

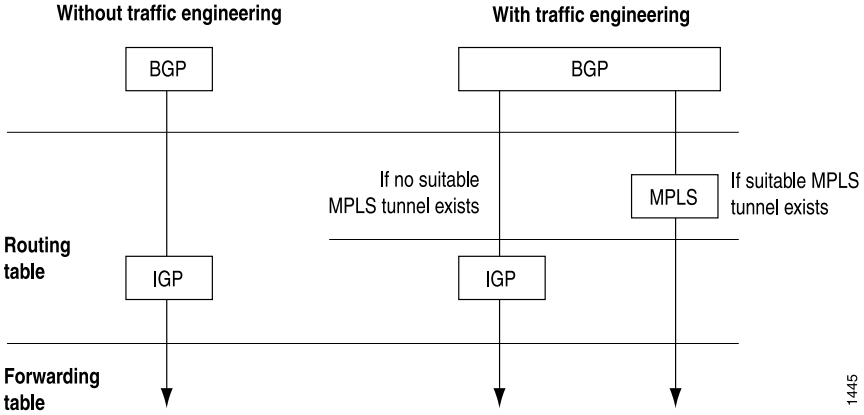
Figure 1 on page 17 shows an MPLS topology that illustrates how MPLS and LSPs work. This topology consists of a single domain with four routers. The two routers at the edges of the domain, Router 1 and Router 4, are running EBGP to communicate with peers outside the domain and IBGP to communicate between themselves. For intradomain communication, all four routers are running an IGP. Finally, an LSP tunnel exists from Router 1 to Router 4.

Figure 1: MPLS Application Topology



When BGP on Router 1 receives prefixes from Router 4, it must determine how to reach a BGP next-hop address. Typically, when traffic engineering is not enabled, BGP uses IGP routes to determine how to reach next-hop addresses. (See the left side of Figure 2 on page 18.) However, when traffic engineering is enabled, if the BGP next-hop matches the LSP tunnel endpoint (that is, the MPLS egress router), those prefixes enter the LSP tunnel. (To track these prefixes, look at the **Active Route** field in the **show mpls lsp** command output or at the output of the **show route label-switched-path** *path-name* command.) If the BGP next hop does not match an LSP tunnel endpoint, those prefixes are sent following the IGP's shortest path. (See Figure 2 on page 18.)

Figure 2: How BGP Determines How to Reach Next-Hop Addresses



IGP and BGP Destinations

You can configure MPLS to control the paths that traffic takes to destinations within an AS.

When traffic engineering is for BGP destinations only, the MPLS host routes are installed in the inet.3 routing table (see Figure 31 on page 376), separate from the routes learned from other routing protocols. Not all inet.3 routes are downloaded into the forwarding table. Packets directly addressed to the egress router do not follow the LSP, which prevents routes learned from LSPs from overriding routes learned from IGPs or other sources.

Traffic within a domain, including BGP control traffic between BGP peers, is not affected by LSPs. MPLS affects interdomain traffic only; that is, it affects only those BGP prefixes that are learned from an external domain. MPLS does not disrupt intradomain traffic, so IS-IS or OSPF routes remain undisturbed. If you issue a **ping** or **traceroute** command to any destination within the domain, the **ping** or **traceroute** packets follow the IGP path. However, if you issue a **ping** or **traceroute** command from Router 1 in Figure 1 on page 17 (the LSP ingress router) to a destination outside of the domain, the packets use the LSP tunnel.

When traffic engineering for IGP and BGP destinations is enabled, the MPLS host routes are installed in the inet.0 table (see Figure 32 on page 377) and downloaded into the forwarding table. Any traffic destined to the egress router could enter the LSP. In effect, it moves all the routes in inet.3 into inet.0, causing the inet.3 table to be emptied.

RSVP packets automatically avoid all MPLS LSPs, including those established by RSVP or LDP. This prevents placing one RSVP session into another LSP, or in other words, nesting one LSP into another.

MPLS Feature Support on QFX Series and EX4600 Switches

MPLS is a set of procedures for augmenting network layer packets with label stacks, thereby turning them into labeled packets. Service providers frequently use MPLS. Simply put, where routers in a traditional network each perform an IP lookup to determine the next hop, the first device in an an MPLS network does a routing lookup for the final destination instead of the next hop. A label is then applied to the packet—this is called *packet switching*. The final destination device removes the label.

A number of Juniper Networks switches are capable of running a subset of MPLS and can, therefore, communicate not only with each other, but with Juniper Networks routers running MPLS. This topic describes the major MPLS features that are supported on QFX Series and EX4600 switches. Be sure to check for any exceptions to this support in "MPLS Limitations on QFX Series and EX4600 Switches" on page 33.

NOTE: **EX4600 switches use the same chipset as QFX5100 switches—this is why that EX Series switch is discussed here along with QFX Series switches. Other EX Series switches also support MPLS but with a different feature set.**

This topic describes:

MPLS Commands Supported by QFX Series and EX4600 Switches

QFX Series and EX4600 switches support a subset of MPLS features. The CLI for switches displays all MPLS related configuration statements, even those that are not supported. However, configuring those unsupported statements on a switch has no effect on the operation of the switch.

MPLS Features Supported by QFX Series and EX4600 Switches

The tables in this section lists the major MPLS features supported on the QFX Series and EX4600 switches, and the Junos OS release in which they were introduced. Table 5 on page 19 lists the features for the QFX10000 switches. Table 6 on page 22 lists the features for the QFX3500, EX4600, EX4650, QFX5100, QFX5120, QFX5110, QFX5200, and QFX5210 switches.

Table 5: QFX10000 MPLS Features with Junos OS Release Support

Feature	QFX10002	QFX10008	QFX10016
QFX10000 standalone switch as an MPLS provider edge (PE) switch or provider switch	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 5: QFX10000 MPLS Features with Junos OS Release Support (continued)

Feature	QFX10002	QFX10008	QFX10016
Label edge router (LER)	15.1X53-D10	15.1X53-D30	15.1X53-D60
Label-switching router (LSR)	15.1X53-D10	15.1X53-D30	15.1X53-D60
BGP MPLS Ethernet VPN (EVPN)	17.4R1	17.4R1	17.4R1
BGP route reflectors	15.1X53-D10	15.1X53-D30	15.1X53-D60

Understanding MPLS Components for QFX Series and EX4600 Switches

MPLS devices include a number of components. While some components are required for all MPLS applications, others might not be, depending on the specific application.

This topic includes:

Provider Edge Switches

To implement MPLS on a network, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch. In addition, you must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets.

The ingress PE switch (the entry point to the MPLS tunnel) receives a packet, analyzes it, and pushes an MPLS label onto it. This label places the packet in a forwarding equivalence class (FEC) and determines its handling and destination through the MPLS tunnel. The egress PE switch (the exit point from the MPLS tunnel) pops the MPLS label off the outgoing packet.

Within an MPLS tunnel, the network traffic is bidirectional. Therefore, each PE switch can be configured to be both an ingress switch and an egress switch, depending on the direction of the traffic.

The following MPLS components are configured on the PE switches but not on the provider switches:

MPLS Protocol and Label-Switched Paths

Each PE switch must be configured to support the MPLS protocol. You must also configure label-switched paths (LSPs) at the **[edit protocols mpls]** hierarchy level.

IP Over MPLS for Customer Edge Interfaces

You can configure the customer edge interfaces of the PE switches for IP over MPLS using a Layer 3 interface and a static route from the ingress PE switch to the egress PE switch. See "Configuring MPLS on Provider Edge Switches" on page 67.

BGP Layer 3 VPN Configuration

If you are implementing a Layer 3 virtual private network (VPN), you must configure the BGP routing protocol on the PE switches.

Routing Instances for Layer 3 VPN

If you are implementing a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

QFX Series and EX4600 devices support VPN routing and forwarding (VRF) routing instances for Layer 3 VPNs.

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

Routing Instances for Layer 2 VPN and Layer 3 VPN

If you are implementing a Layer 2 VPN or a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

Starting in Junos OS Release 15.1, QFX Series devices support the following types of routing instances:

- Layer 2 VPN—To support a Layer 2 VPN (Layer 2 VPNs are not supported on the QFX5100 and EX4600 switches.)
- VPN routing and forwarding (VRF)—To support a Layer 3 VPN

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

Ethernet Encapsulation for Layer 2 VPN

If you are implementing a Layer 2 VPN, you must also configure the physical layer encapsulation type on the customer edge interface and within the routing instance.

Provider Switch

You must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets. You can add provider switches without changing the configuration of the PE switches.

A provider switch does not analyze packets. It refers to an MPLS label forwarding table and swaps one label for another. The new label determines the next hop along the MPLS tunnel. A provider switch cannot perform push or pop operations.

Components Required for All Switches in the MPLS Network

The following MPLS components are configured on both the PE switches and the provider switches:

Interior Gateway Protocol

MPLS works in coordination with OSPF as the interior gateway protocol (IGP). Therefore, you must configure OSPF as the IGP on the loopback interface and CE-facing interfaces of both the PE switches and the provider switches.

The CE-facing interfaces can be either Gigabit Ethernet or 10-Gigabit Ethernet interfaces, and they can be configured as either individual interfaces or as aggregated Ethernet interfaces.

NOTE: The CE-facing interfaces cannot be configured with VLAN tagging or a VLAN ID. When you configure them to belong to family mpls, they are removed from the default VLAN if they were members of that VLAN. They operate as an exclusive tunnel for MPLS traffic.

Traffic Engineering

Traffic engineering maps traffic flows onto an existing physical topology and provides the ability to move traffic flow away from the shortest path selected by the IGP and to a potentially less congested physical path across a network.

Traffic engineering enables the selection of specific end-to-end paths to send given types of traffic through your network. You must configure OSPF traffic engineering on the PE switches and the provider switches.

MPLS Protocol

You must enable the MPLS protocol on all switches that participate in the MPLS network and apply it to the core interfaces of both the PE and provider switches. You do not need to apply it to the loopback interface because the MPLS protocol uses the framework established by the RSVP signaling protocol to create LSPs. On the PE switches, the configuration of the MPLS protocol must also include the definition of an LSP.

RSVP

RSVP is a signaling protocol that allocates and distributes labels throughout an MPLS network. RSVP sets up unidirectional paths between the ingress PE switch and the egress PE switch. RSVP makes the LSPs dynamic; it can detect topology changes and outages and establish new LSPs to allow traffic to move around a failure.

You must enable RSVP and apply it to the loopback interface and the core interface of both the PE and provider switches. The path message contains the configured information about the resources required for the LSP to be established.

When the egress PE switch receives the path message, it sends a reservation message back to the ingress PE switch. This reservation message is passed along from switch to switch along the same path as the original path message. Once the ingress PE switch receives this reservation message, an RSVP path is established.

The established LSP stays active as long as the RSVP session remains active. RSVP continues activity through the transmissions and responses to RSVP path and reservation messages. If the messages stop for three minutes, the RSVP session terminates and the LSP is lost.

RSVP runs as a separate software process in Junos OS and is not in the packet-forwarding path.

Family mpls

You must configure the core interfaces used for MPLS traffic to belong to **family mpls**.

NOTE: **You can enable family mpls on either individual interfaces or on aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.**

Understanding MPLS and Path Protection on EX Series Switches

Junos OS MPLS for Juniper Networks EX Series Ethernet Switches provides path protection to protect your MPLS network from label switched path (LSP) failures.

By default, an LSP routes itself hop-by-hop from the ingress provider edge switch through the provider switches toward the egress provider edge switch. The LSP generally follows the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are "soft" in nature because they automatically reroute themselves whenever a change occurs in a routing table or in the status of a node or link.

Typically, when an LSP fails, the switch immediately upstream from the failure signals the outage to the ingress provider edge switch. The ingress provider edge switch calculates a new path to the egress provider edge switch, establishes the new LSP, and then directs traffic from the failed path to the new path. This rerouting process can be time-consuming and prone to failure. For example, the outage signals to the ingress switch might get lost or the new path might take too long to come up, resulting in significant packet drops.

You can configure path protection by configuring primary and secondary paths on the ingress switch. If the primary path fails, the ingress switch immediately reroutes traffic from the failed path to the standby path, eliminating the need for the ingress switch to calculate a new route and signal a new path. For information about configuring standby LSPs, see "Configuring Path Protection in an MPLS Network (CLI Procedure)" on page 113.

MPLS Limitations on QFX Series and EX4600 Switches

MPLS is a fully implemented protocol on routers, while switches support a subset of the MPLS features. The limitations of each switch are listed in a separate section here, although many of the limitations are duplicates that apply to more than one switch.

- MPLS Limitations on QFX10000 Switches on page 34
- MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches on page 34
- MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches on page 36
- MPLS Limitations on QFX3500 Switches on page 37

MPLS Limitations on QFX10000 Switches

- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.
- These LDP features are not supported on the QFX10000 switches:
  - LDP multipoint
  - LDP link protection
  - LDP Bidirectional Forwarding Detection (BFD)
  - LDP Operation Administration and Management (OAM)
  - LDP multicast-only fast reroute (MoFRR)
- Pseudowire-over-aggregated Ethernet interfaces on UNI are not supported.
- MPLS-over-UDP tunnel limitations
  - MPLS TTL propagation
  - CoS rewrite rules and priority propagation for RSVP LSP labels (ingress tunnels only)

NOTE: **MPLS-over-UDP tunnels are created only if corresponding RSVP-TE, LDP, or BGP-LU tunnels are not available for the destination route.**

MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches

- MPLS support differs on the various switches. EX4600 switches support only basic MPLS functionality while the QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches support some of the more advanced features. See "MPLS Feature Support on QFX Series and EX4600 Switches" on page 19 for details.
- On a QFX5100 switch, configuring integrated bridging and routing (IRB) interfaces on the MPLS core is implemented on the switch by using TCAM rules. This is the result of a chip limitation on the switch, which only allows for a limited amount of TCAM space. There is 1K TCAM space is allocated for IRB. If multiple IRBs exist, make sure that you have enough available TCAM space on the switch. To check the TCAM space, see TCAM Filter Space Allocation and Verification in QFX Devices from Junos OS 12.2x50-D20 Onward.
- (QFX5100, QFX5110, QFX5120, QFX5200, QFX5210, EX4600) When VLAN bridge encapsulation is enabled on a CE connected interface, the switch drops packets if both flexible Ethernet services and VLAN CCC encapsulations are configured on the same logical interface. Only one can be configured, not both. For example:

set interfaces xe-0/0/18 encapsulation flexible-ethernet-services, or **set interfaces xe-0/0/18 encapsulation vlan-ccc**.

- Layer 2 circuits on aggregated Ethernet (AE) interfaces are not supported on QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches.
- Layer 2 circuit local switching is not supported on the EX4600, EX4650, and QFX5100 switches.
- The QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches do not depend on the VRF match for loopback filters configured at different routing instances. Loopback filters per routing instance (such as lo0.100, lo0.103, lo0.105) are not supported and may cause unpredictable behavior. We recommend that you only apply the loopback filter (lo0.0) to the master routing instance
- On EX4600 and EX4650 switches, when loopback filters with both accept and deny terms for the same IP address are configured and if RSVP packets have that IP address in either source IP or destination IP, then those RSVP packets will be dropped even if accept terms have higher priority than deny terms. As per design, if the switch receives an RSVP packet with IP OPTION, the packet is copied to the CPU and then the original packet is dropped. Because RSVP packets are marked for drop, the accept term will not process these packets and the deny term will drop the packets.
- On a link-protected, fast reroute Layer 2 circuit, you might see a traffic convergence delay of 200 to 300 milliseconds.
- Layer 2 circuit local switching is not supported on the EX4600, EX4650, and QFX5100 switches.
- If you configure the BGP labeled unicast address family (using the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level) on a QFX Series switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath informaton.
- Although fast reroute (FRR) on regular interfaces is supported, the **include-all** and **include-any** options for FRR are not supported. See "Fast Reroute Overview" on page 379.
- FRR is not supported on MPLS over IRB interfaces.
- MPLS-based circuit cross-connects (CCC) are not supported—only circuit-based pseudowires are supported.
- Configuring link aggregation groups (LAGs) on user-to-network interface (UNI) ports for L2 circuits is not supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in the data plane.
- With L2 circuit-based pseudowires, if multiple equal-cost RSVP LSPs are available to reach an L2 circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2 circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.

- Firewall filters and policers on **family mpls** are only supported on QFX5100 switches that act as pure label-switching routers (LSRs) in an MPLS network. A pure LSR is a transit router that switches paths solely on the incoming label's instructions. Firewall filters and policers on **family mpls** are not supported on QFX5100 ingress and egress provider edge (PE) switches. This includes switches that perform penultimate hop popping (PHP).
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.
- These are the hardware limitations for EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches:
  - Push of a maximum of three labels is supported in the MPLS edge switch if label swap is not done.
  - Push of a maximum of two labels is supported in the MPLS edge switch if label swap is done.
  - Pop at line rate is supported is supported for a maximum of two labels.
  - Global label space is supported but interface-specific label space is not supported.
  - MPLS ECMP on PHY node with BOS=1 is not supported for single labels.
  - QFX Series switches with Broadcom chips do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes the QFX3500, QFX3600, EX4600, QFX5100, and QFX5200 switches.
  - On EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches, the MPLS MTU command can cause unexpected behavior—this is due to SDK chipset limitations on this platform.
- These LDP features are not supported on the EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches:
  - LDP multipoint
  - LDP link protection
  - LDP Bidirectional Forwarding Detection (BFD)
  - LDP Operation Administration and Management (OAM)
  - LDP multicast-only fast reroute (MoFRR)

MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches

The following MPLS features are not supported by the QFX5100 VC and QFX5100 VCF switches:

- Next-hop LSP
- BFD including BFD triggered FRR
- L2 VPN based on BGP (See RFC 6624)
- VPLS

- Extended VLAN CCC
- Pseudowire protection using Ethernet OAM
- Local switching of pseudo-wire
- Pseudowire fault detection based on VCCV
- QFX Series switches with Broadcom chipsets do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes QFX3500, QFX3600, EX4600, QFX5100, and QFX5200 switches.

MPLS Limitations on QFX3500 Switches

- If you configure the BGP labeled unicast address family (using the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level) on a QFX Series switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath information.
- Although fast reroute is supported, the **include-all** and **include-any** options for fast reroute are not supported. See "Fast Reroute Overview" on page 379 for details.
- MPLS-based circuit cross-connects (CCC) are not supported—only circuit-based pseudowires are supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in the data plane.
- With Layer 2 (L2) circuit-based pseudowires, if multiple equal-cost RSVP label-switched paths (LSPs) are available to reach a L2 circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2 circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.

MPLS Configuration Overview

When you first install Junos OS on your device, MPLS is disabled by default. You must explicitly configure your device to allow MPLS traffic to pass through. Complete the following steps for all devices in your MPLS network that are running Junos OS.

To enable MPLS:

1. Delete all configured security services from the device. If you do not complete this step, you will get a commit failure. See *Example: Deleting Security Services*.
2. Enable MPLS on the device. See "Example: Enabling MPLS" on page 45.
3. Commit the configuration.
4. Reboot the device.
5. Configure MPLS features such as traffic engineering, VPNs, and VPLS. See:
   - MPLS Traffic Engineering and Signaling Protocols Overview on page 638
   - MPLS VPN Overview on page 888
   - CLNS Overview on page 973
   - VPLS Overview on page 992

CAUTION: **When packet forwarding mode is changed to MPLS, all flow-based security features are deactivated, and the device performs packet-based processing only. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device. However, MPLS can be enabled in flow-based packet forwarding mode for selected traffic using firewall filters.**

MPLS Configuration Guidelines

When configuring MPLS on QFX Series devices or on EX4600, note that the number of IP prefixes supported depends on the specific platform being used. See the scale specifications in the data sheet of your device for additional information.

- We recommend the following:
  - If your ingress provider edge (PE) switch needs to support more than 8000 external IP prefixes, use a larger capacity device as an ingress PE switch.
  - If you use a switch as a route reflector for BGP labeled routes, use it as a dedicated route reflector (that is, the switch must not participate in managing data traffic).
  - If you use a switch as a PE switch or as a route reflector for BGP labeled routes, configure routing policies on the PE switch and the route reflector to filter external IP routes from the routing table.

The configuration example for a routing policy named fib_policy (at the **[edit policy-options** and **[edit routing-options** hierarchy levels) to filter BGP labeled routes from the inet.0 routing table is given below:

```
user@switch# show policy-options
policy-statement fib_policy {
   from {
      protocol bgp;
      rib inet.0;
   }
   then reject;
}
```

```
user@switch# show routing-options
forwarding-table {
   export fib_policy;
}
```

- Packet fragmentation using the **allow-fragmentation** statement at the **[edit protocols mpls path-mtu]** hierarchy level is not supported on QFX Series devices or on the EX4600 switch. Therefore, you must ensure that the maximum transmission unit (MTU) values configured on every MPLS interface is sufficient to handle MPLS packets. The packets whose size exceeds the MTU value of an interface will be dropped.

TTL Processing on Incoming MPLS Packets

The flow chart on Figure 3 on page 40 illustrates TTL processing on incoming MPLS packets. On a transit LSR or an egress LER, MPLS pops one or more labels and can push one or more labels. The incoming TTL of the packet is determined by the configured TTL processing tunnel model.

When all of the following conditions are met, the incoming TTL is set to the TTL value found in the immediate inner header:

- The outer label is popped as opposed to being swapped
- The TTL processing model is configured to pipe
- The inner header is MPLS or IP

If any of those conditions is not met, then the incoming TTL is set to the TTL value found in the outermost label. In all cases, the TTL values of any further inner labels are ignored.

When an IP packet is exposed after MPLS pops all the labels that should be popped, MPLS passes the packet to IP for further processing, including TTL checking. When the uniform tunnel model for TTL processing is in effect, MPLS sets the TTL value of the IP packet to the incoming TTL value that was just set. In other words, the TTL value is copied from the outermost label to the IP packet. When the pipe model for TTL processing is in effect, the TTL value in the IP header is left unchanged.

If an IP packet is not exposed by the label popping, then MPLS performs the TTL validation. If the incoming TTL is less than 2, the packet is dropped. If innermost packet is IP, an ICMP packet is built and sent. If the TTL does not expire and the packet needs to be sent out, the outgoing TTL is determined by the rules for outgoing MPLS packets.

PART 2

Configuring MPLS and Associated Features

CHAPTER 2

Configuring MPLS

Configuring MPLS

You must also configure MPLS for a Layer 2 cross-connect to work. The following is a minimal MPLS configuration:

```
[edit]
interfaces {
   interface-name  {
      unit  logical-unit-number;
   }
}
protocols {
   mpls {
      interface all;
   }
}
```

Related Documentation

- Understanding MPLS Label Manager on page 335

Example: Enabling MPLS

This example shows how to enable MPLS for packet-based processing. It also shows how to enable the MPLS family and MPLS process on all of the transit interfaces in the network.

NOTE: When MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, IP packets, and IPsec VPNs are unavailable on the device.

Before changing from flow mode to packet mode, you must remove all security policies remaining under flow mode. To prevent management connection loss, you must bind the management interface to zones and enable host-inbound traffic to prevent the device from losing connectivity.

For information about configuring zones, see *Security Basics Guide for Security Devices*.

Requirements

Before you begin, delete all configured security services. See *Example: Deleting Security Services*.

Overview

The instructions in this topic describe how to enable MPLS on the device. You must enable MPLS on the device before including a device running Junos OS in an MPLS network.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security forwarding-options family mpls mode packet-based
set interfaces ge-1/0/0 unit 0 family mpls
set protocols mpls ge-1/0/0 unit 0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To enable MPLS:

1. Enable MPLS for packet-based processing.

```
[edit security forwarding-options]
user@host# set family mpls mode packet-based
```

2. Enable the MPLS family on each transit interface that you want to include in the MPLS network.

```
[edit interfaces]
user@host# set interfaces ge-1/0/0 unit 0 family mpls
```

3. Enable the MPLS process on all of the transit interfaces in the MPLS network.

```
[edit protocols mpls]
user@host# set interface ge-1/0/0 unit 0
```

Results From configuration mode, confirm your configuration by entering the **show security forwarding-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

NOTE: If you enable MPLS for packet-based processing by using the command **set security forward-option family mpls mode packet**, the mode will not change immediately and the system will display the following messages:

warning: Reboot may required when try reset flow inet mode

warning: Reboot may required when try reset mpls flow mode please check security flow status for detail.

You need to reboot your device for the configuration to take effect.

CAUTION: If you disable MPLS and switch back to using the security services (flow-based processing), the mode will not change immediately and the system will display warning messages instructing you to restart your device. You must reboot your device for the configuration to take effect. This will also result in management sessions being reset and transit traffic getting interrupted.

```
[edit]
user@host# show security forwarding-options
family {
   mpls {
      mode packet-based;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying MPLS Is Enabled at the Protocols Level on page 48
- Verifying MPLS Is Enabled at the Interfaces Level on page 48

Verifying MPLS Is Enabled at the Protocols Level

Purpose Verify that MPLS is enabled at the protocols level.

Action From operational mode, enter the **show protocols** command.

Verifying MPLS Is Enabled at the Interfaces Level

Purpose Verify that MPLS is enabled at the interfaces level.

Action From operational mode, enter the **show interfaces** command.

- MPLS Configuration Overview on page 37
- *Example: Deleting Security Services*

Example: Configuring MPLS on EX8200 and EX4500 Switches

You can configure MPLS on switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

To implement MPLS on the switches, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch— and at least one provider (transit) switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network as either circuit cross-connect (CCC) or IP (**family inet**) interfaces.

This example shows how to configure an MPLS tunnel using a simple interface as a CCC:

NOTE: This example shows how to configure MPLS using a simple interface as a CCC. For information on configuring a tagged VLAN interface as a CCC, see "Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)" on page 1106 or "Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)" on page 1076.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for switches
- Three EX Series switches

Before you begin configuring MPLS, ensure that you have configured the routing protocol (OSPF or IS-IS) on the core interface and the loopback interface on all the switches. This example includes the configuration of OSPF on all the switches. For information on configuring IS-IS as the routing protocol, see the *Junos OS Routing Protocols Configuration Guide*.

Overview and Topology

This example includes an ingress or local PE switch, an egress or remote PE switch, and one provider switch. It includes CCCs that tie the customer edge interface of the local PE switch (PE-1) to the customer edge interface of the remote PE switch (PE-2). It also describes how to configure the core interfaces of the PE switches and the provider switch to support the transmission of the MPLS packets. In this example, the core interfaces that connect the local PE switch and the provider switch are individual interfaces, while the core interfaces that connect the remote PE switch and the provider switch are aggregated Ethernet interfaces.

NOTE:

- Core interfaces cannot be tagged VLAN interfaces.
- Core interfaces can be aggregated Ethernet interfaces. This example includes a LAG between the provider switch and the remote PE switch because this type of configuration is another option you can implement. For information on configuring LAGs, see *Configuring Aggregated Ethernet Links (CLI Procedure)*.

Figure 4 on page 50 shows the topology used in this example.

Figure 4: Configuring MPLS on EX Series Switches

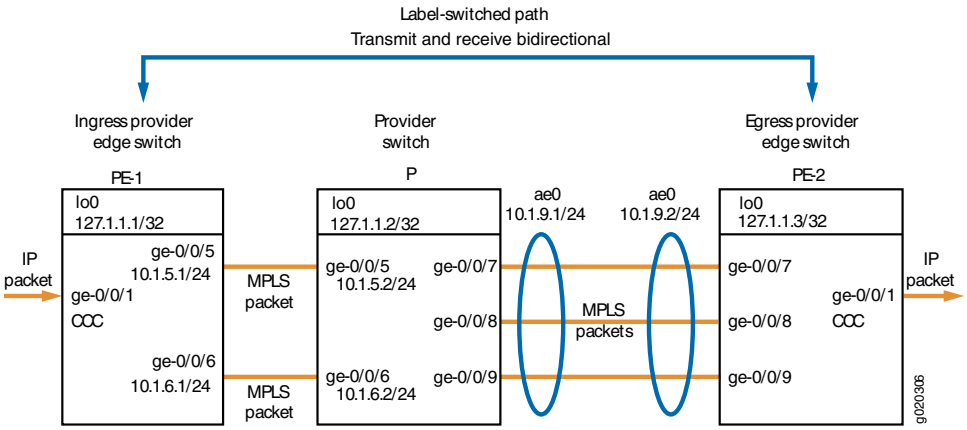

Table 7 on page 50 shows the MPLS configuration components used for the ingress PE switch in this example.

Table 7: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Loopback address	**lo0 127.1.1.1/32**	Identifies PE-1 for interswitch communications.
Routing protocol	**ospf traffic-engineering**	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol and definition of label-switched path	**mpls** **label-switched-path lsp_to_pe2_ge1** **to 127.1.1.13**	Indicates that this PE switch is using the MPLS protocol with the specified LSP to reach the other PE switch (specified by the loopback address). The statement must also specify the core interfaces to be used for MPLS traffic.
RSVP	**rsvp**	Indicates that this switch is using RSVP. The statement must specify the loopback address and the core interfaces that will be used for the RSVP session.
Interface family	**family inet** **family mpls** **family ccc**	The logical units of the core interfaces are configured to belong to both **family inet** and **family mpls**. The logical unit of the customer edge interface is configured to belong to **family ccc**.

Table 7: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC (continued)

Property	Settings	Description
Customer edge interface	**ge-0/0/1**	Interface that connects this network to devices outside the network.
Core interfaces	**ge-0/0/5.0** and **ge-0/0/6.0** with IP addresses **10.1.5.1/24** and **10.1.6.1/24**	Interfaces that connect to other switches within the MPLS network.
CCC definition	**connections** **remote-interface-switch ge-1-to-pe2** **interface ge-0/0/1.0** **transmit-lsp lsp_to_pe2_ge1** **receive-lsp lsp_to_pe1_ge1**	Associates the circuit cross-connect (CCC), **ge-0/0/1**, with the LSPs that have been defined on the local and remote PE switches.

Table 8 on page 51 shows the MPLS configuration components used for the egress PE switch in this example.

Table 8: Components of the Egress PE Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Remote PE switch hardware	EX Series switch	PE-2
Loopback address	**lo0 127.1.1.3/32**	Identifies PE-2 for interswitch communications.
Routing protocol	**ospf traffic-engineering**	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol and definition of label-switched path	**mpls** **label-switched-path lsp_to_pe1_ge1** **to 127.1.1.1**	Indicates that this PE switch is using the MPLS protocol with the specified label-switched path (LSP) to reach the other PE switch. The statement must also specify the core interfaces to be used for MPLS traffic.
RSVP	**rsvp**	Indicates that this switch is using RSVP. The statement must specify the loopback address and the core interfaces that will be used for the RSVP session.
Interface family	**family inet** **family mpls** **family ccc**	The logical unit of the core interface is configured to belong to both **family inet** and **family mpls**. The logical unit of the customer edge interface is configured to belong to **family ccc**.

Table 8: Components of the Egress PE Switch in the Topology for MPLS with Interface-Based CCC (continued)

Property	Settings	Description
Customer edge interface	**ge-0/0/1**	Interface that connects this network to devices outside the network.
Core interface	**ae0** with IP address **10.1.9.2/24**	Aggregated Ethernet interface on PE-2 that connects to aggregated Ethernet interface **ae0** of the provider switch and belongs to **family mpls**.
CCC definition	**connections remote-interface-switch ge-1-to-pe1** **interface ge-0/0/1.0** **transmit-lsp lsp_to_pe1_ge1;** **receive-lsp lsp_to_pe2_ge1;**	Associates the CCC, **ge-0/0/1**, with the LSPs that have been defined on the local and remote PE switches.

Table 9 on page 52 shows the MPLS configuration components used for the provider switch in this example.

Table 9: Components of the Provider Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Loopback address	**lo0 127.1.1.2/32**	Identifies provider switch for interswitch communications.
Routing protocol	**ospf traffic-engineering**	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol	**mpls**	Indicates that this switch is using the MPLS protocol. The statement must specify the core interfaces that will be used for MPLS traffic.
RSVP	**rsvp**	Indicates that this switch is using RSVP. The statement must specify the loopback and the core interfaces that will be used for the RSVP session.
Interface family	**family inet** **family mpls**	The logical units for the loopback interface and the core interfaces belong to **family inet**. The logical units of the core interfaces are also configured to belong to **family mpls**.

Table 9: Components of the Provider Switch in the Topology for MPLS with Interface-Based CCC (continued)

Property	Settings	Description
Core interfaces	**ge-0/0/5.0** and **ge-0/0/6.0** with IP addresses **10.1.5.1/24** and **10.1.6.1/24** and **ae0** with IP address **10.1.9.1/24**	Interfaces that connect the provider switch (P) to PE-1. Aggregated Ethernet interface on P that connects to aggregated Ethernet interface **ae0** of PE-2.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure the local ingress PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
set protocols ospf area 0.0.0.0 interface ge-0/0/6.0
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
set protocols mpls interface ge-0/0/5.0
set protocols mpls interface ge-0/0/6.0
set protocols rsvp interface lo0.0
set protocols rsvp interface ge-0/0/5.0
set protocols rsvp interface ge-0/0/6.0
set interfaces lo0 unit 0 family inet address 127.1.1.1/32
set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
set interfaces ge-0/0/5 unit 0 family mpls
set interfaces ge-0/0/6 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family ccc
set protocols connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/1.0
set protocols connections remote-interface-switch ge-1-to-pe2 transmit-lsp lsp_to_pe2_ge1
set protocols connections remote-interface-switch ge-1-to-pe2 receive-lsp lsp_to_pe1_ge1
```

Step-by-Step Procedure

To configure the local ingress PE switch:

1. Configure OSPF with traffic engineering enabled:

   ```
   [edit protocols]
   user@switchPE-1# set ospf traffic-engineering
   ```

2. Configure OSPF on the loopback address and the core interfaces:

   ```
   [edit protocols]
   user@switchPE-1# set ospf area 0.0.0.0 interface lo0.0
   user@switchPE-1# set ospf area 0.0.0.0 interface ge-0/0/5.0
   user@switchPE-1# set ospf area 0.0.0.0 interface ge-0/0/6.0
   ```

3. Configure MPLS on this PE switch (PE-1) with a label-switched path (LSP) to the other PE switch (PE-2):

   ```
   [edit protocols]
   ```

```
user@switchPE-1# set mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
```

4. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switchPE-1# set mpls interface ge-0/0/5.0
user@switchPE-1# set mpls interface ge-0/0/6.0
```

5. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switchPE-1# set rsvp interface lo0.0
user@switchPE-1# set rsvp interface ge-0/0/5.0
user@switchPE-1# set rsvp interface ge-0/0/6.0
```

6. Configure IP addresses for the loopback interface and the core interfaces:

```
[edit]
user@switchPE-1# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switchPE-1# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switchPE-1# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
```

7. Configure **family mpls** on the logical unit of the core interface addresses:

```
[edit]
user@switchPE-1# set interfaces ge-0/0/5 unit 0 family mpls
user@switchPE-1# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure the logical unit of the customer edge interface as a CCC:

```
[edit interfaces ge-0/0/1 unit 0]
-user@PE-1# set family ccc
```

9. Configure the interface-based CCC from PE-1 to PE-2:

NOTE: You can also configure a tagged VLAN interface as a CCC. See "Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)" on page 1106 or "Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)" on page 1076.

```
[edit protocols]
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/1.0
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp lsp_to_pe2_ge1
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 receive-lsp lsp_to_pe1_ge1
```

Results Display the results of the configuration:

```
user@switchPE-1> show configuration
```

```

      transmit-lsp lsp_to_pe2_ge1;
      receive-lsp lsp_to_pe1_ge1;
    }
  }
```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ae0
set protocols mpls label-switched-path lsp_to_pe1_ge1 to 127.1.1.1
set protocols mpls interface ae0
set protocols rsvp interface lo0.0
set protocols rsvp interface ae0
set interfaces lo0 unit 0 family inet address 127.1.1.3/32
set interfaces ae0 unit 0 family inet address 10.1.9.2/24
set interfaces ae0 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family ccc
set protocols connections remote-interface-switch ge-1-to-pe1 interface ge-0/0/1.0
set protocols connections remote-interface-switch ge-1-to-pe1 transmit-lsp lsp_to_pe1_ge1
set protocols connections remote-interface-switch ge-1-to-pe1 receive-lsp lsp_to_pe2_ge1
```

Step-by-Step Procedure

To configure the remote PE switch (PE-2):

1. Configure OSPF with traffic engineering enabled:

   ```
   [edit protocols]
   user@switchPE-2# set ospf traffic-engineering
   ```

2. Configure OSPF on the loopback interface and the core interface:

   ```
   [edit protocols]
   user@switchPE-2# set ospf area 0.0.0.0 interface lo0.0
   user@switchPE-2# set ospf area 0.0.0.0 interface ae0
   ```

3. Configure MPLS on this switch (PE-2) with a label-switched path (LSP) to the other PE switch (PE-1):

   ```
   [edit protocols]
   user@switchPE-2# set mpls label-switched-path lsp_to_pe1_ge1 to 127.1.1.1
   ```

4. Configure MPLS on the core interface:

   ```
   [edit protocols]
   user@switchPE-2# set mpls interface ae0
   ```

5. Configure RSVP on the loopback interface and the core interface:

   ```
   [edit protocols]
   ser@switchPE-2# set rsvp interface lo0.0
   user@switchPE-2# set rsvp interface ae0
   ```

6. Configure IP addresses for the loopback interface and the core interface:

   ```
   [edit]
   user@switchPE-2# set interfaces lo0 unit 0 family inet address 127.1.1.3/32
   ```

```
user@switchPE-2# set interfaces ae0 unit 0 family inet address 10.1.9.2/24
```

7. Configure **family mpls** on the logical unit of the core interface:

```
[edit]
user@switchPE-2# set interfaces ae0 unit 0 family mpls
```

8. Configure the logical unit of the customer edge interface as a CCC:

```
[edit interfaces ge-0/0/1 unit 0]
user@PE-2# set family ccc
```

9. Configure the interface-based CCC from PE-2 to PE-1:

```
[edit protocols]
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 interface ge-0/0/1.0
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 transmit-lsp lsp_to_pe1_ge1
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 receive-lsp lsp_to_pe2_ge1
```

Results Display the results of the configuration:

```
user@switchPE-2> show configuration
```

```
interfaces {
   ge-0/0/1 {
      unit 0 {
         family ccc;
      }
   }
   ae0 {
      unit 0 {
         family inet {
            address 10.1.9.2/24;
         }
         family mpls;
      }
   }
   lo0 {
      unit 0 {
         family inet {
            address 127.1.1.3/32;
         }
      }
   }
}
protocols {
   rsvp {
      interface lo0.0;
      interface ae0.0;
   }
   mpls {
      label-switched-path lsp_to_pe1_ge1 {
         to 127.1.1.1;
      }
```

```
    interface ae0.0;
  }
  ospf {
    traffic-engineering;
    area 0.0.0.0 {
      interface ae0.0;
    }
  }
  connections {
    remote-interface-switch ge-1-to-pe1 {
      interface ge-0/0/1.0;
      transmit-lsp lsp_to_pe1_ge1;
      receive-lsp lsp_to_pe2_ge1;
    }
  }
}
```

Configuring the Provider Switch

CLI Quick Configuration

To quickly configure the provider switch, copy the following commands and paste them into the switch terminal window:

```
[edit]
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
set protocols ospf area 0.0.0.0 interface ge-0/0/6.0
set protocols ospf area 0.0.0.0 interface ae0
set protocols mpls interface ge-0/0/5.0
set protocols mpls interface ge-0/0/6.0
set protocols mpls interface ae0
set protocols rsvp interface lo0.0
set protocols rsvp interface ge-0/0/5.0
set protocols rsvp interface ge-0/0/6.0
set protocols rsvp interface ae0
set interfaces lo0 unit 0 family inet address 127.1.1.2/32
set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
set interfaces ae0 unit 0 family inet address 10.1.9.1/24
set interfaces ge-0/0/5 unit 0 family mpls
set interfaces ge-0/0/6 unit 0 family mpls
set interfaces ae0 unit 0 family mpls
```

Step-by-Step Procedure

To configure the provider switch:

1. Configure OSPF with traffic engineering enabled:

   ```
   [edit protocols]
   user@switchP# set ospf traffic-engineering
   ```

2. Configure OSPF on the loopback interface and the core interfaces:

   ```
   [edit protocols]
   user@switchP# set ospf area 0.0.0.0 interface lo0.0
   ```

```
user@switchP# set ospf area 0.0.0.0 interface ge-0/0/5
user@switchP# set ospf area 0.0.0.0 interface ge-0/0/6
user@switchP# set ospf area 0.0.0.0 interface ae0
```

3. Configure MPLS on the core interfaces on the switch:

```
[edit protocols]
user@switchP# set mpls interface ge-0/0/5
user@switchP# set mpls interface ge-0/0/6
user@switchP# set mpls interface ae0
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switchP# set rsvp interface lo0.0
user@switchP# set rsvp interface ge-0/0/5
user@switchP# set rsvp interface ge-0/0/6
user@switchP# set rsvp interface ae0
```

5. Configure IP addresses for the loopback interface and the core interfaces:

```
[edit]
user@switchP# set interfaces lo0 unit 0 family inet address 127.1.1.2/32
user@switchP# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switchP# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switchP# set interfaces ae0 unit 0 family inet address 10.1.9.1/24
```

6. Configure **family mpls** on the logical unit of the core interface addresses:

```
[edit]
user@switchP# set interfaces ge-0/0/5 unit 0 family mpls
user@switchP# set interfaces ge-0/0/6 unit 0 family mpls
user@switchP# set interfaces ae0 unit 0 family mpls
```

Results Display the results of the configuration:

```
user@switchP> show configuration
```

```
interfaces {
   ge-0/0/5 {
      unit 0 {
         family inet {
            address 10.1.5.1/24;
         }
         family mpls;
         }
      }
   ge-0/0/6 {
      unit 0 {
         family inet {
            address 10.1.6.1/24;
         }
         family mpls;
         }
```

```
    }
  }
  ae0 {
    unit 0 {
      family inet {
        address 10.1.9.1/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 127.1.1.2/32;
      }
    }
  }
protocols {
  rsvp {
    interface lo0.0;
    interface ge-0/0/5.0;
    interface ge-0/0/6.0;
    interface ae0.0;
  }
  mpls {
    interface ge-0/0/5.0;
    interface ge-0/0/6.0;
    interface ae0.0;
  }
  ospf {
    traffic-engineering;
    area 0.0.0.0 {
      interface lo0.0;
      interface ge-0/0/5.0;
      interface ge-0/0/6.0;
      interface ae0.0;
    }
  }
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying the Physical Layer on the Switches on page 61
- Verifying the Routing Protocol on page 61
- Verifying the Core Interfaces Being Used for MPLS Traffic on page 62
- Verifying the Status of the RSVP Sessions on page 62
- Verifying the Assignment of Interfaces for MPLS Label Operations on page 62
- Verifying the Status of the CCC on page 63

Verifying the Physical Layer on the Switches

Purpose Verify that the interfaces are up. Perform this verification task on each of the switches.

Action

```
user@switchPE-1> show interfaces terse

Interface               Admin Link Proto    Local                 Remote
ge-0/0/0                up    up
ge-0/0/0.0              up    up  eth-switch
ge-0/0/1                up    up
ge-0/0/1.0              up    up  ccc
ge-0/0/2                up    up
ge-0/0/2.0              up    up  eth-switch
ge-0/0/3                up    up
ge-0/0/3.0              up    up eth-switch
ge-0/0/4                up    up
ge-0/0/4.0              up    up eth-switch
ge-0/0/5                up    up
ge-0/0/5.0              up    up inet     10.1.5.1/24
                              mpls
ge-0/0/6                up    up
ge-0/0/6.0              up    up inet     10.1.6.1/24
                              mpls
```

Meaning The **show interfaces terse** command displays status information about the Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (**Proto** column) shows that interface **ge-0/0/1.0** is configured as a circuit cross-connect. The output for the protocol family of the core interfaces (**ge-0/0/5.0** and **ge-0/0/6.0**) shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

Verifying the Routing Protocol

Purpose Verify the state of the configured routing protocol. Perform this verification task on each of the switches. The state must be **Full**.

Action

```
user@switchPE-1> show ospf neighbor

Address          Interface              State     ID               Pri  Dead
127.1.1.2          ge-0/0/5               Full     10.10.10.10      128    39
```

Meaning The **show ospf neighbor** command displays the status of the routing protocol. This output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors.

Verifying the Core Interfaces Being Used for MPLS Traffic

Purpose Verify that the state of the MPLS interface is **Up**. Perform this verification task on each of the switches.

Action

```
user@switchPE-1> show mpls interface

Interface         State       Administrative groups
ge-0/0/5             Up          <none>
ge-0/0/6             Up          <none>
```

Meaning The **show mpls interface** command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is **Up**.

Verifying the Status of the RSVP Sessions

Purpose Verify the status of the RSVP sessions. Perform this verification task on each of the switches.

Action

```
user@switchPE-1> show rsvp session

Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
127.1.13        127.1.1.1         Up       0  1 FF       -   300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
127.1.1.1       127.1.1.3         Up       0  1 FF       299968     lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning This output confirms that the RSVP sessions are **Up**.

Verifying the Assignment of Interfaces for MPLS Label Operations

Purpose Verify which interface is being used as the beginning of the CCC and which interface is being used to push the MPLS packet to the next hop. Perform this task only on the PE switches.

Action

```
user@switchPE-1> show route forwarding-table family mpls
MPLS:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            perm     0                    dscd    50     1
0                  user     0                    recv    49     3
1                  user     0                    recv    49     3
2                  user     0                    recv    49     3
299776             user     0                   Pop     541     2     ge-0/0/1.0
ge-0/0/1.0  (CCC)  user     0 2.0.0.1           Push 299792   540 2   ge-0/0/5.0
```

Meaning

This output shows that the CCC has been set up on interface **ge-0/0/1.0**. The switch receives ingress traffic on **ge-0/0/1.0** and pushes label **299792** onto the packet, which goes out through interface **ge-0/0/5.0**. The output also shows when the switch receives an MPLS packet with label 29976, it pops the label and sends the packet out through interface **ge-0/0/1.0**

After you have checked the local PE switch, run the same command on the remote PE switch.

Verifying the Status of the CCC

Purpose

Verify the status of the CCC. Perform this task only on the PE switches.

Action

```
user@switchPE-1> show connections
CCC and TCC connections [Link Monitoring On]
Legend for status (St)              Legend for connection types
UN -- uninitialized                 if-sw:  interface switching
NP -- not present                   rmt-if: remote interface switching
WE -- wrong encapsulation           lsp-sw: LSP switching
DS -- disabled                      tx-p2mp-sw: transmit P2MP switching
Dn -- down                          rx-p2mp-sw: receive P2MP switching
-> -- only outbound conn is up
 <- -- only inbound  conn is up      Legend for circuit types
Up -- operational                   intf -- interface
RmtDn -- remote CCC down            tlsp -- transmit LSP
Restart -- restarting               rlsp -- receive LSP

Connection/Circuit               Type        St      Time last up     # Up trans
ge1-to-pe2                       rmt-if      Up      Feb 17 05:00:09  1
  ge-0/0/1.0                      intf       Up
  lsp_to_pe1_ge1                    tlsp     Up
  lsp_to_pe2_ge1                    rlsp     Up
```

Meaning

The **show connections** command displays the status of the CCC connections. This output verifies that the CCC interface and its associated transmit and receive LSPs are **Up**. After you have checked the local PE switch, run the same command on the remote PE switch.

- MPLS for EX Series Switches Overview on page 9

Verifying That MPLS Is Working Correctly

To verify that MPLS is working correctly, perform the following tasks:

1. Verifying the Physical Layer on the Switches on page 64
2. Verifying the Routing Protocol on page 65
3. Verifying the Core Interfaces Being Used for the MPLS Traffic on page 65
4. Verifying RSVP on page 65

Verifying the Physical Layer on the Switches

Purpose Verify that the interfaces are up. Perform this verification task on each of the switches.

Action

```
user@switch> show interfaces xe-* terse

Interface               Admin Link Proto    Local                 Remote
xe-0/0/0                up    up
xe-0/0/0.0              up    up
xe-0/0/1.0              up    up
xe-0/0/2.0              up    up
xe-0/0/3.0              up    up   inet       2.2.2.1/16
xe-0/0/4.0              up    up
xe-0/0/5.0              up    up   inet      10.1.5.1/24
                                   mpls
xe-0/0/6.0              up    up   inet      10.1.6.1/24
                                   mpls
```

Meaning The **show interfaces terse** command displays status information about the 10-Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (Proto column) of the core interfaces (xe-0/0/5.0 and xe-0/0/6.0), shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

Verifying the Routing Protocol

Purpose Verify the state of the configured routing protocol. You should perform this verification task on each of the switches. The state should be **Full**. If you have configured OSPF as the routing protocol, use the **show ospf neighbor** command to verify that the routing protocol is communicating with the switch neighbors.

Action

```
user@switch> show ospf neighbor

Address          Interface              State     ID               Pri  Dead
127.1.1.1        xe-0/0/5               Full      10.10.10.10      128    39
```

Meaning The **show ospf neighbor** command displays the status of the routing protocol that has been configured on this switch. The output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors. For additional information on checking and monitoring routing protocols, see the *Junos OS Routing Protocols and Policies Command Reference* .

Verifying the Core Interfaces Being Used for the MPLS Traffic

Purpose Verify that the state of the MPLS interface is **Up**. You should perform this verification task on each of the switches.

Action

```
user@switch> show mpls interface

Interface        State       Administrative groups
ge-0/0/5            Up          <none>
ge-0/0/6            Up          <none>
```

Meaning The **show mpls interface** command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is up.

Verifying RSVP

Purpose Verify the state of the RSVP session. You should perform this verification task on each of the switches.

Action

```
user@switch> show rsvp session

Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
127.1.1.3       127.1.1.1         Up       0  1 FF       -   300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
127.1.1.1       127.1.1.3         Up       0  1 FF  299968        - lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning This output confirms that the RSVP sessions are up.

CHAPTER 3

Configuring MPLS on Provider and Provider Edge Devices

Configuring MPLS on Provider Edge Switches

To implement MPLS, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network using IP over MPLS.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.10.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

NOTE: You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure OSPF traffic engineering:

```
[edit protocols ospf]
user@switch# set traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure MPLS traffic engineering.

```
[edit protocols mpls]
user@switch# set traffic-engineering
```

6. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 121.100.10.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3.0
```

10. Configure an LSP on the ingress PE switch (192.168.10.1) to send IP packets over MPLS to the egress PE switch (192.168.12.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 to 192.168.12.1
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 2.2.2.0/24 next-hop 192.168.10.1
user@switch# set static route 2.2.2.0/24 resolve
```

Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.12.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.21.1/24
```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

NOTE: You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface xe-0/0/5.0
user@switch# set rsvp interface xe-0/0/6.0
```

4. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

6. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 2.2.2.1/16
```

7. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0.0 interface xe-0/0/3
```

8. Configure an LSP on the egress PE switch (192.168.12.1) to send IP packets over MPLS to the ingress PE switch (192.168.10.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 to 192.168.10.1
```

9. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 no-cspf
```

10. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch#  set static route 121.121.121.0/24 next-hop 192.168.12.1
user@switch# set static route 121.121.121.0/24 resolve
```

Configuring MPLS on Provider Switches

To implement MPLS, you must configure at least one provider switch as a transit switch for the MPLS packets.

MPLS requires the configuration of an interior gateway protocol (OSPF) and a signaling protocol (RSVP) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch.

To configure the provider switch, complete the following tasks:

1. Configure OSPF on the loopback and core interfaces:

   NOTE: You can use the switch address as an alternative to the loopback interface.

   ```
   [edit protocols ospf]
   user@switch# set area 0.0.0.0 interface lo0.0
   user@switch# set area 0.0.0.0 interface xe-0/0/5.0
   user@switch# set area 0.0.0.0 interface xe-0/0/6.0
   user@switch# set area 0.0.0.0 interface ae0
   ```

2. Configure MPLS on the core interfaces:

   ```
   [edit protocols mpls]
   user@switch# set interface xe-0/0/5.0
   user@switch# set interface xe-0/0/6.0
   user@switch# set interface ae0
   ```

3. Configure RSVP on the loopback interface and the core interfaces:

   ```
   [edit protocols rsvp]
   user@switch# set interface lo0.0
   user@switch# set interface xe-0/0/5.0
   user@switch# set interface xe-0/0/6.0
   user@switch# set interface ae0
   ```

4. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set ae0 unit 0 family inet address 10.1.9.2/24
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
user@switch# set ae0 unit 0 family mpls
```

NOTE: You can configure **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot configure it on tagged VLAN interfaces.

Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)

You can configure MPLS on EX Series switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network or to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

To implement MPLS on switches, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure customer edge (CE) interfaces on the PE switches of the MPLS network by using either IP over MPLS or MPLS over circuit cross-connect (CCC).

The main differences between configuring IP over MPLS and configuring MPLS over CCC are that for IP over MLPS you configure the customer edge interfaces to belong to **family inet** (rather than **family ccc**) and you configure a static route for the label-switched path (LSP). The configuration of the provider switch is the same regardless of whether you

have used IP over MPLS or MPLS over CCC. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

1. Configuring the Ingress PE Switch on page 73
2. Configuring the Egress PE Switch on page 75

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 100.100.100.100/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
```

2. Configure OSPF on the loopback and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

NOTE: If you want to use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as the core interfaces, replace ge-0/0/5.0 and ge-0/0/6 each with an RVI name (for example, vlan.*logical-interface-number*) or a subinterface name (for example, *interface-name.logical-unit-number*).

RVIs function as logical routers, eliminating the need to have both a switch and a router. Layer 3 subinterfaces allow you to route traffic among multiple VLANs along a single trunk line that connects an EX Series switch to a Layer 2 switch.

3. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
```

5. Configure MPLS traffic engineering:

```
[edit protocols]
```

```
user@switch# set protocols mpls traffic-engineering bgp-igp
```

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit]
user@switch# set interfaces ge-2/0/3 unit 0 family inet 121.121.121.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface ge-2/0/3.0
```

10. Configure an LSP on the ingress PE switch (**100.100.100.100**) to send IP packets over MPLS to the egress PE switch (**208.208.208.208**):

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lspjavae_29 from 100.100.100.100
user@switch# set label-switched-path ip_lspjavae_29 to 208.208.208.208
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lspjavae_29 no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

NOTE: Do not configure a static route if you are using this procedure to configure an MPLS-based Layer 3 VPN.

```
[edit]
user@switch# set routing-options static route 2.2.2.0/24 next-hop 100.100.100.100
user@switch# set routing-options static route 2.2.2.0/24 resolve
```

Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 208.208.208.208/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.21.1/24
```

2. Configure OSPF on the loopback interface (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

NOTE: If you want to use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as the core interfaces, replace ge-0/0/5.0 and ge-0/0/6 each with an RVI name (for example, vlan.*logical-interface-number*) or a subinterface name (for example, *interface-name.logical-unit-number*).

RVIs function as logical routers, eliminating the need to have both a switch and a router. Layer 3 subinterfaces allow you to route traffic among multiple VLANs along a single trunk line that connects an EX Series switch to a Layer 2 switch.

3. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
```

5. Configure MPLS traffic engineering on both BGP and IGP destinations:

```
[edit protocols]
user@switch# set protocols mpls traffic-engineering bgp-igp
```

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit]
user@switch# set interfaces ge-2/0/3 unit 0 family inet address 2.2.2.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface ge-2/0/3
```

10. Configure an LSP on the egress PE switch (**208.208.208.208**) to send IP packets over MPLS to the ingress PE switch (**100.100.100.100**):

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lsp29_javae from 208.208.208.208
user@switch# set label-switched-path ip_lsp29_javae to 100.100.100.100
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lsp29_javae no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

NOTE: Do not configure a static route if you are using this procedure to configure an MPLS-based Layer 3 VPN.

```
[edit]
user@switch#  set routing-options static route 121.121.121.0/24 next-hop 208.208.208.208
user@switch# set routing-options static route 121.121.121.0/24 resolve
```

- Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure) on page 81

Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)

Junos OS MPLS for EX8200 and EX4500 switches supports Layer 2 protocols and Layer 2 virtual private networks (VPNs). You can configure MPLS on switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC). The customer edge interface can be either a simple interface or a tagged VLAN interface.

NOTE: If you are configuring a CCC on a tagged VLAN interface, you do not specify **family ccc**. See Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN and Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit.

NOTE: If you are going through this procedure in preparation for configuring an MPLS-based Layer 2 VPN, you do not need to configure the association of the label-switched path (LSP) with the customer edge interface. The BGP signaling automates the connections, so manual configuration of the **connections** is not required.

The following guidelines apply to CCC configurations:

- When an interface is configured to belong to **family ccc**, it cannot belong to any other family.
- You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.
- If you are configuring a CCC on a tagged VLAN interface, you must explicitly enable VLAN tagging and specify a VLAN ID. The VLAN ID cannot be configured on logical interface unit **0**. The logical unit number must be **1** or higher. See Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN and Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit.

This procedure shows how to set up two CCCs:

- If you are configuring a CCC on a simple interface (**ge-0/0/1**), you do not need to enable VLAN tagging or specify a VLAN ID, so you skip those steps.
- If you are configuring a CCC on a tagged VLAN interface (**ge-0/0/2**), include all the steps in this procedure.

To configure a PE switch with a CCC:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@switch# set ospf area 0.0.0.0 interface ae0
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set interfaces ae0 unit 0 family inet address 10.1.9.1/24
```

4. Enable MPLS and define the LSP:

```
[edit protocols]
user@switch# set mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
```

TIP: **lsp_to_pe2_ge1** is the LSP name. You will need to use the specified name again when configuring the CCC.

5. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
user@switch# set mpls interface ae0
```

6. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
user@switch# set rsvp interface ae0
```

7. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
user@switch# set interfaces ae0 unit 0 family mpls
```

NOTE: You can enable family mpls on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

8. If you are configuring a CCC on a tagged VLAN interface, enable VLAN tagging on the customer edge interface **ge-0/0/2** of the local PE switch:

```
[edit interfaces ge-0/0/2]
user@switch# set vlan-tagging
```

   If you are configuring a CCC on a simple interface (**ge-0/0/1**), omit this step.

9. If you are configuring a CCC on a tagged VLAN interface, configure the logical unit of the customer edge interface with a VLAN ID:

```
[edit interfaces ge-0/0/2 unit 1]
user@switch# set vlan-id 100
```

   If you are configuring a CCC on a simple interface (**ge-0/0/1**), omit this step.

10. Configure the logical unit of the customer edge interface to belong to **family ccc**:

    - On a simple interface:

```
[edit interfaces ge-0/0/1 unit 0]
user@switch# set family ccc
```

    - On a tagged VLAN interface:

```
[edit interfaces ge-0/0/2 unit 1]
user@switch# set family ccc
```

11. Associate the CCC interface with two LSPs, one for transmitting MPLS packets and the other for receiving MPLS packets:

NOTE: If you are configuring a Layer 2 VPN, omit this step. The BGP signaling automates the connections, so manual configuration of the connections is not required.

    - On a simple interface:

```
[edit protocols]
user@switch# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/1.0
user@switch# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp
lsp_to_pe2_ge1
user@switch# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

    - On a tagged VLAN interface:

```
[edit protocols]
user@switch# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/2.1
user@switch# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp
lsp_to_pe2_ge1
user@switch# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

TIP: The **transmit-lsp** option specifies the LSP name that was configured on PE-1 (the local PE switch) by the **label-switched-path** statement within the **[edit protocols mpls]** hierarchy.
The **receive-lsp** option specifies the LSP name that was configured on PE-2 (the remote PE switch) by the **label-switched-path** statement within the **[edit protocols mpls]** hierarchy.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

Related Documentation

- Example: Configuring MPLS on EX8200 and EX4500 Switches on page 48
- Example: Configuring MPLS-Based Layer 2 VPNs on page 907

Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)

You can configure MPLS on EX8200 and EX4500 switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

To implement MPLS on EX Series switches, you must configure at least one provider switch as a transit switch for the MPLS packets. The configuration of all the provider switches remains the same regardless of whether the provider edge (PE) switches are using circuit cross-connect (CCC) or using MPLS over IP for the customer edge interfaces. Likewise, you do not need to change the configuration of the provider switches if you implement an MPLS-based Layer 2 VPN, Layer 3 VPN, or a Layer 2 circuit configuration.

MPLS requires the configuration of a routing protocol (OSPF or IS-IS) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch. For information on configuring IS-IS as the routing protocol, see *Junos OS Routing Protocols Configuration Guide*.

To configure the provider switch, complete the following tasks:

1. Enable the routing protocol (OSPF or IS-IS) on the loopback interface and on the core interfaces:

   

   NOTE: **You can use the switch address as an alternative to the loopback interface.**

   ```
   [edit protocols]
   user@switch# set ospf area 0.0.0.0 interface lo0.0
   user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
   user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
   user@switch# set ospf area 0.0.0.0 interface ae0
   ```

2. Enable traffic engineering for the routing protocol (traffic engineering must be explicitly enabled for OSPF):

   ```
   [edit protocols]
   user@switch# set ospf traffic-engineering
   ```

3. Enable MPLS within the **protocols** stanza and apply it to the core interfaces:

   ```
   [edit protocols]
   user@switch# set mpls interface ge-0/0/5.0
   user@switch# set mpls interface ge-0/0/6.0
   user@switch# set mpls interface ae0
   ```

4. Configure RSVP on the loopback interface and the core interfaces:

   ```
   [edit protocols]
   user@switch# set rsvp interface lo0.0
   user@switch# set rsvp interface ge-0/0/5.0
   ```

```
user@switch# set rsvp interface ge-0/0/6.0
user@switch# set rsvp interface ae0
```

5. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set interfaces ae0 unit 0 family inet address 10.1.9.2/24
```

6. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
user@switch# set interfaces ae0 unit 0 family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

CHAPTER 4

Configuring Bidirectional Forwarding Detection (BFD) for MPLS

Configuring Bidirectional Forwarding Detection for MPLS (CLI Procedure)

You can configure the Bidirectional Forwarding Detection (BFD) protocol on EX8200 standalone switches and EX8200 Virtual Chassis to detect failures in the MPLS label-switch path (LSP). The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply from the neighbor after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than those of the failure detection mechanisms for static routes, and thus provide faster detection. These timers are also adaptive. For example, a timer can adapt to a higher value if an adjacency fails, or a neighbor can negotiate a higher value than the one configured.

This topic describes configuring the provider edge (PE) switches and the provider switches to support for LDP-based LSPs and RSVP-based LSPs.

This topic includes:

Configuring BFD on Provider Edge and Provider Switches for an LDP-Based LSP

You can enable BFD for the LDP-based LSPs or RSVP-based LSPs associated with a specific forwarding equivalence class (FEC). Alternatively, you can configure an Operation Administration and Maintenance (OAM) ingress policy to enable BFD on a range of FEC addresses.

Before you configure BFD for an LDP-based based LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)" on page 72.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

To configure BFD on PE and provider switches:

1. Define an OAM policy:

```
[edit]
user@switch# set protocols ldp oam ingress-policy policy-name
```

2. Specify the FEC on which you want to enable OAM:

```
[edit]
user@switch# set protocols ldp oam fec address
```

3. Specify the minimum transmit and receive interval for the BFD configuration:

NOTE: If you configure the minimum-interval statement, you do not need to configure the minimum-receive-interval statement or the minimum-transmit-interval statement.

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection minimum-interval time
```

or

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection minimum-receive-interval time
user@switch# set protocols ldp oam bfd-liveness-detection minimum-transmit-interval time
```

4. Specify the detection time multiplier. The negotiated transmit interval multiplied by this value gives the detection time for the receiving system in Asynchronous mode:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection multiplier multiplier
```

5. Specify the minimum transmit interval (or the minimum receive interval).

```
[edit]
```

```
user@switch# set protocols ldp oam bfd-liveness-detection transmit-interval
minimum-interval time
```

6. Specify a threshold for detecting the adaptation of the detection time:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection detection-time threshold time
```

7. Configure route and next-hop action in the event of a BFD session failure event on the LDP-based LSP:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection failure-action action
```

NOTE: When a BFD session goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. You can configure a standby LSP path to handle traffic while the primary LSP path is unavailable. The switch can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

8. Specify how long the BFD session must be up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection holddown-interval time
```

9. Enable tracing of FECs for LDP-based LSPs and specify a source address for sending probes. Then, specify a wait interval, after which to send the probe packet.

```
[edit]
user@switch# set protocols ldp oam periodic-traceroute source address
user@switch# set protocols ldp oam periodic-traceroute wait time
```

10. Specify the duration of the LSP ping interval in seconds:

```
[edit]
user@switch# set protocols ldp oam lsp-ping-interval time
```

11. Specify the action to be taken for the OAM policy:

```
[edit]
user@switch# set policy-options policy-statement policy-name then accept
```

12. Apply the BFD configurations at the MPLS hierarchy level for the configuration to inherit the statements in the configuration group:

```
[edit]
user@switch# set apply-groups MPLS
```

Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP

When BFD is configured for an RSVP-based LSP on the ingress switch, it is enabled on the primary path and on all standby secondary paths for that LSP. You can enable BFD for all LSPs on a switch or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden on that LSP. The BFD sessions originate only at the ingress switch and terminate at the egress switch.

Before you configure BFD for an RSVP-based LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)" on page 72.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

To configure BFD on PE and provider switches:

1. Specify the minimum transmit and receive interval for the BFD configuration:

   NOTE: If you configure the **minimum-interval** statement, you do not need to configure the **minimum-receive-interval** statement or the **minimum-transmit-interval** statement.

   ```
   [edit]
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection minimum-interval time
   ```

   or

   ```
   [edit]
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection minimum-receive-interval time
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection minimum-transmit-interval time
   ```

2. Specify the detection time multiplier. The negotiated transmit interval multiplied by this value gives the detection time for the receiving system in Asynchronous mode:

   ```
   [edit]
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection multiplier multiplier
   ```

3. Specify the minimum transmit interval (or the minimum receive interval):

   ```
   [edit]
   user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection transmit-interval minimum-interval time
   ```

4. Configure route and next-hop actions in the event of a BFD session failure event on the RSVP-based LSP:

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
failure-action action
```

NOTE: When a BFD session goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. You can configure a standby LSP path to handle traffic while the primary LSP path is unavailable. The switch can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged if you do not specifically configure a failure action.

BFD-Triggered Local Repair for Rapid Convergence

- Understanding BFD-Triggered Local Protection on page 87

Understanding BFD-Triggered Local Protection

The time it takes for a network to converge following a link or node failure can vary dramatically based on a number of factors, including network size, the protocols used, and network design. However, while each particular convergence event is different, the process of convergence is essentially consistent. The failure is detected, the failure is reported (flooded) in the network, an alternate path is found for traffic, and the forwarding plane is updated to pass traffic on a new path.

This overview discusses how Bidirectional Forwarding Detection (BFD)-triggered local repair contributes to a quicker restoration time for rapid convergence in an MPLS network.

- Purpose of BFD-Triggered Local Repair on page 87
- Configuring BFD-Triggered Local Repair on page 88
- Disabling BFD-Triggered Local Repair on page 88

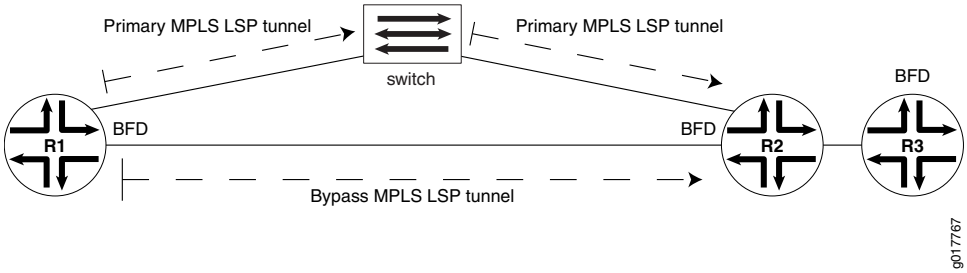
Purpose of BFD-Triggered Local Repair

In Junos OS, general MPLS traffic protection for RSVP-signaled label-switched path (LSP) failures is provided by several complementary mechanisms. These protection mechanisms include local protection (fast reroute, link protection, and node-link protection) and path protection (primary and secondary paths). Local protection in conjunction with path protection can provide minimum packet loss for an LSP, and control the way the LSP is rerouted after a failure. Traditionally, both types of protection rely on fast detection of connectivity failure at the physical level. However, for transmission media without fast physical level detection, Junos OS supports BFD and MPLS ping for fast failure detection.

With links between routers, when a route goes down, the routing protocol process recalculates the next best path. When MPLS fast reroute (FRR) is enabled, ifl messages are flooded to all Flexible PIC Concentrators (FPCs). The edge FPC enables the bypass MPLS LSP tunnel. Lastly, all routes are repaired and sent through the bypass MPLS LSP tunnel. The amount of time it takes to repair all routes is proportional to the number of routes.

This repair scenario becomes more difficult when a switch lies between two links. See Figure 5 on page 88.

Figure 5: Topology with BFD-Triggered Local Repair



When a link goes down at the remote end, the failure is not detected at the local end until the interior gateway protocol (IGP) goes down. To wait for the routing protocol process to recalculate the next best path takes too much time.

With BFD-triggered local repair enabled, the Packet Forwarding Engine completes the repair first, using the bypass MPLS LSP tunnel (that is preconfigured and installed), then informs the routing protocol process to recalculate a new route. By doing this, when the primary MPLS LSP tunnel goes down, the FPC can intermittently and immediately divert traffic to the FPC with the bypass MPLS LSP tunnel.

Using local repair in this way achieves a faster restoration time of less than 50 ms.

Configuring BFD-Triggered Local Repair

BFD-triggered local repair is not configurable, but is part of the default configuration.

BFD-triggered local repair works within the legacy Junos OS features MPLS-FRR, BFD for IGP, and loop-free alternates (LFAs).

Disabling BFD-Triggered Local Repair

By default, BFD-triggered local repair is enabled for all routing interfaces. If desired, you can disable BFD-triggered local repair at the [**edit routing-options**] hierarchy level.

To explicitly disable BFD-triggered local repair:

1. Include the **no-bfd-triggered-local-repair** statement at the [edit routing-options] hierarchy level:

```
user@host# set no-bfd-triggered-local-repair
```

2. (Optional) Verify your configuration settings before committing them by using the **show routing-options** command.

   ```
   user@host# run show routing-options
   ```

Confirm your configuration by issuing the **show routing-options** command.

```
user@host# show routing-options
...
  no-bfd-triggered-local-repair;
}
```

NOTE: When you disable this feature, you must also restart routing by including the **graceful-restart** statement for the IGP. For example, for OSPF, this is accomplished by including the **graceful-restart** statement at the **[edit protocols ospf]** hierarchy level.

Configuring BFD for MPLS IPv4 LSPs

You can configure Bidirectional Forwarding Detection (BFD) protocol on MPLS IPv4 LSPs as outlined in the Internet draft draft-ietf-bfd-mpls-02.txt, *BFD for MPLS LSPs*. BFD is used as a periodic Operation, Administration, and Maintenance (OAM) feature for LSPs to detect LSP data plane faults. You can configure BFD for LSPs that use either LDP or RSVP as the signaling protocol.

NOTE: BFD for MPLS IPv4 LSP is based on the Routing Engine and is not distributed. As a result, the minimum supported BFD timer interval is (100 ms * 3) per one LSP session, and for scaled LSP sessions, the minimum supported BFD timer interval is (300 ms * 3). As you increase the number of LSP sessions with BFD, you must also increase (scale) the interval timers to support the network.

For Routing Engine switchover instances with nonstop active routing (NSR) support, the minimum supported BFD timer interval is (2.5 seconds * 3).

You can also use the LSP **ping** commands to detect LSP data plane faults. However, BFD has a couple of benefits: it requires less computer processing than LSP **ping** commands and can quickly detect faults in large numbers of LSPs (LSP **ping** commands must be issued for each LSP individually). On the other hand, BFD cannot be used to verify the control plane against the data plane at the egress LSR, which is possible when an LSP **ping** echo request is associated with a forwarding equivalence class (FEC).

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down. To so do, you configure the **lsp-ping-interval** statement and the **lsp-ping-multiplier** statement at the **[edit protocols mpls oam]** hierarchy level.

For configuration instructions for LDP-signaled LSPs, see *Configuring BFD for LDP LSPs*. For configuration instructions for RSVP-signaled LSPs, see the following section.

Configuring BFD for RSVP-Signaled LSPs

BFD for RSVP supports unicast IPv4 LSPs. When BFD is configured for an RSVP LSP on the ingress router, it is enabled on the primary path and on all standby secondary paths for that LSP. The source IP address for outgoing BFD packets from the egress side of an MPLS BFD session is based on the outgoing interface IP address. You can enable BFD for all LSPs on a router or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden. The BFD sessions originate only at the ingress router and terminate at the egress router.

An error is logged whenever a BFD session for a path fails. The following example shows how BFD for RSVP LSP log messages might appear:

```
RPD_MPLS_PATH_BFD_UP: MPLS BFD session for path path1 up on LSP R0_to_R3
RPD_MPLS_PATH_BFD_DOWN: MPLS BFD session for path path1 down on LSP R0_to_R3
```

You can configure BFD for all of the RSVP LSPs on the router, a specific LSP, or the primary path of a specific LSP. To configure BFD for RSVP LSPs, include the **oam** and **bfd-liveness-detection** statements.

```
oam {
  bfd-liveness-detection {
    failure-action {
```

```
        make-before-break teardown-timeout seconds;
        teardown;
      }
      failure-action teardown;
      minimum-interval milliseconds;
      minimum-receive-interval milliseconds;
      minimum-transmit-interval milliseconds;
      multiplier detection-time-multiplier;
    }
    lsp-ping-interval time-interval;
    lsp-ping-multiplier multiplier;
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** label-switched-path ***lsp-name*** primary ***path-name*****]**

The **bfd-liveness-detection** statement includes the following options:

- **minimum-interval**—Specifies the minimum transmit and receive interval.
- **minimum-receive-interval**—Specifies the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- **minimum-transmit-interval**—Specifies the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- **lsp-ping-multiplier**—Specifies the detection time multiplier. The range is from 1 through 255.

NOTE: To avoid triggering false negatives, configure a BFD fault detection time that is longer than the fast reroute time.

You can also configure the **lsp-ping-interval** option to adjust the time interval between LSP pings. The LSP ping command for RSVP-signaled LSPs is **ping mpls rsvp**. For more information on the **ping mpls rsvp** command, see the CLI Explorer.

Configuring a Failure Action for the BFD Session on an RSVP LSP

When the BFD session for an RSVP LSP goes down, the LSP is torn down and resignaled. Traffic can be switched to a standby LSP, or you can simply tear down the LSP path. Any actions performed are logged.

When a BFD session for an RSVP LSP path goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. A standby LSP path could be configured to handle traffic while the primary LSP path is unavailable. The router can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

To enable the Junos OS to tear down an RSVP LSP path in the event of a BFD event, include the **failure-action** statement:

```
failure-action {
   make-before-break teardown-timeout seconds;
   teardown;
}
```

For a list of the hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can configure either the **teardown** or **make-before-break** options:

- **teardown**—Causes the LSP path to be taken down and resignaled immediately.
- **make-before-break**—Causes the Junos OS to attempt to signal a new LSP path before tearing down the old LSP path. You can also configure the **teardown-timeout** option to automatically tear down the LSP after the time period specified if the attempt to resignal the LSP fails within the **teardown-timeout** interval. If you specify a value of 0 for the **teardown-timeout** interval, the LSP is taken down and resignaled immediately (the same behavior as when you configure the **teardown** option).

To configure a failure action for all of the RSVP LSPs, include the **failure-action** statement at the **[edit protocols mpls oam bfd-liveness-detection]** hierarchy level. To configure a failure action for a specific RSVP LSP, include the **failure-action** statement at the **[edit protocols mpls label-switched-path *lsp-name* oam bfd-liveness-detection]** hierarchy level.

To configure a failure action for a specific primary path, include the **failure-action** statement at the **[edit protocols mpls label-switched path *lsp-name* primary *path-name* oam bfd-liveness-detection]** hierarchy level. To configure a failure action for a specific secondary LSP path, include the **failure-action** statement at the **[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam bfd-liveness-detection]** hierarchy level.

Release History Table

Release	Description
13.2R4	Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down.

CHAPTER 5

Configuring Firewall Filters, System Log Messages, and SNMP for MPLS

Configuring MPLS Firewall Filters and Policers on Switches

You can configure firewall filters to filter MPLS traffic. To use an MPLS firewall filter, you must first configure the filter and then apply it to an interface you have configured for forwarding MPLS traffic. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached.

NOTE: **You can configure ingress MPLS firewall filters only. Egress MPLS firewall filters are not supported. You cannot apply MPLS firewall filters to loopback interfaces.**

When you configure an MPLS firewall filter, you define filtering criteria (terms, with match conditions) for the packets and an action (action, or action modifier) for the switch to take if the packets match the filtering criteria.

- Table 10 on page 94 describes the match conditions you can configure for MPLS firewall filters at the **[edit firewall family mpls filter *filter-name* term *term-name* from]** hierarchy level.

NOTE: **If a packet has multiple MPLS labels, the filter applies the match conditions to only the bottom label in the label stack.**

Table 10: Supported Match Conditions for MPLS Firewall Filters

Match Condition	Description
exp ***number***	Experimental (EXP) bit number or range of bit numbers in the MPLS header of a packet. For *number*, you can specify one or more values from 0 through 7 in binary, decimal or hexadecimal format, as given below: • A single EXP bit—for example, **exp 3** • Several EXP bits—for example, **exp 0,4** • A range of EXP bits—for example, **exp [0-5]**
label ***number***	MPLS label value or range of label values in the MPLS header of a packet. For *number*, you can specify one or more values from 0 through 1048575 in decimal or hexadecimal format, as given below: • A single label—for example, **label 3** • Several labels—for example, **label 0,4** • A range of labels—for example, **label [0-5]**

- Table 11 on page 94 describes the actions you can configure for MPLS firewall filters at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level.

Table 11: Supported Actions for MPLS Firewall Filters

Action	Description
accept	Accept a packet
count ***counter-name***	Count the number of packets that pass this filter or term. NOTE: We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.
discard	Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message
policer	Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer.
three-color-policer	Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a three-color policer.

- Configuring an MPLS Firewall Filter on page 95
- Applying an MPLS Firewall Filter to an MPLS Interface on page 95
- Configuring Policers for LSPs on page 95

Configuring an MPLS Firewall Filter

To configure an MPLS firewall filter:

1. Configure the filter name, term name, and at least one match condition—for example, match on MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls]
user@switch# set filter ingress-exp-filter term term-one from exp 0,4
```

2. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term—for example, count MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls filter ingress-exp-filter term term-one then]
user@switch# set count counter0
user@switch# set accept
```

Applying an MPLS Firewall Filter to an MPLS Interface

To apply the MPLS firewall filter to an interface you have configured for forwarding MPLS traffic (using the **family mpls** statement at the **[edit interfaces *interface-name* unit *unit-number*]** hierarchy level):

NOTE: You can apply firewall filters only to filter MPLS packets that enter an interface.

1. Apply the firewall filter to an MPLS interface—for example, apply the firewall filter to interface xe-0/0/5:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls filter input ingress-exp-filter
```

2. Review your configuration and issue the **commit** command:

```
[edit interfaces]
user@switch# commit
commit complete
```

Configuring Policers for LSPs

Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer or three-color policer. MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each

multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.

- Supported MPLS Scaling Values on page 11
- *Overview of Policers*

Configuring MPLS Firewall Filters and Policers on Routers

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can also configure policers for MPLS LSPs.

The following sections discuss MPLS firewall filters and policers:

Configuring MPLS Firewall Filters

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can then apply this filter to a specific interface. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic

on the interface to which the filter is attached. You cannot apply MPLS firewall filters to Ethernet (fxp0) or loopback (lo0) interfaces.

You can configure an MPLS firewall filter on the M Series Multiservice Edge Routers and the T Series Core Routers.

You can configure the following match criteria attributes for MPLS filters at the **[edit firewall family mpls filter *filter-name* term *term-name* from]** hierarchy level:

- **exp**
- **exp-except**

These attributes can accept EXP bits in the range 0 through 7. You can configure the following choices:

- A single EXP bit—for example, **exp 3;**
- Several EXP bits—for example, **exp 0, 4;**
- A range of EXP bits—for example, **exp [0-5];**

If you do not specify a match criterion (that is, you do not configure the **from** statement and use only the **then** statement with the **count** action keyword), all the MPLS packets passing through the interface on which the filter is applied will be counted.

You also can configure any of the following action keywords at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level:

- **count**
- **accept**
- **discard**
- **next**
- **policer**

For more information about how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*. For more information about how to configure interfaces, see the *Junos OS Network Interfaces Library for Routing Devices* and the *Junos OS Services Interfaces Library for Routing Devices*.

Examples: Configuring MPLS Firewall Filters

The following examples illustrate how you might configure an MPLS firewall filter and then apply the filter to an interface. This filter is configured to count MPLS packets with EXP bits set to either 0 or 4.

The following shows a configuration for an MPLS firewall filter:

```
[edit firewall]
family mpls {
   filter expf {
```

```
    term expt0 {
      from {
        exp 0,4;
      }
      then {
        count counter0;
        accept;
      }
    }
  }
}
```

The following shows how to apply the MPLS firewall filter to an interface:

```
[edit interfaces]
so-0/0/0 {
  mtu 4474;
  encapsulation ppp;
  sonet-options {
    fcs 32;
  }
  unit 0 {
    point-to-point;
    family mpls {
      filter {
        input expf;
        output expf;
      }
    }
  }
}
```

The MPLS firewall filter is applied to the input and output of an interface (see the **input** and **output** statements in the preceding example).

Configuring Policers for LSPs

MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different

families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

You can configure only those match conditions that apply across all types of traffic. The following are the supported match conditions for LSP policers:

- **forwarding-class**
- **packet-length**
- **interface**
- **interface-set**

To enable a policer on an LSP, first you need to configure a policing filter and then include it in the LSP configuration. For information about how to configure policers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

To configure a policer for an LSP, specify a filter by including the **filter** option to the **policing** statement:

```
policing {
   filter filter-name;
}
```

You can include the **policing** statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** static-label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** static-label-switched-path ***lsp-name*****]**

LSP Policer Limitations

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- LSP policers are not supported on aggregated interfaces.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.
- LSP policers work on all T Series routers and on M Series routers that have the Internet Processor II application-specific integrated circuit (ASIC).

NOTE: Starting with Junos OS Release 12.2R2, on T Series routers only, you can configure an LSP policer for a specific LSP to be shared across different protocol family types. To do so, you must configure the *logical-interface-policer* statement at the **[edit firewall policer *policer-name*]** hierarchy level.

Example: Configuring an LSP Policer

The following example shows how you can configure a policing filter for an LSP:

```
[edit firewall]
policer police-ct1 {
   if-exceeding {
      bandwidth-limit 50m;
      burst-size-limit 1500;
   }
   then {
      discard;
   }
}
policer police-ct0 {
   if-exceeding {
      bandwidth-limit 200m;
      burst-size-limit 1500;
   }
   then {
      discard;
   }
}
family any {
   filter bar {
      term discard-ct0 {
         then {
            policer police-ct0;
            accept;
         }
      }
   }
   term discard-ct1 {
      then {
         policer police-ct1;
         accept;
      }
   }
}
```

Configuring Automatic Policers

Automatic policing of LSPs allows you to provide strict service guarantees for network traffic. Such guarantees are especially useful in the context of Differentiated Services for traffic engineered LSPs, providing better emulation for ATM wires over an MPLS

network. For more information about Differentiated Services for LSPs, see "DiffServ-Aware Traffic Engineering Introduction" on page 688.

Differentiated Services for traffic engineered LSPs allow you to provide differential treatment to MPLS traffic based on the EXP bits. To ensure these traffic guarantees, it is insufficient to simply mark the traffic appropriately. If traffic follows a congested path, the requirements might not be met.

LSPs are guaranteed to be established along paths where enough resources are available to meet the requirements. However, even if the LSPs are established along such paths and are marked properly, these requirements cannot be guaranteed unless you ensure that no more traffic is sent to an LSP than there is bandwidth available.

It is possible to police LSP traffic by manually configuring an appropriate filter and applying it to the LSP in the configuration. However, for large deployments it is cumbersome to configure thousands of different filters. Configuration groups cannot solve this problem either, since different LSPs might have different bandwidth requirements, requiring different filters. To police traffic for numerous LSPs, it is best to configure automatic policers.

When you configure automatic policers for LSPs, a policer is applied to all of the LSPs configured on the router. However, you can disable automatic policing on specific LSPs.

NOTE: When you configure automatic policers for DiffServ-aware traffic engineering LSP, GRES is not supported.

NOTE: You cannot configure automatic policing for LSPs carrying CCC traffic.

The following sections describe how to configure automatic policers for LSPs:

- Configuring Automatic Policers for LSPs on page 101
- Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs on page 102
- Configuring Automatic Policers for Point-to-Multipoint LSPs on page 103
- Disabling Automatic Policing on an LSP on page 103
- Example: Configuring Automatic Policing for an LSP on page 103

Configuring Automatic Policers for LSPs

To configure automatic policers for standard LSPs (neither DiffServ-aware traffic engineered LSPs nor multiclass LSPs), include the **auto-policing** statement with either the **class all** ***policer-action*** option or the **class ct0** ***policer-action*** option:

```
auto-policing {
   class all policer-action;
   class ct0 policer-action;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You can configure the following policer actions for automatic policers:

- **drop**—Drop all packets.
- **loss-priority-high**—Set the packet loss priority (PLP) to high.
- **loss-priority-low**—Set the PLP to low.

These policer actions are applicable to all types of LSPs. The default policer action is to do nothing.

Automatic policers for LSPs police traffic based on the amount of bandwidth configured for the LSPs. You configure the bandwidth for an LSP using the **bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-path-name*]** hierarchy level. If you have enabled automatic policers on a router, change the bandwidth configured for an LSP, and commit the revised configuration, the change does not take affect on the active LSPs. To force the LSPs to use the new bandwidth allocation, issue a **clear mpls lsp** command.

NOTE: You cannot configure automatic policers for LSPs that traverse aggregated interfaces or Multilink Point-to-Point Protocol (MLPPP) interfaces.

Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs

To configure automatic policers for DiffServ-aware traffic engineering LSPs and for multiclass LSPs, include the **auto-policing** statement:

```
auto-policing {
   class all policer-action;
   class ctnumber policer-action;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You include either the **class all *policer-action*** statement or a **class ct*number policer-action*** statement for each of one or more classes (you can configure a different policer action for each class). For a list of the actions that you can substitute for the ***policer-action*** variable, see "Configuring Automatic Policers for LSPs" on page 101. The default policer action is to do nothing.

NOTE: You cannot configure automatic policers for LSPs that traverse aggregated interfaces or MLPPP interfaces.

Configuring Automatic Policers for Point-to-Multipoint LSPs

You can configure automatic policers for point-to-multipoint LSPs by including the **auto-policing** statement with either the **class all** ***policer-action*** option or the **class ct0** ***policer-action*** option. You only need to configure the **auto-policing** statement on the primary point-to-multipoint LSP (for more information on primary point-to-multipoint LSPs, see "Configuring the Primary Point-to-Multipoint LSP" on page 552). No additional configuration is required on the subLSPs for the point-to-multipoint LSP. Point-to-multipoint automatic policing is applied to all branches of the point-to-multipoint LSP. In addition, automatic policing is applied to any local VRF interfaces that have the same forwarding entry as a point-to-multipoint branch. Feature parity for automatic policers for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

The automatic policer configuration for point-to-multipoint LSPs is identical to the automatic policer configuration for standard LSPs. For more information, see "Configuring Automatic Policers for LSPs" on page 101.

Disabling Automatic Policing on an LSP

When you enable automatic policing, all of the LSPs on the router or logical system are affected. To disable automatic policing on a specific LSP on a router where you have enabled automatic policing, include the **policing** statement with the **no-auto-policing** option:

```
policing no-auto-policing;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

Example: Configuring Automatic Policing for an LSP

Configure automatic policing for a multiclass LSP, specifying different actions for class types **ct0**, **ct1**, **ct2**, and **ct3**.

```
[edit protocols mpls]
diffserv-te {
   bandwidth-model extended-mam;
}
auto-policing {
   class ct1 loss-priority-low;
   class ct0 loss-priority-high;
   class ct2 drop;
   class ct3 loss-priority-low;
```

```
}
traffic-engineering bgp-igp;
label-switched-path sample-lsp {
   to 3.3.3.3;
   bandwidth {
      ct0 11;
      ct1 1;
      ct2 1;
      ct3 1;
   }
}
interface fxp0.0 {
   disable;
}
interface t1-0/5/3.0;
interface t1-0/5/4.0;
```

Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets

You can selectively set the DiffServ code point (DSCP) field of MPLS-tagged IPv4 and IPv6 packets to 0 without affecting output queue assignment, and continue to set the MPLS EXP field according to the configured rewrite table, which is based on forwarding classes. You can accomplish this by configuring a firewall filter for the MPLS-tagged packets.

For instructions on how to write different DSCP and EXP values in MPLS-tagged IP packets, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*. For instructions on how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

Configuring System Log Messages and SNMP Traps for LSPs

Whenever an LSP makes a transition from up to down, or down to up, and whenever an LSP switches from one active path to another, the ingress router generates a system log message and sends an SNMP trap. The following shows a sample system log message:

```
RPD_MPLS_LSP_UP: MPLS LSP sheep1 up on primary(any) Route  192.168.1.1 192.168.1.2
 192.168.1.3
RPD_MPLS_LSP_CHANGE: MPLS LSP sheep1 change on primary(any) Route  192.168.1.1
192.168.1.2 192.168.1.3
RPD_MPLS_LSP_DOWN: MPLS LSP sheep1 down on primary(any)
```

For information about the MPLS SNMP traps and the proprietary MPLS MIBs, see the *Network Management and Monitoring Guide*.

System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the **no-syslog** option under the **log-updown** statement:

```
log-updown {
  no-syslog;
}
```

To generate SNMP traps for LSPs, include the **trap** option to the **log-updown** statement:

```
log-updown {
  trap;
}
```

To generate SNMP traps whenever an LSP path goes down, include the **trap-path-down** option to the **log-updown** statement:

```
log-updown {
  trap-path-down;
}
```

To generate SNMP traps whenever an LSP path comes up, include the **trap-path-up** option to the **log-updown** statement:

```
log-updown {
  trap-path-up;
}
```

To disable the generation of system log messages, include the **no-syslog** option to the **log-updown** statement:

```
log-updown {
  no-syslog;
}
```

To disable the generation of SNMP traps, include the **no-trap** statement:

```
no-trap {
  mpls-lsp-traps;
  rfc3812-traps;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** log-updown**]**
- **[edit logical-systems** *logical-system-name* **protocols mpls** log-updown**]**

For scalability reasons, only the ingress router generates SNMP traps. By default, MPLS issues traps for all configured LSPs. If you have many LSPs, the number of traps can become quite large. To disable the generation of SNMP traps, configure the **no-trap** statement.

The **no-trap** statement also includes the following options which allow you to block certain categories of MPLS SNMP traps:

- **mpls-lsp-traps**—Blocks the MPLS LSP traps defined in the **jnx-mpls.mib**, but allows the **rfc3812.mib** traps.
- **rfc-3812-traps**—Blocks the traps defined in the **rfc3812.mib**, but allows the MPLS LSP traps defined in the **jnx-mpls.mib**.

CHAPTER 6

Configuring Graceful Restart for MPLS

Configuring MPLS-Signaled LSPs to Use GRE Tunnels

MPLS LSPs can use generic routing encapsulation (GRE) tunnels to cross routing areas, autonomous systems, and ISPs. Bridging MPLS LSPs over an intervening IP domain is possible without disrupting the outlying MPLS domain.

LSPs can reach any destination that the GRE tunnels can reach. MPLS applications can be deployed without requiring all transit nodes to support MPLS, or requiring all transit nodes to support the same label distribution protocols (LDP or RSVP). If you use CSPF, you must configure OSPF or IS-IS through the GRE tunnel. Traffic engineering is not supported over GRE tunnels; for example, you cannot reserve bandwidth or set priority or preemption.

NOTE: Use the **no-control word** statement to disable the control word when the topology uses GRE as the connection mechanism between provider edge routers and one of the provider edge routers is an M Series Multiservice Edge Router.

For more information about GRE tunnels, see the *Junos OS Services Interfaces Library for Routing Devices*.

Example: Configuring MPLS-Signaled LSPs to Use GRE Tunnels

To configure MPLS over GRE tunnels:

1. Enable **family mpls** under the GRE interface configuration:

```
[edit interfaces]
interface gr-1/2/0 {
   unit 0 {
      tunnel {
         source 192.168.1.1;
         destination 192.168.1.2;
      }
```

```
    family inet {
      address 5.1.1.1/30;
    }
    family iso;
    family mpls;
  }
}
```

2. Enable RSVP and MPLS over the GRE tunnel:

```
[edit protocols]
rsvp {
  interface gr-1/2/0.0;
}
mpls {
  ...
  interface gr-1/2/0.0;
}
```

3. Configure LSPs to travel through the GRE tunnel endpoint address:

```
[edit protocols]
mpls {
  label-switched-path gre-tunnel {
    to 5.1.1.2;
    ...
  }
}
```

Standard LSP configuration options apply. If the routing table specifies that a particular route will traverse a GRE tunnel, the RSVP packets will traverse the tunnel as well.

Graceful Restart and MPLS-Related Protocols

This section contains the following topics:

LDP

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

The reconnect time is configured in Junos OS as 60 seconds and is not user-configurable. The reconnect time is how long the helper router waits for the restarting router to establish a connection. If the connection is not established within the reconnect interval, graceful restart for the LDP session is terminated. The maximum reconnect time is 120 seconds and is not user-configurable. The maximum reconnect time is the maximum value that a helper router accepts from its restarting neighbor.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, so it can continue to forward traffic.

You can configure LDP graceful restart both in the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and for a specific routing instance only.

RSVP

RSVP graceful restart enables a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

CCC and TCC

CCC and TCC graceful restart enables Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the provider edge (PE) routers and provider (P) routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

CHAPTER 7

Configuring Link, Node, and Path Protection for MPLS

Node-Link Protection Overview

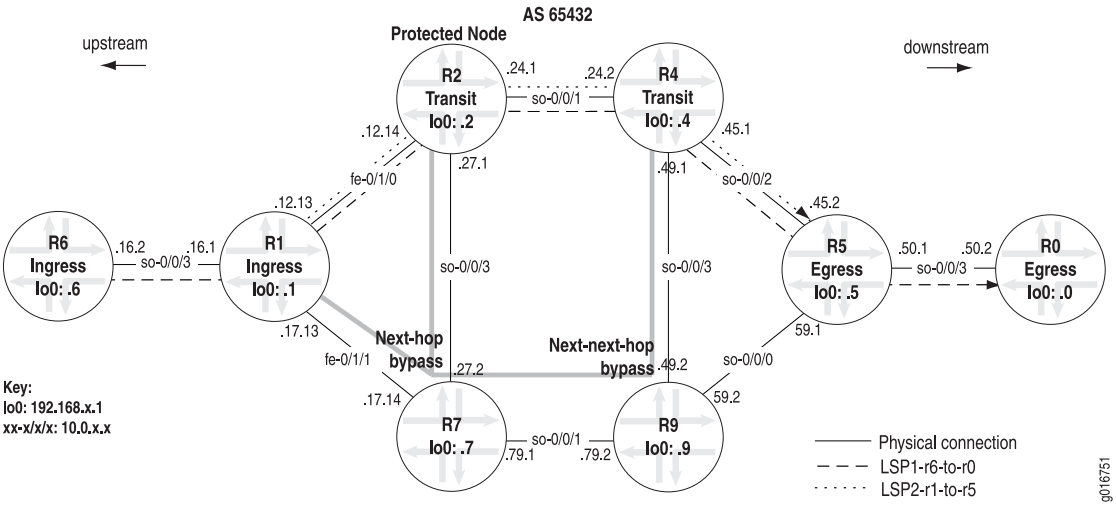
Node-link protection (many-to-one or facility backup) extends the capabilities of link protection and provides slightly different protection from fast reroute. While link protection is useful for selecting an alternate path to the same router when a specific link fails, and fast reroute protects interfaces or nodes along the entire path of an LSP, node-link protection establishes a bypass path that avoids a particular node in the LSP path.

When you enable node-link protection for an LSP, you must also enable link protection on all RSVP interfaces in the path. Once enabled, the following types of bypass paths are established:

- Next-hop bypass LSP—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass path is established when you enable either node-link protection or link protection.
- Next-next-hop bypass LSP—Provides an alternate route for an LSP through a neighboring router en route to the destination router. This type of bypass path is established exclusively when node-link protection is configured.

Figure 6 on page 112 illustrates the example MPLS network topology used in this topic. The example network uses OSPF as the interior gateway protocol (IGP) and a policy to create traffic.

Figure 6: Node-Link Protection



The MPLS network in Figure 6 on page 112 illustrates a router-only network that consists of unidirectional LSPs between **R1** and **R5**, (**lsp2-r1-to-r5**) and between **R6** and **R0** (**lsp1-r6-to-r0**). Both LSPs have strict paths configured that go through interface **fe-0/1/0**.

In the network shown in Figure 6 on page 112, both types of bypass paths are preestablished around the protected node (**R2).** A next-hop bypass path avoids interface **fe-0/1/0** by going through **R7**, and a next-next-hop bypass path avoids **R2** altogether by going through **R7** and **R9** to **R4**. Both bypass paths are shared by all protected LSPs traversing the failed link or node (many LSPs protected by one bypass path).

Node-link protection (many-to-one or facility backup) allows a router immediately upstream from a node failure to use an alternate node to forward traffic to its downstream neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link.

When an outage occurs, the router immediately upstream from the outage switches protected traffic to the bypass node, and then signals the failure to the ingress router. Like fast reroute, node-link protection provides local repair, restoring connectivity faster than the ingress router can establish a standby secondary path or signal a new primary LSP.

Node-link protection is appropriate in the following situations:

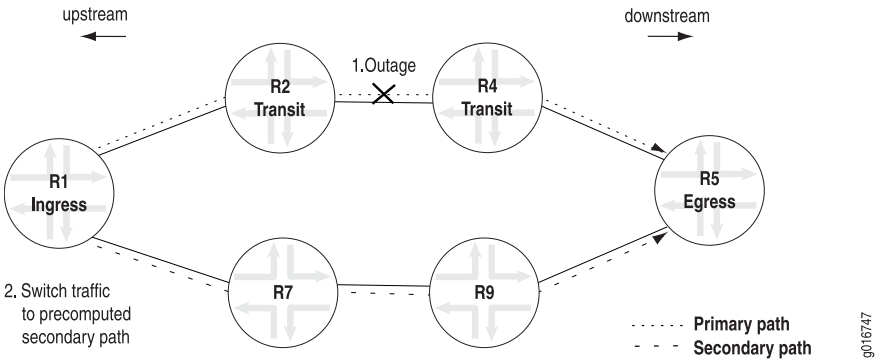
- Protection of the downstream link and node is required.
- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

Path Protection Overview

The main advantages of path protection are control over where the traffic goes after a failure and minimum packet loss when combined with fast reroute (one-to-one backup or link protection). Path protection is the configuration, within a label-switched path (LSP), of two types of paths: a primary path, used in normal operations, and a secondary path used when the primary fails, as shown in Figure 7 on page 113.

In Figure 7 on page 113, an MPLS network consisting of eight routers has a primary path between **R1** and **R5** which is protected by the secondary path between **R1** and **R5**. When a failure is detected, such as an interface down event, an Resource Reservation Protocol (RSVP) error message is sent to the ingress router which switches traffic to the secondary path, maintaining traffic flow.

Figure 7: Path Protection



If the secondary path is pre-signaled or on standby, recovery time from a failure is faster than if the secondary path is not pre-signaled. When the secondary path is not pre-signaled a call-setup delay occurs during which the new physical path for the LSP is established, extending the recovery time. If the failure in the primary path is corrected, and after a few minutes of hold time, the ingress router switches traffic back from the secondary path to the primary path.

Because path protection is provided by the ingress router for the entire path, there can be some disadvantages, for example, double-booking of resources and unnecessary protection of links. By protecting a single resource at a time, local protection can remedy these disadvantages.

Configuring Path Protection in an MPLS Network (CLI Procedure)

The Junos OS implementation of MPLS on EX Series switches provides path protection as a mechanism for protecting against label switched path (LSP) failures. Path protection reduces the time required to recalculate a route in case of a failure within the MPLS tunnel. You configure path protection on the ingress provider edge switch in your MPLS network. You do not configure the egress provider edge switch or the provider switches for path protection. You can explicitly specify which provider switches are used for the

primary and secondary paths, or you can let the software calculate the paths automatically.

Before you configure path protection, be sure you have:

- Configured an ingress provider edge switch and an egress provider edge switch. See "Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)" on page 72 or "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)" on page 77.
- Configured at least one provider (transit) switch. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.
- Verified the configuration of your MPLS network.

To configure path protection, complete the following tasks on the ingress provider edge switch:

1. Configuring the Primary Path on page 115
2. Configuring the Secondary Path on page 115
3. Configuring the Revert Timer on page 116

Configuring the Primary Path

The **primary** statement creates the primary path, which is the LSP's preferred path. The **secondary** statement creates an alternative path if the primary path can no longer reach the egress provider edge switch.

In the tasks described in this topic, the ***lsp-name*** has already been configured on the ingress provider edge switch as **lsp_to_240** and the loopback interface address on the remote provider edge switch has already been configured as **127.0.0.8**.

When the software switches from the primary to the secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable but no sooner than the retry time specified in the **revert-timer** statement.

You can configure zero primary paths or one primary path. If you do not configure a primary path, the first secondary path (if a secondary path has been configured) is selected as the path. If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary for the packets to reach the egress provider edge switch.

To configure a primary path:

1. Create the primary path for the LSP:

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set primary primary_path_lsp_to_240
```

2. Configure an explicit route for the primary path by specifying the IP address of the loopback interface or the switch IP address or hostname of each switch used in the MPLS tunnel. You can specify the link types as either **strict** or **loose** in each **path** statement. If the link type is **strict**, the LSP must go to the next address specified in the **path** statement without traversing other switches. If the link type is **loose**, the LSP can traverse through other switches before reaching this switch. This configuration uses the default **strict** designation for the paths.

NOTE: You can enable path protection without specifying which provider switches are used. If you do not list the specific provider switches to be used for the MPLS tunnel, the switch calculates the route.

TIP: Do not include the ingress provider edge switch in these statements. List the IP address of the loopback interface or switch address or hostname of all other switch hops in sequence, ending with the egress provider edge switch.

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set path primary_path_lsp_to_240 127.0.0.2
user@switch# set path primary_path_lsp_to_240 127.0.0.3
user@switch# set path primary_path_lsp_to_240 127.0.0.8
```

Configuring the Secondary Path

You can configure zero or more secondary paths. All secondary paths are equal, and the software tries them in the order that they are listed in the configuration. The software does not attempt to switch among secondary paths. If the first secondary path in the configuration is not available, the next one is tried, as so on. To create a set of equal paths, specify secondary paths without specifying a primary path. If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress provider edge switch.

To configure the secondary path:

1. Create a secondary path for the LSP:

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set secondary secondary_path_lsp_to_240 standby
```

2. Configure an explicit route for the secondary path by specifying the IP address of the loopback interface or the switch IP address or hostname of each switch used in the MPLS tunnel. You can specify the link types as either **strict** or **loose** in each **path** statement. This configuration uses the default **strict** designation for the paths.

TIP: Do not include the ingress provider edge switch in these statements. List the IP address of the loopback interface or switch address or hostname of all other switch hops in sequence, ending with the egress provider edge switch.

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set path secondary_path_lsp_to_240 127.0.0.4
user@switch# set path primary_path_lsp_to_240 127.0.0.8
```

Configuring the Revert Timer

For LSPs configured with both primary and secondary paths, you can optionally configure a revert timer. If the primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to the primary path. If the primary path experiences any connectivity problems or stability problems during this time, the timer is restarted.

TIP: If you do not explicitly configure the revert timer, it is set by default to 60 seconds.

To configure the revert timer for LSPs configured with primary and secondary paths:

- For all LSPs on the switch:

```
[edit protocols mpls]
user@switch# set revert-timer 120
```

- For a specific LSP on the switch:

```
[edit protocols mpls label-switched-path]
user@switch#  set lsp_to_240 revert-timer 120
```

Preventing Use of a Path That Previously Failed

If you configure an alternate path through the network in case the active path fails, you may not want traffic to revert back to the failed path, even if it is no longer failing. When you configure a primary path, the traffic switches over to the secondary path during a failure, and reverts back to the primary path when it returns.

At times, switching traffic back to a primary path that has previously failed may not be a particularly sound idea. In this case, only configure secondary paths, resulting in the next configured secondary path establishing when the first secondary path fails. Later, if the first secondary path becomes operational, the Junos OS will not revert to it, but will continue using the second secondary path.

Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP

Understanding MPLS Inter-AS Link Protection

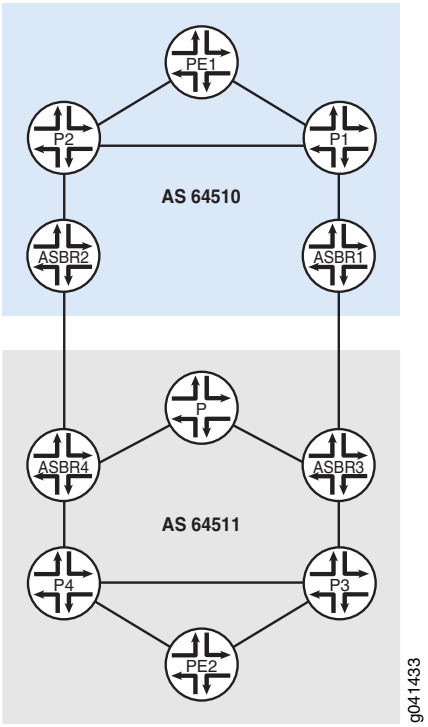
Link protection is essential in an MPLS network to ensure traffic restoration in case of an interface failure. The ingress router chooses an alternate link through another interface to send traffic to its destination.

In Figure 8 on page 118, autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices. If the link from Device ASBR3 to Device ASBR1 goes down, until Device ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped. A fast traffic restoration can be achieved if Device ASBR3 preprograms a backup path either through Device ASBR4 or through a direct path to Device ASBR2 if one exists (not shown in the diagram). This assumes that Device ASBR3 learns a loop-free MPLS path for routes that need to protected either through IBGP or EBGP.

This solution does not handle a failure on Device ASBR3 for traffic going toward AS 64511 from AS 64510 through the ASBR3-ASBR1 link. This solution is limited to downstream inter-AS link-node protection with labeled BGP. This solution does not support service restoration between provider (P) and ASBR routers when there is an ASBR failure. For example, this solution does not handle a failure on the P3-ASBR3 link.

This supported functionality is similar to BGP multipath, except only one next hop is used for active forwarding, and a second path is in protected mode.

Figure 8: MPLS Inter-AS Link-Node Protection Conceptual Topology



In an MPLS inter-AS environment, link protection can be enabled when **labeled-unicast** is used to send traffic between ASs. Hence, MPLS inter-AS link protection is configured on the link between two routers in different ASs.

To configure link protection on an interface, use the **protection** statement at the **[edit protocols bgp group *group-name* family inet labeled-unicast]** hierarchy level:

```
protocols {
   bgp {
      group test1 {
         type external;
         local-address 192.168.1.2;
         family inet {
            labeled-unicast {
               protection;
            }
         }
      }
   }
}
```

NOTE: MPLS inter-AS link protection is supported only with labeled-unicast and external peers in a master routing instance.

The link on which protection is configured is known as the protection path. A protection path is selected only after the best path selection and is not selected in the following cases:

- The best path is a non-BGP path.
- Multiple next hops are active, as in BGP multipath.

This example shows how to configure tail-end protection in an inter-AS deployment with Layer 3 VPNs.

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In Figure 9 on page 120. autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices.

If the link from Device ASBR3 to Device ASBR1 goes down, until ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped.

This example shows how to achieve fast traffic restoration by configuring Device ASBR3 to preprogram a backup path through Device ASBR2.

NOTE: This solution does not handle the Device P3 to Device ASBR3 failure. Nor does it handle a failure on Device ASBR3 for traffic going toward AS 645111 from AS 64510 through the ASBR3-ASBR1 link. This traffic is dropped.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device ASBR1

```
set interfaces fe-1/2/2 unit 0 family inet address 20.20.20.2/30
set interfaces fe-1/2/2 unit 0 family mpls
set interfaces fe-1/2/0 unit 0 family inet address 21.21.21.1/30
```

```
set interfaces fe-1/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 4.4.4.4/32
set protocols rsvp interface fe-1/2/2.0
set protocols rsvp interface lo0.0
set protocols mpls traffic-engineering bgp-igp-both-ribs
set protocols mpls label-switched-path To_PE1 to 2.2.2.2
set protocols mpls interface fe-1/2/2.0
set protocols mpls interface fe-1/2/0.0
set protocols mpls interface lo0.0

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the EBGP scenario:

1. Configure the router interfaces.

```
[edit interfaces]
user@ASBR3# set fe-1/2/0 unit 0 description to-ASBR1
user@ASBR3# set fe-1/2/0 unit 0 family inet address 21.21.21.2/30
user@ASBR3# set fe-1/2/0 unit 0 family mpls
user@ASBR3# set fe-1/2/2 unit 0 description to-P3
user@ASBR3# set fe-1/2/2 unit 0 family inet address 22.22.22.1/30
user@ASBR3# set fe-1/2/2 unit 0 family mpls
user@ASBR3# set fe-1/2/1 unit 0 description to-ASBR2
user@ASBR3# set fe-1/2/1 unit 0 family inet address 26.26.26.2/30
user@ASBR3# set fe-1/2/1 unit 0 family mpls
user@ASBR3# set lo0 unit 0 family inet address 5.5.5.5/32
```

2. Configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf]
user@ASBR3# set traffic-engineering
[edit protocols ospf area 0.0.0.0]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0 passive
user@ASBR3# set interface fe-1/2/1.0
```

3. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@ASBR3# set autonomous-system 64511
```

4. Configure the routing policy.

```
[edit policy-options policy-statement To-ASBR1]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
[edit policy-options policy-statement To-ASBR2]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
[edit policy-options policy-statement next-hop-self]
user@ASBR3# set then next-hop self
```

5. Configure the EBGP sessions.

```
[edit protocols bgp group To-ASBR1]
```

```
user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR1
user@ASBR3# set neighbor 21.21.21.1 peer-as 64510
[edit protocols bgp group To-ASBR2]
user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR2
user@ASBR3# set neighbor 26.26.26.1 peer-as 64510
```

6. Configure the IBGP sessions.

```
[edit protocols bgp group To-PE2]
user@ASBR3# set type internal
user@ASBR3# set local-address 5.5.5.5
user@ASBR3# set family inet unicast
user@ASBR3# set export next-hop-self
user@ASBR3# set neighbor 7.7.7.7 family inet labeled-unicast
```

7. Configure MPLS.

```
[edit protocols mpls]
user@ASBR3# set traffic-engineering bgp-igp-both-ribs
user@ASBR3# set label-switched-path To_PE2 to 7.7.7.7
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface fe-1/2/1.0
```

8. Configure a signaling protocol.

```
[edit protocols rsvp]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/1.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options**, commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@ASBR3# show interfaces
fe-1/2/0 {
   unit 0 {
      description to-ASBR1;
```

```
      family inet {
        address 21.21.21.2/30;
      }

Output Queue[0]: 0
```

Meaning The output shows that the **Protection** option is enabled for the EBGP peers, Device ASBR1 and Device ASBR2.

This is also shown with the **NLRI configured with protection: inet-labeled-unicast** screen output.

Checking the Routes

Purpose Make sure that the backup path is installed in the routing table.

Action

```
user@ASBR3> show route 2.2.2.2
```

```
inet.0: 12 destinations, 14 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.2/32         *[BGP/170] 01:36:25, MED 2, localpref 100
                      AS path: 64510 I, validation-state: unverified
                    > to 21.21.21.1 via fe-1/2/0.0, Push 299824
                      to 26.26.26.1 via fe-1/2/1.0, Push 299808
                    [BGP/170] 01:36:25, MED 2, localpref 100
                      AS path: 64510 I, validation-state: unverified
                    > to 26.26.26.1 via fe-1/2/1.0, Push 299808
```

Meaning The **show route** command displays active as well as backup paths to Device PE1.

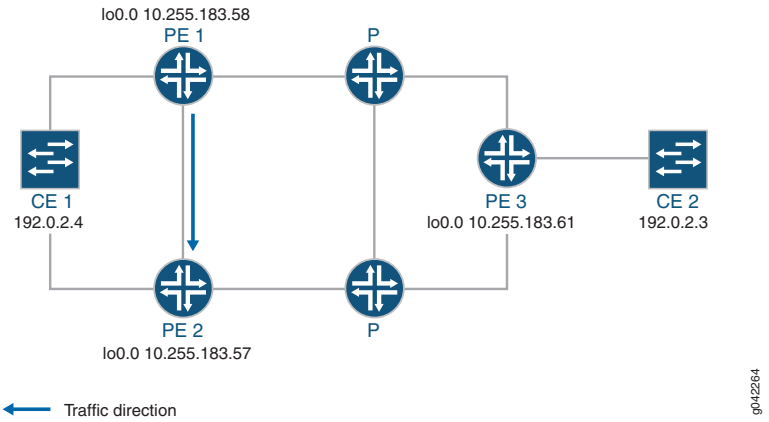
Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

Figure 1 shows a simplified topology of the use case that explains this feature.

Figure 10: Egress Protection LSP Configured from Router PE1 to Router PE2



CE1 is multihomed to PE1 and PE2. There are two paths connecting CE1 and CE2. The working path is CE2-PE3-P-PE1-CE1, via pseudowire PW21. The protecting path is CE2-PE3-P-PE2-CE1, via pseudowire PW22 Traffic is flowing through the working path under normal circumstances. When the end-to-end OAM between CE1 and CE2 detects failure on the working path, traffic will be switched from the working path to the protecting path. The end-to-end failure detection and recovery relies on control plane hence should be relatively slow. To achieve faster protection, local repair mechanisms similar to those used by MPLS fast reroute should be used. In Figure 1 above, if link or node failed in the core network (like link failure on P-PE1, P-PE3, or node failure on P), the MPLS fast reroute will happen on the transport LSPs between PE1 and PE3. The failure could be locally repaired within tens of milliseconds. However, if link or node failure happens at the edge (like link failure on PE3-CE2 or node failure on PE3), there is no local repair currently so we have to rely on the CE1-CE2 end-to-end protection to repair the failure.

- Device CE2—Traffic origin
- Router PE3—Ingress PE router

- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes downs, PE1 will briefly redirect that traffic towards CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was; CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be; CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path; CE2 – PE3 – P – PE2 – CE1.

1. Configure RSVP on PE1, PE2, and PE3.

```
[edit protocols]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

3. Set PE1 as **primary** and PE2 as **protector** nodes.

```
[edit protocols mpls]
user@PE1# set egress-protection context-identifier address primary
user@PE2# set egress-protection context-identifier address protector
```

4. Enable **egress-protection** on PE1 and PE2.

```
[edit protocols bgp]
user@PE1# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp family l2vpn egress-protection
```

5. Configure LDP and ISIS on PE1, PE2, and PE3.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

```
[edit protocols isis]
user@PE1# set interface all point-to-point
```

```
user@PE2# set interface all point-to-point
user@PE3# set interface all point-to-point
```

6. Configure a load balancing policy at PE1, PE2, and PE3.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
user@PE2# set policy-options policy-statement lb then load-balance per-packet
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options at PE1, PE2, and PE3, to export routes based on the load balancing policy.

```
[edit]
user@PE1# set routing-options traceoptions file ro.log
user@PE1# set routing-options traceoptions flag normal
user@PE1# set routing-options traceoptions flag route
user@PE1# set routing-options autonomous-system 100
user@PE1# set routing-options forwarding-table export lb
```

```
[edit]
user@PE2# set routing-options traceoptions file ro.log
user@PE2# set routing-options traceoptions flag normal
user@PE2# set routing-options traceoptions flag route
user@PE2# set routing-options autonomous-system 100
user@PE2# set routing-options forwarding-table export lb
```

```
[edit]
user@PE3# set routing-options traceoptions file ro.log
user@PE3# set routing-options traceoptions flag normal
user@PE3# set routing-options traceoptions flag route
user@PE3# set routing-options autonomous-system 100
user@PE3# set routing-options forwarding-table export lb
```

8. Configure BGP at PE1 to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit]
user@PE1# set routing-instances foo egress-protection context-identifier
  context-identifier
```

9. Configure l2vpn at PE1, PE2, and PE3

   At PE1:

```
[edit routing-instances]
foo {
  instance-type l2vpn;
  egress-protection {
```

```
    context-identifier {
      198.51.100.0;
    }
  }
  interface ge-2/0/2.0;
  route-distinguisher 10.255.183.58:1;
  vrf-target target:9000:1;
  protocols {
    l2vpn {
      encapsulation-type ethernet-vlan;
      site foo {
        site-identifier 1;
        multi-homing;
        site-preference primary;
        interface ge-2/0/2.0 {
          remote-site-id 2;
        }
      }
    }
  }
}
```

At PE2:

```
[edit routing-instances]
foo {
  instance-type l2vpn;
  egress-protection {
    protector;
  }
  interface ge-2/0/2.0;
  route-distinguisher 10.255.183.57:1;
  vrf-target target:9000:1;
  protocols {
    l2vpn {
      encapsulation-type ethernet-vlan;
      site foo{
        site-identifier 1;
        multi-homing;
        site-preference backup;
        interface ge-2/0/2.0 {
          remote-site-id 2;
        }
      }
    }
  }
}
```

At PE3:

```
[edit routing-instances]
foo {
  instance-type l2vpn;
  interface ge-2/1/2.0;
```

```
    route-distinguisher 10.255.183.61:1;
    vrf-target target:9000:1;
    protocols {
      l2vpn {
        encapsulation-type ethernet-vlan;
        site foo {
          site-identifier 2;
          interface ge-2/1/2.0;
        }
      }
    }
}
```

Release History Table

Release	Description
14.2	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.

Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example shows how to configure link protection for BGP signaled Layer 2 services.

Requirements

MX Series Routers running Junos OS Release 14.2 or later.

Overview

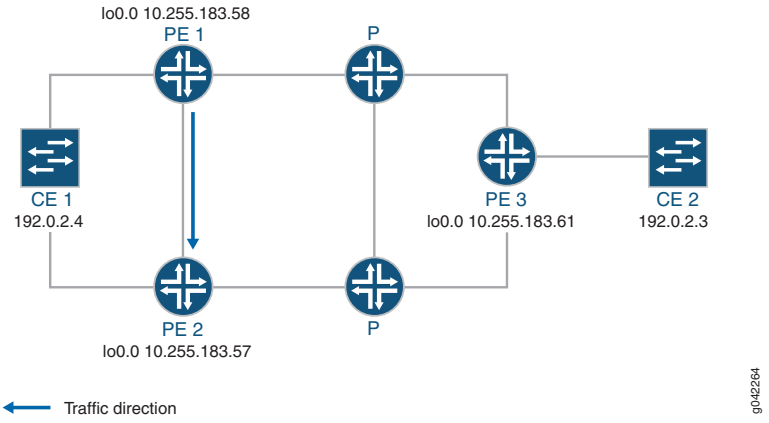
If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the

connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example includes the following configuration concepts and statements that are unique to the configuration of an egress protection LSP:

- **context-identifier**—Specifies an IPv4 or IPv6 address used to define the pair of PE routers participating in the egress protection LSP. It is assigned to each ordered pair of primary PE and the protector to facilitate protection establishment. This address is globally unique, or unique in the address space of the network where the primary PE and the protector reside.
- **egress-protection**—Configures the protector information for the protected Layer 2 circuit and configures the protector Layer 2 circuit at the **[edit protocols mpls]** hierarchy level. Configures an LSP as an egress protection LSP at the **[edit protocols mpls]** hierarchy level.
- **protector**—Configures the creation of standby pseudowires on the backup PE for link or node protection for the instance.

Figure 11: Egress Protection LSP Configured from Router PE1 to Router PE2



In the event of a failure of the egress PE Router PE1, traffic is switched to the egress protection LSP configured between Router PE1 and Router PE2 (the protector PE router):

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes downs, PE1 will briefly redirect that traffic toward CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was: CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be: CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path: CE2 – PE3 – P – PE2 – CE1.

This example shows how to configure routers PE1, PE2, and PE3.

Configuration

CLI Quick Configuration

To quickly configure an egress protection LSP, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configurations, copy and then paste the commands into the CLI and enter **commit** from configuration mode.

Step-by-Step Procedure

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP for router PE1:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

2. Configure MPLS to use the egress protection LSP to protect against a link failure to Device CE1.

```
[edit protocols mpls]
```

```
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set egress-protection context-identifier 198.51.100.3 primary
user@PE1# set egress-protection context-identifier 198.51.100.3 advertise-mode
   stub-alias
user@PE1# set egress-protection traceoptions file ep size 100m
user@PE1# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set traceoptions file bgp.log world-readable
user@PE1# set group ibgp type internal
user@PE1# set group ibgp local-address 10.255.183.58
user@PE1# set group ibgp family inet unicast
user@PE1# set group ibgp family l2vpn signaling egress-protection
user@PE1# set group ibgp neighbor 192.0.2.3
user@PE1# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE1# set traceoptions file isis-edge size 10m world-readable
user@PE1# set traceoptions flag error
user@PE1# set level 1 disable
user@PE1# set level 2 wide-metrics-only
user@PE1# set interface all point-to-point
user@PE1# set interface all level 2 metric 10
user@PE1# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE1# set traceoptions file ro.log
user@PE1# set traceoptions flag all
user@PE1# set autonomous-system 100
user@PE1# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE1# set foo instance-type l2vpn
user@PE1# set foo egress-protection context-identifier 198.51.100.3
user@PE1# set foo interface ge-2/0/2.0
user@PE1# set foo route-distinguisher 10.255.183.58:1
user@PE1# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE1# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE1# set foo protocols l2vpn site foo site-identifier 1
user@PE1# set foo protocols l2vpn site foo multi-homing
user@PE1# set foo protocols l2vpn site foo site-preference primary
user@PE1# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```

10. If you are done configuring the device, enter **commit** from configuration mode.

Step-by-Step Procedure

To configure an egress protection LSP for Router PE2:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

2. Configure MPLS and the LSP that acts as the egress protection LSP.

```
[edit protocols mpls]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 198.51.100.3 protector
user@PE2# set egress-protection context-identifier 198.51.100.3 advertise-mode
   stub-alias
user@PE2# set egress-protection traceoptions file ep size 100m
user@PE2# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE2# set traceoptions file bgp.log world-readable
user@PE2# set group ibgp type internal
user@PE2# set group ibgp local-address 10.255.183.57
user@PE2# set group ibgp family inet unicast
user@PE2# set group ibgp family l2vpn signaling
user@PE2# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp neighbor 192.0.2.3
```

```
user@PE2# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set traceoptions file isis-edge size 10m world-readable
user@PE2# set traceoptions flag error
user@PE2# set level 1 disable
user@PE2# set level 2 wide-metrics-only
user@PE2# set interface all point-to-point
user@PE2# set interface all level 2 metric 10
user@PE2# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE2# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE2# set traceoptions file ro.log
user@PE2# set traceoptions flag all
user@PE2# set autonomous-system 100
user@PE2# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE2# set foo instance-type l2vpn
user@PE2# set foo egress-protection protector
user@PE2# set foo interface ge-2/0/2.0
user@PE2# set foo route-distinguisher 10.255.183.57:1
user@PE2# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE2# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE2# set foo protocols l2vpn site foo hot-standby
user@PE2# set foo protocols l2vpn site foo site-identifier 1
user@PE2# set foo protocols l2vpn site foo multi-homing
```

```
user@PE2# set foo protocols l2vpn site foo site-preference backup
user@PE2# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```

10. If you are done configuring the device, enter **commit** from configuration mode.

Step-by-Step Procedure

To configure an egress protection LSP for Router PE3:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE3# set traceoptions file bgp.log world-readable
user@PE3# set group ibgp type internal
user@PE3# set group ibgp local-address 10.255.183.61
user@PE3# set group ibgp family inet unicast
user@PE3# set group ibgp family l2vpn signaling
user@PE3# set group ibgp neighbor 192.0.2.3
user@PE3# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE3# set traceoptions file isis-edge size 10m world-readable
user@PE3# set traceoptions flag error
user@PE3# set level 1 disable
user@PE3# set level 2 wide-metrics-only
user@PE3# set protocols isis interface all point-to-point
[edit protocols isis]
user@PE3# set protocols isis interface all level 2 metric 10
[edit protocols isis]
user@PE3# set protocols isis interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE3# set interface all
```

```
user@PE3# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE3# set traceoptions file ro.log
user@PE3# set traceoptions flag normal
user@PE3# set traceoptions flag route
user@PE3# set autonomous-system 100
user@PE3# set forwarding-table export lb
```

8. Configure BGP to advertise nlri from the routing instance with context-ID as next-hop.

```
[edit]
user@PE3# set routing-instances foo instance-type l2vpn
user@PE3# set routing-instances foo interface ge-2/1/2.0
user@PE3# set routing-instances foo route-distinguisher 10.255.183.61:1
user@PE3# set routing-instances foo vrf-target target:9000:1
```

9. Configure l2vpn to specify the interface that connects to the site and the remote interface to which you want the specified interface to connect.

```
[edit routing-instances]
user@PE3# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE3# set foo protocols l2vpn site foo site-identifier 2
user@PE3# set foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1
```

10. If you are done configuring the device, enter **commit** from configuration.

Results

From configuration mode, confirm your configuration on Router PE1 by entering the **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@PE1# show protocols

}
```

Verification

Confirm that the configuration is working properly.

- Verifying the L2VPN Configuration on page 153
- Verifying the Routing Instance Details on page 154

- Verifying the IS-IS Configuration on page 154
- Verifying the MPLS Configuration on page 155

Verifying the L2VPN Configuration

Purpose Verify that LSP is protected by the connection protection logic.

Action From operational mode, run the **show l2vpn connections extensive** command.

```
user@PE2> show l2vpn connections extensive
```

```
Layer-2 VPN connections:
Legend for connection status (St)
EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch     WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down    NP -- interface hardware not present
CM -- control-word mismatch      -> -- only outbound connection is up
CN -- circuit not provisioned    <- -- only inbound connection is up
OR -- out of range               Up -- operational
OL -- no outgoing label          Dn -- down
LD -- local site signaled down   CF -- call admission control failure
RD -- remote site signaled down  SC -- local and remote site ID collision
LN -- local site not designated  LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status  IL -- no incoming label
MM -- MTU mismatch               MI -- Mesh-Group ID not available
BK -- Backup connection          ST -- Standby connection
PF -- Profile parse failure      PB -- Profile busy
RS -- remote site standby        SN -- Static Neighbor
LB -- Local site not best-site   RB -- Remote site not best-site
VM -- VLAN ID mismatch
Legend for interface status
Up -- operational
Dn -- down
Instance: foo
Local site: foo (1)
   connection-site           Type  St  Time last up          # Up trans
    2                         rmt   Up  Aug  3 00:08:14 2001           1
      Local circuit: ge-2/0/2.0, Status: Up
      Remote PE: 192.0.2.3
      Incoming label: 32769, Outgoing label: 32768
      Egress Protection: Yes
        Time                  Event            Interface/Lbl/PE
        Aug  3 00:08:14 2001  PE route up
        Aug  3 00:08:14 2001  Out lbl Update              32768
        Aug  3 00:08:14 2001  In lbl Update               32769
        Aug  3 00:08:14 2001  ckt0 up                fe-0/0/0.0
```

Meaning The **Egress Protection: Yes** output shows that the given PVC is protected by connection protection logic.

Verifying the Routing Instance Details

Purpose Verify the routing instance information and the context identifier configured on the primary, which is used as the next-hop address in case of node-link failure.

Action From operational mode, run the **show route foo detail** command.

```
user@PE2> show route foo detail
```

```
foo:
  Router ID: 0.0.0.0
  Type: l2vpn non-forwarding State: Active
  Interfaces:
    lt-1/2/0.56
  Route-distinguisher: 10.255.255.11:1
  Vrf-import: [ __vrf-import-foo-internal__ ]
  Vrf-export: [ __vrf-export-foo-internal__ ]
  Vrf-import-target: [ target:100:200 ]
  Vrf-export-target: [ target:100:200 ]
  Fast-reroute-priority: low
  Vrf-edge-protection-id:  198.51.100.3
  Tables:
    foo.l2vpn.0           : 5 routes (3 active, 0 holddown, 0 hidden)
    foo.l2id.0            : 6 routes (2 active, 0 holddown, 0 hidden)
```

Meaning The context-id is set to **198.51.100.3** and the **Vrf-import: [__vrf-import-foo-internal__]** in the output mentions the policy used for rewriting the next-hop address.

Verifying the IS-IS Configuration

Purpose Verify the IS-IS context identifier information.

Action From operational mode, run the **show isis context-identifier detail** command.

```
user@PE2> show isis context-identifier detail
```

```
IS-IS context database:
Context               L  Owner     Role       Primary      Metric
198.51.100.3             2  MPLS      Protector  pro17-b-lr-R1 0
  Advertiser pro17-b, Router ID 10.255.107.49, Level 2, tlv protector
  Advertiser pro17-b-lr-R1, Router ID 10.255.255.11, Metric 1, Level 2, tlv prefix
```

Meaning Router PE2 is the protector and the configured context identifier is in use for the MPLS protocol.

Verifying the MPLS Configuration

Purpose Verify the context identifier details on the primary and protector PEs.

Action From operational mode, run the **show mpls context-identifier detail** command.

```
user@PE1> show mpls context-identifier detail
```

```
ID: 198.51.100.3
  Type: primary, Metric: 1, Mode: alias

Total 1, Primary 1, Protector 0
```

```
user@PE2> show mpls context-identifier detail
```

```
ID: 198.51.100.3
  Type: protector, Metric: 16777215, Mode: alias
  Context table: __198.51.100.3__.mpls.0, Label out: 299968
```

```
user@PE2> show mpls egress-protection detail
```

```
Instance                Type      Protection-Type
foo                   local-l2vpn Protector
  Route Target 100:200
```

Meaning Context-id is **198.51.100.3**, advertise-mode is **alias**, the MPLS table created for egress protection is **__198.51.100.3__.mpls.0**, and the egress instance name is **foo**, which is of type **local-l2vpn**.

Release History Table

Release	Description
14.2	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.

Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector

This example shows how to configure fast service restoration at the egress of a Layer 3 VPN when the customer is multihomed to the service provider.

Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair. Instead, the PLR or the protector can send the traffic directly to the target CE (in Co-located protector model where the PLR or the protector is also the backup PE that is directly connected to the CE) or to the backup PE (in Centralized protector model where the backup PE is a separate router).

Requirements

No special configuration beyond device initialization is required before configuring this example.

This example requires Junos OS Release 15.1 or later.

Overview

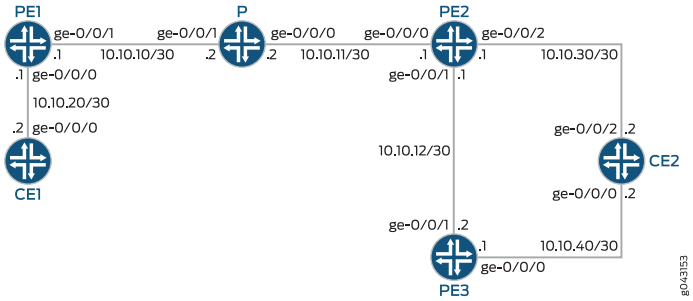
As a special scenario of egress node protection, if a router is both a Protector and a PLR, it installs backup next hops to protect the transport LSP. In particular, it does not need a bypass LSP for local repair.

In the Co-located protector model, the PLR or the Protector is directly connected to the CE via a backup AC, while in the Centralized protector model, the PLR or the protector has an MPLS tunnel to the backup PE. In either case, the PLR or the Protector will install a backup next hop with a label followed by a lookup in a **context label** table, i.e. **__context__.mpls.0**. When the egress node fails, the PLR or the Protector will switch traffic to this backup next hop in PFE. The outer label (the transport LSP label) of packets is popped, and the inner label (the layer 3 VPN label allocated by the egress node) is looked up in **__context__.mpls.0**, which results in forwarding the packets directly to the CE (in Collocated protector model) or the backup PE (in Centralized protector model).

Topology

Figure 12 on page 157 shows the sample network.

Figure 12: Co-located PLR and protector in collocated protector model



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device CE1

```
set interfaces ge-0/0/0 unit 0 family inet address 10.10.20.2/30
set interfaces lo0 unit 0 family inet address 10.255.162.87/32
```

Device PE1

```
set interfaces ge-0/0/0 unit 0 family inet address 10.10.20.1/30
set interfaces ge-0/0/1 unit 0 family inet address 10.10.10.1/30
set interfaces ge-0/0/1 unit 0 family inet6

set interfaces lo0 unit 0 family inet6 address abcd::10:255:162:88/128 primary
```

Configuring Device CE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure interfaces.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 0 family inet address 10.10.20.2/30
user@CE1# set lo0 unit 0 family inet address 10.255.162.87/32
```

Configuring Device PE1

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 10.10.20.1/30
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/30
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE1# set lo0 unit 0 family inet address 10.255.162.84/32 primary
user@PE1# set lo0 unit 0 family iso address
   47.0005.80ff.f800.0000.0108.0001.0102.5516.2084.00
user@PE1# set lo0 unit 0 family inet6 address abcd::10:255:162:84/128 primary
```

2. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set autonomous-system 65000
user@PE1# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE1# set interface all link-protection
user@PE1# set interface fxp0.0 disable
```

4. Enable MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group vpn type internal
user@PE1# set group vpn local-address 10.255.162.84
user@PE1# set group vpn family inet-vpn unicast
user@PE1# set group vpn neighbor 10.255.162.91
user@PE1# set group vpn neighbor 10.255.162.89
user@PE1# set vpn-apply-export
```

6. Enable IS-IS.

```
[edit protocols isis]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set interface lo0.0 passive
```

7. (Optional) Configure OSPF

```
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface all
user@PE1# set area 0.0.0.0 interface fxp0.0 disable
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set traffic-engineering
```

8. Configure the routing instance.

```
[edit routing-instances]
user@PE1# set vpn instance-type vrf
user@PE1# set vpn interface ge-1/0/0.0
user@PE1# set vpn route-distinguisher 100:100
user@PE1# set vpn vrf-import vpn-imp
user@PE1# set vpn vrf-export vpn-exp
user@PE1# set vpn vrf-table-label
user@PE1# set vpn protocols bgp group vpn type external
user@PE1# set vpn protocols bgp group vpn family inet unicast
user@PE1# set vpn protocols bgp group vpn family inet6 unicast
user@PE1# set vpn protocols bgp group vpn peer-as 65001
user@PE1# set vpn protocols bgp group vpn as-override
user@PE1# set vpn protocols bgp group vpn neighbor 10.10.20.2
```

9. Configure the routing policy.

```
[edit]
user@PE1# set policy-options policy-statement vpn-exp term 1 from protocol direct
user@PE1# set policy-options policy-statement vpn-exp term 1 from route filter
  10.10.20.0/24 exact
user@PE1# set policy-options policy-statement vpn-exp term 1 then community
  add vpn
user@PE1# set policy-options policy-statement vpn-exp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 1 from community
  vpn
```

```
user@PE1# set policy-options policy-statement vpn-imp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 2 then reject
user@PE1# set policy-options community vpn members traget:1:1
```

Configuring Device P

Step-by-Step Procedure

1. Configure the device interfaces.

```
[edit interfaces]
user@P# set ge-0/0/0 unit 0 family inet address 10.10.11.2/30
user@P# set ge-0/0/0 unit 0 family inet6
user@P# set ge-0/0/0 unit 0 family iso
user@P# set ge-0/0/0 unit 0 family mpls
user@P# set ge-0/0/1 unit 0 family inet address 10.10.10.2/30
user@P# set ge-0/0/1 unit 0 family inet6
user@P# set ge-0/0/1 unit 0 family iso
user@P# set ge-0/0/1 unit 0 family mpls
user@P# set lo0 unit 0 family inet address 127.0.0.1/32
user@P# set lo0 unit 0 family inet address 10.255.162.86/32 primary
user@P# set lo0 unit 0 family inet6 address abcd::10:255:162:86/128 primary
user@P# set lo0 unit 0 family iso address
  47.0005.80ff.f800.0000.0108.0001.0102.5516.2086.00
```

2. Enable IS-IS.

```
[edit protocols isis]
user@P# set interface all
user@P# set interface fxp0.0 disable
```

3. Enable MPLS.

```
[edit protocols mpls ]
user@P# set interface all
user@P# set interface fxp0.0 disable
```

4. Configure RSVP.

```
[edit protocols rsvp]
user@P# set interface all link-protection
user@P# set interface fxp0.0 disable
```

5. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@P# set area 0.0.0.0 interface all
user@P# set area 0.0.0.0 interface fxp0.0 disable
user@P# set area 0.0.0.0 interface lo0.0 passive
user@P# set traffic-engineering
```

Configuring Device PE2

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/0 unit 0 family inet address 10.10.11.1/30
user@PE2# set ge-0/0/0 unit 0 family iso
user@PE2# set ge-0/0/0 unit 0 family inet6
user@PE2# set ge-0/0/0 unit 0 family mpls
user@PE2# set ge-0/0/1 unit 0 family inet address 10.10.12.1/30
user@PE2# set ge-0/0/1 unit 0 family iso
user@PE2# set ge-0/0/1 unit 0 family inet6
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 10.10.30.1/30
user@PE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE2# set lo0 unit 0 family inet address 10.255.162.91/32 primary
user@PE2# set lo0 unit 0 family iso address
   47.0005.80ff.f800.0000.0108.0001.0102.5516.2091.00
user@PE2# set lo0 unit 0 family inet6 address abcd::10:255:162:91/128 primary
```

2. Configure autonomous number(AS).

```
[edit routing-options]
user@PE2# set autonomous-system 65000
user@PE2# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE2# set interface all link-protection
user@PE2# set interface fxp0.0 disable
```

4. Configure MPLS.

```
[edit protocols mpls]
user@PE2# set label-switched-path to_PE1 to 10.255.162.84
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 1.1.1.1 protector
user@PE2# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE2# set group vpn family inet-vpn unicast egress-protection
user@PE2# set group vpn local-address 10.255.162.91
user@PE2# set group vpn neighbor 10.255.162.84
user@PE2# set group vpn neighbor 10.255.162.89
user@PE2# set group vpn type internal
```

```
user@PE2# set vpn-apply-export
```

6. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set interface lo0.0 passive
user@PE2# set level 2 disable
user@PE2# set traceoptions file isis.log
user@PE2# set traceoptions flag all detail
```

7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE2# set area 0.0.0.0 interface all
user@PE2# set area 0.0.0.0 interface fxp0.0 disable
user@PE2# set area 0.0.0.0 interface lo0.0 passive
user@PE2# set traffic-engineering
```

8. Configure the routing policy.

```
[edit policy-options]
user@PE2# set community vpn members target:1:1
user@PE2# set policy-statement pplb term 1 then load-balance per-packet
user@PE2# set policy-statement vpn-exp term 1 from protocol bgp
user@PE2# set policy-statement vpn-exp term 1 then community add vpn
user@PE2# set policy-statement vpn-exp term 1 then accept
user@PE2# set policy-statement vpn-imp term 1 from community vpn
user@PE2# set policy-statement vpn-imp term 1 then accept
user@PE2# set policy-statement vpn-imp term 2 then reject
```

9. Configure the routing instance.

```
[edit routing-instances]
user@PE2# set vpn instance-type vrf
user@PE2# set vpn interface ge-3/2/4.0
user@PE2# set vpn route-distinguisher 100:100
user@PE2# set vpn vrf-import vpn-imp
user@PE2# set vpn vrf-export vpn-exp
user@PE2# set vpn vrf-table-label
user@PE2# set vpn protocols bgp group vpn type external
user@PE2# set vpn protocols bgp group vpn family inet unicast
user@PE2# set vpn protocols bgp group vpn family inet6 unicast
user@PE2# set vpn protocols bgp group vpn peer-as 65001
user@PE2# set vpn protocols bgp group vpn as-override
user@PE2# set vpn protocols bgp group vpn neighbor 10.10.30.2
```

Configuring Device PE3

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE3# set ge-0/0/0 unit 0 family inet address 10.10.40.1/30
user@PE3# set ge-0/0/1 unit 0 family inet address 10.10.12.2/30
user@PE3# set ge-0/0/1 unit 0 family iso
user@PE3# set ge-0/0/1 unit 0 family inet6
user@PE3# set ge-0/0/1 unit 0 family mpls
user@PE3# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE3# set lo0 unit 0 family inet address 10.255.162.89/32 primary
user@PE3# set lo0 unit 0 family iso address
   47.0005.80ff.f800.0000.0108.0001.0102.5516.2089.00
user@PE3# set lo0 unit 0 family inet6 address abcd::10:255:162:89/128 primary
```

2. Configure the autonomous number (AS).

```
[edit routing-options]
user@PE3# set autonomous-system 65000
user@PE3# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all link-protection
user@PE3# set interface fxp0.0 disable
```

4. Configure MPLS.

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set egress-protection context-identifier 1.1.1.1 primary
user@PE3# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
user@PE3# set label-switched-path to_PE2 to 10.255.162.91
user@PE3# set label-switched-path to_PE1 to 10.255.162.84
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE3# set group vpn type internal
user@PE3# set group vpn local-address 10.255.162.89
user@PE3# set group vpn family inet-vpn unicast
user@PE3# set group vpn neighbor 10.255.162.84 local-preference 300
user@PE3# set group vpn neighbor 10.255.162.91
user@PE3# set vpn-apply-export
```

6. Configure IS-IS.

```
[edit protocols isis]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set interface lo0.0 passive
user@PE3# set level 2 disable
```

7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface all
user@PE3# set area 0.0.0.0 interface fxp0.0 disable
user@PE3# set area 0.0.0.0 interface lo0.0 passive
user@PE3# set traffic-engineering
```

8. Configure the routing instance.

```
[edit routing-instances]
user@PE3# set vpn egress-protection context-identifier 1.1.1.1
user@PE3# set vpn instance-type vrf
user@PE3# set vpn interface ge-1/1/0.0
user@PE3# set vpn protocols bgp group vpn type external
user@PE3# set vpn protocols bgp group vpn family inet unicast
user@PE3# set vpn protocols bgp group vpn family inet6 unicast
user@PE3# set vpn protocols bgp group vpn peer-as 65001
user@PE3# set vpn protocols bgp group vpn as-override
user@PE3# set vpn protocols bgp group vpn neighbor 10.10.40.2
user@PE3# set vpn route-distinguisher 100:100
user@PE3# set vpn vrf-export vpn-exp
user@PE3# set vpn vrf-import vpn-imp
user@PE3# set vpn vrf-table-label
```

Configuring Device CE2

Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@CE2# set ge-0/0/0 unit 0 family inet address 10.10.40.2/30
user@CE2# set ge-0/0/2 unit 0 family inet address 10.10.30.2/30
user@CE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@CE2# set lo0 unit 0 family inet address 10.255.162.88/32 primary
user@CE2# set lo0 unit 0 family iso address
    47.0005.80ff.f800.0000.0108.0001.0102.5516.2088.00
user@CE2# set lo0 unit 0 family inet6 address abcd::10:255:162:88/128 primary
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device CE1

```
user@CE1# show interfaces

Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair.

Verifying Path Protection in an MPLS Network

To verify that path protection is working correctly on EX Series switches, perform the following tasks:

1. Verifying the Primary Path on page 183
2. Verifying the RSVP-Enabled Interfaces on page 184
3. Verifying a Secondary Path on page 185

Verifying the Primary Path

Purpose Verify that the primary path is operational.

Action `user@switch>` **show mpls lsp extensive ingress**

```
Ingress LSP: 2 sessions

127.1.8.8
  From: 127.1.9.9, State: Up, ActiveRoute: 0, LSPname: lsp_to_240
  ActivePath: primary_path_lsp_to_240 (primary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   primary_path_lsp_to_240 State: Up
    Priorities: 7 0
    SmartOptimizeTimer: 180
          Exclude: red
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 2)
 10.3.3.2 S 10.3.4.2 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt
 20=Node-ID):
          10.3.3.2 10.3.4.2
    6 Mar 11 23:58:01.684 Selected as active path: due to 'primary'
    5 Mar 11 23:57:00.750 Record Route:  10.3.3.2 10.3.4.2

  Created: Wed Mar 11 23:44:37 2009
 [Output truncated]
```

Meaning As indicated by the **ActivePath** in the output, the LSP **primary_path_lsp_to_240** is active.

Verifying the RSVP-Enabled Interfaces

Purpose Verify the status of Resource Reservation Protocol (RSVP)-enabled interfaces and packet statistics.

Action

```
user@switch> show rsvp interfaces

RSVP interface: 1 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
ge-0/0/20.0 Up         2   100%  1000Mbps    1000Mbps    0bps        0bps
```

Meaning This output verifies that RSVP is enabled and operational on interface **ge-0/0/20.0**.

Verifying a Secondary Path

Purpose Verify that a secondary path is established.

Action Deactivate a switch that is critical to the primary path and then issue the following command:

```
user@switch> show mpls lsp extensive

Ingress LSP: 1 sessions

127.0.0.8
  From: 127.0.0.1, State: Up, ActiveRoute: 0, LSPname: lsp_to_240

CHAPTER 8

Configuring MPLS Load Balancing and Statistics

MPLS Encapsulated Payload Load-balancing Overview

Routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on the information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm.

In case of multiple transport layer networks such as Ethernet over MPLS or Ethernet pseudowire, the hash algorithm needs to look beyond the outer header of the payload and into the inner headers to generate an even distribution. To determine the inner encapsulation, the PFE relies on the presence of certain codes or numbers at fixed payload offets; for example the presence of payload type 0X800 or the presence of protocol number 4 for an IPv4 packet. In Junos OS, you can configure **zero-control-word** option to

indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, which is four bytes having a numerical value of all zeros, the hash generator assumes the start of an Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

NOTE: For DPC I-chip-based cards, configure the **zero-control-word** option at the **[edit forwarding-options hash-key family mpls ether-pseudowire]** hierarchy level; and for MPC cards, configure the **zero-control-word** option at the **[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]** hierarchy level.

Configuring MPLS Encapsulated Payload for Load Balancing

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. Configure the **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, four bytes having a numerical value of all zeros, the hash generator assumes the start of the Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

Before you begin to configure MPLS encapsulated payload for load balancing, configure routing and signaling protocols.

To configure MPLS encapsulated payload for load balancing:

1. Configure the **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.
   - For DPC I-chip-based cards, configure the **zero-control-word** option at the **[edit forwarding-options hash-key family mpls ether-pseudowire]** hierarchy level.

     ```
     [edit forwarding-options hash-key family mpls ether-pseudowire]
     user@host# set zero-control-word
     ```

   - For MPC cards, configure the **zero-control-word** option at the **[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]** hierarchy level.

     ```
     [edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]
     user@host# set zero-control-word
     ```

Configuring MPLS to Gather Statistics

You can configure MPLS so that it periodically gathers traffic statistics about all MPLS sessions, including transit sessions, by configuring the **statistics** statement. You must configure the **statistics** statement if you want to collect MPLS traffic statistics using SNMP polling of MPLS Management Information Bases (MIBs).

To enable or disable MPLS statistics collection, include the **statistics** statement:

```
statistics {
```

```
    auto-bandwidth (MPLS Statistics);
    file filename <files number> <size size> <world-readable | no-world-readable>;
    interval seconds;
    no-transit-statistics;
    transit-statistics-polling;
}
```

You can configure these statements at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The default interval is 300 seconds.

If you configure the **file** option, the statistics are placed in a file, with one entry per LSP. During the specified interval, the following information is recorded in this file:

- The number of packets, number of bytes, packets per second, and bytes per second transmitted by each LSP. Feature parity for the display of packet and byte statistics for sub-LSPs of a point-to-multipoint LSP on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.
- The percent of bandwidth transmitted over a given LSP in relation to the bandwidth percentage configured for that LSP. If no bandwidth is configured for an LSP, 0 percent is recorded in the percentage column.

At the end of each periodic report, a summary shows the current time, total number of sessions, number of sessions read, number of sessions ignored, and read errors, if any. Ignored sessions are typically those not in the up state or those with a reserved (0 through 15) incoming label (typically the egress point of an LSP). The reason for a read error appears on the same line as the entry for the LSP on which the error occurred. Gathering statistics is an unreliable process; occasional read errors might affect their accuracy. Sample output follows:

```
lsp6                    0 pkt              0 Byte      0 pps        0 Bps    0
lsp5                    0 pkt              0 Byte      0 pps        0 Bps    0
lsp6.1              34845 pkt        2926980 Byte   1049 pps    88179 Bps  132
lsp5.1                  0 pkt              0 Byte      0 pps        0 Bps    0
lsp4                    0 pkt              0 Byte      0 pps        0 Bps    0
Dec  7 17:28:38 Total 6 sessions: 5 success, 0 fail, 1 ignored
```

On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview

This topic describes methods for measuring packet loss, delay, and throughput for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to enable monitoring of network performance.

Importance of Measuring Packet Loss and Delay

The rise of bandwidth-consuming applications, such as IPTV and mobile video, coupled with the pressure to minimize the cost per bit and maximize the value per bit, is forcing carriers to transition their transport networks from circuit-based technologies to packet-based technologies. MPLS is a widely successful, connection-oriented packet transport technology that is ideally suited for packet-based transport networks.

With the emergence of new applications on data networks, it is becoming increasingly important for service providers to accurately predict the impact of new application rollouts. Understanding and modelling network performance in the network is especially relevant for deployment of new-world applications to ensure successful implementations. In packet networks, packet loss and delay are two of the most fundamental measures of performance. Their role is even more central when it comes to end-to-end measurements.

The traffic belonging to most of the end-to-end user applications is either loss sensitive (file transfer), delay sensitive (voice or video applications), or both (interactive computing applications). The service-level agreements (SLAs) of service providers depend on the ability to measure and monitor these network performance metrics, as the SLAs are directly or indirectly dependent on the loss and delay the customer traffic experiences in the service provider network.

To ensure compliance to the SLA, service providers need tools to measure and monitor the performance metrics for packet loss, one-way delay and two-way delay, and related metrics, such as delay variation and channel throughput. This measurement capability provides service providers with greater visibility into the performance characteristics of their networks, thereby facilitating planning, troubleshooting, and network performance evaluation.

Defining Packet Loss, Delay, and Throughput

In packet networks, packet loss and delay are two of the most fundamental measures of performance.

- **Loss**—Packet loss is the failure of one or more transmitted packets to arrive at their destination. Packet loss refers to the packets of data that are dropped by the network to manage congestion.

  Data applications are very tolerant to packet loss, as they are generally not time sensitive and can retransmit the packets that were dropped. However, in video conference environments and pure audio communications, such as VoIP, packet loss can create jitter.

- **Delay**—Packet delay (also called latency) is the amount of time it takes for a packet of data to get from one designated point to another, depending on the speed of the transmission medium, such as copper wire, optical fiber, or radio waves, and the delays in transmission by devices along the way, such as routers and modems.

  A low latency indicates a high network efficiency.

- **Throughput**—Packet delay measures the amount of time between the start of an action and its completion, whereas throughput is the total number of such actions that occur in a given amount of time.

Packet Loss and Delay Measurement Mechanisms

Packet delay and loss are two fundamental measures of network performance. Junos OS provides an on-demand mechanism to measure packet loss and delay over associated bidirectional MPLS ultimate hop popping (UHP) label-switched paths (LSPs).

The on-demand delay and packet loss measurement mechanism is initiated using the following CLI commands:

- **monitor mpls loss rsvp**—Performs an on-demand loss measurement for associated bidirectional UHP LSPs.
- **monitor mpls delay rsvp**—Performs an on-demand delay measurement for associated bidirectional UHP LSPs.
- **monitor mpls loss-delay rsvp**—Performs an on-demand combined loss and delay measurement for associated bidirectional UHP LSPs.

For initiating the delay and packet loss measuring mechanism, the desired parameters for measurement, such as the type of measurement and LSP name, need to be entered. On receiving the parameters, a summary of the performance monitoring data is displayed and the mechanism is terminated.

Packet Loss and Delay Metrics

The following performance metrics are measured using the on-demand packet loss and delay mechanisms:

- Loss measurement (packet and octet)
- Throughput measurement (packet and octet)
- Two-way channel delay

- Round-trip delay
- Inter-packet delay variation (IPDV)

The **monitor mpls loss rsvp** command performs the loss and throughput measurement, and the **monitor mpls delay rsvp** command performs the two-way channel delay, round-trip delay, and IPDV measurements. The **monitor mpls loss-delay rsvp** command performs a combined loss and delay measurement and measures all of the above-mentioned performance metrics simultaneously.

Packet Loss and Delay Measurement Concepts

The following concepts help to better understand the functionality of packet loss and delay:

- **Querier**—A querier is the ingress provider edge (PE) router, which originates the query message for loss or delay measurement.
- **Responder**—A responder is the egress PE router, which receives and responds to the query messages from a querier.
- **Associated bidirectional LSP**—An associated bidirectional LSP consists of two unidirectional LSPs that are tied together (or associated with each other) through configuration on both of the LSP end points.

  The on-demand loss and delay measurement can be carried out only on associated bidirectional UHP LSPs.
- **Generic associated channel (G-Ach)**—The performance monitoring messages for the on-demand loss and delay measurement flow over the MPLS G-Ach. This type of channel supports only in-band responses, and does not provide support for out-of-band or no-response modes.
- **Measurement point (MP)**—MP is the location at which a condition is described for the measurement.

  The MP for packet loss on the transmit side is between the switching fabric and the transmit interface. The counter value is stamped in the loss measurement message in the hardware before it is queued for transmission.

  The MP for packet loss on the receive side is between the receive interface and the switching fabric. The MP is distributed on the receive side. Furthermore, when the transmit interface is an aggregate interface, the MP is distributed as well.
- **Query rate**—Query rate is the interval between two queries sent for loss and delay measurement.

  Because the loss and delay measurement messages originate from the Routing Engine, a high query rate for multiple channels puts a heavy burden on the Routing Engine. The minimum query interval supported is 1 second.

  The query rate should be high for 32-bit counters, because the counters might wrap quickly when data traffic rate is very high. The query rate can be low when 64-bit counters are in use at all the four measurement point locations involved in loss measurement. Junos OS supports only 64-bit counters.

- **Traffic class**—By default, loss measurement is supported for the whole channel. Junos OS also supports traffic class scoped packet loss measurement, where counters that maintain data traffic statistics per traffic class have to be created.

  Per traffic class counters are not created by default. To configure traffic class scoped loss measurement, include the **traffic-class-statistics** statement at the **[edit protocols mpls statistics]** hierarchy level.

  When **traffic-class-statistics** is configured, control packets flowing over the G-Ach are not counted in the transmit and receive counters.

  NOTE: **Enabling and disabling of traffic class statistics results in the resetting of all counters (aggregate counter and per-class counters) for the LSPs.**

- **Loss measurement mode**—Junos OS supports the direct-mode of on-demand loss measurement, and does not provide support for the inferred-mode.

  Direct loss measurement requires data traffic statistics to be maintained at the ingress and egress of two unidirectional LSPs of the associated bidirectional LSP. When an MX Series router is using only MPCs and MICs, counters to maintain data traffic statistics are created by default at the ingress of all types of LSPs and egress of UHP LSPs.

  However, the direct-mode of loss measurement is not fully accurate due to the following reasons:

  - Parallel forwarding nature of the hardware.
  - Presence of equal cost multipath (ECMP) in the network, such as aggregated Ethernet interfaces, which can result in re-ordering of data packets relative to the loss measurement messages.
  - Control packets that do not flow over G-Ach are not counted at the LSP ingress, but are counted at the LSP egress.
  - Data traffic re-ordering relative to the loss measurement message when a Diffserv is implemented in the MPLS network and loss measurement scope is the complete channel and not traffic class scoped.

    To overcome this limitation, perform traffic class scoped loss measurement when a Diffserv is implemented.

  NOTE: **Direct mode loss measurement is vulnerable to disruption when the ingress or egress interface associated with the LSP changes.**

- **Loss measurement synchronization**—The synchronization conditions specified in section 2.9.8 of RFC 6374 do not hold true in the absolute sense. However, as the loss measurement counters are stamped in hardware, the errors introduced due to not satisfying the synchronization conditions are relatively small. These errors need to be quantified.

When the transmit or receive interface of the LSP is an aggregate interface, more errors are introduced as compared to when the interfaces are non-aggregate interfaces. In any case, the loss measurement counters are stamped in hardware, and the error needs to be quantified.

- **Delay measurement accuracy**—When the transmit and receive interfaces reside on different Packet Forwarding Engines, the clock must be synchronized on these Packet Forwarding Engines for two-way delay measurements. This condition holds true for the platform on which the on-demand delay measurement feature is implemented.

  When there are aggregate interfaces or ECMP, the delay is measured for only one of the potential paths.

  When a combined loss and delay message is used for delay calculation, the accuracy of delay is lower compared to when the delay measurement message is used in some cases, such as when the transmit or receive interface is an aggregate interface.

  Delay measurement is always performed on a per-traffic-class basis, and the accuracy of the measurement needs to be quantified after testing.

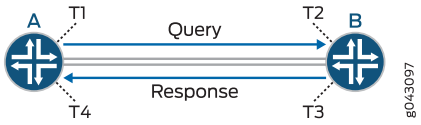
- **Timestamp format**—Junos OS supports only the IEEE 1588 Precision Time Protocol (PTP) [IEEE1588] format for recording delay measurement messages. Network Time Format (NTP) is not supported.

- **Operations, administration, and maintenance (OAM)**—To indicate that all the OAM messages for MPLS LSPs flow over the MPLS G-Ach, and to enable the MPLS performance monitoring messages to be carried over the MPLS G-Ach, the **oam mpls-tp-mode** statement must be included at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level.

Packet Loss and Delay Measurement Functionality

Figure 13 on page 195 illustrates the basic methods used for the bidirectional measurement of packet loss and delay. A bidirectional channel exists between the two routers, Router A and Router B. The temporal reference points – T1, T2, T3, and T4 – are associated with a measurement operation that takes place at Router A. The operation consists of Router A sending a query message to Router B, and Router B sending back a response. Each reference point indicates the point of time at which either the query or the response message is transmitted or received over the channel.

Figure 13: Basic Bidirectional Measurement



In Figure 13 on page 195, Router A can arrange to measure the packet loss over the channel in the forward and reverse directions by sending loss measurement query messages to Router B. Each of the forward and reverse messages contain the count of packets transmitted prior to time T1 over the channel to Router B (A_TxP).

When the message reaches Router B, two values are appended to the message and the message is reflected back to Router A. The two values are the count of packets received prior to time T2 over the channel from Router A (B_RxP) and the count of packets transmitted prior to time T3 over the channel to Router A (B_TxP).

When the response reaches Router A, a fourth value is appended to the message – the count of packets received prior to time T4 over the channel from Router B (A_RxP).

These four counter values – (A_TxP), (B_RxP), (B_TxP), and (A_RxP) – enable Router A to compute the desired loss statistics. Because the transmit count at Router A and the receive count at Router B (and vice versa) might not be synchronized at the time of the first message, and to limit the effects of counter wrap, the loss is computed in the form of a delta between the messages.

The transmit loss (A_TxLoss[n-1,n]) and receive loss (A_RxLoss[n-1,n]) within the measurement interval marked by the messages LM[n-1] and LM[n] are computed by Router A as follows:

A_TxLoss[n-1,n] = (A_TxP[n] - A_TxP[n-1]) - (B_RxP[n] - B_RxP[n-1])

A_RxLoss[n-1,n] = (B_TxP[n] - B_TxP[n-1]) - (A_RxP[n] - A_RxP[n-1])

The arithmetic is modulo the counter size.

To measure at Router A the delay over the channel to Router B, a delay measurement query message is sent from Router A to Router B containing a timestamp recording the instant at which it is transmitted. In Figure 13 on page 195, the timestamp is recorded in T1.

When the message reaches Router B, a timestamp is added, recording the instant at which it is received (T2). The message can now be reflected from Router B to Router A, with Router B adding its transmit timestamp (T3) and Router A adding its receive timestamp (T4).

These four timestamps – T1, T2, T3, and T4 – enable Router A to compute the one-way delay in each direction, as well as the two-way delay for the channel. The one-way delay computations require that the clocks of Routers A and B be synchronized.

At this point, Router A can compute the two-way channel delay and round-trip delay associated with the channel as follows:

Two-way channel delay = (T4 - T1) - (T3 - T2)

Round-trip delay = T4 - T1

Packet Loss and Delay Features

Supported Features of Packet Loss and Delay

Junos OS supports the following features with on-demand loss and delay measurement:

- Performance monitoring for associated bidirectional MPLS point-to-point UHP LSPs only
- Loss measurement
- Throughput measurement
- Two-way delay measurement (channel delay and round-trip delay)
- Inter-packet delay variation (IPDV)
- Direct-mode loss measurement
- Aggregated Ethernet and aggregated SONET interfaces
- Multichassis support
- 64-bit compatible

Unsupported Features of Packet Loss and Delay

Junos OS does not support the following on-demand loss and delay measurement functionality:

- Loss and delay measurement for pseudowires (section 2.9.1 of RFC 6374)
- Unidirectional measurement (section 2.6 of RFC 6374)
- Dyadic measurement (section 2.7 of RFC 6374)
- Loss and delay measurement in loopback mode (section 2.8 of RFC 6374)
- Loss and delay measurement to an intermediate node from an LSP endpoint (section 2.9.5 of RFC 6374)
- External post-processing (section 2.9.7 of RFC 6374)
- Inferred-mode loss measurement (section 2.9.8 of RFC 6374)
- Pro-active mode
- Logical systems
- SNMP

- monitor mpls loss-delay rsvp on page 2238

Example: Configuring On-Demand Loss and Delay Measurement

This example shows how to enable on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance.

Requirements

This example uses the following hardware and software components:

- Two MX Series 5G Universal Routing Platforms that contain MPC/MICs only
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - OSPF

Overview

Starting with Junos OS Release 14.2, an on-demand tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs) is introduced. The tool can be enabled using the following CLI commands – **monitor mpls loss rsvp**, **monitor mpls delay rsvp**, and **monitor mpls loss-delay rsvp**.

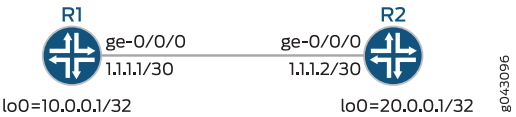
These commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Topology

Figure 14 on page 199 illustrates the on-demand loss and delay measurement using a simple two-router topology.

Figure 14: Configuring On-Demand Loss and Delay Measurement



In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics is measured.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

R1

```
set chassis fpc 0 pic 3 tunnel-services bandwidth 1g
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.1/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set interfaces lo0 unit 0 family mpls
set routing-options router-id 10.0.0.1
set protocols rsvp interface ge-0/0/0.0
set protocols rsvp interface lo0.0
set protocols rsvp interface fxp0.0 disable
set protocols mpls statistics traffic-class-statistics
set protocols mpls label-switched-path R1-R2 to 20.0.0.1
set protocols mpls label-switched-path R1-R2 oam mpls-tp-mode
set protocols mpls label-switched-path R1-R2 ultimate-hop-popping
set protocols mpls label-switched-path R1-R2 associate-lsp R2-R1
set protocols mpls interface ge-0/0/0.0
set protocols mpls interface lo0.0
set protocols mpls interface fxp0.0 disable
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
```

R2

```
set chassis fpc 0 pic 3 tunnel-services bandwidth 1g
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.2/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 20.0.0.1/32
set interfaces lo0 unit 0 family mpls
set routing-options router-id 20.0.0.1
set protocols rsvp interface ge-0/0/0.0
set protocols rsvp interface lo0.0
set protocols rsvp interface fxp0.0 disable
set protocols mpls statistics traffic-class-statistics
set protocols mpls label-switched-path R2-R1 to 10.0.0.1
set protocols mpls label-switched-path R2-R1 oam mpls-tp-mode
```

```
set protocols mpls label-switched-path R2-R1 ultimate-hop-popping
set protocols mpls label-switched-path R2-R1 associate-lsp R1-R2
set protocols mpls interface ge-0/0/0.0
set protocols mpls interface lo0.0
set protocols mpls interface fxp0.0 disable
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0.interface fxp0.0 disable
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R1:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```
[edit chassis]
user@R1# set fpc 0 pic 3 tunnel-services bandwidth 1g
user@R1# set network-services enhanced-ip
```

2. Configure the interfaces for Router R1.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls
```

3. Configure the router ID for Router R1.

```
[edit routing-options]
user@R1# set router-id 10.0.0.1
```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable
```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable
```

6. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

8. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
fpc 0 {
   pic 3 {
      tunnel-services {
         bandwidth 1g;
      }
   }
}
network-services enhanced-ip;
```

```
user@R1# show interfaces
ge-0/0/0 {
   unit 0 {
      family inet {
         address 1.1.1.1/30;
      }
      family mpls;
   }
}
```

```
lo0 {
   unit 0 {
      family inet {
         address 10.0.0.1/32;
      }
      family mpls;
   }
}
```

```
user@R1# show routing-options
router-id 10.0.0.1;
```

```
user@R1# show protocols
rsvp {
   interface ge-0/0/0.0;
   interface lo0.0;
   interface fxp0.0 {
      disable;
   }
}
mpls {
   statistics {
      traffic-class-statistics;
   }
   label-switched-path R1-R2 {
      to 20.0.0.1;
      oam mpls-tp-mode;
      ultimate-hop-popping;
      associate-lsp R2-R1;
   }
   interface ge-0/0/0.0;
   interface lo0.0;
   interface fxp0.0 {
      disable;
   }
}
ospf {
   traffic-engineering;
   area 0.0.0.0 {
      interface ge-0/0/0.0;
      interface lo0.0;
      interface fxp0.0 {
         disable;
      }
   }
}
```

Verification

Confirm that the configuration is working properly.

- Verifying the LSP Status on page 203
- Verifying Packet Loss Measurement on page 203

- Verifying Packet Delay Measurement on page 205
- Verifying Packet Loss-Delay Measurement on page 205

Verifying the LSP Status

Purpose Verify that the associated bidirectional LSP between Routers R1 and R2 is up.

Action From operational mode, run the **show mpls lsp** command.

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
20.0.0.1        10.0.0.1        Up     0 *                      R1-R2 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.0.0.1        20.0.0.1        Up       0  1 FF  299776       - R2-R1 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The associated bidirectional LSP R1-R2 is up and active.

Verifying Packet Loss Measurement

Purpose Verify the on-demand loss measurement result.

Action From operational mode, run the **monitor mpls loss rsvp R1-R2 count 2 detail** command.

```
user@R1> monitor mpls loss rsvp R1-R2 count 2 detail
(0)
Response code                           : Success
Origin timestamp                        : 1404129082 secs, 905571890 nsecs

Current forward transmit count          : 582
Current forward receive count           : 582
Current forward loss                    : 0 packets
Current forward loss ratio              : 0.000000
Current forward throughput              : 0.582 kpps
Current reverse transmit count          : 583
Current reverse receive count           : 583
Current reverse loss                    : 0 packets
Current reverse loss ratio              : 0.000000
Current reverse throughput              : 0.583 kpps

Cumulative forward transmit count       : 1383
Cumulative forward loss                 : 0 packets
Average forward loss ratio              : 0.000000
Average forward throughput              : 0.692 kpps
Cumulative reverse transmit count       : 1387
Cumulative reverse loss                 : 0 packets
Average reverse loss ratio              : 0.000000
Average reverse throughput              : 0.694 kpps

LM queries sent                         : 3
LM responses received                   : 3
LM queries timedout                     : 0
LM responses dropped due to errors      : 0
```

Meaning The packet loss measurement for two counts is displayed.

Verifying Packet Delay Measurement

Purpose Verify the on-demand delay measurement result.

Action From operational mode, run the **monitor mpls delay rsvp R1-R2 count 2 detail** command.

```
user@R1> monitor mpls delay rsvp R1-R2 count 2 detail
(1)
Response code                           : Success
Querier transmit timestamp              : 1404129122 secs, 479955401 nsecs

- monitor mpls delay rsvp on page 2228
- monitor mpls loss-delay rsvp on page 2238

Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs

This example shows how to configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance.

Requirements

This example uses the following hardware and software components:

- Two MX Series 5G Universal Routing Platforms that contain MPC/MICs only
- Junos OS Release 15.1 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   a. MPLS
   b. OSPF
   c. RSVP

Overview

Starting with Junos OS Release 15.1, a pro-active tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate-hop popping point-to-point label-switched paths (LSPs) is introduced.

This feature provides the following performance metrics:

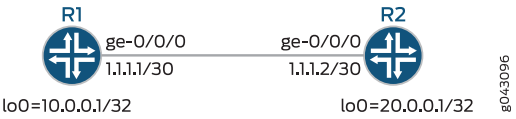
- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Topology

Figure 14 on page 199 illustrates the pro-active loss and delay measurements using a simple two-router topology.

Figure 15: Configuring Pro-Active Loss and Delay Measurements



In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics are measured.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

R1

```
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.1/30
set interfaces ge-0/0/0 unit 0 family mpls

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R1:

1. Enable the enhanced IP network services configuration.

```
[edit chassis]
user@R1# set network-services enhanced-ip
```

2. Configure the interfaces for Router R1.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls
```

3. Configure the router ID for Router R1.

```
[edit routing-options]
user@R1# set router-id 10.0.0.1
```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable
```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
```

```
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable
```

6. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 install 20.10.30.0/24 active
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss and delay measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

8. Configure performance monitoring at the querier side.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
  delay traffic-class tc-0 query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
  loss traffic-class none query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
  loss-delay traffic-class tc-0 query-interval 1000
```

9. Configure performance monitoring at the responder side.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring
  responder delay min-query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring
  responder loss min-query-interval 1000
```

10. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
network-services enhanced-ip;
```

```
user@R1# show interfaces
ge-0/0/0 {
   unit 0 {
      family inet {
         address 1.1.1.1/30;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.0.0.1/32;
      }
      family mpls;
   }
}
```

```
user@R1# show routing-options
router-id 10.0.0.1;
```

```
user@R1# show protocols
rsvp {
   interface ge-0/0/0.0;
   interface lo0.0;
   interface fxp0.0 {
      disable;
   }
}

         mpls-tp-mode;
         performance-monitoring {
            querier {
               loss {
                  traffic-class none {
                     query-interval 1000;
                  }
               }
```

```
            delay {
              traffic-class tc-0 {
                query-interval 1000;
              }
            }
            loss-delay {
              traffic-class none {
                query-interval 1000;
              }
            }
          }
          responder {
            loss {
              min-query-interval 1000;
            }
            delay {
              min-query-interval 1000;
            }
          }
        }
      }
      ultimate-hop-popping;
      associate-lsp R2-R1;
    }
  }
  ospf {
    traffic-engineering;
    area 0.0.0.0 {
      interface ge-0/0/0.0;
      interface lo0.0;
      interface fxp0.0 {
        disable;
      }
    }
  }
```

Verification

Verifying Loss and Delay Measurement

Purpose Verify the loss and delay measurement.

Action From operational mode, run the **show performance-monitoring mpls lsp** command.

```
user@R1> show performance-monitoring mpls lsp
Session Total: 3 Up: 3 Down: 0
  LSP name:R1-R2, PM State:Up
    Loss measurement Data:
      Duration: 00:04:43

Configuring On-Demand Loss and Delay Measurement

You can configure an on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance. The **monitor mpls loss rsvp**, **monitor mpls delay rsvp**, and **monitor mpls loss-delay rsvp** CLI commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID.
3. Configure the following protocols:
   - RSVP
   - OSPF

     Enable traffic engineering capabilities.
   - MPLS

To configure the PE device:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```
[edit chassis]
user@R1# set fpc fpc-slot pic pic-slot tunnel-services bandwidth bandwidth
user@R1# set network-services enhanced-ip
```

2. Configure an associated bidirectional LSP to the remote router.

```
[edit protocols]
user@R1# set mpls label-switched-path lsp-name to remote-router-ip-address
user@R1# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@R1# set mpls label-switched-path lsp-name ultimate-hop-popping
user@R1# set mpls label-switched-path lsp-name associate-lsp lsp-name
```

3. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss measurement.

```
[edit protocols]
```

```
user@R1# set mpls statistics traffic-class-statistics
```

- **monitor mpls loss-delay rsvp on page 2238**

Configuring Pro-Active Loss and Delay Measurements

You can configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance. The **show performance-monitoring mpls lsp** CLI command provides a summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

This feature provides the following performance metrics:

- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - MPLS
   - OSPF
   - RSVP

To configure pro-active loss and delay measurements on the PE device:

1. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
```

```
user@host# set mpls label-switched-path lsp-name to remote-router-ip-address
user@host# set mpls label-switched-path lsp-name install
  destination-prefix/prefix-length active
user@host# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@host# set mpls label-switched-path lsp-name ultimate-hop-popping
user@host# set mpls label-switched-path lsp-name associate-lsp remote-lsp-name
```

2. Create traffic classes for maintaining data traffic statistics per traffic class.

   This enables traffic class scoped loss and delay measurements.

```
[edit protocols]
user@host# set mpls statistics traffic-class-statistics
```

3. Configure performance monitoring at the querier side.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
  querier delay traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
  querier loss traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
  querier loss-delay traffic-class tc-value query-interval milliseconds
```

4. Configure performance monitoring at the responder side.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
  responder delay min-query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
  responder loss min-query-interval milliseconds
```

CHAPTER 9

Configuring Shared Risk Link Group (SRLG)

SRLG Overview

In MPLS traffic engineering, a Shared Risk Link Group (SRLG) is a set of links sharing a common resource, which affects all links in the set if the common resource fails. These links share the same risk of failure and are therefore considered to belong to the same SRLG. For example, links sharing a common fiber are said to be in the same SRLG because a fault with the fiber might cause all links in the group to fail.

An SRLG is represented by a 32-bit number unique within an IGP (OSPFv2 and IS-IS) domain. A link might belong to multiple SRLGs. The SRLG of a path in a label-switched path (LSP) is the set of SRLGs for all the links in the path. When computing the secondary path for an LSP, it is preferable to find a path such that the secondary and primary paths do not have any links in common in case the SRLGs for the primary and secondary paths are disjoint. This ensures that a single point of failure on a particular link does not bring down both the primary and secondary paths in the LSP.

When the SRLG is configured, the device uses the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive. If the primary path goes down, the CSPF algorithm computes the secondary path by trying to avoid links that share any SRLG with the primary path. In addition, when computing the path for a bypass LSP, CSPF tries to avoid links that share any SRLG with the protected links.

When the SRLG is not configured, CSPF only takes into account the costs of the links when computing the secondary path.

Any change in link SRLG information triggers the IGP to send LSP updates for the new link SRLG information. CSPF recomputes the paths during the next round of reoptimization.

Junos OS Release 11.4 and later supports SRLG based on the following RFCs:

- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.
- RFC 5307, *IS-IS Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.

NOTE: Currently, the "Fate Sharing" feature continues to be supported with the SRLG feature.

Example: Configuring SRLG

This example shows how to configure Shared Risk Link Groups (SRLGs) on a device.

Requirements

This example uses the following hardware and software components:

- Seven routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 11.4 or later running on all the devices

Overview

Junos OS Release 11.4 and later support SRLG configuration in an IGP (OSPFv2 and IS-IS) domain. In this example, you configure SRLG and associate it with the MPLS interface on a device.

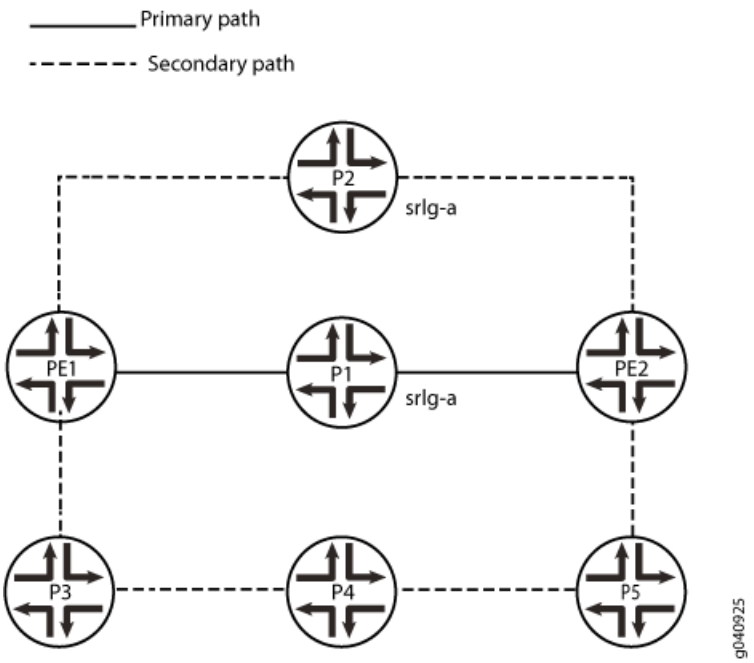
The device uses the SRLG cost parameter for the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive by avoiding links that share any SRLG with the primary path.

To configure the SRLG, you first define the SRLG parameters at the **[edit routing-options srlg *srlg-name*]** hierarchy level and then associate the SRLG with an MPLS interface at the **[edit mpls interface *interface-name*]** hierarchy level.

The **srlg *srlg-name*** statement has the following options:

- **srlg-cost**—Include a cost for the SRLG ranging from 1 through 65535. The cost of the SRLG determines the level of impact this SRLG has on the CSPF algorithm for path computations. The higher the cost, the less likely it is for a secondary path to share the same SRLG as the primary path. By default, the **srlg-cost** is 1.
- **srlg-value**—Include a group ID for the SRLG ranging from 1 through 4294967295.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. The effective link metric, with the added **srlg-cost** of 10, becomes 11. Therefore, the computed secondary path is PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.



Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router PE1

```
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
```

```

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.12.1/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.13.1/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
```

```
            address 192.168.14.1/24;
          }
          family mpls;
        }
      }
      lo0 {
        unit 0 {
          family inet {
            address 10.255.0.1/32;
          }
        }
      }
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;;
   interface ge-0/0/2.0;
   interface ge-0/0/3.0;
   interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
   to 10.255.0.7;
   primary via-p1;
   secondary path2 {
      standby;
   }
}
path via-p1 {
   10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
routing-options {
   srlg {
      srlg-a {
         srlg-value 101;
         srlg-cost 10;
      }
   }
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

Verification

Confirm that the configuration is working properly.

- Verifying SRLG Definitions on page 227
- Verify TE-Link SRLG on page 227
- Verify Standby Secondary Path on page 228

Verifying SRLG Definitions

Purpose Verify SRLG-to-value mappings and SRLG cost.

Action

```
user@PE1> show mpls srlg

SRLG              Value      Cost
srlg-a              101        10
```

Verify TE-Link SRLG

Purpose Verify the traffic engineering link SRLG association.

Action `user@PE1>` **show ted link detail**

```
...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 1, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
      Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps  [1] 0bps  [2] 0bps  [3] 0bps
  localBW [4] 0bps  [5] 0bps  [6] 0bps  [7] 0bps

...
10.255.0.3->192.168.37.7-1, Local: 192.168.37.3, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 0, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
      Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps  [1] 0bps  [2] 0bps  [3] 0bps
  localBW [4] 0bps  [5] 0bps  [6] 0bps  [7] 0bps

...
```

Meaning Links P1-PE2 and P2-PE2 are associated with SRLG **srlg-a**.

Verify Standby Secondary Path

Purpose Check the SRLG link cost and its impact on the CSPF computation of the standby secondary path link.

Action `user@PE1> show mpls lsp ingress extensive`

```
Ingress LSP: 1 sessions

```

Meaning Check the standby secondary path. The effective link cost for P2>PE2 is 11 (with the added **srlg-cost** of 10). CSPF computes the secondary path as PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.

Related Documentation

- SRLG Overview on page 219
- Example: Excluding SRLG Links Completely for the Secondary LSP on page 230
- **srlg on page 1965**
- **srlg-cost on page 1966**
- **srlg-value on page 1966**

Example: Excluding SRLG Links Completely for the Secondary LSP

This example shows how to configure the **exclude-srlg** option to exclude Shared Risk Link Group (SRLG) links for the secondary label-switched path (LSP).

Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

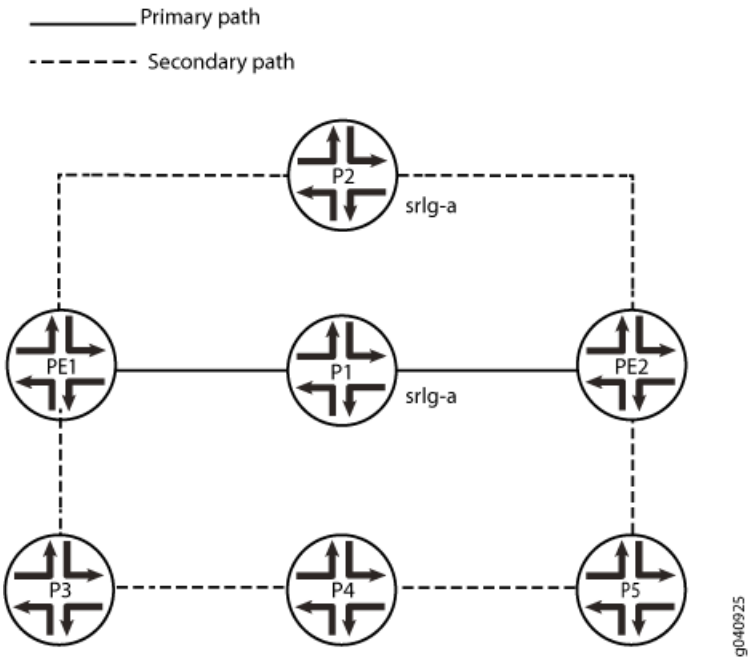
Overview

For critical links where it is imperative to keep the secondary and primary paths completely disjoint from any common SRLG, you can optionally configure the **exclude-srlg** statement at the **[edit protocols mpls]** or **[edit protocols mpls label-switched-path *path-name*]** hierarchy levels. For logical systems, you configure the **exclude-srlg** statement at the **edit logical-systems protocols mpls[edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]** hierarchy level.

If **exclude-srlg** is configured, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. If **exclude-srlg** is not configured, and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. Because

exclude-srlg is configured, CSPF rejects link P2>PE2 as the link belongs to the SRLG **srlg-a**. Therefore, the computed standby secondary path is PE1>P3>P4>P5>PE2.



Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router PE1

```
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces ge-0/0/2 unit 0 family inet address 192.168.13.1/24
set interfaces ge-0/0/2 unit 0 family mpls
set interfaces ge-0/0/3 unit 0 family inet address 192.168.14.1/24
set interfaces ge-0/0/3 unit 0 family mpls

set protocols mpls path via-p1 10.255.0.2 strict
set protocols mpls path path2
set protocols mpls interface ge-0/0/1.0
set protocols mpls interface ge-0/0/2.0
```

```
set protocols mpls interface ge-0/0/3.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface lo0.0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set routing-options srlg srlg-a srlg-value 101
```

4. Configure MPLS and the LSPs.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set exclude-srlg
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Configure the **exclude-srlg** statement to forcibly keep the links for the secondary path completely disjoint from the primary LSP path.

```
user@PE1 set protocols mpls exclude-srlg
```

6. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
   ge-0/0/1 {
      unit 0 {
         family inet {
            address 192.168.12.1/24;
         }
         family mpls;
      }
   }
   ge-0/0/2 {
      unit 0 {
         family inet {
            address 192.168.13.1/24;
         }
         family mpls;
      }
   }
   ge-0/0/3 {
      unit 0 {
         family inet {
            address 192.168.14.1/24;
         }
         family mpls;
      }
   }
   lo0 {
      unit 0 {
         family inet {
            address 10.255.0.1/32;
         }
      }
   }
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;;
   interface ge-0/0/2.0;
   interface ge-0/0/3.0;
   interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
   to 10.255.0.7;
   primary via-p1;
   secondary path2 {
      standby;
   }
}
path via-p1 {
   10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
routing-options {
   srlg {
      srlg-a srlg-value 101;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

Verification

Confirm that the configuration is working properly.

Verifying the Secondary Path Link for the LSP

Purpose Verify that the link for the secondary path is completely disjoint from the primary path.

Action

```
user@PE1> show mpls lsp detail
Ingress LSP: 1 sessions

10.255.0.7
  From: 10.255.0.1, State: Up, ActiveRoute: 0, LSPname: pe1-pe2
  ActivePath: via-p1 (primary)
  LSPtype: Static Configured
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   via-p1           State: Up
    Priorities: 7 0
    OptimizeTimer: 120
    SmartOptimizeTimer: 180
    SRLG: srlg-a
    Reoptimization in 77 second(s).
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 2)
 192.168.12.2 S 192.168.27.7 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt
 20=Node-ID):
          192.168.12.2 192.168.27.7
  Standby   path2            State: Up
    Priorities: 7 0
    OptimizeTimer: 120
    SmartOptimizeTimer: 180
    Reoptimization in 106 second(s).
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 4)
 192.168.14.4 S 192.168.45.5 S 192.168.56.6 S 192.168.67.7 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt
 20=Node-ID):
          192.168.14.4 192.168.45.5 192.168.56.6 192.168.67.7
Total 1 displayed, Up 1, Down 0

Link P1->PE2: SRLG srlg-a
Link P2->PE2: SRLG srlg-a

Primary path:      PE1-P1-PE2       (CSPF metric: 2)
Standby secondary: PE1-P3-P4-P5-PE2 (CSPF metric: 4)
```

Meaning Primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. CSPF rejects link P2>PE2 because the link belongs to the SRLG **srlg-a**.

Example: Configuring SRLG with Link Protection

This example shows how to configure SRLG with link protection without the **exclude-srlg** option.

Requirements

This example uses the following hardware and software components:

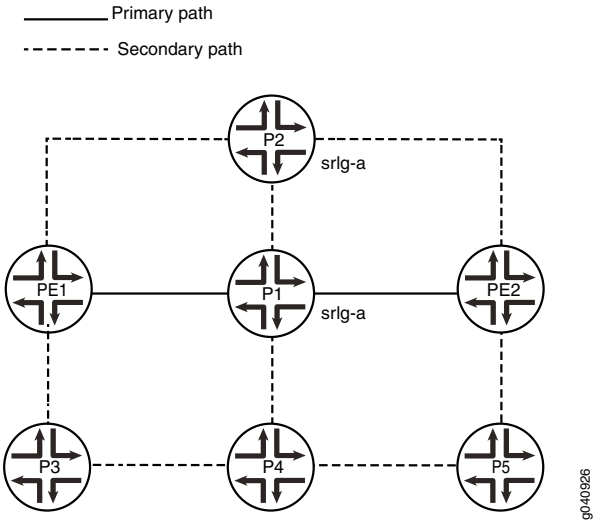
- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

Overview

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG srlg-a.

You configure link protection for the interface P1>PE2 by including the **link-protection** statement.

When SRLG srlg-a is configured on the link P1>PE2 and P2>PE2, the bypass takes the longer path P1>P4>P5>PE2, not selecting the link P2>PE2 because of the added SRLG cost for srlg-a.



Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
```

```
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs and configure link protection for the **pe1-pe2** LSP.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.12.1/24;
      }
      family mpls;
   }
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.13.1/24;
```

```
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.14.1/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.1/32;
    }
  }
}
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
  to 10.255.0.7;
  link-protection;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
path via-p1 {
  10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
srlg {
   srlg-a {
      srlg-value 101;
      srlg-cost 10;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure device P1:

1. Configure the device interfaces.

```
[edit interfaces]
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P1# set srlg srlg-a srlg-value 101
user@P1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG **srlg-a** with interface **ge-0/0/2.0** for the P1>PE2 link.

```
[edit protocols mpls]
```

```
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and configure **link-protection** for interface **ge-0/0/2.0**.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.27.2/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.23.2/24;
    }
    family mpls;
  }
}
ge-0/0/4 {
  unit 0 {
    family inet {
      address 192.168.25.2/24;
    }
    family mpls;
  }
}
```

```
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.2/32;
    }
  }
}
```

```
user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P2:

1. Configure the device interfaces.

```
[edit interfaces]
user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P2# set srlg srlg-a srlg-value 101
user@P2# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG **srlg-a** with interface **ge-0/0/2.0** for the P2>PE2 link.

```
[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P2# show interfaces
ge-0/0/1 {
   unit 0 {
```

```
      family inet {
        address 192.168.13.3/24;
      }
      family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.37.3/24;
      }
      family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
      family inet {
        address 192.168.23.3/24;
      }
      family mpls;
    }
}
lo0 {
    unit 0 {
      family inet {
        address 10.255.0.3/32;
      }
    }
}
}
```

```
user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
}
```

```
user@P2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P2# show routing-options
srlg {
   srlg-a {
      srlg-value 101;
      srlg-cost 10;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P3

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P3:

1. Configure the device interfaces.

```
[edit interfaces]
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P3# set srlg srlg-a srlg-value 101
user@P3# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
```

```
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces
interfaces {
   ge-0/0/1 {
      unit 0 {
         family inet {
            address 192.168.14.4/24;
         }
         family mpls;
      }
   }
   ge-0/0/2 {
      unit 0 {
         family inet {
            address 192.168.45.4/24;
         }
         family mpls;
      }
   }
   lo0 {
      unit 0 {
         family inet {
            address 10.255.0.4/32;
         }
      }
   }
}
```

```
user@P3# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
   interface lo0.0;
}
```

```
user@P3# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show routing-options
srlg {
   srlg-a {
      srlg-value 101;
      srlg-cost 10;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P4

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P4:

1. Configure the device interfaces.

```
[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P4# set srlg srlg-a srlg-value 101
user@P4# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.45.5/24;
      }
      family mpls;
   }
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.56.5/24;
      }
      family mpls;
   }
}
ge-0/0/3 {
   unit 0 {
      family inet {
         address 192.168.25.5/24;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.255.0.5/32;
      }
   }
}
```

```
user@P4# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
   interface ge-0/0/3.0;
   interface lo0.0;
```

```
}
```

```
user@P4# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show routing-options
srlg {
   srlg-a {
      srlg-value 101;
      srlg-cost 10;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P5

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P5:

1. Configure the device interfaces.

```
[edit interfaces]
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P5# set srlg srlg-a srlg-value 101
```

```
user@P5# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P5# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.56.6/24;
      }
      family mpls;
   }
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.67.6/24;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.255.0.6/32;
      }
   }
}
```

```
user@P5# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
```

```
    interface lo0.0;
}
```

```
user@P5# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device PE2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set srlg srlg-a srlg-value 101
user@PE2# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.27.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.37.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
                address 192.168.67.7/24;
            }
            family mpls;
        }
    }
    lo0 {
```

```
      unit 0 {
        family inet {
          address 10.255.0.7/32;
        }
      }
    }
}
```

```
user@PE2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}
```

```
user@PE2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the SRLG Cost Is Added to the TE Link

Purpose Verify that the SRLG cost is added to the TE link if it belongs to the SRLG of the protected link. Issue the **show ted link detail** and **show rsvp session extensive bypass** commands on device P1.

Action user@P1> **show ted link detail**

```
...

```

Meaning The shortest path for the bypass protecting the link P1->PE2 would have been P1->P2->PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG **srlg-a**, the SRLG cost of 10 for **srlg-a** is added to the metric for the link P2>PE2. This makes the metric for the link P2>PE2 too high to be selected for the shortest path. Therefore, the CSPF result for the computed path for the bypass becomes P1>P4>P5>PE2.

- Example: Configuring SRLG with Link Protection with the exclude-srlg Option on page 258

Example: Configuring SRLG with Link Protection with the exclude-srlg Option

This example shows how to configure SRLG with link protection with the **exclude-srlg** option.

Requirements

This example uses the following hardware and software components:

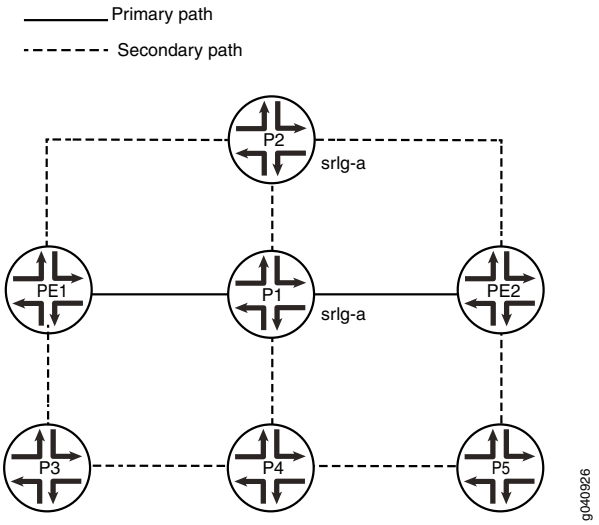
- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

Overview

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG **srlg-a**.

You configure link protection for the interface P1>PE2 by including the **link-protection** statement along with the **exclude-srlg** option. This makes the bypass LSP and the protected link completely disjoint in any SRLG.

When SRLG **srlg-a** is configured on the link P1>PE2 and P2>PE2, the link P2>PE2 is rejected for CSPF consideration due to the **exclude-srlg** configuration. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.



Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router PE1

```
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces ge-0/0/2 unit 0 family inet address 192.168.13.1/24
set interfaces ge-0/0/2 unit 0 family mpls

```

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
```

```
user@PE1# set routing-options srlg srlg-a srlg-value 101
user@PE1# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs and configure link protection for the **pe1-pe2** LSP.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.12.1/24;
      }
      family mpls;
   }
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.13.1/24;
      }
      family mpls;
   }
}
ge-0/0/3 {
   unit 0 {
      family inet {
         address 192.168.14.1/24;
```

```
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.1/32;
    }
  }
}
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
  to 10.255.0.7;
  link-protection;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
path via-p1 {
  10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure device P1:

1. Configure the device interfaces.

```
[edit interfaces]
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P1# set routing-options srlg srlg-a srlg-value 101
user@P1# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P1>PE2 link.

```
[edit protocols mpls]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and include the **link-protection** statement with the **exclude-srlg** option for interface **ge-0/0/2.0**.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection exclude-srlg
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 192.168.12.2/24;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.27.2/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            address 192.168.23.2/24;
        }
        family mpls;
    }
}
ge-0/0/4 {
    unit 0 {
        family inet {
            address 192.168.25.2/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.2/32;
        }
    }
}
```

```
user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
   interface ge-0/0/3.0;
   interface ge-0/0/4.0;
   interface lo0.0;
}
```

```
user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
   srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;
```

```
user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
   link-protection {
      exclude-srlg;
   }
interface ge-0/0/3.0;
interface ge-0/0/4.0;
}
```

```
user@P1# show routing-options
srlg {
   srlg-a {
      srlg-value 101;
      srlg-cost 10;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P2:

1. Configure the device interfaces.

```
[edit interfaces]
user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
```

```
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P2# set routing-options srlg srlg-a srlg-value 101
user@P2# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P2>PE2 link.

```
[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P2# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.13.3/24;
      }
      family mpls;
   }
```

```
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.37.3/24;
      }
      family mpls;
   }
}
ge-0/0/3 {
   unit 0 {
      family inet {
         address 192.168.23.3/24;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.255.0.3/32;
      }
   }
}
}
```

```
user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
   interface ge-0/0/3.0;
   interface lo0.0;
}
```

```
user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
   srlg srlg-a;
}
interface ge-0/0/3.0;
}
```

```
user@P2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P2# show routing-options
srlg {
   srlg-a {
      srlg-value 101;
      srlg-cost 10;
```

```
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P3

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P3:

1. Configure the device interfaces.

```
[edit interfaces]
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P3# set routing-options srlg srlg-a srlg-value 101
user@P3# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces
interfaces {
   ge-0/0/1 {
      unit 0 {
         family inet {
            address 192.168.14.4/24;
         }
         family mpls;
      }
   }
   ge-0/0/2 {
      unit 0 {
         family inet {
            address 192.168.45.4/24;
         }
         family mpls;
      }
   }
   lo0 {
      unit 0 {
         family inet {
            address 10.255.0.4/32;
         }
      }
   }
}
```

```
user@P3# show protocols ospf
traffic-engineering;

```

```
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P4

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P4:

1. Configure the device interfaces.

```
[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P4# set routing-options srlg srlg-a srlg-value 101
user@P4# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
```

```
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.45.5/24;
      }
      family mpls;
   }
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.56.5/24;
      }
      family mpls;
   }
}
ge-0/0/3 {
   unit 0 {
      family inet {
         address 192.168.25.5/24;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.255.0.5/32;
      }
   }
}
```

```
user@P4# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
   interface ge-0/0/3.0;
   interface lo0.0;
}
```

```

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device P5

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P5:

1. Configure the device interfaces.

```
[edit interfaces]
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P5# set routing-options srlg srlg-a srlg-value 101
user@P5# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P5# show interfaces
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.168.56.6/24;
      }
      family mpls;
   }
}
ge-0/0/2 {
   unit 0 {
      family inet {
         address 192.168.67.6/24;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.255.0.6/32;
      }
   }
}
```

```
user@P5# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
   interface ge-0/0/1.0;
   interface ge-0/0/2.0;
   interface lo0.0;
}
```

```
user@P5# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp
interface ge-0/0/1.0;

   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring Device PE2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set routing-options srlg srlg-a srlg-value 101
user@PE2# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces, show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
    ge-0/0/1 {
        unit 0 {
            family inet {
                address 192.168.27.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/2 {
        unit 0 {
            family inet {
                address 192.168.37.7/24;
            }
            family mpls;
        }
    }
    ge-0/0/3 {
        unit 0 {
            family inet {
                address 192.168.67.7/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 10.255.0.7/32;
            }
        }
```

```
    }
}
```

```
user@PE2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
```

```
user@PE2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the SRLG Cost Is Added to the TE Link

Purpose Verify that the TE link is excluded if it belongs to the SRLG of the protected link when **link-protection** is configured with **exclude-srlg**. Issue the **show ted link detail** and **show rsvp session extensive bypass** commands on device P1.

Action

```
user@P1> show ted link detail

```

Meaning The shortest path for the bypass protecting the link P1>PE2 would have been P1>P2>PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG **srlg-a**, the link P2>PE2 is rejected for CSPF consideration due to the **exclude-srlg** constraint. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

CHAPTER 10

Configuring MPLS Tunnels

Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

This example shows how to configure the Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

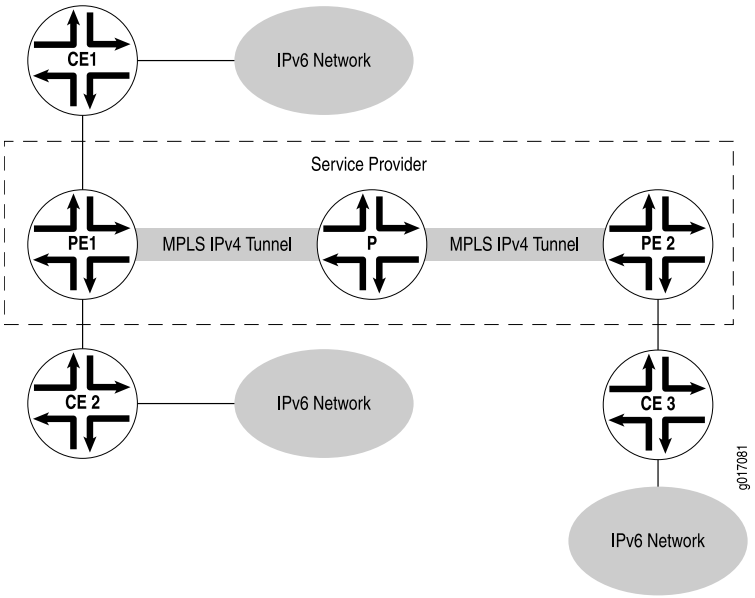
- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at http://www.ietf.org/.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In Figure 16 on page 282, Routers PE1 and PE2 are dual-stack BGP routers, meaning they have both IPv4 and IPv6 stacks. The PE routers link the IPv6 networks through the customer edge (CE) routers to the IPv4 core network. The CE routers and the PE routers connect through a link layer that can carry IPv6 traffic. The PE routers use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

Figure 16: IPv6 Networks Linked by MPLS IPv4 Tunnels



The two PE routers are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE routers can learn the IPv6 routes from the CE routers connected to them using routing protocols Routing Information Protocol next generation (RIPng) or MP-BGP, or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE router and CE router could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGP, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of either LDP or RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE routers always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE router is not a Juniper Networks routing platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE routers to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 router in Figure 16 on page 282 receives an IPv6 packet from the CE1 router, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 router, then no labels need to be pushed and the packet is simply sent to the CE2 router. If the destination matches a prefix that was learned from the PE2 router, then the PE1 router pushes two labels onto the packet and sends it to the provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the **family inet6** statement on all the CE router–facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.
- You enable IPv6 tunneling by including the **ipv6-tunneling** statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

NOTE: BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the inet6.3 routing table.

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the **explicit-null** statement in the BGP configuration.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device PE1

```
set interfaces fe-1/2/0 unit 2 family inet6 address ::10.1.1.2/126
set interfaces fe-1/2/0 unit 2 family mpls

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
user@PE1# set fe-1/2/0 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set fe-1/2/0 unit 2 family mpls
user@PE1# set fe-1/2/1 unit 5 family inet address 10.1.1.5/30
user@PE1# set fe-1/2/1 unit 5 family inet6
user@PE1# set fe-1/2/1 unit 5 family mpls
user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface fe-1/2/0.2
user@PE1# set interface fe-1/2/1.5
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1
user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6
user@PE1# set group toPE2 neighbor 1.1.1.4
```

4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface fe-1/2/1.5
user@PE1# set interface lo0.2 passive
```

5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set ldp interface fe-1/2/1.5
```

6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self
user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept
user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```

7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
```

```
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
   unit 2 {
      family inet6 {
         address ::10.1.1.2/126;
      }
      family mpls;
   }
}
fe-1/2/1 {
   unit 5 {
      family inet {
         address 10.1.1.5/30;
      }
      family inet6;
      family mpls;
   }
}
lo0 {
   unit 2 {
      family inet {
         address 1.1.1.2/32;
      }
   }
}
```

```
user@R1# show policy-options
policy-statement next-hop-self {
   then {
      next-hop self;
   }
}
policy-statement send-bgp6 {
   from {
      family inet6;
      protocol bgp;
   }
   then accept;
}
policy-statement send-v6 {
   from {
      family inet6;
      protocol [ bgp direct ];
```

```
    }
    then accept;
}
```

```
user@R1# show protocols
mpls {
    ipv6-tunneling;
    interface fe-1/2/0.2;
    interface fe-1/2/1.5;
}
bgp {
    group toCE1 {
        type external;
        local-address ::10.1.1.2;
        family inet6 {
            unicast;
        }
        export send-bgp6;
        peer-as 1;
        neighbor ::10.1.1.1;
    }
    group toPE2 {
        type internal;
        local-address 1.1.1.2;
        family inet6 {
            labeled-unicast {
                explicit-null;
            }
        }
        export [ next-hop-self send-v6 ];
        neighbor 1.1.1.4;
    }
}
ospf {
    area 0.0.0.0 {
        interface fe-1/2/1.5;
        interface lo0.2 {
            passive;
        }
    }
}
ldp {
    interface fe-1/2/1.5;
}
```

```
user@R1# show routing-options
router-id 1.1.1.2;
autonomous-system 2;
```

If you are done configuring the device, enter **commit** from configuration mode. Configure the other devices in the topology, as shown in "CLI Quick Configuration" on page 284.

Verification

Confirm that the configuration is working properly.

Verifying That the CE Devices Have Connectivity

Purpose Make sure that the tunnel is operating.

Action From operational mode, enter the **ping** command.

```
user@CE1> ping ::10.1.1.14
PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms
```

```
user@CE3> ping ::10.1.1.1
PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

Meaning The IPv6 CE devices can communicate over the core IPv4 network.

Configuring IPv6 Tunneling for MPLS (CLI Procedure)

You can configure the IPv6 tunneling for MPLS to tunnel IPv6 traffic over an MPLS-based IPv4 network. This configuration allows you to interconnect a number of smaller IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the switches in your core network. BGP is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

To configure IPv6 tunneling for MPLS on your EX Series switch:

1. Configure IPv4 and IPv6 IP addresses for all the core interfaces:

   ```
   [edit]
   user@switch# set interfaces interface-name unit logical-unit-number family inet address address
   ```

2. Configure the number assigned to you by the Network Information Center (NIC) as the autonomous system (AS) number

```
[edit routing-options]
user@switch# set autonomous-system number
```

3. Advertise label 0 to the egress router of the LSP:

```
[edit protocols]
user@switch# set mpls explicit-null
```

4. Configure the LSP to allow IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table:

```
[edit protocols]
user@switch# set mpls ipv6-tunneling
```

5. Set the local AS number:

```
[edit protocols bgp]
user@switch# set local-as local-autonomous-system-number
```

6. Configure the default import and export policies:

```
[edit protocols bgp]
user@switch# set local-address address
user@switch# set import default-import
user@switch# set family inet6 labeled-unicast explicit-null
user@switch# set export default-export
```

7. Configure a BGP group that recognizes only the specified BGP systems as peers. Define a group name, group type, local end of a BGP session, and a neighbor (peer). To configure multiple BGP peers, include multiple neighbor statements:

```
[edit protocols bgp]
user@switch# set group group-name type internal
user@switch# set group group-name local-address address-of-the-local-end-of-a-bgp-session
user@switch# set group group-name family inet6 labeled-unicast explicit-null
user@switch# set group group-name peer-as peer-autonomous-system-number
user@switch# set group group-name neighbor address family inet6 labeled-unicast explicit-null
```

8. Configure routing options to accept the default import and export policies:

```
[edit policy-options]
user@switch# set policy-statement default-import then accept
user@switch# set policy-statement default-export then accept
```

Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels

This example shows how to configure a dynamic MPLS-over-UDP tunnel that includes a tunnel composite next hop. The MPLS-over-UDP feature provides a scaling advantage on the number of IP tunnels supported on a device.

Starting in Junos OS Release 18.3R1, MPLS-over-UDP tunnels are supported on PTX Series routers and QFX Series switches. For every dynamic tunnel configured on a PTX router or a QFX switch, a tunnel composite next hop, an indirect next hop, and a forwarding next hop is created to resolve the tunnel destination route. You can also use policy control to resolve the dynamic tunnel over select prefixes by including the **forwarding-rib** configuration statement at the **[edit routing-options dynamic-tunnels]** hierarchy level.

Requirements

This example uses the following hardware and software components:

- Five MX Series routers with MPCs and MICs.
- Junos OS Release 16.2 or later running on the PE routers.

Before you begin:

1. Configure the device interfaces, including the loopback interface.
2. Configure the router ID and autonmous system number for the device.
3. Establish an internal BGP (IBGP) session with the remote PE device.
4. Establish OSPF peering among the devices.

Overview

Starting with Junos OS Release 16.2, a dynamic UDP tunnel supports the creation of a tunnel composite next hop for every UDP tunnel configured. These next-hop-based dynamic UDP tunnels are referred to as MPLS-over-UDP tunnels. The tunnel composite next hop are enabled by default for the MPLS-over-UDP tunnels.

Starting in Junos OS Release 17.1, on MX Series routers with MPCs and MICs, the scaling limit of MPLS-over-UDP tunnels is increased.

NOTE: **For the same tunnel destination, the next-hop-based dynamic tunnel encapsulation can either be GRE or UDP. Having both tunnel encapsulations for the same tunnel destination causes a commit error under the dynamic-tunnel configuration.**

The existing dynamic tunnel feature requires complete static configuration. Currently, the tunnel information received from peer devices in advertised routes is ignored. Starting in Junos OS Release 17.4R1, on MX Series routers, the next-hop-based dynamic MPLS-over-UDP tunnels are signaled using BGP encapsulation extended community.

BGP export policy is used to specify the tunnel types, advertise the sender side tunnel information, and parse and convey the receiver side tunnel information. A tunnel is created according to the received type tunnel community.

Multiple tunnel encapsulations are supported by BGP. On receiving multiple capability, the next-hop-based dynamic tunnel is created based on the configured BGP policy and tunnel preference. The tunnel preference should be consistent across both the tunnel ends for the tunnel to be set up. By default, MPLS-over-UDP (MPLSoUDP) tunnel is preferred over GRE tunnels. If dynamic tunnel configuration exists, it takes precedence over received tunnel community.

When configuring a next-hop-based dynamic MPLS-over-UDP tunnel, be aware of the following considerations:

- An IBGP session must be configured between the PE devices.
- A switchover between the next-hop-based dynamic tunnel encapsulations (UDP and GRE) is allowed, and this can impact network performance in terms of the supported IP tunnel scaling values in each mode.
- Having both GRE and UDP next-hop-based dynamic tunnel encapsulation types for the same tunnel destination leads to a commit failure.
- Graceful Routing Engine switchover (GRES) is supported with MPLS-over-UDP, and the MPLS-over-UDP tunnel type flags are unified ISSU and NSR compliant.
- MPLS-over-UDP tunnels are supported on virtual MX (vMX).
- MPLS-over-UDP tunnels support dynamic GRE tunnel creation based upon new IPv4-mapped-IPv6 next hops.
- MPLS-over-UDP tunnel are supported in interoperability with contrail, wherein the MPLS-over-UDP tunnels are created from the contrail vRouter to an MX gateway. To enable this, the following community is required to be advertised in the route from the MX Series router to the contrail vRouter:

  ```
  [edit policy-options community]
  udp members 0x030c:64512:13;
  ```

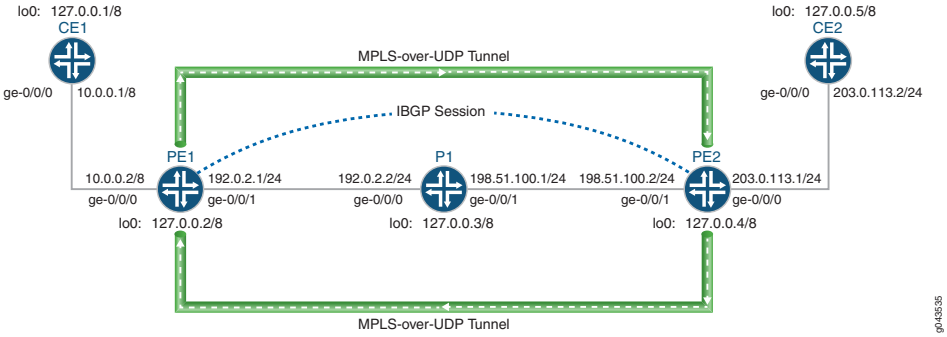
  At a given point in time, only one tunnel type is supported on the contrail vRouter—next-hop-based dynamic GRE tunnels, MPLS-over-UDP tunnels, or VXLAN.
- The following features are not supported with the next-hop-based dynamic MPLS-over-UDP tunnel configuration:
  - RSVP automatic mesh
  - Plain IPV6 GRE and UDP tunnel configuration
  - Logical systems

Topology

Figure 17 on page 294 illustrates a Layer 3 VPN scenario over dynamic MPLS-over-UDP tunnels. The customer edge (CE) devices, CE1 and CE2, connect to provider edge (PE)

devices, PE1 and PE2, respectively. The PE devices are connected to a provider device (Device P1), and an internal BGP (IBGP) session interconnects the two PE devices. Two dynamic next-hop-based MPL-over-UDP tunnels are configured between the PE devices.

Figure 17: Dynamic MPLS-over-UDP Tunnels



The MPLS-over-UDP tunnel is handled as follows:

1. After a MPLS-over-UDP tunnel is configured, a tunnel destination mask route with a tunnel composite next hop is created for the tunnel in the inet.3 routing table. This IP tunnel route is withdrawn only when the dynamic tunnel configuration is deleted.

   The tunnel composite next-hop attributes include the following:

   - When Layer 3 VPN composite next hop is disabled—Source and destination address, encapsulation string, and VPN label.
   - When Layer 3 VPN composite next hop and per-prefix VPN label allocation are enabled—Source address, destination address, and encapsulation string.
   - When Layer 3 VPN composite next hop is enabled and per-prefix VPN label allocation is disabled—Source address, destination address, and encapsulation string. The route in this case is added to the other virtual routing and forwarding instance table with a secondary route.

2. The PE devices are interconnected using an IBGP session. The IBGP route next hop to a remote BGP neighbor is the protocol next hop, which is resolved using the tunnel mask route with the tunnel next hop.

3. After the protocol next hop is resolved over the tunnel composite next hop, indirect next hops with forwarding next hops are created.

4. The tunnel composite next hop is used to forward the next hops of the indirect next hops.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

CE1

```
set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.1/8

```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the device interfaces including the loopback interface of the device.

   ```
   [edit interfaces]
   ```

```
user@PE1# set ge-0/0/0 unit 0 family inet address 10.0.0.2/8
user@PE1# set ge-0/0/1 unit 0 family inet address 192.0.2.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.2/8
```

2. Configure a static route for routes from Device PE1 with Device P1 as the next-hop destination.

```
[edit routing-options]
user@PE1# set static route 33.0.0.0/8 next-hop 192.0.2.2
```

3. Configure the router-ID and autonomous system number for Device PE1.

```
[edit routing-options]
user@PE1# set router-id 127.0.0.2
user@PE1# set autonomous-system 100
```

4. (PTX Series only) Configure policy control to resolve the MPLS-over-UDP dynamic tunnel route over select prefixes.

```
[edit routing-options dynamic-tunnels]
user@PTX-PE1# set forwarding-rib inet.0 inet-import
  dynamic-tunnel-fwd-route-import
```

5. (PTX Series only) Configure the inet-import policy for resolving dynamic tunnel destination routes over .

```
[edit policy-options]
user@PTX-PE1# set policy-statement dynamic-tunnel-fwd-route-import term 1
  from route-filter 127.0.0.0/8 exact
user@PTX-PE1# set policy-statement dynamic-tunnel-fwd-route-import term 1
  then accept
user@PTX-PE1# set policy-options policy-statement
  dynamic-tunnel-fwd-route-import then reject
```

6. Configure IBGP peering between the PE devices.

```
[edit protocols]
user@PE1# set bgp group IBGP type internal
user@PE1# set bgp group IBGP local-address 127.0.0.2
user@PE1# set bgp group IBGP family inet-vpn unicast
user@PE1# set bgp group IBGP neighbor 127.0.0.4
```

7. Configure OSPF on all the interfaces of Device PE1, excluding the management interface.

```
[edit protocols]
```

```
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Enable next-hop-based dynamic GRE tunnel configuration on Device PE1.

NOTE: This step is required only for illustrating the implementation difference between next-hop-based dynamic GRE tunnels and MPLS-over-UDP tunnels.

```
[edit routing-options]
user@PE1# set dynamic-tunnels gre next-hop-based-tunnel
```

9. Configure the MPLS-over-UDP tunnel parameters from Device PE1 to Device PE2.

```
[edit routing-options]
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 source-address 127.0.0.2
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 udp
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 destination-networks
  127.0.0.0/8
```

10. Configure a VRF routing instance on Device PE1 and other routing instance parameters.

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 instance-type vrf
user@PE1# set MPLS-over-UDP-PE1 interface ge-0/0/0.0
user@PE1# set MPLS-over-UDP-PE1 route-distinguisher 127.0.0.2:1
user@PE1# set MPLS-over-UDP-PE1 vrf-target target:600:1
```

11. Enable BGP in the routing instance configuration for peering with Device CE1.

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 peer-as 200
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 neighbor 10.0.0.1
  as-override
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
```

```
ge-0/0/0 {
   unit 0 {
      family inet {
         address 10.0.0.2/8;
      }
   }
}
ge-0/0/1 {
   unit 0 {
      family inet {
         address 192.0.2.1/24;
      }
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 127.0.0.2/8;
      }
   }
}
```

```
user@PE1# show routing-options
static {
   route 33.0.0.0/8 next-hop 192.0.2.2;
}
router-id 127.0.0.2;
autonomous-system 100;
forwarding-table {
   export pplb;
}
dynamic-tunnels {
   gre next-hop-based-tunnel;
   udp-dyn-tunnel-to-pe2 {
      source-address 127.0.0.2;
      udp;
      destination-networks {
         127.0.0.0/8;
      }
   }
}
```

```
user@PE1# show protocols
bgp {
   group IBGP {
      type internal;
      local-address 127.0.0.2;
      family inet-vpn {
         unicast;
      }
      neighbor 127.0.0.4;
   }
}
```

```
ospf {
   area 0.0.0.0 {
      interface ge-0/0/1.0;
      interface lo0.0 {
         passive;
      }
   }
}
```

```
user@PE1# show routing-instances
MPLS-over-UDP-PE1 {
   instance-type vrf;
   interface ge-0/0/0.0;
   route-distinguisher 127.0.0.2:1;
   vrf-target target:600:1;
   protocols {
      bgp {
         group pe1-ce1 {
            peer-as 200;
            neighbor 10.0.0.1 {
               as-override;
            }
         }
      }
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the Connection Between PE Devices

Purpose Verify the BGP peering status between Device PE1 and Device PE2, and the BGP routes received from Device PE2.

Action From operational mode, run the **show bgp summary** and **show route receive-protocol bgp *ip-address* table bgp.l3vpn.0** commands.

```
user@PE1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
bgp.l3vpn.0
                       2          2          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
127.0.0.4             100        139        136       0       0       58:23 Establ

  bgp.l3vpn.0: 2/2/2/0
  MPLS-over-UDP-PE1.inet.0: 2/2/2/0
10.0.0.1              200        135        136       0       0       58:53
Establ
  MPLS-over-UDP-PE1.inet.0: 1/1/1/0
```

```
user@PE1> show route receive-protocol bgp 127.0.0.4 table bgp.l3vpn.0

bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
  127.0.0.4:1:127.0.0.5/8
*                         127.0.0.4                    100        200 I
  127.0.0.4:1:200.1.1.0/24
*                         127.0.0.4                    100        I
```

Meaning

- In the first output, the BGP session state is **Establ**, which means that the session is up and the PE devices are peered.
- In the second output, Device PE1 has learned two BGP routes from Device PE2.

Verify the Dynamic Tunnel Routes on Device PE1

Purpose Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE1.

Action From operational mode, run the **show route table inet.3**, **show dynamic-tunnels database terse**, **show dynamic-tunnels database**, and **show dynamic-tunnels database summary** commands.

```
user@PE1> show route table inet.3
```

```
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.0/8      *[Tunnel/300] 00:21:18
                       Tunnel
127.0.0.4/8     *[Tunnel/300] 00:21:18
                       Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
```

```
Table: inet.3

Destination-network: 127.0.0.0/8
Destination         Source          Next-hop                  Type        Status
127.0.0.4/8      127.0.0.2     0xb395b10 nhid 613    udp    Up
```

```
user@PE1> show dynamic-tunnels database
```

```
Table: inet.3

Destination-network: 55.0.0.0/8

Destination-network: 55.66.0.0/16

Destination-network: 55.66.77.0/24
Tunnel to: 127.0.0.4/8
  Reference count: 2
  Next-hop type: UDP
    Source address: 127.0.0.2 Tunnel Id: 2
    Next hop: tunnel-composite, 0xb395b10, nhid 613
      VPN Label: Push 299776 Reference count: 3
      Traffic Statistics: Packets 0, Bytes 0
      State: Up
```

```
user@PE1> show dynamic-tunnels database summary
```

```
Dynamic Tunnels,  Total 1 displayed
GRE Tunnel:
Active Tunnel Mode, Next Hop Base
  IFL Based,  Total 0 displayed, Up 0, Down 0
  Nexthop Based,  Total 0 displayed, Up 0, Down 0
RSVP Tunnel:
  Total 0 displayed
UDP Tunnel:
  Total 1 displayed, Up 1, Down 0
```

Meaning

- In the first output, because Device PE1 is configured with the MPLS-over-UDP tunnel, a tunnel composite route is created for the inet.3 routing table route entry.

- In the remaining outputs, the MPLS-over-UDP tunnel is displayed with the tunnel encapsulation type, tunnel next hop parameters, and tunnel status.

Verify the Dynamic Tunnel Routes on Device PE2

Purpose Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE2.

Action From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@PE2> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.0/8      *[Tunnel/300] 00:39:31
                       Tunnel
127.0.0.2/8     *[Tunnel/300] 00:24:53
                       Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
Table: inet.3

Destination-network: 127.0.0.0/8
Destination         Source          Next-hop                  Type        Status
127.0.0.2/8      127.0.0.4     0xb395450 nhid 615    udp    Up
```

Meaning The outputs show the MPLS-over-UDP tunnel creation and the next-hop ID assigned as the next-hop interface, similar to Device PE1.

Verifying That the Routes Have the Expected Indirect-Next-Hop Flag

Purpose Verify that Device PE1 and Device PE2 are configured to maintain the indirect next hop to forwarding next-hop binding on the Packet Forwarding Engine forwarding table.

Action From operational mode, run the **show krt indirect-next-hop** command on Device PE1 and Device PE2.

```
user@PE1> show krt indirect-next-hop
Indirect Nexthop:
Index: 1048574 Protocol next-hop address: 127.0.0.4
  RIB Table: bgp.l3vpn.0

  Locks: 3                              0xb2ab740
  Flags: 0x0
  INH Session ID: 0x0
  INH Version ID: 0
  Ref RIB Table: unknown
        Tunnel type: UDP, Reference count: 3, nhid: 615
        Destination address: 127.0.0.2, Source address: 127.0.0.4
        Tunnel id: 1, VPN Label: Push 299776, TTL action: prop-ttl
      IGP FRR Interesting proto count : 2
      Chain IGP FRR Node Num          : 1
         IGP Resolver node(hex)       : 0xb3d3a28
         IGP Route handle(hex)        : 0xb1ae634      IGP rt_entry protocol
    : Tunnel
        IGP Actual Route handle(hex) : 0x0          IGP Actual rt_entry protocol
 : Any
```

Meaning The outputs show that a next-hop-based dynamic MPLS-over-UDP tunnel is created between the PE devices.

Troubleshooting

To troubleshoot the next-hop-based dynamic tunnels, see:

- Troubleshooting Commands on page 304

Troubleshooting Commands

Problem The next-hop-based dynamic MPLS-over-UDP tunnel configuration is not taking effect.

Solution

To troubleshoot the next-hop-based MPLS-over-UDP tunnel configuration, use the following **traceroute** commands at the **[edit routing-options dynamic-tunnels]** statement hierarchy:

- **traceoptions file *file-name***
- **traceoptions file size *file-size***
- **traceoptions flag all**

For example:

```
[edit routing-options dynamic-tunnels]
traceoptions {
   file udp_dyn_pe1.wri size 4294967295;
   flag all;
}
```

Release History Table

Release	Description
18.3R1	Starting in Junos OS Release 18.3R1, MPLS-over-UDP tunnels are supported on PTX Series routers and QFX Series switches.
17.4R1	Starting in Junos OS Release 17.4R1, on MX Series routers, the next-hop-based dynamic MPLS-over-UDP tunnels are signaled using BGP encapsulation extended community.
17.1R1	Starting in Junos OS Release 17.1, on MX Series routers with MPCs and MICs, the scaling limit of MPLS-over-UDP tunnels is increased.

Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels Overview

With the rise in deployment of high-scale IP tunnels in data centers, there is a need to add security measures that allow users to limit malicious traffic from compromised virtual machines (VMs). One possible attack is the injecting of traffic into an arbitrary customer VPN from a compromised server through the gateway router. In such cases, anti-spoofing checks on IP tunnels ensure that only legitimate sources are injecting traffic into data centers from their designated IP tunnels.

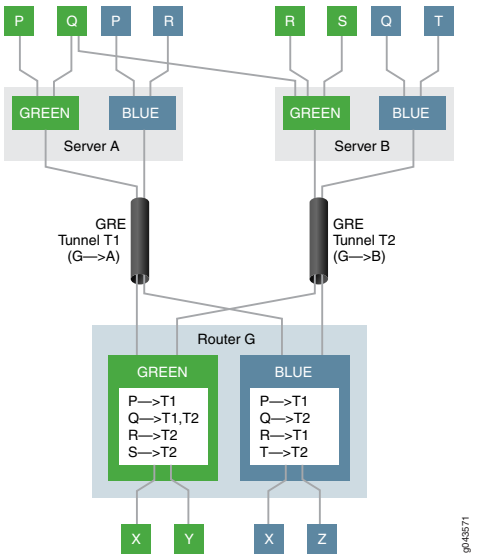
Next-hop-based dynamic IP tunnels create a tunnel composite next hop for every dynamic tunnel created on the device. Because next-hop-based dynamic tunnels remove the dependency on physical interfaces for every new dynamic tunnel configured, configuring next-hop-based dynamic tunnels provides a scaling advantage over the number of dynamic tunnels that can be created on a device. Starting in Junos OS Release 17.1, anti-spoofing capabilities for next-hop-based dynamic IP tunnels is provided for

next-hop-based dynamic tunnels. With this enhancement, a security measure is implemented to prevent injecting of traffic into an arbitrary customer VPN from a compromised server through the gateway router.

Anti-spoofing is implemented using reverse path forwarding checks in the Packet Forwarding Engine. The checks are implemented for the traffic coming through the tunnel to the routing instance. Currently, when the gateway router receives traffic from a tunnel, only the destination lookup us done and the packet is forwarded accordingly. When anti-spoofing protection is enabled, the gateway router also does a source address lookup of the encapsulation packet IP header in the VPN, in addition to the tunnel destination lookup. This ensures that legitimate sources are injecting traffic through their designated IP tunnels. As a result, anti-spoofing protection ensures that the tunnel traffic is received from a legitimate source on the designated tunnels.

Figure 18 on page 306 illustrates a sample topology with the requirements for anti-spoofing protection.

Figure 18: Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels



In this example, the gateway router is Router G. Router G has two VPNs—Green and Blue. The two servers, Server A and Server B, can reach the Green and Blue VPNs on Router G through the next-hop-based dynamic tunnels T1 and T2, respectively. Several hosts and virtual machines (P, Q, R, S, and T) connected to the servers can reach the VPNs through the gateway router, Router G. Router G has the virtual routing and forwarding (VRF) tables for Green and Blue VPNs, each populated with the reachability information for the virtual machines in those VPNs.

For example, in VPN Green, Router G uses tunnel T1 to reach host P, tunnel T2 to reach hosts R and S, and load balancing is done between tunnels T1 and T2 to reach the multihomed host Q. In VPN Blue, Router G uses tunnel T1 to reach hosts P and R, and tunnel T2 to reach hosts Q and T.

The check passes for reverse path forwarding when:

- A packet comes from a legitimate source on its designated tunnel.

  Host P in VPN Green sends a packet to host X using tunnel T1. Because Router G can reach host P through tunnel T1, it allows the packet to pass and forwards the packet to host X.

- A packet comes from a multihomed source on its designated tunnels.

  Host Q in VPN Green is multihomed on servers A and B, and can reach Router G through tunnels T1 and T2. Host Q sends a packet to host Y using tunnel T1, and a packet to host X using tunnel T2. Because Router G can reach host Q through tunnels T1 and T2, it allows the packets to pass and forwards them to hosts Y and X, respectively.

Layer 3 VPNs do not have anti-spoofing protection enabled by default. To enable anti-spoofing for next-hop-based dynamic tunnels, include the **ip-tunnel-rpf-check** statement at the **[edit routing-instances *routing-instance-name* routing-options forwarding-table]** hierarchy level. The reverse path forwarding check is applied to the VRF routing instance only. The default mode is set to **strict**, where the packet that comes from a source on a nondesignated tunnel does not pass the check. The **ip-tunnel-rpf-check** mode can be set as **loose**, where the reverse path forwarding check fails when the packet comes from a nonexistent source. An optional firewall filter can be configured under the **ip-tunnel-rpf-check** statement to count and log the packets that failed the reverse path forwarding check.

The following sample output shows an anti-spoofing configuration:

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
ip-tunnel-rpf-check {
   mode loose;
   fail-filter filter-name;
}
```

Take the following guidelines under consideration when configuring anti-spoofing protection for next-hop-based dynamic tunnels:

- Anti-spoofing protection can be enabled for IPv4 tunnels and IPv4 data traffic only. The anti-spoofing capabilities are not supported on IPv6 tunnels and IPv6 data traffic.
- Anti-spoofing for next-hop-based dynamic tunnels can detect and prevent a compromised virtual machine (inner source reverse path forwarding check) but not a compromised server that is label-spoofing.
- The next-hop-based IP tunnels can originate and terminate on an inet.0 routing table.
- Anti-spoofing protection is effective when the VRF routing instance has label-switched interfaces (LSIs) (using the **vrf-table-label**), or virtual tunnel (VT) interfaces. With **per-next-hop** label on the VRF routing instance, anti-spoofing protection is not supported.
- The **rpf fail-filter** is applicable only to the inner IP packet.
- Enabling anti-spoofing checks does not affect the scaling limit of the next-hop-based dynamic tunnels on a device.

- The system resource utilization with anti-spoofing protection enabled for the VRF routing instance is slightly higher than the utilization of next-hop-based dynamic tunnels without the anti-spoofing protection enabled.
- Anti-spoofing protection requires additional source IP address checks, which has minimal impact on network performance.
- Graceful Routing Engine switchover (GRES) and in-service software upgrade (ISSU) are supported with anti-spoofing protection.

- ip-tunnel-rpf-check on page 1845
- Example: Configuring Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels on page 308

Example: Configuring Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels

This example shows how to configure reverse path forwarding checks for the virtual routing and forwarding (VRF) routing instance to enable anti-spoofing protection for next-hop-based dynamic tunnels. The checks ensure that legitimate sources are injecting traffic through their designated IP tunnels.

Requirements

This example uses the following hardware and software components:

- Three MX Series Routers with MICs, each connected to a host device.
- Junos OS Release 17.1 or later running on one or all the routers.

Before you begin:

- Enable tunnel services configuration on the Flexible PIC Concentrator.
- Configure the router interfaces.
- Configure the router-ID and assign an autonomous system number for the router.
- Establish an internal BGP (IBGP) session with the tunnel endpoints.
- Configure RSVP on all the routers.
- Configure OSPF or any other interior gateway protocol on all the routers.
- Configure two dynamic next-hop-based IP tunnels between the two routers.
- Configure a VRF routing instance for every router-to-host connection.

Overview

Starting in Junos OS Release 17.1, anti-spoofing capabilities are added to next-hop-based dynamic IP tunnels, where checks are implemented for the traffic coming through the tunnel to the routing instance using reverse path forwarding in the Packet Forwarding Engine.

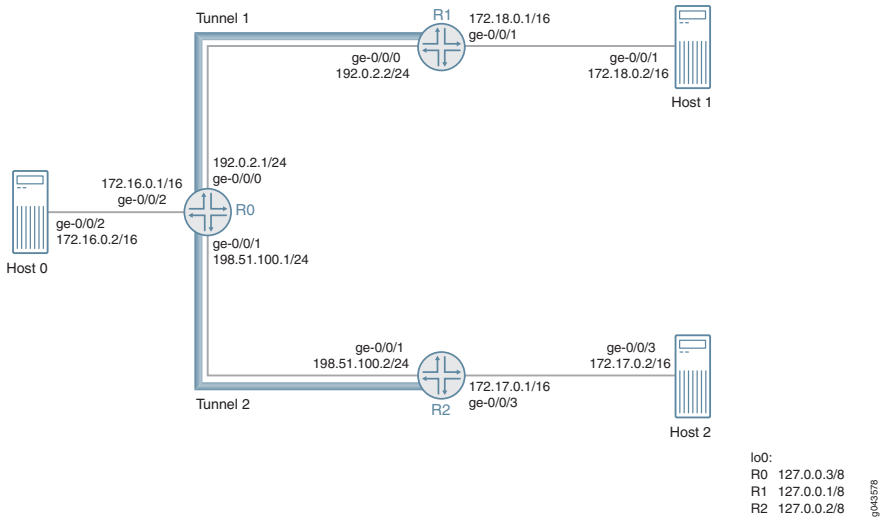
Currently, when the gateway router receives traffic from a tunnel, only the destination address lookup is done before forwarding. With anti-spoofing protection, the gateway router does a source address lookup of the encapsulation packet IP header in the VPN to ensure that legitimate sources are injecting traffic through their designated IP tunnels. This is called the strict mode and is the default behavior of anti-spoofing protection. To pass traffic from nondesignated tunnels, the reverse path forwarding check is enabled in the lose mode. For traffic received from nonexistent sources, the reverse path forwarding check fails for both the strict and loose modes.

Anti-spoofing is supported on VRF routing instances. To enable anti-spoofing for dynamic tunnels, include the **ip-tunnel-rpf-check** statement at the **[edit routing-instances routing-instance-name routing-options forwarding-table]** hierarchy level.

Topology

Figure 19 on page 309 illustrates a sample network topology enabled with anti-spoofing protection. Routers R0, R1 and R2 are each connected to hosts Host0, Host1, and Host2, respectively. Two generic routing encapsulation (GRE) next-hop-based dynamic tunnels, Tunnel 1 and Tunnel 2 – connect Router R0 with Routers R1 and R2, respectively. The VRF routing instance is running between each router and its connected host devices.

Figure 19: Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels



Taking as an example, three packets (Packets A, B, and C) are received on Router 0 from Router R2 through the next-hop-based dynamic GRE tunnel (Tunnel 2). The source IP address of these packets are 172.17.0.2 (Packet A), 172.18.0.2 (Packet B), and 172.20.0.2 (Packet C).

The source IP address of Packets A and B belong to Host 2 and Host 1, respectively. Packet C is a nonexistent source tunnel. The designated tunnel in this example is Tunnel 2, and the nondesignated tunnel is Tunnel 1. Therefore, the packets are processed as follows:

- **Packet A**—Because the source is coming from a designated tunnel (Tunnel 2), Packet A passes the reverse path forwarding check and is processed for forwarding through Tunnel 2.
- **Packet B**—Because the source is coming from Tunnel 1, which is a nondesinated tunnel, by default, Packet B fails the reverse path forwarding check in the strict mode. If loose mode is enabled, Packet B is allowed for forwarding.
- **Packet C**—Because the source is a nonexistent tunnel source, Packet C fails the reverse path forwarding check, and the packet is not forwarded.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Router R0

```
set interfaces ge-0/0/0 unit 0 family inet address 192.0.2.1/24
set interfaces ge-0/0/1 unit 0 family inet address 198.51.100.1/24

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R0:

1. Configure Router R0's interfaces, including the loopback interface.

```
[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 192.0.2.1/24
user@R0# set ge-0/0/1 unit 0 family inet address 198.51.100.1/24
user@R0# set ge-0/0/2 vlan-tagging
user@R0# set ge-0/0/2 unit 0 vlan-id 1
user@R0# set ge-0/0/2 unit 0 family inet address 172.16.0.1/16
user@R0# set lo0 unit 0 family inet address 10.1.1.1/32
```

2. Assign the router ID and autonomous system number for Router R0.

```
[edit routing-options]
user@R0# set router-id 10.1.1.1
user@R0# set autonomous-system 100
```

3. Configure IBGP peering between the routers.

```
[edit protocols]
user@R0# set bgp group IBGP type internal
user@R0# set bgp group IBGP local-address 10.1.1.1
user@R0# set bgp group IBGP family inet-vpn unicast
user@R0# set bgp group IBGP neighbor 20.1.1.1
user@R0# set bgp group IBGP neighbor 30.1.1.1
```

4. Configure OSPF on all the interfaces of Router R0, excluding the management interface.

```
[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface lo0.0 passive
```

```
user@R0# set ospf area 0.0.0.0 interface all
```

5. Configure RSVP on all the interfaces of Router R0, excluding the management interface.

```
[edit protocols]
user@R0# set rsvp interface all
user@R0# set rsvp interface fxp0.0 disable
```

6. Enable next-hop-based dynamic GRE tunnel configuration on Router R0.

```
[edit routing-options]
user@R0# set dynamic-tunnels gre next-hop-based-tunnel
```

7. Configure the dynamic GRE tunnel parameters from Router R0 to Router R1.

```
[edit routing-options]
user@R0# set dynamic-tunnels T1 source-address 192.0.2.1
user@R0# set dynamic-tunnels T1 gre
user@R0# set dynamic-tunnels T1 destination-networks 192.0.2.0/24
```

8. Configure the dynamic GRE tunnel parameters from Router R0 to Router R2.

```
[edit routing-options]
user@R0# set dynamic-tunnels T2 source-address 198.51.100.1
user@R0# set dynamic-tunnels T2 gre
user@R0# set dynamic-tunnels T2 destination-networks 198.51.100.0/24
```

9. Configure a virtual routing and forwarding (VRF) routing instance on Router R0, and assign the interface connecting to Host 1 to the VRF instance.

```
[edit routing-instances]
user@R0# set VPN1 instance-type vrf
user@R0# set VPN1 route-distinguisher 100:100
user@R0# set VPN1 vrf-target target:100:1
user@R0# set VPN1 vrf-table-label
user@R0# set VPN1 interface ge-0/0/2.0
```

10. Configure an external BGP session with Host 1 for the VRF routing instance.

```
[edit routing-instances]
user@R0# set VPN1 protocols bgp group External type external
user@R0# set VPN1 protocols bgp group External family inet unicast
user@R0# set VPN1 protocols bgp group External peer-as 200
user@R0# set VPN1 protocols bgp group External neighbor 172.16.0.1
```

11. Configure anti-spoofing protection for the VRF routing instance on Router R0. This enables reverse path forwarding check for the next-hop-based dynamic tunnels, T1 and T2, on Router 0.

```
[edit routing-instances]
user@R0# set VPN1 routing-options forwarding-table ip-tunnel-rpf-check mode
   strict
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
   unit 0 {
      family inet {
         address 192.0.2.1/24;
      }
   }
}
ge-0/0/1 {
   unit 0 {
      family inet {
         address 198.51.100.1/24;
      }
   }
}
ge-0/0/2 {
   vlan-tagging;
   unit 0 {
      vlan-id 1;
      family inet {
         address 172.16.0.1/16;
      }
   }
}
lo0 {
   unit 0 {
      family inet {
         address 10.1.1.1/32;
      }
   }
}
```

```
user@R0# show routing-options
router-id 10.1.1.1;
autonomous-system 100;
dynamic-tunnels {
```

```
    gre next-hop-based-tunnel;
    T1 {
        source-address 192.0.2.1;
        gre;
        destination-networks {
            192.0.2.0/24;
        }
    }
    T2 {
        source-address 198.51.100.1;
        gre;
        destination-networks {
            198.51.100.0/24;
        }
    }
}
```

```
user@R0# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
bgp {
    group IBGP {
        type internal;
        local-address 10.1.1.1;
        family inet-vpn {
            unicast;
        }
        neighbor 20.1.1.1;
        neighbor 30.1.1.1;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface lo0.0 {
            passive;
        }
        interface all;
    }
}
```

```
user@R0# show routing-instances
VPN1 {
    instance-type vrf;
    interface ge-0/0/2.0;
    route-distinguisher 100:100;
    vrf-target target:100:1;
    vrf-table-label;
    routing-options {
        forwarding-table {

        ip-tunnel-rpf-check {
          mode strict;
        }
      }
    }
    protocols {
      bgp {
        group External {
          type external;
          family inet {
            unicast;
          }
          peer-as 200;
          neighbor 172.16.0.1;
        }
      }
    }
}
```

Verification

Confirm that the configuration is working properly.

- Verifying Basic Configuration on page 316
- Verifying Dynamic Tunnel Configuration on page 317
- Verifying Anti-Spoofing Protection Configuration on page 318

Verifying Basic Configuration

Purpose Verify the OSPF and BGP peering status between the Router R0 and Routers R1 and R2.

Action From operational mode, run the **show ospf neighbor** and **show bgp summary**commands.

```
user@R0> show ospf neighbor
Address          Interface              State     ID               Pri  Dead
192.0.2.2        ge-0/0/0.0             Full      20.1.1.1         128    32
198.51.100.2     ge-0/0/1.0             Full      30.1.1.1         128    32
```

```
user@R0> show bgp summary
Groups: 2 Peers: 3 Down peers: 1
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
bgp.l3vpn.0
                       0          0          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
20.1.1.1                100        182        178       0       0     1:20:27
Establ
  bgp.l3vpn.0: 0/0/0/0
30.1.1.1                100        230        225       0       0     1:41:51
Establ
  bgp.l3vpn.0: 0/0/0/0
172.16.0.1              200          0          0       0       0     1:42:08
Establ
```

Meaning The OSPF and BGP sessions are up and running between the Routers R0, R1, and R2.

Verifying Dynamic Tunnel Configuration

Purpose Verify the status of the next-hop-based dynamic GRE tunnels between the Router R0 and Routers R1 and R2.

Action From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@R0> show route table inet.3

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.0/24       *[Tunnel/300] 01:47:57
                      Tunnel
192.0.2.2/24       *[Tunnel/300] 01:47:57
                      Tunnel Composite

198.51.100.0/24    *[Tunnel/300] 01:47:57
                      Tunnel
198.51.100.2/24    *[Tunnel/300] 01:47:57
                      Tunnel Composite
```

```
user@R0> show dynamic-tunnels database terse
Table: inet.3

Destination-network: 192.0.2.0/24
Destination    Source    Next-hop      Type   Status
192.0.2.2/24   192.0.2.1  0xb395e70 nhid 612   gre    Up

Destination-network: 198.51.100.0/24
Destination    Source      Next-hop      Type   Status
198.51.100.2   198.51.100.1  0xb395e70 nhid 612   gre    Up
```

Meaning The two next-hop-based dynamic GRE tunnels, Tunnel 1 and Tunnel 2, are up.

Verifying Anti-Spoofing Protection Configuration

Purpose Verify that the reverse path forwarding check has been enabled on the VRF routing instance on Router R0.

Action From the operational mode, run the **show krt table VPN1.inet.0 detail**.

```
user@R0> show krt table VPN1.inet.0 detail
KRT tables:
VPN1.inet.0                  : GF: 1 krt-index: 8     ID: 0 kernel-id: 8
        flags: (null)
        tunnel rpf config data : enable, strict, filter [0], 0x2
        tunnel rpf tlv data : enable, strict, filter [0], 0x4
        unicast reverse path: disabled
        fast-reroute-priority: 0
        Permanent NextHops
          Multicast        : 0 Broadcast : 0
          Receive          : 0   Discard   : 0
          Multicast Discard: 0   Reject    : 0
          Local            : 0   Deny      : 0
          Table            : 0
```

Meaning The configured reverse path forwarding check is enabled on the VRF routing instance in the strict mode.

Next-Hop-Based Dynamic Tunnel Localization Overview

Next-hop-based dynamic tunnels includes generic routing encapsulation (GRE) tunnels and MPLS-over-UDP tunnels. These tunnels provide a scaling advantage over the interface-based tunnels, however, unlike the interface-based tunnels, the next-hop-based dynamic tunnels are anchorless in nature, where the forwarding information of the tunnels is distributed to the Packet Forwarding Engines (PFEs) on every line card on the device. This limits the maximum number of tunnels supported on the device to the tunnel capacity of a single line card. With the support for localization, you can configure next-hop-based dynamic tunnel localization to create the forwarding information only on the PFE of a line card that is designated as the anchor PFE. The PFEs on the other line cards on the device have state forwarding information to steer the packets to the anchor PFE. This provides a scaling advantage by increasing the maximum number of tunnels supported on a device.

Benefits of Next-Hop-Based Dynamic Tunnel Localization

Provides a scaling advantage by increasing the maximum number of tunnels supported on a device.

Use Cases for Next-Hop-Based Dynamic Tunnel Localization

- The IPsec gateway devices that host a number of MS-MPC are used to terminate IPSec tunnels and are required to support moderate load. This support is affected with the use of next-hop-based dynamic tunnels when the scaling limit of the device is reached. With the localization of next-hop-based dynamic tunnels, the maximum number of the tunnels supported is increased, allowing the device to accommodate more tunnels at the cost of an extra fabric hop.
- For Internet or VPN gateway devices, such as a virtual public cloud data center, there is a need for the gateway devices to communicate with a large number of servers. The data center servers are reachable through next-hop-based dynamic tunnels. The anchorless property of the dynamic tunnels limits the overall scaling numbers of the device. The gateway devices host multiple MPCs, with increased traffic demands. With the localization of the next-hop-based dynamic tunnels, the tunnels can be spread across the MPCs, thereby facilitating an increase in the tunnel scaling numbers.

Traffic Handling with Localization of Next-Hop-Based Dynamic Tunnels

With support for localization, the next-hop-based dynamic tunnel state is localized to an anchor Packet Forwarding Engine, and the other Packet Forwarding Engine has the tunnel state for steering traffic to the tunnel anchor.

Figure 20 on page 320 illustrates the forwarding path of next-hop-based dynamic tunnels without localization.

Figure 20: Forwarding Path of Next-Hop-Based Dynamic Tunnels Without Localization

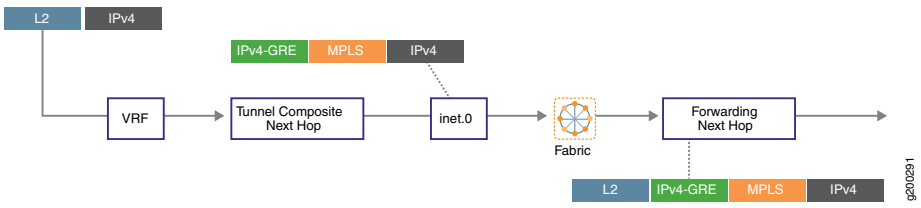

Figure 21 on page 321 illustrates the forwarding path of next-hop-based dynamic tunnels with localization.

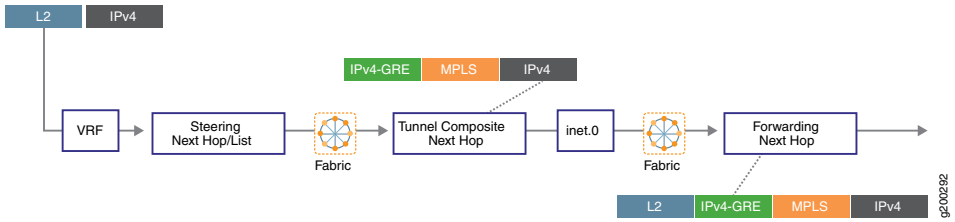
Figure 21: Forwarding Path of Next-Hop-Based Dynamic Tunnels With Localization



Configuring Next-Hop-Based Dynamic Tunnels Localization

Localization support can be configured for newly created next-hop-based dynamic tunnels, or for existing non-local dynamic tunnels.

- Configuring Localization for New Next-Hop-Based Dynamic Tunnels on page 321
- Configuring Localization for Existing Next-Hop-Based Dynamic Tunnels on page 322

Configuring Localization for New Next-Hop-Based Dynamic Tunnels

The localization of next-hop-based dynamic tunnels uses a policy-based approach to specify prefix groups. In other words, route policies are used to apply the localization properties to the next-hop-based dynamic tunnels. Dynamic tunnel attribute profiles are created and configured under routing options for association with the prefix group using the policy.

1. Creating dynamic tunnel profiles.

   The dynamic tunnel profile specifies the tunnel type and the anchor Packet Forwarding Engine information. Multiple dynamic tunnel profiles can be created for localization of the dynamic tunnels.

   The values for the dynamic tunnel type can be GRE, UDP, or BGP-SIGNAL. Although BGP-SIGNAL is not a valid tunnel type, on assigning BGP-SIGNAL as the tunnel type, the tunnels created from the BGP-signalled attributes are localized. BGP-SIGNAL avoids the need of changing the tunnel attributes based on BGP advertisement of tunnel type.

   The anchor Packet Forwarding Engine value is the line card of the anchor Packet Forwarding Engine, for example, pfe-x/y/0. This information can be viewed from the **show interfaces terse *pfe**** command output.

   Sample Configuration:

```
[edit routing-options]
dynamic-tunnels {
  dynamic-tunnel-attributes attribute-1 {
    dynamic-tunnel-type <GRE | UDP | BGP-SIGNAL>;
    dynamic-tunnel-anchor-pfe pfe-1/0/0;
  }
}
```

2. Associating dynamic tunnel profile to prefix list.

   Configuring a policy with **dynamic-tunnel-attributes** as the action associates the dynamic tunnel to the prefix list. The policy **from** action allows the creation of tunnel with specified attributes for any matching condition, such as a prefix range, community, or source address of BGP routes, and so on.

   Sample configuration:

```
[edit policy-options]
policy-statement policy-name {
  term term {
    from {
      <route-filter | next-hop | community>>;
    }
    then {
      dynamic-tunnel-attributes <attribute-name>;
    }
  }
}
```

3. Including the tunnel policy under the forwarding table export policy.

   After the policy is configured, it is included in the forwarding table export policy for the parsing of the policy.

   Using the export-policy, the tunnel attributes get associated with the route. Whenever a route from BGP is queued for resolution, the forwarding table export policy is evaluated, and the tunnel attributes are obtained from the policy module based on the applied filters. The obtained tunnel attributes are then attached to the next hop in form of a tunnel composite next hop. The corresponding anchor forwarding structures, based on the Packet Forwarding Engine name and tunnel type, are created and sent to the forwarding table before a tunnel composite next hop is sent. However, if none of the attributes map to the tunnel composite next hop, then the forwarding structure is created on every Packet Forwarding Engine, similar to the non-localized dynamic tunnels.

   Sample configuration:

```
[edit routing-options]
forwarding-table {
  export dynamic-tunnel;
}
```

Configuring Localization for Existing Next-Hop-Based Dynamic Tunnels

CAUTION: Making on the fly changes to dynamic tunnel attributes can result in an FPC crash due to high memory utilization. Hence, we recommend deactivating the dynamic-tunnels configuration before configuring localization.

To update tunnel attributes for existing next-hop-based dynamic tunnels, the following should be performed:

1. Deactivate **dynamic-tunnels** configuration under the **[edit routing-options]** hierarchy level.

   Sample configuration:

   ```
   [edit routing-options]
   user@host# deactivate dynamic-tunnels
   user@host# commit
   ```

2. Change tunnel attributes as required.

3. Activate **dynamic-tunnels** configuration under the **[edit routing-options]** hierarchy level.

   Sample configuration:

   ```
   [edit routing-options]
   user@host# activate dynamic-tunnels
   user@host# commit
   ```

To configure localization for existing non-local next-hop-based dynamic tunnels:

CAUTION: Making on the fly changes to configure localization for existing non-local next-hop-based dynamic tunnels can result in an FPC crash due to high memory utilization. Hence, we recommend deactivating the dynamic-tunnels configuration before configuring localization.

1. Deactivate the **dynamic-tunnels** configuration at the **[edit routing-options]** hierarchy level.

2. Create tunnel-attributes profile and add policy for localizing the dynamic tunnels, similar to new next-hop-based dynamic tunnels.

3. Activate the **dynamic-tunnels** configuration.

Troubleshooting Localized Next-Hop-Based Dynamic Tunnels

With localization of next-hop-based dynamic tunnels, the tunnel composite next hops are associated with anchor Packet Forwarding Engine IDs. The following traceroute configuration statements at the **[edit routing-options]** hierarchy level help in troubleshooting the localized dynamic tunnels:

- **dynamic-tunnels traceoptions flag all**—Tracking creation and deletion of tunnel in DTM.
- **resolution traceoptions flag tunnel**—Tracking resolver operations on BGP route.

- **forwarding-table traceoptions flag all**—Tracking tunnels sent to the kernel.
- **traceoptions flag all**—Tracking of route learning process.

The following commands can be used to check if a route is using a localized next-hop-based dynamic tunnel:

1. **show route *prefix* extensive**—To obtain the indirect next hop.

   For example:

   ```
   user@host> show route 1.2.3.4 extensive
   MPLS-over-UDP-PE1.inet.0: 24 destinations, 26 routes (24 active, 0 holddown,
   0 hidden)
   1.2.3.4/32 (1 entry, 1 announced)
   TSI:
   KRT in-kernel 1.2.3.4/32 -> {indirect(1048577)}
   Page 0 idx 1, (group pe1-ce1 type External) Type 1 val 0xb209a78 (adv_entry)
      Advertised metrics:
     Nexthop: Self
     AS path: [100] I
     Communities: target:600:1 encapsulation:mpls-in-udp(0xd)
   ```

2. **show krt indirect-next-hop index *indirect-next-hop* detail**—To check for anchor Packet Forwarding Engine field in the detailed output of the indirect next hop.

   For example:

   ```
   user@host> show krt indirect-next-hop index 1048577 detail
   Indirect Nexthop detail:
   Index: 1048577 Protocol next-hop address: 1.1.1.6
     RIB Table: bgp.l3vpn.0             Label: Push 299808
     Policy Version: 2                  References: 11
     Locks: 3                           0xb227980
     Flags: 0x0
     INH Session ID: 0x0
     Ref RIB Table: unknown
     Export policy detail:
     (Dynamic tunnel hash : 309985522)
        Tunnel type: UDP, Reference count: 4, nhid: 1016
        Destination address: 1.1.1.6, Source address: 1.1.1.2
        Anchored-PFE: pfe-1/0/0
        VPN Label: Push 299808, TTL action: prop-ttl

   ```

Unsupported Features for Next-Hop-Based Dynamic Tunnels Localization

Junos OS does not support the following functionality with localization for next-hop-based dynamic tunnels:

- Chained composite next hops at the **[edit routing-options forwarding-table chained-composite-next-hop ingress l3vpn]** hierarchy level.
- Anchor Packet Forwarding Engine resiliency.

  There is no resiliency support for next-hop-based dynamic tunnels with localization. After localization of the next-hop-based dynamic tunnels, the anchor Packer Forwarding Engine becomes the single entity for processing any given tunnel on the device. Although anchor Packer Forwarding Engine resiliency is not supported, for gateway devices, redundancy at the gateway device ensures that when the Packer Forwarding Engine to which the tunnel composite next hop is delegated goes down, the traffic must be rerouted to the redundant gateway device. The routing protocol process monitors the state of the Packer Forwarding Engine, and withdraws BGP advertisement of all the routes pointing to the tunnel composite next hops anchored on that Packer Forwarding Engine.

  Only the anchored Packet Forwarding Engine has the full-fledged tunnel composite next hop and all the other Packet Forwarding Engines have only steering entries to forward traffic to the anchor Packet Forwarding Engine. These steering entries are not withdrawn, when an anchor FPC goes down.
- Localization of next-hop-based dynamic tunnels is not supported on logical systems.
- IPv6 is not supported with localization of next-hop-based dynamic tunnels.
- With localization, the **show dynamic-tunnels database summary** command does not display accurate tunnels summary when the state of the anchor Packet Forwarding Engine line card is not up. As a workaround, use the **show dynamic-tunnels database** and **show dynamic-tunnels database terse** command output.

PART 3

MPLS Label-Switched Paths

CHAPTER 11

MPLS Label Operations

MPLS Label Overview

Packets traveling along an LSP are identified by a label—a 20-bit, unsigned integer in the range 0 through 1,048,575. For push labels on ingress routers, no labels in this range are restricted. For incoming labels on the transit static LSP, the label value is restricted to 1,000,000 through 1,048,575.

On MX Series, PTX Series, and T Series routers, the value for entropy and flow labels is restricted to 16 through 1,048,575.

MPLS Label Allocation

In the Junos OS, label values are allocated per router or switch—the rest of this explanation uses router to cover both. The display output shows only the label (for example, **01024**).

Labels for multicast packets are independent of those for unicast packets. Currently, the Junos OS does not support multicast labels.

Labels are assigned by downstream routers relative to the flow of packets. A router receiving labeled packets (the next-hop router) is responsible for assigning incoming labels. A received packet containing a label that is unrecognized (unassigned) is dropped. For unrecognized labels, the router does not attempt to unwrap the label to analyze the network layer header, nor does it generate an Internet Control Message Protocol (ICMP) destination unreachable message.

A packet can carry a number of labels, organized as a last-in, first-out stack. This is referred to as a *label stack*. At a particular router, the decision about how to forward a labeled packet is based exclusively on the label at the top of the stack.

Figure 22 on page 330 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 22: Label Encoding

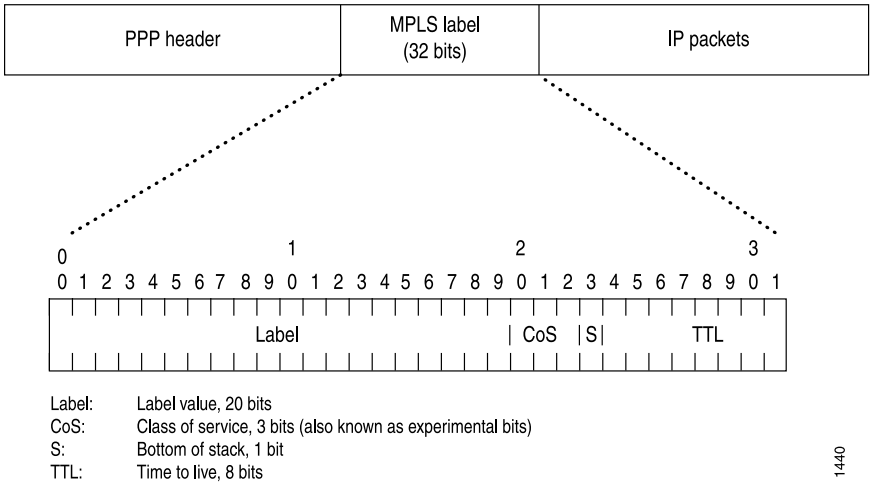

Figure 23 on page 331 illustrates the purpose of the class-of-service bits (also known as the EXP or experimental bits). Bits 20 and 21 specify the queue number. Bit 22 is the packet loss priority (PLP) bit used to specify the random early detection (RED) drop profile. For more information about class of service and the class-of-service bits, see "Configuring Class of Service for MPLS LSPs" on page 795.

Operations on MPLS Labels

The router supports the following label operations:

- Push—Add a new label to the top of the packet. For IPv4 packets, the new label is the first label. The time-to-live (TTL) and s bits are derived from the IP packet header. The MPLS class of service (CoS) is derived from the queue number. If the push operation is performed on an existing MPLS packet, you will have a packet with two or more labels. This is called label stacking. The top label must have its s bit set to 0, and might derive CoS and TTL from lower levels. The new top label in a label stack always initializes its TTL to 255, regardless of the TTL value of lower labels.
- Pop—Remove the label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet. In the case of multiple labels in a packet (label stacking), removal of the top label yields another MPLS packet. The new top label might derive CoS and TTL from a previous top label. The popped TTL value from the previous top label is not written back to the new top label.
- Swap—Replace the label at the top of the label stack with a new label. The S and CoS bits are copied from the previous label, and the TTL value is copied and decremented (unless the **no-decrement-ttl** or **no-propagate-ttl** statement is configured). A transit router supports a label stack of any depth.
- Multiple Push—Add multiple labels (up to three) on top of existing packets. This operation is equivalent to pushing multiple times.
- Swap and Push—Replace the existing top of the label stack with a new label, and then push another new label on top.

Understanding MPLS Label Operations

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is forwarded based on its IP routing information.

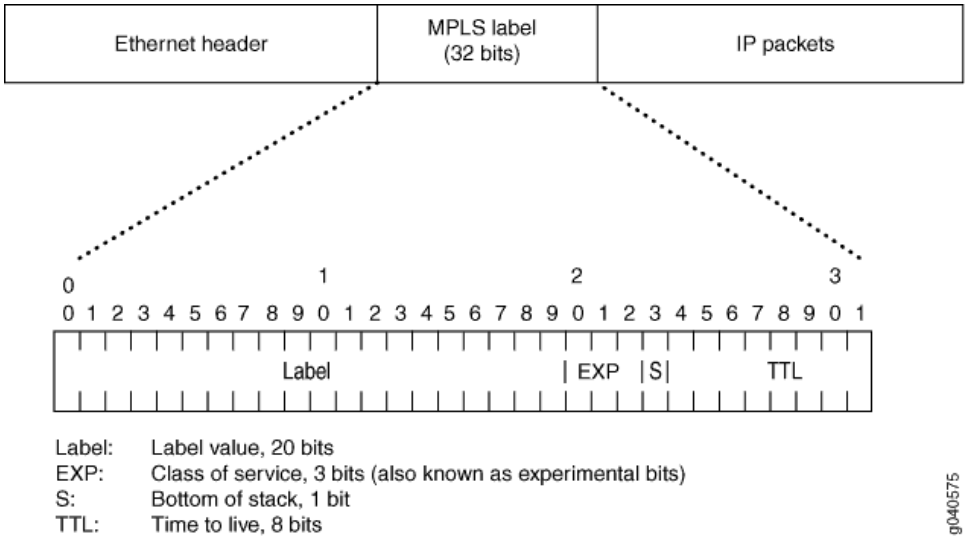
This topic describes:

MPLS Label-Switched Paths and MPLS Labels

When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

Figure 22 on page 330 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 24: Label Encoding



Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings. The following reserved labels are used by QFX Series and EX4600 devices:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

MPLS Label Operations

QFX Series and EX4600 devices support the following MPLS label operations:

- Push
- Pop
- Swap

NOTE: There is a limit with regard to the number of labels that QFX and EX4600 devices can affix (push operations) to the label stack or remove (pop operations) from the label stack.

- For Push operations—As many as three labels are supported.
- For Pop operations—As many as three labels are supported.

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 25 on page 334 shows an IP packet without a label arriving on the customer edge interface (ge-0/0/1) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (ge-0/0/5). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface ge-0/0/5 with label 100. The provider switch swaps label 100 with label 200 and forwards the MPLS packet through its core interface (ge-0/0/7) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch receives the MPLS packet through its core interface (ge-0/0/7), removes the MPLS label, and sends the IP packet out of its customer edge interface (ge-0/0/1) to a destination that is beyond the tunnel.

Figure 25: MPLS Label Swapping

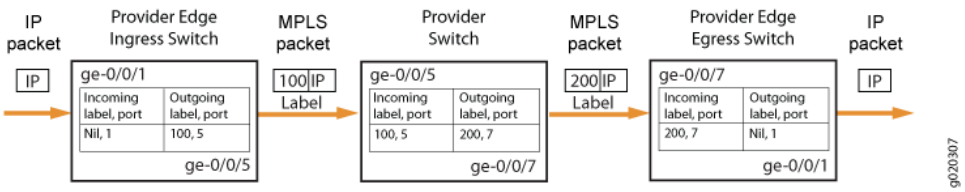


Figure 25 on page 334 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

Understanding MPLS Label Manager

MPLS label manager is used to manage different label types such as LSI, dynamic, block, and static, which are supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. These line cards provide more flexibility and scalability, when the **enhanced-ip** command is configured on the device.

The existing behavior of **label-space** command is retained, which is *not recommended*. To provide additional functionality such as multiple ranges for each type of label, **label-range** command is introduced under the **[edit protocols mpls label usage]** hierarchy, which is independent of **label-space** configuration. You can choose either style if only one range is needed for each type of label.

The following features are optimized with the **enhanced-ip** command configured on the device:

- Allows you to define the system wide global label pool to be used by segment-routing global block (SRGB) through IS-IS routing protocol.
- Increases the **vrf-table-label** space to at least 16,000, if the platform can support the scale.
- Allows you to specify the label value to be used by static VRF table label.
- Allows you to specify the label value range to be used by supported label application types.
- Allows you to change dynamically the SRGB and label type ranges.

Understanding MPLS Label Operations on EX Series Switches

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

This topic describes:

- MPLS Label-Switched Paths and MPLS Labels on the Switches on page 336
- Reserved Labels on page 337
- MPLS Label Operations on the Switches on page 337
- Penultimate-Hop Popping and Ultimate-Hop Popping on page 338

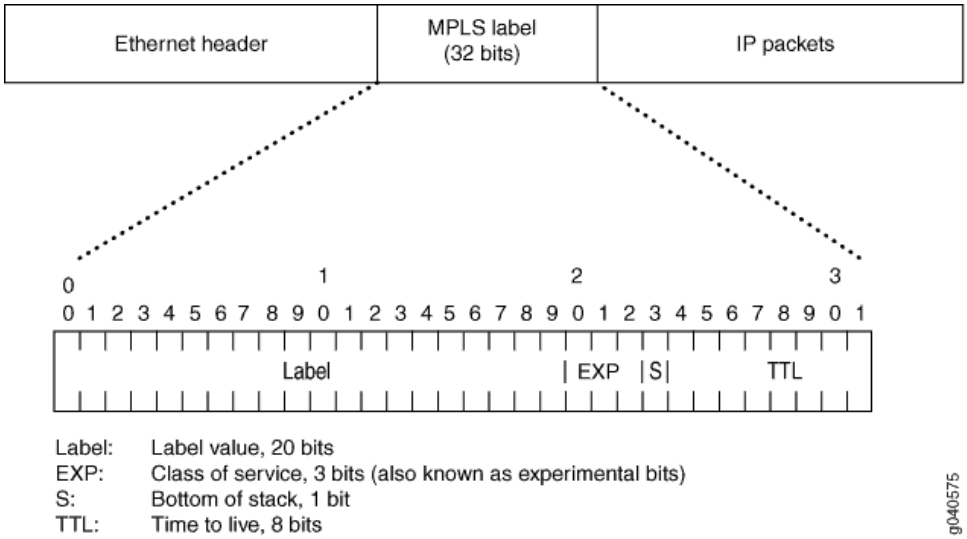
MPLS Label-Switched Paths and MPLS Labels on the Switches

When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

NOTE: The implementation of MPLS on Juniper Networks EX3200 and EX4200 Ethernet Switches supports only single-label packets. However, MPLS on Juniper Networks EX8200 Ethernet Switches supports packets with as many as three labels.

Figure 22 on page 330 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 26: Label Encoding



Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings. The following reserved labels are used by the switches:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 2, IPv6 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

MPLS Label Operations on the Switches

EX Series switches support the following label operations:

- Push
- Pop
- Swap

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 25 on page 334 shows an IP packet without a label arriving on the customer edge interface (**ge-0/0/1**) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (**ge-0/0/5**). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface **ge-0/0/5** with label 100. The provider switch swaps label 100 to label 200 and forwards the MPLS packet through its core interface (**ge-0/0/7**) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch receives the MPLS packet through its core interface (**ge-0/0/7**), removes the MPLS label, and sends the IP packet out of its customer edge interface (**ge-0/0/1**) to a destination that is beyond the tunnel.

Figure 27: MPLS Label Swapping

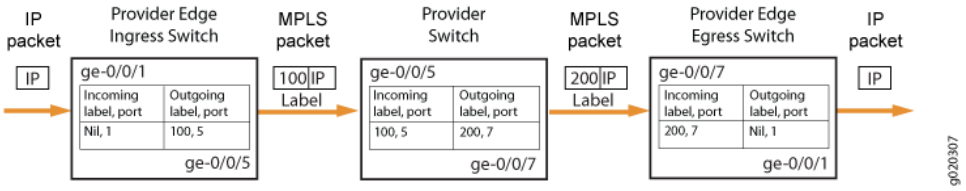


Figure 25 on page 334 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

On EX8200 switches, you can choose to use either the default, PHP, or to configure ultimate-hop popping.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

How a Packet Travels Along an LSP

When an IP packet enters an LSP, the ingress router examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label.

The packet is then forwarded to the next router in the LSP. This router and all subsequent routers in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next router in the path.

When the packet reaches the egress router, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

Types of LSPs

There are three types of LSPs:

- Static LSPs—For static paths, you must manually assign labels on all routers involved (ingress, transit, and egress). No signaling protocol is needed. This procedure is similar to configuring static routes on individual routers. Like static routes, there is no error reporting, liveliness detection, or statistics reporting.
- LDP-signaled LSPs—See *LDP Introduction*.

- RSVP-signaled LSPs—For signaled paths, RSVP is used to set up the path and dynamically assign labels. (RSVP signaling messages are used to set up signaled paths.) You configure only the ingress router. The transit and egress routers accept signaling information from the ingress router, and they set up and maintain the LSP cooperatively. Any errors encountered while establishing an LSP are reported to the ingress router for diagnostics. For signaled LSPs to work, a version of RSVP that supports tunnel extensions must be enabled on all routers.

There are two types of RSVP-signaled LSPs:

- Explicit-path LSPs—All intermediate hops of the LSP are manually configured. The intermediate hops can be strict, loose, or any combination of the two. Explicit path LSPs provide you with complete control over how the path is set up. They are similar to static LSPs but require much less configuration.
- Constrained-path LSPs—The intermediate hops of the LSP are automatically computed by the software. The computation takes into account information provided by the topology information from the IS-IS or OSPF link-state routing protocol, the current network resource utilization determined by RSVP, and the resource requirements and constraints of the LSP. For signaled constrained-path LSPs to work, either the IS-IS or OSPF protocol and the IS-IS or OSPF traffic engineering extensions must be enabled on all routers.

Scope of LSPs

For constrained-path LSPs, the LSP computation is confined to one IGP domain, and cannot cross any AS boundary. This prevents an AS from extending its IGP into another AS.

Explicit-path LSPs, however, can cross as many AS boundaries as necessary. Because intermediate hops are manually specified, the LSP does not depend on the IGP topology or a local forwarding table.

Special MPLS Labels

Some of the reserved labels (in the 0 through 15 range) have well-defined meanings. For more complete details, see RFC 3032, *MPLS Label Stack Encoding*.

- 0, IPv4 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped upon receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 2, IPv6 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 6 (IPv6) packet.
- 3, Implicit Null label—This label is used in the control protocol (LDP or RSVP) only to request label popping by the downstream router. It never actually appears in the

encapsulation. Labels with a value of 3 should not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

- 4 through 6—Unassigned.
- 7, Entropy label indicator—This label is used when an Entropy label is in the label stack and precedes the Entropy label.
- 8 through 15—Unassigned.

Special labels are commonly used between the egress and penultimate routers of an LSP. If the LSP is configured to carry IPv4 packets only, the egress router might signal the penultimate router to use 0 as a final-hop label. If the LSP is configured to carry IPv6 packets only, the egress router might signal the penultimate router to use 2 as a final-hop label.

The egress router might simply signal the penultimate router to use 3 as the final label, which is a request to perform penultimate-hop label popping. The egress router will not process a labeled packet; rather, it receives the payload (IPv4, IPv6, or others) directly, reducing one MPLS lookup at egress.

For label-stacked packets, the egress router receives an MPLS label packet with its top label already popped by the penultimate router. The egress router cannot receive label-stacked packets that use label 0 or 2. It typically requests label 3 from the penultimate router.

Entropy Label Support in Mixed Mode Overview

Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration. The entropy label helps transit routers load-balance MPLS traffic across ECMP paths or link aggregation groups. The entropy label introduces a load-balancing label to be used by routers to load balance traffic rather than relying on deep packet inspection, reducing the packet processing requirements in the forwarding plane at the expense of increased label stack depth. Junos OS supports the entropy label only for MX Series routers with MPCs or MICs and can be enabled with enhanced-ip mode. But, this leads to a packet drop if the core-facing interface has an entropy label configured on the MPC or MIC and the other end of this core-facing connection has a DPC line card. In order to avoid this, the entropy label is now supported in mixed mode where the entropy label can be configured without enhanced-ip configuration. This allows MX Series router DPCs to support a pop out entropy label. However, this does not support a flow label.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration.

Abstract Hops for MPLS LSPs Overview

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), which results in a user-defined group or cluster of routers that can be sequenced and used as constraints for setting up an MPLS label-switched path (LSP). Abstract hops overcome the limitations of existing path constraint specifications and provide several benefits to the traffic engineering capabilities of MPLS.

- Understanding Abstract Hops on page 342
- Benefits of Using Abstract Hops on page 343
- Junos OS Implementation of Abstract Hops on page 345

Understanding Abstract Hops

The path constraint for setting up of an MPLS LSP can be specified as either individual routers in the form of real hops or as a set of routers by way of administrative group or color specification. When a path constraint uses real hops (strict or loose), the LSP is set up along a specified sequence of routers (for example, R1, R2, ... R*n*). When a path constraint uses an administrative group or color specification, a group of routers that meet the specified criteria is used to set up the LSP without picking a specific router, and unlike real-hop constraint, there is no sequence among the different groups of routers used in the constraint.

The drawback of real-hop constraint is that in a failure scenario, if any of the router hops goes down or the bandwidth utilization of the attached interface gets saturated, the path

goes down (or relies on local or end-to-end protection). Although other alternative routers might be available to recover or set up the LSP, the LSP remains down until the operator configures another router hop sequence as the path constraint to bring the path up again or to disengage the protection path.

The administrative group or color specification constraint overcomes this limitation of a real-hop constraint to a certain extent. Here, when one of the routers in the group goes down or has its link capacity saturated, setting up of the LSP is not affected. This is because the next hop router to be used in the path constraint is not picked beforehand, and the LSP is set up along other routers that have the same administrative group or color without operator intervention. However, the drawback with router group constraints is that a sequence cannot be specified among the hop constraints.

Abstract hops overcome these drawbacks by creating user-defined router groups, where each member router meets a user-defined constraint. The user-defined constraint is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs). Ordering is achieved among the router groups by specifying a sequence of abstract hops used in a path constraint. As a result, abstract hops combine the ordering property of real-hop constraint specification and the resilience that comes with the other traffic engineering constraints.

A path can use a combination of real and abstract hops as constraints. When using abstract hops, instead of specifying a sequence of routers (R1, R2, ... R*n*) as with real hops, you specify an ordered set of router groups or abstract hops (G1, G2, ... G*n*) as the path constraint. Each specified router group, G*i* for example, consists of some user-defined set of routers—R1, R2, R*j*, ... R*n*. When one of the routers in the group goes down, say Router R*j* in group G*i*, another router, say Router R*k*, from the same group G*i* is picked up by path computation to replace the router that went down (that is, Router R*j*). This is because the path constraint is sequenced and has to go through a sequence of abstract hops, instead of a sequence of individual routers.

Benefits of Using Abstract Hops

Abstract hops are user-defined router groups. Similar to real-hop constraints that use a sequence of individual routers, a sequence of abstract hops can be used for setting up a label-switched path (LSP). The use of abstract hops provides resiliency to sequenced path constraints. The other benefits of using abstract hops include:

- Specifying a Sequence of Constraint Combinations on page 343
- Avoiding New Network Configuration on Transit Nodes on page 344
- Combining Centralized and Distributed Path Computation Paradigms on page 344

Specifying a Sequence of Constraint Combinations

Currently, it is possible to specify a path that can go through links that satisfy multiple attributes. Such a path constraint is called a compound constraint combination; for example, a constraint (Ci) that includes low latency links of green color and also excludes SRLG north.

However, there is no support for specifying a path with a sequence of compound constraint combinations. For example, a sequenced constraint (C1, C2, Ci, ...Cn) that includes low latency green links, no latency blue links, and then low latency red links.

The need for such a sequenced compound constraint combination arises when there is a requirement to establish paths through a sequence of geographical regions with a different link affinity (attributes) requirement in each region. Abstract hops meet this requirement by allowing computing nodes to map each constraint combination (Ci, for example) with the user-defined group of routers—that is, the abstract hops.

Avoiding New Network Configuration on Transit Nodes

With current path constraint specification capabilities, it is possible to include or exclude links of certain attributes along an entire path; for example, excluding SRLG west from a path. However, there is no support to either conditionally exclude or include attributes, or to apply different exclude or include attributes in different parts of the path; for example, excluding SRLG west only when traversing red links.

As a workaround, a new administrative group can be created to identify all such red links that do not have SRLG west, and configure all the relevant links appropriately with that administrative group. The drawback of this approach is that configuration changes are required throughout the network to reflect the new administrative group membership.

Instead, by using abstract hops, the configuration changes can be contained on the ingress router only. At the ingress router, the constraint combination is mapped to the abstract hop, thereby meeting the aforementioned requirement without the need for any new configuration on the transit nodes.

Combining Centralized and Distributed Path Computation Paradigms

Traffic engineering of MPLS paths can be achieved by distributed computing or with a centralized controller for computing paths. A combination of both the computation types is called the hybrid computation paradigm. The key feature of the hybrid computation approach is the ability of the centralized controller—referred to as a Path Computation Element (PCE)—to loosely specify the path computation directives, per path, to the ingress router—referred to as a Path Computation Client (PCC)—and the ability of the ingress router to use it as input for path computation.

A sequence of abstract hops serves the purpose of acting as the guideline from the centralized controller. Abstract hops provide the flexibility to the controller to weave into the path constraint and attributes. This also enables the controller to build in the element of sequence in the constraint. The controller does not have to specify each hop the path needs to take, leaving room for the ingress router to act within the limits of the guideline or directive.

Table 12 on page 344 lists the key features of the hybrid computation paradigm and provides a comparison of this approach with the current path computation methods.

Table 12: Hybrid Computation for Abstract Hops

Features	Distributed Constrained Shortest Path First	Centralized Constrained Shortest Path First	Hybrid Constrained Shortest Path First

Table 12: Hybrid Computation for Abstract Hops (continued)

React to frequent changes in a large network	Yes		Yes
Sophisticated path computation with global view		Yes	Yes
Incorporation of business logic in path computation		Yes	Yes
Resilience (no single point of failure)	Yes		Yes
Predictability		Yes	Yes
React to network load in (close to) real time	Yes		Yes
Field tested (versus early adoption)	Yes		Yes

Junos OS Implementation of Abstract Hops

The order-aware abstract hops feature is introduced in Junos OS Release 17.1. The following sections describe the implementation of abstract hops in Junos OS:

- Defining Abstract Hops on page 345
- Using Abstract Hops in Path Constraint on page 348
- Path Computation and Backtracking on page 352
- Sample Backtracking on page 352

Defining Abstract Hops

An abstract hop is a group of routers that users can define to be used in setting up a label-switched path (LSP). The user can control which routers to include in the group by defining a logical combination of heterogeneous link attributes or constraints called constituent attributes. The routers with links that satisfy the defined constituent attributes make it to the group of routers representing the abstract hop.

The mapping of constituent attributes with the abstract hop is local to the computing node or the ingress of the LSP being setup. As a result, abstract hops do not have associated interior gateway protocol updates or signaling protocol extensions, and implementing abstract hops in a network does not require new configuration on the transit nodes.

A constituent list enables defining of a set of constituent traffic engineering attributes, that is identified by a user-defined name. Constituent lists are used in an abstract hop definition by using any of the following configuration statements:

- **include-any-list**—Link satisfies the constituent-list if any of the specified constituent attributes are true for the link.
- **include-all-list**—Link satisfies the constituent-list if all the specified constituent attributes are true for the link.

- **exclude-all-list**—Link satisfies the constituent-list if none of the specified constituent attributes are true for the link.
- **exclude-any-list**—Link satisfies the constituent-list if at least one of the specified constituent attributes is not true for the link.

An abstract hop is defined as a logical combination of constituent-list references that can belong to any of the aforementioned categories. To achieve this, logical operators **AND** and **OR** are included in the abstract hop definition, and applied to the constituent list.

- **OR**—At least one of the constituent-list references in the abstract hop definition must be satisfied by a link for the attached node to be part of the abstract hop.
- **AND**—All of the constituent-list references in the abstract hop definition must be satisfied by a link for the attached node to be part of the abstract hop.

Sample Abstract Hop Definition

Taking as an example, the definition of abstract hops hopA is as follows:

Abstract hops hopA must include all routers whose emanating links satisfy the logical combination of the following link attributes, respectively:

- **hopA**—((administrative group red && Srlg south) || (administrative group green || Srlg north)), where:
  - *administrative group red* and *Srlg south* belong to include-all constituent list (listA1, in this example).
  - *administrative group green* and *Srlg north* belong to include-any constituent list (listA2, in this example).
  - || is the OR operator.

The configuration for abstract hops hopA is as follows:

- **hopA configuration**

```
[edit protocols mpls]
Constituent-list listA1 {
   administrative-group red;
   Srlg south;
}
Constituent-list listA2 {
   administrative-group green;
   Srlg north;
}
Abstract-hop hopA{
   Operator OR;
   Constituent-list listA1 include-all-list;
   Constituent-list listA2 include-any-list;
}
```

Verifying Abstract Hop Configuration

The **show mpls abstract hop membership <*abstract hop name*>** command is used to view members of an abstract hop. The command output provides the abstract hop to traffic engineering database node mapping.

```
user@host> show mpls abstract-hop-membership
Abstract hop: hop1A
   Credibility: 0
Address: 128.102.165.105
Address: 128.102.166.237
Address: 128.102.168.0
Address: 128.102.173.123

Abstract hop: hopB
   Credibility: 0
Address: 128.102.160.211
Address: 128.102.165.5
Address: 128.102.166.237
Address: 128.102.172.157
Address: 128.102.172.196
```

Here, the output field **Credibility** indicates the credibility associated with interior gateway protocol in use.

The output of the **show ted database extensive local** command provides the view captured in traffic engineering database. A keyword **local** is added to indicate that the output would include any local instrumentation. The command output shows the abstract hop as an attribute of links that satisfy the associated logical combination of link attributes.

```
user@host> show ted database extensive local
TED database: 0 ISIS nodes 8 INET nodes
NodeID: 128.102.173.123

        [4] 960Mbps      [5] 960Mbps      [6] 960Mbps      [7] 960Mbps
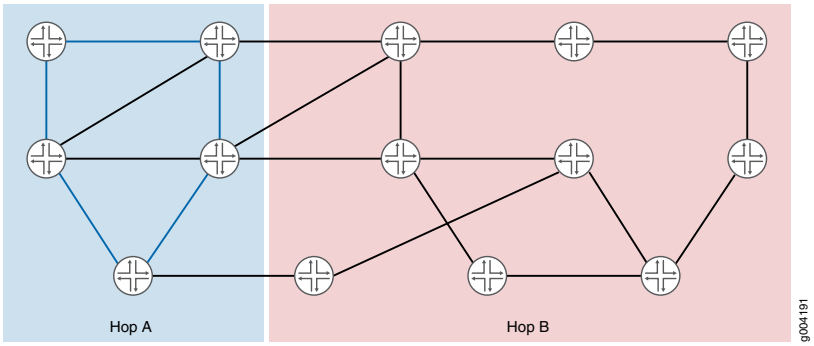
```

Abstract hop hopA is for low latency AND SRLG west, and abstract hop hopB is for excluding SRLG west. Figure 28 on page 348 displays the ingress view of these abstract hops.

Figure 28: Ingress View of Abstract Hops



Using Abstract Hops in Path Constraint

The user associates a unique identifier with each abstract hop definition. This identifier is used for referring to the abstract hop in the path constraint. A sequence of abstract hops can be specified as the path constraint, similar to how real IP hops are used. The path constraint could also be a sequence of abstract hops interleaved by real IP hops.

Using abstract hops or real hops in a path constraint requires more than one Constrained Shortest Path First pass to the destination, typically one pass per hop. When real hops are provided as the path constraint, the constraint computation involves as many passes as the number of hops in the path constraint, where each pass ends on reaching a hop in the constraint list. The starting point for each pass is the destination of the previous pass, with the first pass using the ingress router as the start.

Alternatively, when path constraint uses strict or loose abstract hops, constraint computation comprises passes where each pass processes the subsequent abstract hop in the constraint list. In such a case, more than one node qualifies to be the destination for the pass. The set of nodes is called the viable router set for the pass.

An abstract hop traverses member nodes by using the following:

- Links that satisfy the logical combination of defined constituent attributes
- Any kind of links

The means of abstract hops traversing the member nodes is controlled by the use of the abstract hop qualifiers—strict, loose, and loose-link—in defining the path constraint. Taking for example, abstract hop hopA is processed differently with different qualifiers:

- **Strict**—After the last processed hop in the constraint list, the path traverses only links or nodes having membership of abstract hop hopA, before reaching a node with hopA's membership that is a feasible starting point for processing the next abstract hop.
- **Loose**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of hopA, before reaching a node with abstract hop membership hopA, which is a feasible starting point for processing the next abstract hop.
- **Loose-link**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of hopA, before reaching a node with abstract hop membership hopA, which is a feasible starting point for processing the next abstract hop. But the path should have traversed at least one link of abstract hop hopA membership in the course of the same.

  In other words, the abstract hop of type loose-link is said to be processed only if any of the viable routers in the constraint is reachable through a link of associated abstract hop membership.

Sample Abstract Hops Specification

Table 13 on page 349 provides sample use case for using abstract hops in path constraints.

Table 13: Using Abstract Hops in Path Constraints

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity

Traverse nodes that are members of hopA taking only links that satisfy hopA.	Strict	[edit protocols mpls]
		Path path_hopA_s {
		  hopA abstract strict;
		}
			All members of abstract hopA. That is, A1, A2…A*n*.	hopA (pick only links that satisfy abstract hopA).

Traverse nodes that are members of hopA but not necessarily links that satisfy hopA	Loose	[edit protocols mpls]
		Path path_hopA_l {
		  hopA abstract loose;
		}
			All members of abstract hopA. That is, A1, A2…A*n*.	None (any kind of links).

Table 13: Using Abstract Hops in Path Constraints (continued)

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity

Traverse nodes that are members of hopA by taking at least one link that satisfies hopA.	Loose-link
	
	NOTE: The loose-link qualifier is viewed as loose followed by strict for the same abstract hop. In other words, hopA loose-link is the same as hopA loose and hopA strict.
		[edit protocols mpls]
		Path path_hopA_ll {
		  hopA abstract loose-link;
		}
			In this case, there are two computation passes associated with hopA in the path constraint. The viable router set for both passes is:
			
			All members of abstract hopA. That is, A1, A2...A*n*.
			
			NOTE: During path computation, a router is traversed only once.
				In this case, there are two computation passes associated with hopA in the path constraint. The affinity for the two passes is:
				
				• Pass 1—None (any kind of links).
				• Pass 2—hopA (pick only links that satisfy abstract hopA).

Traverse nodes that are members of hopA, taking only links that satisfy hopA, followed by nodes that are members of hopB taking only links that satisfy hopB.	Strict	[edit protocols mpls]
		Path path_hopA_hopB_s {
		  hopA abstract strict;
		  hopB abstract strict;
		}
			• hopA—Intersection of member set of hopA and hopB.
			
			NOTE: When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.
			
			• hopB—All members of abstract hopB. That is, B1, B2...B*n*.
				• hopA—hopA (pick only links that satisfy abstract hopA).
				• hopB—hopB (pick only links that satisfy abstract hopB).

Traverse nodes that are members of hopA taking only links that satisfy hopA, followed by nodes that are members of hopB taking any kind of links.	Strict and loose	[edit protocols mpls]
		Path path_hopA_s_hopB_l {
		  hopA abstract strict;
		  hopB abstract loose;
		}
			• hopA—All members of abstract hopA. That is, A1, A2...A*n*.
			• hopB—All members of abstract hopB. That is, B1, B2...B*n*.
				• hopA—hopA (pick only links that satisfy abstract hopA).
				• hopB—None (pick any links).

Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking any kind of links.	Loose	[edit protocols mpls]
		Path path_hopA_l_hopB_l {
		  hopA abstract loose;
		  hopB abstract loose;
		}
			• hopA—All members of abstract hopA. That is, A1, A2...A*n*.
			• hopB—All members of abstract hopB. That is, B1, B2...B*n*.
				None (pick any links).

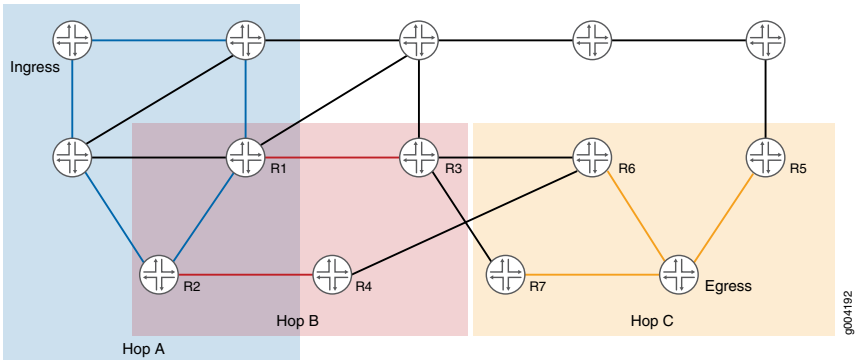
Table 13: Using Abstract Hops in Path Constraints (continued)

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity

Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking only links that satisfy hopB.	Loose and strict	[edit protocols mpls]
		Path path_hopA_l_hopB_s {
		hopA abstract loose;
		hopB abstract strict;
		}
			• hopA—Intersection of the members of hopA and hopB.
			When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.
			• hopB—All members of abstract hopB. That is, B1, B2...B*n*.
				• hopA—None (pick any links).
				• hopB—hopB (pick only links that satisfy abstract hopB).

Figure 29 on page 351 displays path constraints for abstract hops hopA, hopB, and hopC with loose, strict, and loose abstract hop qualifiers, respectively.

Figure 29: Sample Path Constraints for Abstract Hops



The Constrained Shortest Path First passes for the abstract hops are as follows:

- Pass 1 associated with hopA
  - Viable routers—Routers R1 and R2 (intersection of hopA and hopB, as hopB is a strict abstract hop).
  - Affinity—None (as hopA is loose).
- Pass 2 associated with hopB
  - Viable routers—Routers R1, R2, R3, and R4
  - Affinity—Pick only hopB-compliant links (as hopB is a strict abstract hop).
- Pass 3 associated with hopC
  - Viable routers—Routers R5, R6, R7, and the egress router.
  - Affinity—None (as hopC is a loose abstract hop).

Path Computation and Backtracking

In each Constrained Shortest Path First pass, when the nearest router from a viable router set is reached using links satisfying the affinity figured for the pass, the abstract hop associated with the pass is said to be processed. The viable router thus reached serves as the start for the next constraint pass. If any constraint pass fails, and it is not the one with the ingress router as start router, then the pass is backtracked to the previous pass and the process is repeated.

Sample Backtracking

When a Constrained Shortest Path First pass p (other than the first one) fails, the exit router of the previous pass (p – 1) that served as start for the current pass p is disqualified in the viable router set of the previous pass (p – 1). Then the previous pass (p – 1) is re-executed to find the next best exit router or destination for the pass p – 1 from the viable router set.

The router thus determined serves as the new start router for the pass p. This procedure is repeated as long as there are failures and there are viable routers that are not explored.

The **show mpls lsp abstract-hop-computation name *lsp-name*** command provides the various computation passes involved per LSP and the qualifying exit routers for each pass. The command output also gives the affinity per pass, and shows the current start router chosen for the pass. For each viable router, the state of backtracking is displayed, where it can be either valid or disqualified.

```
user@host> show mpls lsp abstract-computation
Path computation using abstract hops for LSP: lsp1
Path type: Primary, Path name: path1

Credibility: 0, Total no of CSPF passes: 2
CSPF pass no: 0 Start address of the pass: 128.102.173.123
Affinity: hopA
CSPF pass no: 1 Start address of the pass: 0.0.0.0
Destination: 128.102.172.157, , State: VALID

Path type: Standby, Path name: path2

Credibility: 0, Total no of CSPF passes: 3
CSPF pass no: 0 Start address of the pass: 128.102.173.123
Destination: 128.102.166.237, , State: VALID
Affinity: hopA
CSPF pass no: 1 Start address of the pass: 128.102.166.237
Destination: 128.102.160.211, , State: VALID
Destination: 128.102.165.5, , State: VALID
Destination: 128.102.166.237, , State: VALID
Destination: 128.102.172.157, , State: VALID
Destination: 128.102.172.196, , State: VALID
Affinity: hopB
CSPF pass no: 2 Start address of the pass: 128.102.172.196
Destination: 128.102.172.157, , State: VALID
```

The output field **Credibility** indicates the credibility associated with the interior gateway protocol in use.

Example: Configuring Abstract Hops for MPLS LSPs

This example shows how to configure abstract hops for MPLS label-switched paths (LSPs). Abstract hops combine the key features of existing traffic engineering constraints that enables the user to specify an order-aware and resilient path constraint for MPLS LSPs.

Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers.
- Junos OS Release 17.1 or later running on all the devices.

Before you begin:

- Configure the device interfaces.
- Configure the device router ID and assign an autonomous system (AS) number.
- Configure RSVP on all the devices.
- Configure OSPF or any other interior gateway protocol on all the devices.
- Configure administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs) on all the devices.

Overview

Junos OS Release 17.1 introduces abstract hops, which are user-defined router clusters or groups. Similar to the sequence of real-hop constraints (strict or loose), a sequence of abstract hops can be used for setting up a label-switched path (LSP). A path can use a combination of real and abstract hops as constraints.

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes.

To configure abstract hops:

- Create constituent lists with constituent traffic engineering attributes by including the **constituent-list *list-name*** statement at the **[edit protocols mpls]** hierarchy level.
- Include the constituent lists in the abstract hop definition at the **[edit protocols mpls abstract-hop *abstract-hop-name*]** hierarchy level.
- Define path constraints that use abstract hops at the **[edit protocols mpls path *path-name*]** hierarchy level.

Take the following guidelines under consideration when configuring abstract hops for MPLS LSPs:

- Abstract hops are supported only in the master routing instance of a device.
- IPv6 destinations are not supported in abstract hop constraints (only IPv4 destinations work).
- Abstract hops can be strict or loose constraints.
- Abstract hops support in Junos OS Release 17.1 is provided only for intra-area MPLS LSPs and not for inter-domain, or inter-area LSPs.
- Abstract hop constraints is enabled for regular point-to-point LSPs only. Other types of MPLS LSPs, such as point-to-multipoint LSPs, externally controlled bidirectional LSPs, dynamic container LSPs, RSVP automesh LSPs, and inter-area LSPs are not supported with abstract hops configuration.
- Abstract hops do not enable computation of overall shortest path for LSPs.
- An abstract hop must not be referred to more than once in the same path constraint.
- Abstract hop constraint specifications do not affect the support for Graceful Routing Engine switchover (GRES), unified in-service software upgrade (ISSU), and nonstop routing (NSR).
- Abstract hop constraint specifications do not affect overall network performance. However, the time taken for constrained shortest path first computation increases with abstract hop configuration. The setup time for an abstract hop LSP is more than the time taken to set up an LSP without abstract hop configuration.

Topology

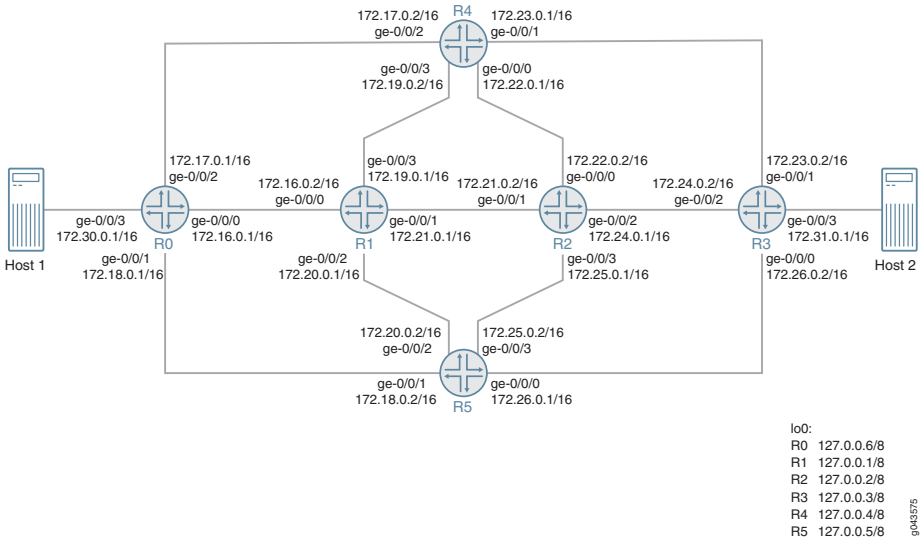
Figure 30 on page 355 illustrates a sample network topology configured with abstract hops. Devices R0 and R3 are each connected to hosts (Host 1 and Host 2). Devices R4 and R5 are each connected to Devices R0, R1, R2, and R3. Devices R1 and R2 are also directly connected to each other.

Devices R0 and R3 are configured under the same autonomous system—AS 64496. An MPLS LSP is configured from Device R0 through Device R3 with one primary path and two secondary paths (standby and nonstandby secondary paths).

Four constituent lists—c1, c2, c3, and c4—are created using three SRLGs (g1, g2, and g3), three administrative groups (green, blue, and red), and one extended administrative group (gold). Three abstract hops (ah1, ah2, and ah3) are defined using the configured

constituent lists, and are specified as path constraints. Abstract hop ah1 is specified as constraint for the primary path, while abstract hops ah2 and ah3 are specified as constraints for the secondary standby path and the secondary nonstandby path, respectively.

Figure 30: Configuring Abstract Hop Path Constraint



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Device R0

```
set chassis network-services ip
set interfaces ge-0/0/0 unit 0 family inet address 172.16.0.1/16
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family inet address 172.18.0.1/16

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R0:

1. Enable enhanced IP network services on Device R0.

```
[edit chassis]
user@R0# set network-services ip
```

2. Configure the interfaces on Device R0, including the loopback interface.

```
[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 172.16.0.1/16
user@R0# set ge-0/0/0 unit 0 family mpls
user@R0# set ge-0/0/1 unit 0 family inet address 172.18.0.1/16
user@R0# set ge-0/0/1 unit 0 family mpls
user@R0# set ge-0/0/2 unit 0 family inet address 172.17.0.1/16
user@R0# set ge-0/0/2 unit 0 family mpls
user@R0# set ge-0/0/3 unit 0 family inet address 172.30.0.1/16
user@R0# set lo0 unit 0 family inet address 127.0.0.6/8
```

3. Assign the router ID and autonomous system number for Device R0.

```
[edit routing-options]
user@R0# set router-id 127.0.0.6
user@R0# set autonomous-system 64496
```

4. Configure the SRLG definitions.

```
[edit routing-options]
user@R0# set srlg g1 srlg-value 100
user@R0# set srlg g1 srlg-cost 1000
user@R0# set srlg g2 srlg-value 200
user@R0# set srlg g2 srlg-cost 2000
user@R0# set srlg g3 srlg-value 300
user@R0# set srlg g3 srlg-cost 3000
```

5. Configure the extended administrative group definitions.

```
[edit routing-options]
user@R0# set administrative-groups-extended-range minimum 50000
user@R0# set administrative-groups-extended-range maximum 60000
user@R0# set administrative-groups-extended gold group-value 50000
```

6. Configure the administrative group definitions.

```
[edit protocols]
user@R0# set mpls administrative-groups green 0
user@R0# set mpls administrative-groups blue 1
user@R0# set mpls administrative-groups red 2
```

7. Configure MPLS on all the interfaces of Device R0, excluding the management interface.

```
[edit protocols]
user@R0# set mpls interface all
user@R0# set mpls interface fxp0.0 disable
```

8. Assign the interfaces of Device R0 with the configured traffic engineering attributes.

```
[edit protocols]
user@R0# set mpls interface ge-0/0/0.0 srlg g1
user@R0# set mpls interface ge-0/0/0.0 administrative-group green
user@R0# set mpls interface ge-0/0/0.0 administrative-group-extended gold
user@R0# set mpls interface ge-0/0/2.0 srlg g2
user@R0# set mpls interface ge-0/0/2.0 administrative-group red
user@R0# set mpls interface ge-0/0/2.0 administrative-group-extended gold
user@R0# set mpls interface ge-0/0/1.0 srlg g3
user@R0# set mpls interface ge-0/0/1.0 administrative-group blue
user@R0# set mpls interface ge-0/0/1.0 administrative-group-extended gold
```

9. Configure an LSP connecting Device R0 with Device R3, and assign primary and secondary path attributes to the LSP.

```
[edit protocols]
user@R0# set mpls label-switched-path R0-R31 to 127.0.0.3
user@R0# set mpls label-switched-path R0-R31 primary prim
user@R0# set mpls label-switched-path R0-R31 secondary stdby standby
user@R0# set mpls label-switched-path R0-R31 secondary nonstdby
```

10. Define the primary and secondary paths for the R0-R31 LSP.

```
[edit protocols]
user@R0# set mpls path path_primary 172.16.0.2 strict
user@R0# set mpls path path_primary 172.21.0.2 strict
user@R0# set mpls path path_primary 172.24.0.2 strict
user@R0# set mpls path path_ter_nonstdby 172.18.0.1 strict
user@R0# set mpls path path_ter_nonstdby 172.26.0.2 strict
user@R0# set mpls path path_sec_stdby 172.17.0.2 strict
user@R0# set mpls path path_sec_stdby 172.23.0.2 strict
```

11. Create constituent lists with constituent traffic engineering attributes for abstract-hop definitions.

```
[edit protocols]
user@R0# set mpls constituent-list c1 srlg g1
user@R0# set mpls constituent-list c1 administrative-group green
user@R0# set mpls constituent-list c2 administrative-group green
user@R0# set mpls constituent-list c2 administrative-group-extended gold
user@R0# set mpls constituent-list c3 srlg g2
user@R0# set mpls constituent-list c3 administrative-group red
user@R0# set mpls constituent-list c3 administrative-group-extended gold
user@R0# set mpls constituent-list c4 srlg g3
user@R0# set mpls constituent-list c4 administrative-group blue
user@R0# set mpls constituent-list c4 administrative-group-extended gold
```

12. Define abstract hops by assigning the configured constituent lists and respective operators.

```
[edit protocols]
user@R0# set mpls abstract-hop ah1 operator AND
user@R0# set mpls abstract-hop ah1 constituent-list c1 include-all-list
user@R0# set mpls abstract-hop ah1 constituent-list c2 include-all-list
user@R0# set mpls abstract-hop ah2 operator AND
user@R0# set mpls abstract-hop ah2 constituent-list c3 include-all-list
user@R0# set mpls abstract-hop ah3 operator AND
user@R0# set mpls abstract-hop ah3 constituent-list c4 include-all-list
```

13. Define constraints for the configured paths by including abstract hop definitions.

```
[edit protocols]
```

```
user@R0# set mpls path prim ah1 abstract
user@R0# set mpls path prim ah1 strict
user@R0# set mpls path stdby ah2 abstract
user@R0# set mpls path stdby ah2 strict
user@R0# set mpls path nonstdby ah3 abstract
user@R0# set mpls path nonstdby ah3 strict
```

14. Configure RSVP on Device R0. Enable RSVP on all the interfaces of Device R0, excluding the management interface and interface connecting to Host1, and assign bandwidth values.

```
[edit protocols]
user@R0# set rsvp interface all aggregate
user@R0# set rsvp interface fxp0.0 disable
user@R0# set rsvp interface ge-0/0/0.0 bandwidth 80m
user@R0# set rsvp interface ge-0/0/2.0 bandwidth 200m
user@R0# set rsvp interface ge-0/0/1.0 bandwidth 500m
```

15. Configure OSPF on all the interfaces of Device R0, excluding the management interface, and assign traffic engineering capabilities.

```
[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface all
user@R0# set ospf area 0.0.0.0 interface fxp0.0 disable
```

16. Configure a policy on Device R0 to enable load balancing on a per-packet basis.

```
[edit policy-options]
user@R0# set forwarding-table export test
```

17. Export the load-balancing policy to the forwarding table.

```
[edit policy-options]
user@R0# set policy-statement test then load-balance per-packet
```

Results From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show chassis

Verification

Confirm that the configuration is working properly.

- Verifying Abstract Hop Configuration on page 367
- Verifying Abstract Hop Path Computation on page 368

Verifying Abstract Hop Configuration

Purpose Verify the members of the abstract hop definition on Device R0 by issuing the **show mpls abstract-hop-membership** command, which displays the abstract hop membership tables.

Action From operational mode, run the **show mpls abstract-hop-membership** command.

```
user@R0> show mpls abstract-hop-membership
Abstract hop: ah1
   Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.1
Address: 127.0.0.2
Address: 127.0.0.3

Abstract hop: ah2
   Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.3
Address: 127.0.0.4

Abstract hop: ah3
   Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.3
Address: 127.0.0.5
```

Meaning The **show mpls abstract-hop-membership** command output provides the abstract hop to traffic engineering database node mapping. The **Credibility** field displays the credibility value associated with the interior gateway protocol in use (OSPF).

Verifying Abstract Hop Path Computation

Purpose Verify the abstract computation preprocessing for LSPs on Device R0 by issuing the **show mpls lsp abstract-computation** command.

Action From operational mode, run the **show mpls lsp abstract-computation** command.

```
user@R0> show mpls lsp abstract-computation
Path computation using abstract hops for LSP: R0-R31
   Path type: Primary, Path name: prim

   Credibility: 0, Total no of CSPF passes: 2
     CSPF pass no: 0
      Start address of the pass: 127.0.0.6
       Destination: 127.0.0.1, State: VALID
       Destination: 127.0.0.2, State: VALID
       Destination: 127.0.0.3, State: VALID
       Affinity: ah1
     CSPF pass no: 1
      Start address of the pass: 127.0.0.1
       Destination: 127.0.0.3, State: VALID
   Path type: Secondary, Path name: nonstdby
   Path type: Standby, Path name: stdby

   Credibility: 0, Total no of CSPF passes: 2
     CSPF pass no: 0
      Start address of the pass: 127.0.0.6
       Destination: 127.0.0.3, State: VALID
       Destination: 127.0.0.4, State: VALID
       Affinity: ah2
     CSPF pass no: 1
      Start address of the pass: 127.0.0.4
       Destination: 127.0.0.3, State: VALID
```

Meaning The **show mpls lsp abstract-hop-computation** command output provides the various computation passes involved per LSP, and the qualifying exit devces for each pass. The command output also gives the affinity per pass, and shows the current start device chosen for the pass. For each viable router (device), the state of backtracking is displayed, where it can either be valid or disqualified.

The **Credibility** field indicates the credibility value associated with the interior gateway protocol in use (OSPF).

Configuring the Maximum Number of MPLS Labels

For interfaces that you configure for MPLS applications, you can set the maximum number of labels upon which MPLS can operate.

By default, the maximum number of labels is three. You can change the maximum to four labels or five labels for applications that require four or five labels.

NOTE: **When the maximum number of MPLS labels of an interface is modified, the MPLS interface is bounced. All LDP and RSVP sessions on that interface are restarted, resulting in all LSPs over that interface to flap.**

For example, suppose you configure a two-tier carrier-of-carriers VPN service for customers who provide VPN service. A carrier-of-carrier VPN is a two-tiered relationship between a provider carrier (Tier 1 ISP) and a customer carrier (Tier 2 ISP). In a carrier-of-carrier VPN, the provider carrier provides a VPN backbone network for the customer carrier. The customer carrier in turn provides Layer 3 VPN service to its end customers. The customer carrier sends labeled traffic to the provider carrier to deliver it to the next hop on the other side of the provider carrier's network. This scenario requires a three-label stack: one label for the provider carrier VPN, another label for the customer carrier VPN, and a third label for the transport route.

If you add fast reroute service, the PE routers in the provider carrier's network must be configured to support a fourth label (the reroute label). If the customer carrier is using LDP as its signaling protocol and the provider carrier is using RSVP, the provider carrier must support LDP over RSVP tunnel service. This additional service requires an additional label, for a total of five labels.

To the customer carrier, the router it uses to connect to the provider carrier's VPN is a PE router. However, the provider carrier views this device as a CE router.

Table 14 on page 370 summarizes the label requirements.

Table 14: Sample Scenarios for Using 3, 4, or 5 MPLS Labels

Number of Labels Required	Scenarios
3	Carrier-of-carriers VPN or a VPN with two labels and fast reroute
4	Combination of carrier-of-carriers and fast reroute
5	Carrier-of-carriers with fast reroute and the customer carrier running LDP, with the provider carrier running RSVP

The system reserves label space when you configure the maximum number of labels on the interface. When you configure features that require MPLS labels, the label push is automatic. You do not need to explicitly push the labels. The transport route can be a static, LDP-signaled, or RSVP-signaled LSP.

This feature is supported on the following devices:

- MX Series 5G Universal Routing Platform
- M120 Multiservice Edge Router
- M320 Multiservice Edge Router with Enhanced III FPCs
- M7i Multiservice Edge Router and M10i Multiservice Edge Router with Enhanced Compact Forwarding Engine Board (CFEB-E)
- T640, T1600, TX Matrix, and TX Matrix Plus routers with Enhanced Scaling FPC1, Enhanced Scaling FP2, Enhanced Scaling FPC3, and Enhanced Scaling FPC4.
- QFX10000 switches.

To configure and monitor the maximum number of labels:

1. Specify the maximum on the logical interface. Apply this configuration to the carrier's PE routers.

```
[edit interfaces ge-0/1/3 unit 0 family mpls]
user@switch# set maximum-labels 5
```

2. Verify the configuration.

```
[edit system]
user@switch# show interfaces ge-0/1/3.0
Logical interface ge-0/1/3.0 (Index 77) (SNMP ifIndex 507)
    Flags: SNMP-Traps Encapsulation: ENET2
    Input packets : 0
    Output packets: 0
    Protocol mpls, MTU: 1480, Maximum labels: 5
      Flags: Is-Primary
```

The command output includes the **Maximum labels: 5** field under the logical interface unit 0.

Configuring MPLS to Pop the Label on the Ultimate-Hop Router

You can control the label value advertised on the egress router of a label-switched path (LSP). The default advertised label is label 3 (Implicit Null Label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. By enabling ultimate-hop popping, label 0 (IPv4 Explicit Null Label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

NOTE: Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure MPLS to pop the label on the ultimate-hop router, include the **explicit-null** statement:

```
explicit-null;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Advertising Explicit Null Labels to BGP Peers

For the IPv4 (**inet**) family only, BGP peers in a routing group can send an explicit NULL label for a set of connected routes (direct and loopback routes) for the inet labeled-unicast and inet6 labeled-unicast NLRI. By default, peers advertise label 3 (implicit NULL). If the **explicit-null** statement is enabled, peers advertise label 0 (explicit NULL). The explicit NULL labels ensures that labels are always present on packets traversing an MPLS network. If the implicit NULL label is used. the penultimate hop router removes the label and sends the packet as a plain IP packet to the egress router. This might cause issues in queuing the packet properly on the penultimate hop router if the penultimate hop is another vendor's router. Some other vendors queue packets based on the CoS bits in the outgoing label rather than the incoming label.

To advertise an explicit null label, include the following statements in the configuration:

```
family inet {
  labeled-unicast {
    aggregate-label {
      community community-name:
    }
    explicit-null {
      connected-only;
    }
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The **connected-only** statement is required to advertise explicit null labels.

To verify that the explicit NULL label is being advertised for connected routes, use the **show route advertising-protocol bgp *neighbor-address*** command.

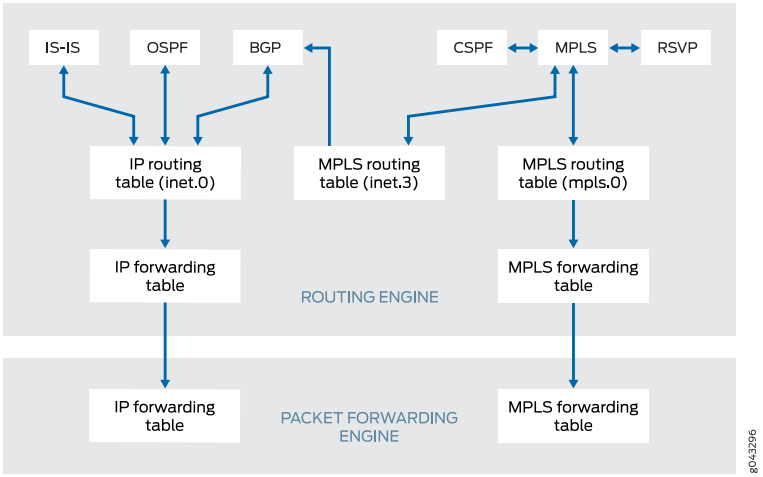
CHAPTER 12

MPLS LSP Routes

MPLS and Routing Tables

The IGPs and BGP store their routing information in the inet.0 routing table, the main IP routing table. If the **traffic-engineering bgp** command is configured, thereby allowing only BGP to use MPLS paths for forwarding traffic, MPLS path information is stored in a separate routing table, inet.3. Only BGP accesses the inet.3 routing table. BGP uses both inet.0 and inet.3 to resolve next-hop addresses. If the **traffic-engineering bgp-igp** command is configured, thereby allowing the IGPs to use MPLS paths for forwarding traffic, MPLS path information is stored in the inet.0 routing table. (Figure 31 on page 376 and Figure 32 on page 377 illustrate the routing tables in the two traffic engineering configurations.)

Figure 31: Routing and Forwarding Tables, traffic-engineering bgp



The inet.3 routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route packets to the destination egress router. BGP uses the inet.3 routing table on the ingress router to help in resolving next-hop addresses.

MPLS also maintains an MPLS path routing table (mpls.0), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

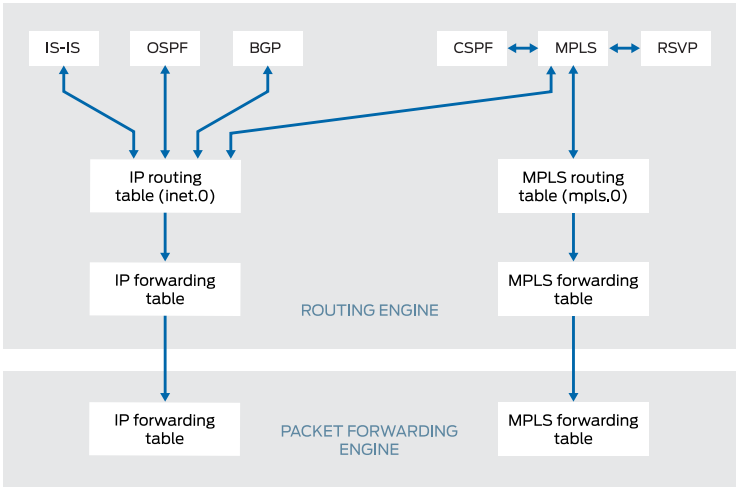
Typically, the egress router in an LSP does not consult the mpls.0 routing table. (This router does not need to consult mpls.0 because the penultimate router in the LSP either

changes the packet's label to a value of 0 or pops the label.) In either case, the egress router forwards it as an IPv4 packet, consulting the IP routing table, inet.0, to determine how to forward the packet.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or to determine that this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the inet.0 and inet.3 routing tables, seeking the next hop with the lowest preference. If it finds a next-hop entry with an equal preference in both routing tables, BGP prefers the entry in the inet.3 routing table.

Figure 32: Routing and Forwarding Tables, traffic-engineering bgp-igp



Generally, BGP selects next-hop entries in the inet.3 routing table because their preferences are always lower than OSPF and IS-IS next-hop preferences. When you configure LSPs, you can override the default preference for MPLS LSPs, which might alter the next-hop selection process.

When BGP selects a next-hop entry from the inet.3 routing table, it installs that LSP into the forwarding table in the Packet Forwarding Engine, which causes packets destined for that next hop to enter and travel along the LSP. If the LSP is removed or fails, the path is removed from the inet.3 routing table and from the forwarding table, and BGP reverts to using a next hop from the inet.0 routing table.

MPLS and Traffic Protection

Typically, when an LSP fails, the router immediately upstream from the failure signals the outage to the ingress router. The ingress router calculates a new path to the egress router, establishes the new LSP, and then directs the traffic from the failed path to the new path. This rerouting process can be time-consuming and prone to failure. For example, the outage signals to the ingress router might get lost, or the new path might take too long to come up, resulting in significant packet drops. The Junos OS provides several complementary mechanisms for protecting against LSP failures:

- Standby secondary paths—You can configure primary and secondary paths. You configure secondary paths with the **standby** statement. To activate traffic protection, you need to configure these standby paths only on the ingress router. If the primary path fails, the ingress router immediately reroutes traffic from the failed path to the standby path, thereby eliminating the need to calculate a new route and signal a new path. For information about configuring standby LSPs, see "Configuring Hot Standby of Secondary Paths for LSPs" on page 462.
- Fast reroute—You configure fast reroute on an LSP to minimize the effect of a failure in the LSP. Fast reroute enables a router upstream from the failure to route around the failure quickly to the router downstream of the failure. The upstream router then signals the outage to the ingress router, thereby maintaining connectivity before a new LSP is established. For a detailed overview of fast reroute, see "Fast Reroute Overview" on page 379. For information about configuring fast reroute, see "Configuring Fast Reroute" on page 381.
- Link protection—You can configure link protection to help ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails. When link protection is configured for an interface and configured for an LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. For information about configuring link protection, see *Configuring Link Protection on Interfaces Used by LSPs*.

When standby secondary path, and fast reroute or link protection are configured on an LSP, full traffic protection is enabled. When a failure occurs in an LSP, the router upstream from the failure routes traffic around the failure and notifies the ingress router of the failure. This rerouting keeps the traffic flowing while waiting for the notification to be processed at the ingress router. After receiving the failure notification, the ingress router immediately reroutes the traffic from the patched primary path to the more optimal standby path.

Fast reroute and link protection provide a similar type of traffic protection. Both features provide a quick transfer service and employ a similar design. Fast reroute and link protection are both described in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*. However, you need to configure only one or the other. Although you can configure both, there is little, if any, benefit in doing so.

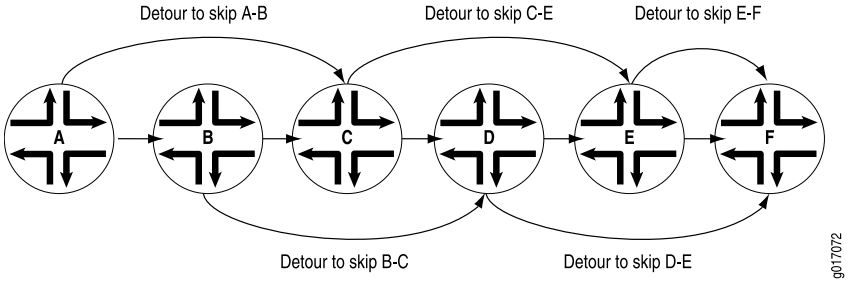
Fast Reroute Overview

Fast reroute provides redundancy for an LSP path. When you enable fast reroute, detours are precomputed and preestablished along the LSP. In case of a network failure on the current LSP path, traffic is quickly routed to one of the detours. Figure 33 on page 379 illustrates an LSP from Router A to Router F, showing the established detours. Each detour is established by an upstream node to avoid the link toward the immediate downstream node and the immediate downstream node itself. Each detour might traverse through one or more label-switched routers (or switches) that are not shown in the figure.

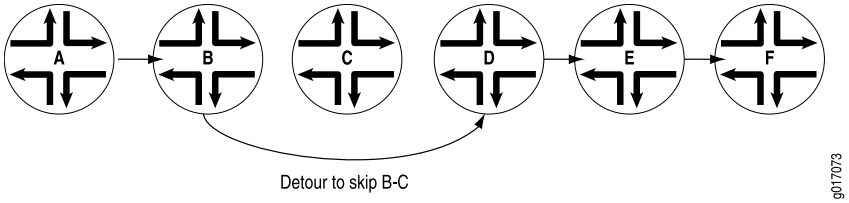
Fast reroute protects traffic against any single point of failure between the ingress and egress routers (or switches). If there is a failure in a scaled fast reroute scenario, the devices lose reachability to all the peers that were connected through the failed link. This leads to traffic interruption, as the BGP session among the devices goes down. If there are multiple failures along an LSP, fast reroute itself might fail. Also, fast reroute does not protect against failure of the ingress or egress routers.

Figure 33: Detours Established for an LSP Using Fast Reroute



If a node detects that a downstream link has failed (using a link-layer-specific liveness detection mechanism) or that a downstream node has failed (for example, using the RSVP neighbor hello protocol), the node quickly switches the traffic to the detour and, at the same time, signals the ingress router about the link or node failure.
Figure 34 on page 379 illustrates the detour taken when the link between Router B and Router C fails.

Figure 34: Detour After the Link from Router B to Router C Fails



If the network topology is not rich enough (there are not enough routers with sufficient links to other routers), some of the detours might not succeed. For example, the detour from Router A to Router C in Figure 33 on page 379 cannot traverse link A-B and Router B. If such a path is not possible, the detour does not occur.

Note that after the node switches traffic to the detour, it might switch the traffic again to a newly calculated detour soon after. This is because the initial detour route might not be the best route. To make rerouting as fast as possible, the node switches traffic onto the initial detour without first verifying that the detour is valid. Once the switch is made, the node recomputes the detour. If the node determines that the initial detour is still valid, traffic continues to flow over this detour. If the node determines that the initial detour is no longer valid, it again switches the traffic to a newly computed detour.

NOTE: **If you issue show commands after the node has switched traffic to the initial detour, the node might indicate that the traffic is still flowing over the original LSP. This situation is temporary and should correct itself quickly.**

The time required for a fast-rerouting detour to take effect depends on two independent time intervals:

- Amount of time to detect that there is a link or node failure—This interval depends greatly on the link layer in use and the nature of the failure. For example, failure detection on an SONET/SDH link typically is much faster than on a Gigabit Ethernet link, and both are much faster than detection of a router failure.
- Amount of time required to splice the traffic onto the detour—This operation is performed by the Packet Forwarding Engine, which requires little time to splice traffic onto the detour. The time needed can vary depending on the number of LSPs being switched to detours.

Fast reroute is a short-term patch to reduce packet loss. Because detour computation might not reserve adequate bandwidth, the detours might introduce congestion on the alternate links. The ingress router is the only router that is fully aware of LSP policy constraints and, therefore, is the only router able to come up with adequate long-term alternate paths.

Detours are created by use of RSVP and, like all RSVP sessions, they require extra state and overhead in the network. For this reason, each node establishes at most one detour for each LSP that has fast reroute enabled. Creating more than one detour for each LSP increases the overhead, but serves no practical purpose.

To reduce network overhead further, each detour attempts to merge back into the LSP as soon as possible after the failed node or link. If you can consider an LSP that travels through n router nodes, it is possible to create $n - 1$ detours. For instance, in Figure 35 on page 381, the detour tries to merge back into the LSP at Router D instead of at Router E or Router F. Merging back into the LSP makes the detour scalability problem more manageable. If topology limitations prevent the detour from quickly merging back into the LSP, detours merge with other detours automatically.

Figure 35: Detours Merging into Other Detours

Configuring Fast Reroute

Fast reroute provides a mechanism for automatically rerouting traffic on an LSP if a node or link in an LSP fails, thus reducing the loss of packets traveling over the LSP.

To configure fast reroute on an LSP, include the **fast-reroute** statement on the ingress router (or switch):

```
fast-reroute {
  (bandwidth bps | bandwidth-percent percentage);
  (exclude [ group-names ] | no-exclude );
  hop-limit number;
  (include-all [ group-names ] | no-include-all);
  (include-any [ group-names ] | no-include-any);
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

You do not need to configure fast reroute on the LSP's transit and egress routers (or switches). Once fast reroute is enabled, the ingress router (or switch) signals all the downstream routers (or switches) that fast reroute is enabled on the LSP, and each downstream router does its best to set up detours for the LSP. If a downstream router does not support fast reroute, it ignores the request to set up detours and continues to support the LSP. A router that does not support fast reroute will cause some of the detours to fail, but otherwise has no impact on the LSP.

NOTE: To enable PFE fast reroute, configure a routing policy statement with the **load-balance per-packet** statement at the **[edit policy-options policy-statement *policy-name* then]** hierarchy level on each of the routers where traffic might be rerouted. See also *Configuring Load Balancing Across RSVP LSPs*.

By default, no bandwidth is reserved for the rerouted path. To allocate bandwidth for the rerouted path, include either the **bandwidth** statement or the **bandwidth-percent** statement. You can only include one of these statements at a time. If you do not include either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path.

When you include the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. The bandwidth does not need to be identical to that allocated for the LSP.

When you specify a bandwidth percent using the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying the bandwidth percentage by the bandwidth configured for the main traffic-engineered LSP. For information about how to configure the bandwidth for a traffic-engineered LSP, see "Configuring Traffic-Engineered LSPs" on page 705.

Hop-limit constraints define how many more routers a detour is allowed to traverse compared with the LSP itself. By default, the hop limit is set to 6. For example, if an LSP traverses 4 routers, any detour for the LSP can be up to 10 (that is, 4 + 6) router hops, including the ingress and egress routers.

By default, a detour inherits the same administrative (coloring) group constraints as its parent LSP when CSPF is determining the alternate path. Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the "color" of links, such that links with the same color conceptually belong to the same class. If you specify the **include-any** statement when configuring the parent LSP, all links traversed by the alternate session must have at least one color found in the list of groups. If you specify the **include-all** statement when configuring the parent LSP, all links traversed by the alternate session must have all of the colors found in the list of groups. If you specify the **exclude** statement when configuring the parent LSP, none of the links must have a color found in the list of groups. For more information about administrative group constraints, see "Configuring Administrative Groups for LSPs" on page 429.

Detour Merging Process

This section describes the process used by a router to determine which LSP to select when the router receives path messages from different interfaces with identical Session

and Sender Template objects. When this occurs, the router needs to merge the path states.

The router employs the following process to determine when and how to merge path states:

- When all the path messages do not include a fast reroute or a detour object, or when the router is the egress of the LSP, no merging is required. The messages are processed according to RSVP traffic engineering.
- Otherwise, the router *must* record the path state in addition to the incoming interface. If the path messages do not share the same outgoing interface and next-hop router, the router considers them to be independent LSPs and does not merge them.
- For all the path messages that share the same outgoing interface and next-hop router, the router uses the following process to select the final LSP:
  - If only one LSP originates from this node, select it as the final LSP.
  - If only one LSP contains a fast reroute object, select it as the final LSP.
  - If there are several LSPs and some of them have a detour object, eliminate those containing a detour object from the final LSP selection process.
  - If several final LSP candidates remain (that is, there are still both detour and protected LSPs), select the LSPs with fast reroute objects.
  - If none of the LSPs have fast reroute objects, select the ones without detour objects. If all the LSPs have detour objects, select them all.
  - Of the remaining LSP candidates, eliminate from consideration those that traverse nodes that other LSPs avoid.
  - If several candidate LSPs still remain, select the one with the shortest explicit route object (ERO) path length. If more than one LSP has the same path length, select one randomly.
- Once the final LSP has been identified, the router must transmit only the path messages that correspond to this LSP. All other LSPs are considered merged at this node.

Detour Computations

Computing and setting up detours is done independently at each node. On a node, if an LSP has fast reroute enabled and if a downstream link or node can be identified, the router performs a Constrained Shortest Path First (CSPF) computation using the information in the local traffic engineering database. For this reason, detours rely on your IGP supporting traffic engineering extensions. Without the traffic engineering database, detours cannot be established.

CSPF initially attempts to find a path that skips the next downstream node. Attempting to find this path provides protection against downstream failures in either nodes or links. If a node-skipping path is not available, CSPF attempts to find a path on an alternate link to the next downstream node. Attempting to find an alternate link provides protection against downstream failures in links only. Detour computations might not succeed the

first time. If a computation fails, the router recomputes detours approximately once every refresh interval until the computation succeeds. The RSVP metric for each detour is set to a value in the range from 10,000 through 19,999.

Fast Reroute Path Optimization

A fast reroute protection path is nondeterministic. The actual protection path of a particular node depends on the history of the LSP and the network topology when the fast reroute path was computed. The lack of deterministic behavior can lead to operational difficulties and poorly optimized paths after multiple link flaps in a network. Even in a small network, after a few link flaps fast reroute paths can traverse an arbitrarily large number of nodes and can remain in that state indefinitely. This is inefficient and makes the network less predictable.

Fast reroute optimization addresses this deficiency. It provides a global path optimization timer, allowing you to optimize all LSPs that have fast reroute enabled and a detour path up and running. The timer value can be varied depending on the expected RE processing load.

The fast reroute optimization algorithm is based on the IGP metric only. As long as the new path's IGP metric is lower than the old path's, the CSPF result is accepted, even if the new path might be more congested (higher bandwidth utilization) or traverses more hops.

In conformance with RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, when a new path is computed and accepted for fast reroute optimization, the existing detour is destroyed first and then the new detour is established. To prevent traffic loss, detours actively protecting traffic are not optimized.

Configuring the Optimization Interval for Fast Reroute Paths

You can enable path optimization for fast reroute by configuring the fast reroute optimize timer. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

To enable fast reroute path optimization, specify the number of seconds using the optimize-timer option for the **fast-reroute** statement:

```
fast-reroute seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table

By default, a host route toward the egress router is installed in the inet.3 or inet6.3 routing table. (The host route address is the one you configure in the **to** statement.) Installing the host route allows BGP to perform next-hop resolution. It also prevents the host route

from interfering with prefixes learned from dynamic routing protocols and stored in the inet.0 or inet6.0 routing table.

Unlike the routes in the inet.0 or inet6.0 table, routes in the inet.3 or inet6.3 table are not copied to the Packet Forwarding Engine, and hence they cause no changes in the system forwarding table directly. You cannot use the **ping** or **traceroute** command through these routes. The only use for inet.3 or inet6.3 is to permit BGP to perform next-hop resolution. To examine the inet.3 or inet6.3 table, use the **show route table inet.3** or **show route table inet6.3** command.

To inject additional routes into the inet.3 or inet6.3 routing table, include the **install** statement:

```
install {
  destination-prefix <active>;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** static-label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** static-label-switched-path ***lsp-name*****]**

The specified routes are installed as aliases into the routing table when the LSP is established. Installing additional routes allows BGP to resolve next hops within the specified prefix and to direct additional traffic for these next hops to a particular LSP.

Including the **active** option with the **install** statement installs the specified prefix into the inet.0 or inet6.0 routing table, which is the primary forwarding table. The result is a route that is installed in the forwarding table any time the LSP is established, which means you can ping or trace the route. Use this option with care, because this type of prefix is very similar to a static route.

You use alias routes for routers that have multiple addresses being used as BGP next hops, or for routers that are not MPLS capable. In either of these cases, the LSP can be configured to another MPLS capable system within the local domain, which then acts as a “border” router. The LSP then terminates on the border router and, from that router, Layer 3 forwarding takes the packet to the true next-hop router.

In the case of an interconnect, the domain’s border router can act as the proxy router and can advertise the prefix for the interconnect if the border router is not setting the BGP next hop to itself.

In the case of a point of presence (POP) that has routers that do not support MPLS, one router (for example, a core router) that supports MPLS can act as a proxy for the entire POP and can inject a set of prefixes that cover the POP. Thus, all routers within the POP can advertise themselves as interior BGP (IBGP) next hops, and traffic can follow the

LSP to reach the core router. This means that normal IGP routing would prevail within the POP.

You cannot use the **ping** or **traceroute** commands on routes in the inet.3 or inet6.3 routing table.

For BGP next-hop resolution, it makes no difference whether a route is in inet.0/inet6.0 or inet.3/inet6.3; the route with the best match (longest mask) is chosen. Among multiple best-match routes, the one with the highest preference value is chosen.

NOTE: The **install** *destination-prefix* **active** statement is not supported on static LSPs. When the **install** *destination-prefix* **active** statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

Constrained-Path LSP Computation

The Constrained Shortest Path First (CSPF) algorithm is an advanced form of the shortest-path-first (SPF) algorithm used in OSPF and IS-IS route computations. CSPF is used in computing paths for LSPs that are subject to multiple constraints. When computing paths for LSPs, CSPF considers not only the topology of the network, but also the attributes of the LSP and the links, and it attempts to minimize congestion by intelligently balancing the network load.

The constraints that CSPF considers include:

- LSP attributes
  - Administrative groups (that is, link color requirements)
  - Bandwidth requirements
  - Explicit route (strict or loose)
  - Hop limitations
  - Priority (setup and hold)
- Link attributes
  - Administrative groups (that is, link colors assigned to the link)
  - Reservable bandwidth of the links (static bandwidth minus the currently reserved bandwidth)

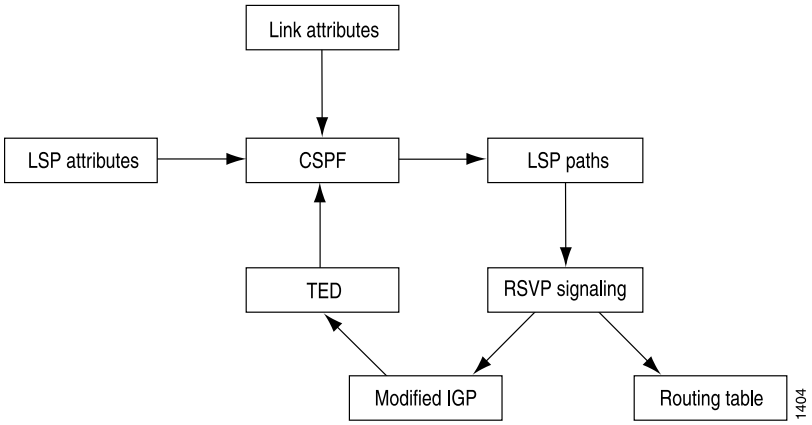
The data that CSPF considers comes from the following sources:

- Traffic engineering database—Provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors. For the CSPF algorithm

to perform its computations, a link-state IGP (such as OSPF or IS-IS) with special extensions is needed. For CSPF to be effective, the link-state IGP on all routers must support the special extensions. While building the topology database, the extended IGP must take into consideration the current LSPs and must flood the route information everywhere. Because changes in the reserved link bandwidth and link color cause database updates, an extended IGP tends to flood more frequently than a normal IGP. See Figure 36 on page 387 for a diagram of the relationships between these components.

- Currently active LSPs—Includes all the LSPs that should originate from the router and their current operational status (up, down, or timeout).

Figure 36: CSPF Computation Process



This section discusses the following topics:

- How CSPF Selects a Path on page 387
- CSPF Path Selection Tie-Breaking on page 388
- Computing CSPF Paths Offline on page 389

How CSPF Selects a Path

To select a path, CSPF follows certain rules. The rules are as follows:

1. Computes LSPs one at a time, beginning with the highest priority LSP (the one with the lowest setup priority value). Among LSPs of equal priority, CSPF services the LSPs in alphabetical order of the LSP names.
2. Prunes the traffic engineering database of all the links that are not full duplex and do not have sufficient reservable bandwidth.
3. If the LSP configuration includes the **include** statement, prunes all links that do not share any included colors.
4. If the LSP configuration includes the **exclude** statement, prunes all links that contain excluded colors. If the link does not have a color, it is accepted.
5. If several paths have equal cost, chooses the one whose last-hop address is the same as the LSP's destination.

6. If several equal cost paths remain, selects the one with the fewest number of hops.
7. If several equal-cost paths remain, applies the CSPF load-balancing rule configured on the LSP (least fill, most fill, or random).

CSPF finds the shortest path toward the LSP's egress router, taking into account explicit-path constraints. For example, if the path must pass through Router A, two separate SPFs are computed, one from the ingress router to Router A, the other from Router A to the egress router. All CSPF rules are applied to both computations.

Related Documentation

- Configuring CSPF Tie Breaking on page 389
- CSPF Path Selection Tie-Breaking on page 388

CSPF Path Selection Tie-Breaking

If more than one path is still available after the CSPF rules ("How CSPF Selects a Path" on page 387) have been applied, a tie-breaking rule is applied to choose the path for the LSP. The rule used depends on the configuration. There are three tie-breaking rules:

- Random—One of the remaining paths is picked at random. This rule tends to place an equal number of LSPs on each link, regardless of the available bandwidth ratio. This is the default behavior.
- Least fill—The path with the largest minimum available bandwidth ratio is preferred. This rule tries to equalize the reservation on each link.
- Most fill—The path with the smallest minimum available bandwidth ratio is preferred. This rule tries to fill a link before moving on to alternative links.

The following definitions describe how a figure for minimum available bandwidth ratio is derived for the least fill and most fill rules:

- Reservable bandwidth = bandwidth of link x subscription factor of link
- Available bandwidth = reservable bandwidth – (sum of the bandwidths of the LSPs traversing the link)
- Available bandwidth ratio = available bandwidth/reservable bandwidth
- Minimum available bandwidth ratio (for a path) = the smallest available bandwidth ratio of the links in a path

NOTE: For the least fill or most fill behaviors to be used, the paths must have their bandwidth (specified using the **bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level) or minimum bandwidth (specified using the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-name* auto-bandwidth]** hierarchy level) configured to a value greater than 0. If the bandwidth or minimum bandwidth for the paths is either not configured or configured as 0, the minimum available bandwidth cannot be calculated and the random path selection behavior is used instead.

Computing CSPF Paths Offline

The Junos OS provides online, real-time CSPF computation only; each router performs CSPF calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status.

To optimize links globally across the network, you can use an offline tool to perform the CSPF calculations and determine the paths for the LSPs. You can create such a tool yourself, or you can modify an existing network design tool to perform these calculations. You should run the tool periodically (daily or weekly) and download the results into the router. An offline tool should take the following into account when performing the optimized calculations:

- All the LSP's requirements
- All link attributes
- Complete network topology

Configuring CSPF Tie Breaking

When selecting a path for an LSP, CSPF uses a tie-breaking process if there are several equal-cost paths. For information about how CSPF selects a path, see "How CSPF Selects a Path" on page 387.

You can configure one of the following statements (you can only configure one of these statements at a time) to alter the behavior of CSPF tie-breaking:

- By default, a random tie-breaking rule for CSPF is used to select a path from the set of equal-cost paths. However, you can also explicitly configure this behvior using the **random** statement:

```
random;
```

- To prefer the path with the least-utilized links, include the **least-fill** statement:

```
least-fill;
```

- To prefer the path with the most-utilized links, include the **most-fill** statement:

```
most-fill;
```

You can include each of these statements at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]**

Related Documentation

- How CSPF Selects a Path on page 387

Disabling Constrained-Path LSP Computation

If the IGP is a link-state protocol (such as IS-IS or OSPF) and supports extensions that allow the current bandwidth reservation on each router's link to be reported, constrained-path LSPs are computed by default.

The Junos implementations of IS-IS and OSPF include the extensions that support constrained-path LSP computation.

- IS-IS—These extensions are enabled by default. To disable this support, include the **disable** statement at the **[edit protocols isis traffic-engineering]** hierarchy level, as discussed in the *Junos OS Routing Protocols Library*.
- OSPF—These extensions are disabled by default. To enable this support, include the **traffic-engineering** statement in the configurations of all routers running OSPF, as described in the *Junos OS Routing Protocols Library*.

If IS-IS is enabled on a router or you enable OSPF traffic engineering extensions, MPLS performs the constrained-path LSP computation by default. For information about how constrained-path LSP computation works, see "Constrained-Path LSP Computation" on page 386.

Constrained-path LSPs have a greater chance of being established quickly and successfully for the following reasons:

- The LSP computation takes into account the current bandwidth reservation.
- Constrained-path LSPs reroute themselves away from node failures and congestion.

When constrained-path LSP computation is enabled, you can configure the LSP so that it is periodically reoptimized, as described in "Optimizing Signaled LSPs" on page 437.

When an LSP is being established or when an existing LSP fails, the constrained-path LSP computation is repeated periodically at the interval specified by the retry timer until the LSP is set up successfully. Once the LSP is set up, no recomputation is done. For more information about the retry timer, see "Configuring the Connection Between Ingress and Egress Routers" on page 419.

By default, constrained-path LSP computation is enabled. You might want to disable constrained-path LSP computation when all nodes do not support the necessary traffic engineering extensions. To disable constrained-path LSP computation, include the **no-cspf** statement:

```
no-cspf;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you disable constrained-path LSP computation on LSPs by configuring the **no-cspf** statement and then attempt to advertise other LSPs with lower metrics than the IGPs from this router in either IS-IS or OSPF, new LSPs cannot be established.

Configuring Load Balancing Based on MPLS Labels

Load balancing occurs on a per-packet basis for MPLS flows on supported platforms. Entropy, or random distribution, is essential for the uniform distribution of packets to their next hops. By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across a set of equal-cost label switched paths (LSPs).

To ensure entropy for VPLS & VPWS traffic, Junos OS can create a hash based on data from the IP header and as many as three MPLS labels (the so-called top labels).

In some cases, as the number of network feature that use labels grows (such as MPLS Fast Reroute, and RFC 3107, RSVP and VPN) data in the top three labels can become static and thus not a sufficient source for entropy. Load balancing can become skewed as a result, or the incidence of out-of-order packet delivery may rise. For these cases, labels from the bottom of the label stack can be used (see Table 1, below for qualifications). Top labels and bottom labels cannot be used at the same time.

NOTE: MPC cards do not support the regular hash key configuration. For the MPC-based hash key configuration to be effective, you need an enhanced-hash-key configuration.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

An LSP tends to load-balance its placement by randomly selecting one of the equal-cost next hops and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces as well as multiple equal-cost MPLS next hops. In addition, on the T Series, MX Series, M120, and M320 routers only, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

To load-balance based on the MPLS label information, configure the **family mpls** statement:

```
[edit forwarding-options hash-key]
family mpls {
    all-labels;
    bottom-label-1;
    bottom-label-2;
    bottom-label-3;
    label-1;
    label-2;
    label-3;
    no-labels;
    no-label-1-exp;
    payload {
        ether-pseudowire;
        ip {
            disable;
            layer-3-only;
            port-data {
                destination-lsb;
                destination-msb;
                source-lsb;
                source-msb;
            }
        }
    }
}
```

You can include this statement at the following hierarchy levels:

- **[edit forwarding-options hash-key]**

Table 15 on page 393 provides detailed information about all of the possible MPLS LSP load-balancing options.

Table 15: MPLS LSP Load Balancing Options

Statement	Supported Platforms	MPLS LSP Load Balancing Options
all-labels	PTX Series	Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This value is set by default.
bottom-label-1	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the bottom-most label for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
bottom-label-2	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the second label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
bottom-label-3	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the third label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
label-1	M Series, MX Series, T Series	Include the first label in the hash key. Use this option for single label packets.
label-2	M Series, MX Series, T Series	Include the second label in the hash key. You must also configure the **label-1** option. The entire first label and the first 16 bits of the second label are used in the hash key.
label-3	M Series, MX Series, T Series	Include the third label in the hash key. You must also configure the **label-1** option and the **label-2** option.
no-labels	All	Excludes MPLS labels from the hash key.
no-label-1-exp	M Series, MX Series, T Series	Excludes the EXP bit of the top label from the hash key. You must also configure the **label-1** option. For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem.
payload	All	Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Router, this value is set by default.
disable	PTX Series	Exclude IP payload from the hash key.
ether-pseudowire	M120, M320, MX Series, T Series	Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
ip	All	Include the IPv4 or IPv6 address in the hash key. You must also configure either **label-1** or **no-labels**.
layer-3-only	All	Include only the Layer 3 IP information in the hash key. Excludes all of the **port-data** bytes from the hash key.

Table 15: MPLS LSP Load Balancing Options (continued)

Statement	Supported Platforms	MPLS LSP Load Balancing Options
port-data	M Series, MX Series, T Series	Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the **source-msb**, **source-lsb**, **destination-msb**, and **destination-lsb** options at the **[edit forwarding-options hash-key family mpls payload ip port-data]** hierarchy level. To prevent all four bytes from being hashed, include the **layer-3-only** statement at the **[edit forwarding-options hash-key family mpls payload ip]** hierarchy level.
destination-lsb	M Series, MX Series, T Series	Include the least significant byte of the destination port in the hash key. Can be combined with any of the other **port-data** options.
destination-msb	M Series, MX Series, T Series	Include the most significant byte of the destination port in the hash key. Can be combined with any of the other **port-data** options.
source-lsb	M Series, MX Series, T Series	Include the least significant byte of the source port in the hash key. Can be combined with any of the other **port-data** options.
source-msb	M Series, MX Series, T Series	Include the most significant byte of the source port in the hash key. Can be combined with any of the other **port-data** options.

The following examples illustrate ways in which you can configure MPLS LSP load balancing:

- To include the IP address as well as the first label in the hash key:
  - For M Series, MX Series, and T Series routers, configure the **label-1** statement and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

    ```
    [edit forwarding-options hash-key family mpls]
    label-1;
    payload {
       ip;
    }
    ```

  - For PTX Series Packet Transport Routers, the **all-labels** and **ip payload** options are configured by default, so no configuration is necessary.
- (M320 and T Series routers only) To include the IP address as well as both the first and second labels in the hash key, configure the **label-1** and **label-2** options and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

  ```
  [edit forwarding-options hash-key family mpls]
  label-1;
  label-2;
  payload {
     ip;
  }
  ```

NOTE: You can include this combination of statements on M320 and T Series routers only. If you include them on an M Series Multiservice Edge Router, only the first MPLS label and the IP payload are used in the hash key.

- For T Series routers, ensure proper load balancing by including the **label-1**, **label-2**, and **label-3** options at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

- (M Series, MX Series, and T Series routers only) For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem. To exclude the EXP bit of the first label from the hash calculations, include the **no-label-1-exp** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
no-label-1-exp;
payload {
   ip;
}
```

Related Documentation

- Configuring Load Balancing for Ethernet Pseudowires on page 792

Configuring Load Balancing Based on MPLS Labels on ACX Series Routers

ACX Series routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops. This feature is enabled on supported platforms by default and requires no configuration.

Load balancing is used to evenly distribute traffic when there is a single next hop over an aggregated interface or a LAG bundle. Load balancing using MPLS labels is supported only for LAG interfaces and not for equal-cost multipath (ECMP) links.

By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across interfaces in an aggregated Ethernet (ae) interface.

An LSP tends to load-balance its placement by randomly selecting one of the interfaces in an **ae-** interface bundle and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

To load-balance based on the MPLS label information, configure the **family mpls** statement:

```
[edit forwarding-options hash-key]
family mpls {
   all-labels;
   label-1;
   label-2;
   label-3;
   no-labels;
   payload {
      ether-pseudowire;
      ip {
         layer-3-only;
         port-data {
            destination-lsb;
            destination-msb;
            source-lsb;
            source-msb;
         }
      }
   }
}
```

You can include this statement at the **[edit forwarding-options hash-key]** hierarchy level.

NOTE: When you configure payload ip (**user@host# set forwarding-options hash-key family mpls payload ip**), configuring **layer-3-only** and **port-data** is mandatory.

Load balancing functionality, without proper hash-keys configuration, may result in an unpredictable behavior.

For Layer 2 VPN/pseudowire tunnel termination, upto two labels are used for hashing and payload MAC destination and source addresses can be optionally selected. These controls can be used to support ether-pseudowire knob in family mpls under hash-key configuration shown above. However, since ACX2000 and ACX4000 also support TDM pseudowires, the ether-pseudowire knobs needs to be used only when TDM pseudowires are not being used.

For Layer 3 VPN tunnel termination, upto two labels are used for hasing and payload IP source and destination addresses and Layer 4 source and destination ports can be optionally selected. These controls can be used for supporting ip port-data knobs in family mpls under hash-key configuration shown above. However, since Layer 4 port MSB and LSB cannot be individually selected, one of destination-lsb or destination-msb

knobs or one of source-lsb or source-msb knobs would select Layer 4 destination or source ports, respectively.

For LSR case, upto three labels are used for hashing. If a BOS is seen when parsing the first three labels, BCM examines the first nibble of payload - if the nibble is 4, the payload is treated as IPv4 and if the first nibble is 6, the payload is treated as IPv6 and in such cases payload source and destination IP addresses can be speculatively used for hashing. These controls can be used for supporting ip port-data knobs in family mpls under hash-key configuration. However, Layer 4 ports cannot be used for hashing in LSR case, and only layer-3-only knob is applicable. BCM does not claim support for hashing on fields beyond the three MPLS labels. Load Balancing for a single pseudowire session does not take place in case of LSR as all the traffic specific to that session will carry the same set of MPLS labels.

Load balancing on LSR AE interfaces can be achieved for a higher number of MPLS sessions, that is minimum of 10 sessions. This is applicable for CCC/VPLS/L3VPN. In case of Layer 3 VPN, the traffic may not be equally distributed across the member links as the layer 3 addresses also get accounted for (along with the labels) for the hash input function.

For LER scenarios, in case of ACX5048 and ACX5096, hashing based on Layer 3 and Layer 4 fields is possible by configuring the payload option under the “family mpls” hierarchy. Hashing on the LER is not be based on Labels. For Layer 3 service, it is mandatory to mention the payload as “layer-3-only” and specify “port-data” in case of Layer 4 service. You can also mention the label count while configuring hash-keys on LER routers.

NOTE: LER and LSR load balancing behavior is applicable for CCC/VPLS/Layer 3 VPN and other IP MPLS scenarios.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces. In addition, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

Table 15 on page 393 provides detailed information about all of the possible MPLS LSP load-balancing options.

Table 16: MPLS LSP Load Balancing Options

Statement	MPLS LSP Load Balancing Options
label-l	Include the first label in the hash key. Use this option for single label packets.
label-2	Include the second label in the hash key. You must also configure the **label-1** option. The entire first label and the first 16 bits of the second label are used in the hash key.
label-3	Include the third label in the hash key. You must also configure the **label-1** option and the **label-2** option.
no-labels	Excludes MPLS labels from the hash key.

Table 16: MPLS LSP Load Balancing Options (continued)

Statement	MPLS LSP Load Balancing Options
payload	Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Switch, this value is set by default.
disable	Exclude IP payload from the hash key.
ether-pseudowire	Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
ip	Include the IPv4 or IPv6 address in the hash key. You must also configure either **label-1** or **no-labels**.
layer-3-only	Include only the Layer 3 IP information in the hash key. Excludes all of the **port-data** bytes from the hash key.
port-data	Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the **source-msb**, **source-lsb**, **destination-msb**, and **destination-lsb** options at the **[edit forwarding-options hash-key family mpls payload ip port-data]** hierarchy level. To prevent all four bytes from being hashed, include the **layer-3-only** statement at the **[edit forwarding-options hash-key family mpls payload ip]** hierarchy level.
destination-lsb	Include the least significant byte of the destination port in the hash key. Can be combined with any of the other **port-data** options.
destination-msb	Include the most significant byte of the destination port in the hash key. Can be combined with any of the other **port-data** options.
source-lsb	Include the least significant byte of the source port in the hash key. Can be combined with any of the other **port-data** options.
source-msb	Include the most significant byte of the source port in the hash key. Can be combined with any of the other **port-data** options.

To include the IP address as well as the first label in the hash key, configure the **label-1** statement and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
payload {
   ip;
}
```

To include the IP address as well as both the first and second labels in the hash key, configure the **label-1** and **label-2** options and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
payload {
```

```
    ip;
}
```

Ensure proper load balancing by including the **label-1**, **label-2**, and **label-3** options at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

Example: Configuring a Constrained-Path LSP for Which Junos OS Makes All Forwarding Decisions

On the ingress router, create a constrained-path LSP in which the Junos OS makes all the forwarding decisions. When the LSP is successfully set up, a route toward 10.1.1.1/32 is installed in the inet.3 table so that all BGP routes with matching BGP next-hop addresses can be forwarded through the LSP.

```
[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
    rsvp {
        interface so-0/0/0;
    }
    mpls {
        label-switched-path to-hastings {
            to 10.1.1.1;
        }
        interface so-0/0/0;
    }
}
```

Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most Forwarding Decisions and Considers Hop Constraints

On the ingress router, create a constrained-path LSP in which the Junos OS makes most of the forwarding decisions, taking into account the hop constraints listed in the **path** statements. The LSP is adaptive so that no bandwidth double-counting occurs on links shared by primary and secondary paths. To acquire the necessary link bandwidth, this

LSP is allowed to preempt lower priority sessions. Finally, this path always keeps the secondary path in hot-standby state for quick failover.

```
[edit protocols]
mpls {
   path to-hastings {
      14.1.1.1 loose;
   }
   path alt-hastings {
      12.1.1.1 loose;
      11.1.1.1 strict;
   }
   label-switched-path hastings {
      to 11.1.1.1;
      bandwidth 10m; # Reserve 10 Mbps
      priority 0 0; # Preemptive, but not preemptable
      adaptive; # Set adaptivity
      primary to-hastings;
      secondary alt-hastings {
         standby;
         bandwidth 1m; # Reserve only 1 Mbps for the secondary path
      }
   }
   interface all;
}
```

Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most Forwarding Decisions and the Secondary Path Is Explicit

On the ingress router, create a constrained-path LSP in which the Junos OS makes most of the forwarding decisions for the primary path, subject to constraints of the path **to-hastings**, and in which the secondary path is an explicit path. The primary path must transit green or yellow links and must stay away from red links. The primary path is periodically recomputed and reoptimized. Finally, this path always keeps the secondary path in hot-standby state for quick failover.

When the LSP is up—either because the primary or secondary path is up, or because both paths are up—the prefix 16.0.0.0/8 is installed in the inet.3 table so that all BGP routes whose BGP next hop falls within that range can use the LSP. Also, the prefix 17.0.0.0/8 is installed in the inet.0 table so that BGP can resolve only its next hop through that prefix. The route also can be reached with the **traceroute** or **ping** command. These two routes are in addition to the 11.1.1.1/32 route.

```
[edit protocols]
mpls {
   admin-groups {
      green 1;
      yellow 2;
      red 3;
   }
   path to-hastings {
      14.1.1.1 loose;
```

```
    }
    path alt-hastings {
      14.1.1.1 strict;
      13.1.1.1 strict;
      12.1.1.1 strict;
      11.1.1.1 strict;
    }
    label-switched-path hastings {
      to 11.1.1.1;
      bandwidth 100m;
      install 16.0.0.0/8; # in inet.3; cannot use to traceroute or ping
      install 17.0.0.0/8 active; # installed in inet.0; can use to traceroute or ping
      primary to-hastings {
        admin-group { # further constraints for path computation
        include-all [ green yellow ];
        exclude red;
      }
      optimize-timer 3600; # reoptimize every hour
    }
    secondary alt-hastings {
      standby;
      no-cspf; # do not perform constrained-path computation
    }
}
interface all;
```

Path Computation for LSPs on an Overloaded Router

Setting the overload bit in a router running IS-IS causes it to appear overloaded and prevents it from being used for transit traffic. Any new MPLS LSPs, including RSVP-signaled or LDP-signaled LSPs, are re-reouted away from an overloaded router. In the case of RSVP, this behavior applies to both Constrained Shortest Path First (CSPF) and non-CSPF LSPs. However, this behavior does not apply to new or existing bypass LSPs. Bypass LSPs are recalculated only when a different event triggers a path recalculation. For example, if you set the smart optimize timer with the smart-optimize-timer statement, the bypass LSP is rerouted away from the overloaded router only after the specified time elapses. Otherwise, the bypass LSP continues to transit the overloaded router.

You cannot establish any new transit LSPs through an overloaded router. However, you can configure ingress and egress LSPs through an overloaded router.

NOTE: When you set the overload bit on an IS-IS router, any new LSPs transiting through it are recomputed and re-routed away from it. However, existing CSPF LSPs remain active and are not torn down.

An example of when you might want to establish transit LSPs through an overloaded router is illustrated in Figure 37 on page 402, which shows an aggregation router (Router A) dual-homed on two core routers (Router B and Router C). You want to include the aggregation router in the LSP mesh, but transit LSPs should not pass through it,

because it is a less capable router with relatively low-bandwidth uplinks to the core. Certain failure and rerouting scenarios could make it impossible for the aggregation router to establish some of its LSPs. Consequently, you run the router in a steady state with the overload bit set, but you are still able to establish ingress and egress LSPs through it.

Computing Backup Paths for LSPs Using Fate Sharing

Fate sharing allows you to create a database of information that CSPF uses to compute one or more backup paths to use in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. You can specify one or more elements within a group.

Through fate sharing, you can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible, to ensure that if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path, ensuring that a single point of failure will not affect the primary and backup paths simultaneously.

Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts

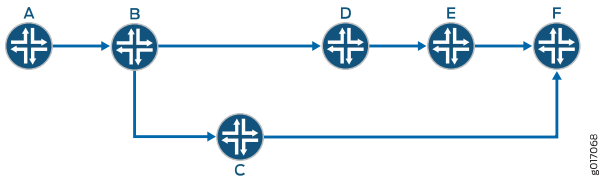
Link-state protocols, such as OSPF and IS-IS, use the shortest-path-first (SPF) algorithm to compute the shortest-path tree to all nodes in the network. The results of such computations can be represented by the destination node, next-hop address, and output interface, where the output interface is a physical interface. Label-switched paths (LSPs) can be used to augment the SPF algorithm.

IGP typically performs two independent computations. The first is performed without considering any LSP. The result of the computation is stored in the inet.0 table. This step is no different from traditional SPF computations and is always performed even if IGP shortcut is disabled.

The second computation is performed considering only LSPs as a logical interface. Each LSP's egress router is considered. The list of destinations whose shortest path traverses the egress router (established during the first computation) is placed in the inet.3 routing table. These destinations are given the egress router of the LSP as a next hop, enabling BGP on the local router to use these LSPs to access BGP next hops beyond the egress router. Normally, BGP can use only LSPs that terminate at the BGP next hop.

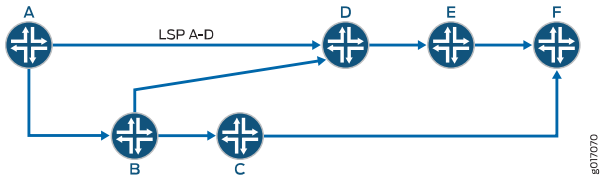
As an illustration, begin with a typical SPF tree (see Figure 38 on page 403).

Figure 38: Typical SPF Tree, Sourced from Router A



If an LSP connects Router A to Router D and if IGP shortcuts are enabled on Router A, you might have the SPF tree shown in Figure 39 on page 403.

Figure 39: Modified SPF Tree, Using LSP A–D as a Shortcut



Note that Router D is now reachable through LSP A–D.

When computing the shortest path to reach Router D, Router A has two choices:

- Use IGP path A–B–D.
- Use LSP A–D.

Router A decides between the two choices by comparing the IGP metrics for path A–B–D with the LSP metrics for LSP A–D. If the IGP metric is lower, path A–B–D is chosen (Figure 38 on page 403). This path A–B–D is valid only when node D is not the tail-end of the LSP. If node D is the tail end of the LSP, even if the LSP metric is lower or both IGP and LSP metrics are equal, LSP A–D is used (Figure 39 on page 403).

Note that Router E is reachable through LSP A–D and Router F will take the IGP path.

Enabling IGP Shortcuts

IGP shortcuts are supported for both IS-IS and OSPF. A link-state protocol is required for IGP shortcuts. Shortcuts are disabled by default. You can enable IGP shortcuts on a per-router basis; you do not need to enable shortcuts globally. A router's shortcut computation does not depend on another router performing similar computations, and shortcuts performed by other routers are irrelevant.

Related Documentation

- *Example: Enabling IS-IS Traffic Engineering Support*
- *Example: Enabling OSPF Traffic Engineering Support*
- Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts on page 402

LSPs Qualified in IGP Shortcut Computations

Not all LSPs are used in IGP shortcuts. Only those LSPs whose egress point (using the **to** statement) matches the router ID of the egress node are considered. Other LSPs, whose egress point matches the egress node interface address, are ignored in IGP shortcuts.

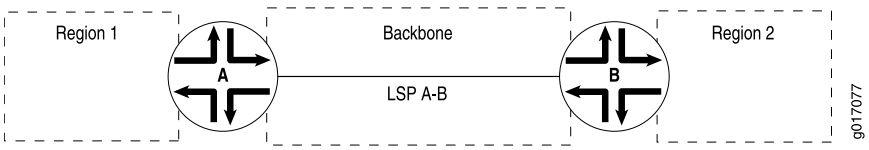
There are exceptions, however. If an LSP has an alias egress point (using the **install** statement) and it matches certain router IDs, it is included in the shortcut computation as well. If multiple equal metric LSPs destined to the same router ID exist, traffic can load-share among them.

IGP Shortcut Applications

You can use shortcuts to engineer traffic traveling toward destination nodes that do not support MPLS LSPs. For example, in Figure 39 on page 403, traffic traveling toward Router F enters LSP A–E. You can control traffic between Router A and Router F by manipulating LSP A–E; you do not need to explicitly set up an LSP between Router A and Router F.

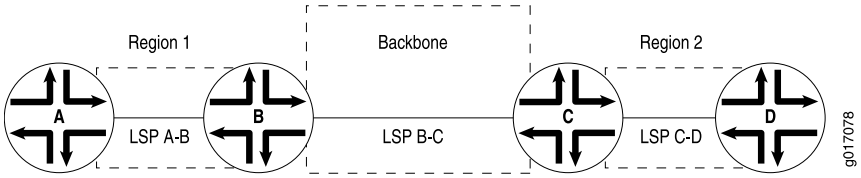
In Figure 40 on page 404, all traffic from Region 1 to Region 2 traverses LSP A–B if IGP shortcuts are enabled on the ingress router (Router A), permitting aggregation of interregional traffic into one LSP. To perform traffic engineering on the interregional traffic, you have to manipulate LSP A-B only, which avoids creating n2 LSPs from all routers in Region 1 to all routers in Region 2 and allows efficient resource controls on the backbone network.

Figure 40: IGP Shortcuts



Shortcuts allow you to deploy LSPs into a network in an incremental, hierarchical fashion. In Figure 41 on page 405, each region can choose to implement traffic engineering LSPs independently, without requiring cooperation from other regions. Each region can choose to deploy intraregion LSPs to fit the region's bandwidth needs, at the pace appropriate for the region.

Figure 41: IGP Shortcuts in a Bigger Network



When intraregion LSPs are in place, interregional traffic automatically traverses the intraregion LSPs as needed, eliminating the need for a full mesh of LSPs between edge routers. For example, traffic from Router A to Router D traverses LSPs A–B, B–C, and C–D.

IGP Shortcuts and Routing Tables

IGP typically performs two independent computations. The first is performed without considering any LSP. The result of the computation is stored in the inet.0 table. This step is no different from traditional SPF computations and is always performed even if IGP shortcut is disabled.

The second computation is performed considering only LSPs as a logical interface. Each LSP's egress router is considered. The list of destinations whose shortest path traverses the egress router (established during the first computation) is placed in the inet.3 routing table. These destinations are given the egress router of the LSP as a next hop, enabling BGP on the local router to use these LSPs to access BGP next hops beyond the egress router. Normally, BGP can use only LSPs that terminate at the BGP next hop. Note that BGP is the only protocol that uses the inet.3 routing table. Other protocols will not route traffic through these LSPs.

If traffic engineering for IGP and BGP is enabled (see "IGP and BGP Destinations" on page 18), IGP moves all routes in inet.3 into inet.0, merging all routes while emptying the inet.3 table. The number of routes in inet.0 will be exactly the same as before. Route next-hops can traverse a physical interface, an LSP, or the combination of the two if the metrics are equal.

IGP shortcuts are enabled on a per-node basis. You do not need to coordinate with other nodes.

IGP Shortcuts and VPNs

You can configure IGP shortcuts for either IS-IS or OSPF. IGP shortcuts allow the IGP to use an LSP as the next hop instead of the IGP route. IGP shortcuts can also be enabled for VPNs by also specifying the **bgp-igp-both-ribs** or **mpls-forwarding** options for the **traffic-engineering** statement at the **[edit protocols mpls]** hierarchy level. VPNs are dependant on routes stored in the inet.3 routing table. The **bgp-igp** option for the

traffic-engineering statement moves all routes from the inet.3 routing table to the inet.0 routing table and is therefore incompatible with VPNs.

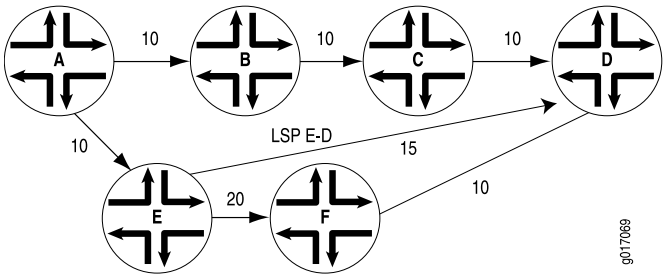
Advertising LSPs into IGPs

You can configure your IGP to treat an LSP as a link. IGP shortcuts allow only the ingress router of an LSP to use the LSP in its SPF computation. However, other routers on the network do not know of the existence of that LSP, so they cannot use it. This can lead to suboptimal traffic engineering. In addition, only BGP can use an IGP shortcut to an LSP. When you advertise an LSP as a link into the IGP, all traffic can traverse it, and all routers know about it.

As an example, consider the network shown in Figure 42 on page 406.

Figure 42: SPF Computations with Advertised LSPs



Assume that Router A is computing a path to Router D. The link between Router E and Router F has a metric of 20; all other links have a metric of 10. Here, the path chosen by Router A is A–B–C–D, which has a metric of 30, instead of A–E–F–D, which has a metric of 40.

If Router E has an LSP to Router D with a metric of 15, you want traffic from Router A to Router D to use the path A–E–D, which has a metric of 25, instead of the path A–B–C–D. However, because Router A does not know about the LSP between Router E and Router D, it cannot route traffic through this path.

For all routers on the network to know about the LSP between Router E and Router D, you need to advertise it. This advertisement announces the LSP as a unidirectional, point-to-point link in the link-state database, and all routers can compute paths using the LSP. The link-state database maintains information about the AS topology and contains information about the router's local state (for example, the router's usable interfaces and reachable neighbors). In Figure 42 on page 406, Router A will see the link from Router E to Router D and route traffic along this lower-metric path.

Because an LSP is announced as a unidirectional link, you might need to configure a reverse LSP (one that starts at the egress router and ends at the ingress router) so that

the SPF bidirectionality check succeeds. As a step in the SPF computation, IS-IS considers a link from Router E to Router D. Before IS-IS uses any link, it verifies that there is a link from Router D to Router E (there is bidirectional connectivity between router E and D). Otherwise, the SPF computation will not use an announced LSP.

When an LSP is advertised to the IGP, the advertising router uses the LSP as the forwarding path for regular routes after installing them in the inet.0 routing table. All packets traversing the router could be forwarded through the LSP. Conversely, IGP shortcuts are used only to forward packets that are following BGP routes.

NOTE: Do not configure IGP shortcuts and advertise LSPs to the IGP at the same time.

Selecting a Forwarding LSP Next Hop

If more than one LSP tunnel to a BGP next hop exists, the prefixes learned from the BGP next hop are randomly divided among the LSP tunnels. To control which LSP BGP uses to forward data for a given prefix, use the **install-nexthop** statement in the export policy applied to the forwarding table.

Example: Assigning Different Forwarding Next-Hop LSPs to Different Destination Prefixes

Assign different forwarding next-hop LSPs to different destination prefixes learned from BGP.

```
routing-options {
   router-id 10.10.20.101;
   autonomous-system 2;
   forwarding-table {
      export forwarding-policy;
   }
}
policy-options {
   policy-statement forwarding-policy {
      term one {
         from {
            protocol bgp;
            route-filter 10.1.0.0/16 orlonger;
         }
         then {
            install-nexthop lsp mc-c-lsp-1;
            accept;
         }
      }
```

```
      term two {
        from {
          protocol bgp;
          route-filter 10.2.0.0/16 orlonger;
        }
        then {
          install-nexthop lsp mc-c-lsp-2;
          accept;
        }
      }
      term three {
        from {
          protocol bgp;
          route-filter 10.3.0.0/16 orlonger;
        }
        then {
          install-nexthop lsp mc-c-lsp-3;
          accept;
        }
      }
    }
  }
  protocols {
    mpls {
      label-switched-path mc-c-lsp-1 {
        from 10.10.20.101;
        to 10.10.20.103;
      }
      label-switched-path mc-c-lsp-2 {
        from 10.10.20.101;
        to 10.10.20.103;
      }
      label-switched-path mc-c-lsp-3 {
        from 10.10.20.101;
        to 10.10.20.103;
      }
    }
  }
```

ECMP Flow-Based Forwarding on ACX Series Routers

An equal-cost multipath (ECMP) set is formed when the routing table contains multiple next-hop addresses for the same destination with equal cost. (Routes of equal cost have the same preference and metric values.) If there is an ECMP set for the active route, the Junos OS software uses a hash algorithm to choose *one* of the next-hop addresses in the ECMP set to install in the forwarding table.

You can configure the Junos OS so that multiple next-hop entries in an ECMP set are installed in the forwarding table. On ACX Series routers, per-flow load balancing can be performed to spread traffic across multiple paths between routing devices. ECMP flow-based forwarding is supported for IPv4, IPv6, and MPLS packets on aggregated Ethernet (ae) interfaces.

Load balancing is used to evenly distribute traffic when there are multiple equal-cost next hops over different interfaces or a single next hop over an aggregated interface. By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table.

If a next-hop address is no longer part of the ECMP set or if it is removed from the routing table because of a route change, a flow that uses the next hop is rerouted and the session is not affected. Rerouting of the flow also occurs if there is a configuration change that takes away the next-hop address or if an administrator takes down the next-hop interface without deleting it. If a next-hop address is removed from the routing table because the interface is deleted or the session is intentionally cleared, the session is killed without being rerouted.

To select which packet header data to use for per-flow load balancing, include the **hash-key** statement at the **[edit forwarding-options]** hierarchy level. To load-balance IPv4 traffic by using the port data into the hash key, include the **family-inet** statement at the **[edit forwarding-options hash-key]** hierarchy level. You can incorporate either the Layer 3 IP port data, or the Layer 4 TCP or UDP port data into the hash key. To load-balance based on the MPLS label information, configure the **family mpls** statement at the **[edit forwarding-options hash-key]** hierarchy level.

Forwarding of MPLS traffic by using penultimate-hop popping (PHP) and label-switched routing (LSR) is not supported on ACX Series routers. For ECMP flow-based forwarding over pseudowires, MPLS flows are assigned to one of the ECMP routes by using the hashing algorithm based on user-to-network interface (UNI) index.

To configure ECMP flow-based forwarding on ACX Series routers, first define a load-balancing routing policy by including one or more **policy-statement** configuration statements at the [**edit policy-options**] hierarchy level, with the action **load-balance per-packet**. Then apply the routing policy to routes exported from the routing table to the forwarding table. To do this, include the **forwarding-table** and **export** configuration statements at the [**edit routing-options**] hierarchy level.

To view the details of the ECMP next hops and to obtain information for debugging any problem with the ECMP functionality, issue the **show route** or the **show route summary** command.

The maximum number of next-hop addresses in an ECMP set that can be installed in the forwarding table of ACX Series routers is 16. A maximum of 2047 ECMP next-hops are supported.

CHAPTER 13

MPLS LSP Routers

Routers in an LSP

Each router in an LSP performs one of the following functions:

- Ingress router—The router at the beginning of an LSP. This router encapsulates IP packets with an MPLS Layer 2 frame and forwards it to the next router in the path. Each LSP can have only one ingress router.
- Egress router—The router at the end of an LSP. This router removes the MPLS encapsulation, thus transforming it from an MPLS packet to an IP packet, and forwards the packet to its final destination using information in the IP forwarding table. Each LSP can have only one egress router. The ingress and egress routers in an LSP cannot be the same router.
- Transit router—Any intermediate router in the LSP between the ingress and egress routers. A transit router forwards received MPLS packets to the next router in the MPLS path. An LSP can contain zero or more transit routers, up to a maximum of 253 transit routers in a single LSP.

A single router can be part of multiple LSPs. It can be the ingress or egress router for one or more LSPs, and it also can be a transit router in one or more LSPs. The functions that each router supports depend on your network design.

Configuring the Ingress and Egress Router Addresses for LSPs

The following sections describe how to specify the addresses of an LSP's ingress and egress routers:

Configuring the Ingress Router Address for LSPs

The local router always is considered to be the ingress router, which is the beginning of the LSP. The software automatically determines the proper outgoing interface and IP address to use to reach the next router in an LSP.

By default, the router ID is chosen as the address of the ingress router. To override the automatic selection of the source address, specify a source address in the **from** statement:

```
from address;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

The outgoing interface used by the LSP is not affected by the source address that you configure.

Configuring the Egress Router Address for LSPs

When configuring an LSP, you must specify the address of the egress router by including the **to** statement:

```
to address;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** static-label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** static-label-switched-path ***lsp-name*****]**

When you are setting up a signaled LSP, the **to** statement is the only required statement. All other statements are optional.

After the LSP is established, the address of the egress router is installed as a host route in the routing table. This route can then be used by BGP to forward traffic.

To have the software send BGP traffic over an LSP, the address of the egress router is the same as the address of the BGP next hop. You can specify the egress router's address as any one of the router's interface addresses or as the BGP router ID. If you specify a different address, even if the address is on the same router, BGP traffic is not sent over the LSP.

To determine the address of the BGP next hop, use the **show route detail** command. To determine the destination address of an LSP, use the **show mpls lsp** command. To determine whether a route has gone through an LSP, use the **show route** or **show route forwarding-table** command. In the output of these last two commands, the **label-switched-path** or **push** keyword included with the route indicates it has passed through an LSP. Also, use the **traceroute** command to trace the actual path to which the route leads. This is another indication whether a route has passed through an LSP.

You also can manipulate the address of the BGP next hop by defining a BGP import policy filter that sets the route's next-hop address.

Preventing the Addition of Egress Router Addresses to Routing Tables

You must configure an address using the **to** statement for all LSPs. This address is always installed as a **/32** prefix in the inet.3 or inet.0 routing tables. You can prevent the egress router address configured using the **to** statement from being added to the inet.3 and inet.0 routing tables by including the **no-install-to-address** statement.

Some reasons not to install the **to** statement address in the inet.3 and inet.0 routing tables include the following:

- Allow Constrained Shortest Path First (CSPF) RSVP LSPs to be mapped to traffic intended for secondary loopback addresses. If you configure an RSVP tunnel, including the **no-install-to-address** statement, and then configure an **install pfx/ <active>** policy later, you can do the following:
  - Verify that the LSP was set up correctly without impacting traffic.
  - Map traffic to the LSP in incremental steps.
  - Map traffic to the destination loopback address (the BGP next hop) by removing the **no-install-to-address** statement once troubleshooting is complete.
- Prevent CCC connections from losing IP traffic. When an LSP determines that it does not belong to a connection, it installs the address specified with the **to** statement in the inet.3 routing table. IP traffic is then forwarded to the CCC remote endpoint, which can cause some types of PICs to fail.

To prevent the egress router address configured using the **to** statement from being added to the inet.3 and inet.0 routing tables, include the **no-install-to-address** statement:

```
no-install-to-address;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** static-label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** static-label-switched-path ***lsp-name*****]**

Configuring the Ingress Router for MPLS-Signaled LSPs

MPLS-signaled label-switched paths (LSPs) run from a specific ingress router to a specific egress router. For basic MPLS-signaled LSP function, you must configure the ingress router, but do not have to configure any other routers.

To configure signaled LSPs, perform the following tasks on the ingress router:

- Creating Named Paths on page 414
- Configuring Alternate Backup Paths Using Fate Sharing on page 416

Creating Named Paths

To configure signaled LSPs, you must first create one or more named paths on the ingress router. For each path, you can specify some or all transit routers in the path, or you can leave it empty.

Each pathname can contain up to 32 characters and can include letters, digits, periods, and hyphens. The name must be unique within the ingress router. Once a named path is created, you can use the named path with the **primary** or **secondary** statement to configure LSPs at the **[edit protocols mpls label-switched-path** ***label-path-name*****]** hierarchy level. You can specify the same named path on any number of LSPs.

To determine whether an LSP is associated with the primary or secondary path in an RSVP session, issue the show rsvp session **detail** command.

To create an empty path, create a named path by including the following form of the **path** statement. This form of the **path** statement is empty, which means that any path between the ingress and egress routers is accepted. In actuality, the path used tends to be the same path as is followed by destination-based, best-effort traffic.

```
path path-name;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls]**

To create a path in which you specify some or all transit routers in the path, include the following form of the **path** statement, specifying one address for each transit router:

```
path path-name {
```

```
    (address | hostname) <strict | loose>;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

In this form of the **path** statement, you specify one or more transit router addresses. Specifying the ingress or egress routers is optional. You can specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path up to the egress router (optional) or the router immediately before the egress router. You need to specify only one address per router hop. If you specify more than one address for the same router, only the first address is used; the additional addresses are ignored and truncated.

For each router address, you specify the type, which can be one of the following:

- **strict**—(Default) The route taken from the previous router to this router is a direct path and cannot include any other routers. If ***address*** is an interface address, this router also ensures that the incoming interface is the one specified. Ensuring that the incoming interface is the one specified is important when there are parallel links between the previous router and this router. It also ensures that routing can be enforced on a per-link basis.

  For strict addresses, you must ensure that the router immediately preceding the router you are configuring has a direct connection to that router. The address can be a loopback interface address, in which case the incoming interface is not checked.

- **loose**—The route taken from the previous router to this router need not be a direct path, can include other routers, and can be received on any interface. The address can be any interface address or the address of the loopback interface.

Examples: Creating Named Paths

Configure a path, **to-hastings**, to specify the complete strict path from the ingress to the egress routers through **14.1.1.1**, **13.1.1.1**, **12.1.1.1**, and **11.1.1.1**, in that order. There cannot be any intermediate routers except the ones specified. However, there can be intermediate routers between **11.1.1.1** and the egress router because the egress router is not specifically listed in the **path** statement. To prevent intermediate routers before egress, configure the egress router as the last router, with a **strict** type.

```
[edit protocols mpls]
path to-hastings {
    14.1.1.1 strict;
    13.1.1.1 strict;
    12.1.1.1 strict;
    11.1.1.1 strict;
}
```

Create a path, **alt-hastings**, to allow any number of intermediate routers between routers **14.1.1.1** and **11.1.1.1**. In addition, intermediate routers are permitted between **11.1.1.1** and the egress router.

```
[edit protocols mpls]
path alt-hastings {
   14.1.1.1 strict;
   11.1.1.1 loose;
}
```

Configuring Alternate Backup Paths Using Fate Sharing

You can create a database of information that Constrained Shortest Path First (CSPF) uses to compute one or more backup paths in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. Because these network elements share the same fate, this relationship is called fate sharing.

You can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible to ensure that, if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path. This ensures that a single point of failure will not affect the primary and backup paths at the same time.

The following sections describe how to configure fate sharing and how it affects CSPF, and provides a fate sharing configuration example:

- Configuring Fate Sharing on page 416
- Implications for CSPF on page 417
- Implications for CSPF When Fate Sharing with Bypass LSPs on page 418
- Example: Configuring Fate Sharing on page 418

Configuring Fate Sharing

To configure fate sharing, include the **fate-sharing** statement:

```
fate-sharing {
   group group-name {
      cost value;
      from address <to address>;
   }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Each fate-sharing group must have a name, which can be up to 32 characters long and can contain letters, digits, periods (.) and hyphens (-). You can define up to 512 groups.

Fate-sharing groups contain three types of objects:

- Point-to-point links—Identified by the IP addresses at each end of the link. Unnumbered point-to-point links are typically identified by borrowing IP addresses from other interfaces. Order is not important; **from 1.2.3.4 to 1.2.3.5** and **from 1.2.3.5 to 1.2.3.4** have the same meaning.
- Non-point-to-point links—Include links on a LAN interface (such as Gigabit Ethernet interfaces) or nonbroadcast multiaccess (NBMA) interfaces (such as Asynchronous Transfer Mode [ATM] or Frame Relay). You identify these links by their individual interface address. For example, if the LAN interface **192.168.200.0/24** has four routers attached to it, each router link is individually identified:

  ```
  from 192.168.200.1; # LAN interface of router 1
  from 192.168.200.2; # LAN interface of router 2
  from 192.168.200.3; # LAN interface of router 3
  from 192.168.200.4; # LAN interface of router 4
  ```

  You can list the addresses in any order.
- A router node—Identified by its configured router ID.

All objects in a group share certain similarities. For example, you can define a group for all fibers that share the same fiber conduit, all optical channels that share the same fiber, all links that connect to the same LAN switch, all equipment that shares the same power source, and so on. All objects are treated as /32 host addresses.

For a group to be meaningful, it should contain at least two objects. You can configure groups with zero or one object; these groups are ignored during processing.

An object can be in any number of groups, and a group can contain any number of objects. Each group has a configurable cost attributed to it, which represents the level of impact this group has on CSPF computations. The higher the cost, the less likely a backup path will share with the primary path any objects in the group. The cost is directly comparable to traffic engineering metrics. By default, the cost is 1. Changing the fate-sharing database does not affect established LSPs until the next reoptimization of CSPF. The fate-sharing database does influence fast-reroute computations.

Implications for CSPF

When CSPF computes the primary paths of an LSP (or secondary paths when the primary path is not active), it ignores the fate-sharing information. You always want to find the best possible path (least IGP cost) for the primary path.

When CSPF computes a secondary path while the primary path (of the same LSP) is active, the following occurs:

1. CSPF identifies all fate-sharing groups that are associated with the primary path. CSPF does this by identifying all links and nodes that the primary path traverses and compiling group lists that contain at least one of the links or nodes. CSPF ignores the ingress and egress nodes in the search.
2. CSPF checks each link in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group. If a link is a member of multiple groups, all group costs are added together.

3. CSPF performs the check for every node in the traffic engineering database, except the ingress and egress node. Again, a node can belong to multiple groups, so costs are additive.
4. The router performs regular CSPF computation with the adjusted topology.

Implications for CSPF When Fate Sharing with Bypass LSPs

When fate sharing is enabled with link protection or link-node protection, CSPF operates as follows when calculating the bypass LSP path:

- CSPF identifies the fate-sharing groups that are associated with the primary LSP path. CSPF does this by identifying the immediate downstream link and immediate downstream nodes that the bypass is trying to protect. CSPF compiles group lists that contain the immediate downstream link and immediate downstream nodes.
- CSPF checks each link (from ingress to the immediate downstream node) in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group.
- CSPF identifies the downstream link that is not in the fate-shared path.

This calculation prevents bypasses from using the same physical link as the primary LSP path when viable alternatives are available.

Example: Configuring Fate Sharing

Configure fate-sharing groups **east** and **west**. Because **west** has no objects, it is ignored during processing.

```
[edit routing-options]
fate-sharing {
   group east {
      cost 20; # Optional, default value is 1
      from 1.2.3.4 to 1.2.3.5; # A point-to-point link
      from 192.168.200.1; # LAN interface
      from 192.168.200.2; # LAN interface
      from 192.168.200.3; # LAN interface
      from 192.168.200.4; # LAN interface
      from 10.168.1.220; # Router ID of a router node
      from 10.168.1.221; # Router ID of a router node
   }
   group west {
      .....
   }
}
```

Configuring the Intermediate and Egress Routers for MPLS-Signaled LSPs

To configure signaled LSPs on all MPLS routers that should participate in MPLS, you need to enable MPLS and RSVP on these routers.

Related Documentation

- MPLS Configuration Overview on page 37
- *Minimum RSVP Configuration*

Configuring the Connection Between Ingress and Egress Routers

The ingress router might make many attempts to connect and reconnect to the egress router using the primary path. You can control how often the ingress router tries to establish a connection using the primary path and how long it waits between retry attempts.

The retry timer configures how long the ingress router waits before trying to connect again to the egress router using the primary path. The default retry time is 30 seconds. The time can be from 1 through 600 seconds. To modify this value, include the **retry-timer** statement:

```
retry-timer seconds;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

By default, no limit is set to the number of times an ingress router attempts to establish or reestablish a connection to the egress router using the primary path. To limit the number of attempts, include the **retry-limit** statement:

```
retry-limit number;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

The limit can be a value up to 10,000. When the retry limit is exceeded, no more attempts are made to establish a path connection. At this point, intervention is required to restart the primary path.

If you set a retry limit, it is reset to 1 each time a successful primary path is created.

Pinging LSPs

The following sections describe how to use the **ping mpls** command to confirm LSP functioning.

- Pinging MPLS LSPs on page 420
- Pinging Point-to-Multipoint LSPs on page 420
- Pinging the Endpoint Address of MPLS LSPs on page 420

Pinging MPLS LSPs

You can ping a specific LSP. Echo requests are sent over the LSP as MPLS packets. The payload is a User Datagram Protocol (UDP) packet forwarded to an address in the 127/8 range (127.0.0.1 by default, this address is configurable) and port 3503. The label and interface information for building and sending this information as an MPLS packet is the same as for standard LSP traffic.

When the echo request arrives at the egress node, the receiver checks the contents of the packet and sends a reply containing the correct return value, by using UDP. The router sending the echo request waits to receive an echo reply after a timeout of 2 seconds (you cannot configure this value).

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router to be able to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

To ping an MPLS LSP use the **ping mpls <count *count*> <ldp <fec>> <rsvp <exp *forwarding-class*> <*lsp-name*>>** command. To ping a secondary MPLS LSP, use the **ping mpls <count *count*> <rsvp <*lsp-name*>> standby *path-name*** command. For a detailed description of this command, see the CLI Explorer.

NOTE: The **ping mpls** command is not supported within routing instances.

NOTE: Self-ping is supported for the master instance and not supported for VLAN-based LSPs or LSPs used in CCC. The message is displayed for each LSP and reduces the readability of the configuration.

Pinging Point-to-Multipoint LSPs

To ping a point-to-multipoint LSP, use the **ping mpls rsvp *lsp-name* multipoint** or **ping mpls rsvp egress *address*** commands. The **ping mpls rsvp *lsp-name* multipoint** command returns a list of all of the egress router identifiers and the current status of the point-to-multipoint LSP egress routers. The **ping mpls rsvp *lsp-name* multipoint egress *address*** command returns the current status of the specified egress router.

Pinging the Endpoint Address of MPLS LSPs

To determine whether an LSP between two provider edge (PE) routers is up and running, you can ping the endpoint address of the LSP. To ping an MPLS LSP endpoint, use the **ping mpls lsp-end-point *address*** command. This command tells you what type of LSP (RSVP or LDP) terminates at the address specified and whether that LSP is up or down.

For a detailed description of this command, see the CLI Explorer.

Pinging CCC LSPs

You can ping a specific CCC LSP. The CCC LSP ping command is identical to the one used for MPLS LSPs. The command you use is **ping mpls <count *count*> <rsvp <*lsp-name*>>**. You can also ping a secondary standby CCC LSP by using the **ping mpls <count *count*> <rsvp <*lsp-name*>> standby *path-name*** command.

For a detailed description of this command, see the CLI Explorer.

Pinging Layer 3 VPNs

You can use a similar command, **ping mpls l3vpn *vpn-name* prefix *prefix* <count *count*>**, to ping a Layer 3 VPN. For more information about this command, see the *Junos OS VPNs Library for Routing Devices* and the CLI Explorer.

Support for LSP Ping and Traceroute Commands Based on RFC 4379

The Junos OS supports LSP **ping** and **traceroute** commands based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

LSP **ping** and **traceroute** commands based on RFC 4379 attempt to trace the path taken by an LSP by relying on MPLS TTL expiration. An LSP can take multiple paths from ingress to egress. This occurs in particular with Equal Cost Multipath (ECMP). The LSP **traceroute** command can trace all possible paths to an LSP node.

CHAPTER 14

Configuring MPLS LSPs

Configuring LSP Metrics

The LSP metric is used to indicate the ease or difficulty of sending traffic over a particular LSP. Lower LSP metric values (lower cost) increase the likelihood of an LSP being used. Conversely, high LSP metric values (higher cost) decrease the likelihood of an LSP being used.

The LSP metric can be specified dynamically by the router or explicitly by the user as described in the following sections:

Configuring Dynamic LSP Metrics

If no specific metric is configured, an LSP attempts to track the IGP metric toward the same destination (the **to** address of the LSP). IGP includes OSPF, IS-IS, Routing Information Protocol (RIP), and static routes. BGP and other RSVP or LDP routes are excluded.

For example, if the OSPF metric toward a router is 20, all LSPs toward that router automatically inherit metric 20. If the OSPF toward a router later changes to a different value, all LSP metrics change accordingly. If there are no IGP routes toward the router, the LSP raises its metric to 65,535.

Note that in this case, the LSP metric is completely determined by IGP; it bears no relationship to the actual path the LSP is currently traversing. If LSP reroutes (such as through reoptimization), its metric does not change, and thus it remains transparent to users. Dynamic metric is the default behavior; no configuration is required.

Configuring Static LSP Metrics

You can manually assign a fixed metric value to an LSP. Once configured with the **metric** statement, the LSP metric is fixed and cannot change:

```
metric number;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** static-label-switched-path ***lsp-name*****]**

- **[edit logical-systems *logical-system-name* protocols mpls** label-switched-path ***lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls** static-label-switched-path ***lsp-name*]**

The LSP metric has several uses:

- When there are parallel LSPs with the same egress router, the metrics are compared to determine which LSP has the lowest metric value (the lowest cost) and therefore the preferred path to the destination. If the metrics are the same, the traffic is shared.

  Adjusting the metric values can force traffic to prefer some LSPs over others, regardless of the underlying IGP metric.

- When an IGP shortcut is enabled (see "Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts" on page 402), an IGP route might be installed in the routing table with an LSP as the next hop, if the LSP is on the shortest path to the destination. In this case, the LSP metric is added to the other IGP metrics to determine the total path metric. For example, if an LSP whose ingress router is X and egress router is Y is on the shortest path to destination Z, the LSP metric is added to the metric for the IGP route from Y to Z to determine the total cost of the path. If several LSPs are potential next hops, the total metrics of the paths are compared to determine which path is preferred (that is, has the lowest total metric). Or, IGP paths and LSPs leading to the same destination could be compared by means of the metric value to determine which path is preferred.

  By adjusting the LSP metric, you can force traffic to prefer LSPs, prefer the IGP path, or share the load among them.

- If router X and Y are BGP peers and if there is an LSP between them, the LSP metric represents the total cost to reach Y from X. If for any reason the LSP reroutes, the underlying path cost might change significantly, but X's cost to reach Y remains the same (the LSP metric), which allows X to report through a BGP multiple exit discriminator (MED) a stable metric to downstream neighbors. As long as Y remains reachable through the LSP, no changes are visible to downstream BGP neighbors.

It is possible to configure IS-IS to ignore the configured LSP metric by including the **ignore-lsp-metrics** statement at the **[edit protocols isis traffic-engineering shortcuts]** hierarchy level. This statement removes the mutual dependency between IS-IS and MPLS for path computation. For more information, see the *Junos OS Routing Protocols Library*.

Configuring a Text Description for LSPs

You can provide a textual description for an LSP by enclosing any descriptive text that includes spaces within quotation marks (" "). The descriptive text you include is displayed in the detail output of the **show mpls lsp** or the **show mpls container-lsp** command.

Adding a text description for an LSP has no effect on the operation of the LSP. The LSP text description can be no more than 80 characters in length.

To provide a textual description for an LSP, include the **description** statement at any of the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** container-label-switched-path ***lsp-name*****]**
- **[edit protocols mpls** static-label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** static-label-switched-path ***lsp-name*****]**

Before you begin:

- Configure the device interfaces.
- Configure the device for network communication.
- Enable MPLS on the device interfaces.
- Configure an LSP in the MPLS domain.

To add a text description for an LSP:

1. Enter any text describing the LSP.

   ```
   [edit protocols mpls lsp lsp-name]
   user@host# set description text
   ```

   For example:

   ```
   [edit protocols mpls lsp LSP1]
   user@host# set description "Connecting remote device"
   ```

2. Verify and commit the configuration.

   For example:

   ```
   [edit protocols mpls lsp]
   user@host# set protocols mpls label-switched-path LSP1 to 1.1.1.1
   user@host# set protocols mpls label-switched-path LSP1 description "Connecting
     remote device"
   user@host# set protocols mpls interface ge-1/0/8.0
   ```

   ```
   [edit]
   user@host# commit
   commit complete
   ```

3. View the description of an LSP using the **show mpls lsp detail** or **show mpls container-lsp detail** command, depending on the type of LSP configured.

   ```
   user@host> show mpls lsp detail
   ```

```
Ingress LSP: 1 sessions

Configuring MPLS Soft Preemption

Soft preemption attempts to establish a new path for a preempted LSP before tearing down the original LSP. The default behavior is to tear down a preempted LSP first, signal a new path, and then reestablish the LSP over the new path. In the interval between when the path is taken down and the new LSP is established, any traffic attempting to use the LSP is lost. Soft preemption prevents this type of traffic loss. The trade-off is that during the time when an LSP is being soft preempted, two LSPs with their corresponding bandwidth requirements are used until the original path is torn down.

MPLS soft preemption is useful for network maintenance. For example, you can move all LSPs away from a particular interface, then take the interface down for maintenance without interrupting traffic. MPLS soft preemption is described in detail in RFC 5712, *MPLS Traffic Engineering Soft Preemption*.

Soft preemption is a property of the LSP and is disabled by default. You configure it at the ingress of an LSP by including the **soft-preemption** statement:

```
soft-preemption;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

You can also configure a timer for soft preemption. The timer designates the length of time the router should wait before initiating a hard preemption of the LSP. At the end of the time specified, the LSP is torn down and resignaled. The soft-preemption cleanup timer has a default value of 30 seconds; the range of permissible values is 0 through 180 seconds. A value of 0 means that soft preemption is disabled. The soft-preemption cleanup timer is global for all LSPs.

Configure the timer by including the **cleanup-timer** statement:

```
cleanup-timer seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp** preemption soft-preemption**]**
- **[edit logical-systems** *logical-system-name* **protocols rsvp** preemption soft-preemption**]**

NOTE: Soft preemption cannot be configured on LSPs for which secondary paths or fast reroute has been configured. The configuration fails to commit. However, you can enable soft preemption in conjunction with node and link protection.

NOTE: The counter value for *SoftPreemptionCnt* initializes with a value of 0 (zero), visible in the command **show rsvp interface detail** output.

Configuring Priority and Preemption for LSPs

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to free the bandwidth. You do this by preempting the existing LSP.

Whether an LSP can be preempted is determined by two properties associated with the LSP:

- Setup priority—Determines whether a new LSP that preempts an existing LSP can be established. For preemption to occur, the setup priority of the new LSP must be higher than that of the existing LSP. Also, the act of preempting the existing LSP must produce sufficient bandwidth to support the new LSP. That is, preemption occurs only if the new LSP can be set up successfully.
- Reservation priority—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. When the reservation priority is high, the existing LSP is less likely to give up its reservation, and hence it is unlikely that the LSP can be preempted.

You cannot configure an LSP with a high setup priority and a low reservation priority, because permanent preemption loops might result if two LSPs are allowed to preempt

each other. You must configure the reservation priority to be higher than or equal to the setup priority.

The setup priority also defines the relative importance of LSPs on the same ingress router. When the software starts, when a new LSP is established, or during fault recovery, the setup priority determines the order in which LSPs are serviced. Higher-priority LSPs tend to be established first and hence enjoy more optimal path selection.

To configure the LSP's preemption properties, include the **priority** statement:

```
priority setup-priority reservation-priority;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Both ***setup-priority*** and ***reservation-priority*** can be a value from 0 through 7. The value 0 corresponds to the highest priority, and the value 7 to the lowest. By default, an LSP has a setup priority of 7 (that is, it cannot preempt any other LSPs) and a reservation priority of 0 (that is, other LSPs cannot preempt it). These defaults are such that preemption does not happen. When you are configuring these values, the setup priority should always be less than or equal to the hold priority.

Configuring Administrative Groups for LSPs

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the "color" of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups.

Administrative groups are meaningful only when constrained-path LSP computation is enabled.

You can assign up to 32 names and values (in the range 0 through 31), which define a series of names and their corresponding values. The administrative names and values must be identical across all routers within a single domain.

NOTE: The administrative value is distinct from the priority. You configure the priority for an LSP using the priority statement. See "Configuring Priority and Preemption for LSPs" on page 428.

To configure administrative groups, follow these steps:

1. Define multiple levels of service quality by including the **admin-groups** statement:

```
admin-groups {
  group-name group-value;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The following configuration example illustrates how you might configure a set of administrative names and values for a domain:

```
[edit protocols mpls]
admin-groups {
   gold 1;
   silver 2;
   copper 3;
   best-effort 4;
}
```

2. Define the administrative groups to which an interface belongs. You can assign multiple groups to an interface. Include the **interface** statement:

```
interface interface-name {
   admin-group [ group-names ];
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

If you do not include the **admin-group** statement, an interface does not belong to any group.

IGPs use the group information to build link-state packets, which are then flooded throughout the network, providing information to all nodes in the network. At any router, the IGP topology, as well as administrative groups of all the links, is available.

Changing the interface's administrative group affects only new LSPs. Existing LSPs on the interface are not preempted or recomputed to keep the network stable. If LSPs need to be removed because of a group change, issue the **clear rsvp session** command.

NOTE: When configuring administrative groups and extended administrative groups together for a link, both the types of administrative groups must be configured on the interface.

3. Configure an administrative group constraint for each LSP or for each primary or secondary LSP path. Include the **label-switched-path** statement:

```
label-switched-path lsp-name {
   to address;
   ...
   admin-group {
      exclude [ group-names ];
```

```
    include-all [ group-names ];
    include-any [ group-names ];
  }
  primary path-name {
    admin-group {
      exclude [ group-names ];
      include-all [ group-names ];
      include-any [ group-names ];
    }
  }
  secondary path-name {
    admin-group {
      exclude [ group-names ];
      include-all [ group-names ];
      include-any [ group-names ];
    }
  }
}
```

You can include the **label-switched-path** statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

If you omit the **include-all**, **include-any**, or **exclude** statements, the path computation proceeds unchanged. The path computation is based on the constrained-path LSP computation. For information about how the constrained-path LSP computation is calculated, see "How CSPF Selects a Path" on page 387.

NOTE: **Changing the LSP's administrative group causes an immediate recomputation of the route; therefore, the LSP might be rerouted.**

- Configuring Extended Administrative Groups for LSPs on page 431

Configuring Extended Administrative Groups for LSPs

In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in the interior gateway protocol (IGP) (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. Juniper Networks routers normally interpret this 32-bit value as a bit mask with each bit representing a group, limiting each network to a total of 32 distinct administrative groups (value range 0 through 31).

You configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. The original range of values available for administrative groups is still supported for backwards compatibility.

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by Constrained Shortest Path First (CSPF) for path computation.

The following procedure describes how to configure extended administrative groups:

1. Configure the admin-groups-extended-range statement:

   ```
   admin-groups-extended-range {
     maximum maximum-number;
     mininum minimum-number;
   }
   ```

   You can include this statement at the following hierarchy levels:

   - **[edit routing-options]**
   - **[edit logical-systems *logical-system-name* routing-options]**

   The **admin-groups-extended-range** statement includes the **minimum** and **maximum** options. The range maximum must be greater than the range minimum.

2. Configure the admin-groups-extended statement:

   ```
   admin-groups-extended group-name {
     group-value group-identifier;
   }
   ```

   You can include this statement at the following hierarchy levels:

   - **[edit routing-options]**
   - **[edit logical-systems *logical-system-name* routing-options]**

   The **admin-groups-extended** statement enables you to configure a group name and group value for the administrative group. The group value must be within the range of values configured using the **admin-groups-extended-range** statement.

3. The extended administrative groups for an MPLS interface consist of the set of extended administrative group names assigned for the interface. The interface extended administrative group names must be configured for the global extended administrative groups.

   To configure an extended administrative group for an MPLS interface, specify the administrative group name within the MPLS interface configuration using the **admin-groups-extended** statement:

   ```
   admin-groups-extended group-name;
   ```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls interface *interface-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]**

4. The LSP extended administrative groups define the set of include and exclude constraints for an LSP and for a path's primary and secondary paths. The extended administrative group names must be configured for the global extended administrative groups.

   To configure extended administrative groups for an LSP, include the admin-group-extended statement at an LSP hierarchy level:

   ```
   admin-group-extended {
     apply-groups group-value;
     apply-groups-except group-value;
     exclude group-value;
     include-all group-value;
     include-any group-value;
   }
   ```

   The **admin-group-extended** statement includes the following options: **apply-groups**, **apply-groups-except**, **exclude**, **include-all**, and **include-any**. Each option enables you to configure one or more extended administrative groups.

   For the list of the hierarchy levels at which you can configure this statement, see the statement summary for this statement.

5. To display the currently configured extended administrative groups, issue the **show mpls admin-groups-extended** command.

NOTE: When configuring administrative groups and extended administrative groups together for a link, both the types of administrative groups must be configured on the interface.

- Configuring Administrative Groups for LSPs on page 429

Configuring Preference Values for LSPs

As an option, you can configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for RSVP LSPs is 7 and for LDP LSPs is 9. These preference values are lower (more preferred) than all learned routes except direct interface routes.

To change the default preference value, include the **preference** statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Disabling Path Route Recording by LSPs

The Junos implementation of RSVP supports the Record Route object, which allows an LSP to actively record the routers through which it transits. You can use this information for troubleshooting and to prevent routing loops. By default, path route information is recorded. To disable recording, include the **no-record** statement:

```
no-record;
```

For a list of hierarchy levels at which you can include the **record** and **no-record** statements, see the statement summary section for the statement.

Achieving a Make-Before-Break, Hitless Switchover for LSPs

Adaptive label-switched paths (LSPs) might need to establish a new LSP instance and transfer traffic from an old LSP instance onto the new LSP instance before tearing down the old one. This type of configuration is referred to as a *make before break* (MBB).

RSVP-TE is a protocol used to establish LSPs in MPLS networks. The Junos OS implementation of RSVP-TE to achieve a hitless (no traffic loss) MBB switchover has relied on configuring the timer values in the following configuration statements:

- **optimize-switchover-delay**—Amount of time to wait before switching to the new LSP instance.
- **optimize-hold-dead-delay**—Amount of time to wait after switchover and before deletion of the old LSP instance.

Both the **optimize-switchover-delay** and **optimize-hold-dead-delay** statements apply to all LSPs that use the make-before-break behavior for LSP setup and teardown, not just for LSPs for which the **optimize-timer** statement has also been configured. The following MPLS features cause LSPs to be set up and torn down using make-before-break behavior:

- Adaptive LSPs
- Automatic bandwidth allocation
- BFD for LSPs
- Graceful Routing Engine switchover
- Link and node protection
- Nonstop active routing
- Optimized LSPs
- Point-to-multipoint (P2MP) LSPs

- Soft preemption
- Standby secondary paths

Both the **optimize-switchover-delay** and **optimize-hold-dead-delay** statements when configured add an artificial delay to the MBB process. The value of the **optimize-switchover-delay** statement varies with the size of the Explicit Route Objects (EROs). An ERO is an extension to RSVP that allows an RSVP PATH message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The value of the **optimize-switchover-delay** statement also depends on the CPU load on each of the routers on the path. Customers set the **optimize-switchover-delay** statement by trial and error.

The value of the **optimize-hold-dead-delay** statement depends on how fast the ingress router moves all application prefixes to point to the new LSP. This is determined by the Packet Forwarding Engine load, which can vary from platform to platform. Customers have to set the **optimize-hold-dead-delay** statement by trial and error.

However, as of Release 15.1, Junos OS is able to achieve a hitless MBB switchover without configuring the artificial delays that such timer values introduce.

This topic summarizes the three methods of achieving a MBB switchover from an old LSP to a new LSP using Junos OS:

- Specifying the Amount of Time the Router Waits to Switch Over to New Paths on page 435
- Specifying the Amount of Time to Delay the Tear Down of Old Paths on page 436
- Achieving a Hitless, MBB Switchover Without Artificial Delays on page 436

Specifying the Amount of Time the Router Waits to Switch Over to New Paths

To specify the amount of time the router waits to switch over LSP instances to newly optimized paths, use the **optimize-switchover-delay** statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that the new optimized paths have been established before traffic is switched over from the old paths. This timer can only by enabled or disabled for all of the LSPs configured on the router.

To configure the amount of time the router waits to switch over LSP instances to newly optimized paths, specify the time in seconds by using the **optimize-switchover-delay** statement:

```
optimize-switchover-delay seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Specifying the Amount of Time to Delay the Tear Down of Old Paths

To specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the **optimize-hold-dead-delay** statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths. This timer can be enabled for specific LSPs or for all of the LSPs configured on the router.

To configure the amount of time in seconds to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the **optimize-hold-dead-delay** statement:

```
optimize-hold-dead-delay seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Achieving a Hitless, MBB Switchover Without Artificial Delays

As of Junos OS Release 15.1, there is another way to relinquish the old LSP instances after MBB switchover without relying on the arbitrary time intervals set up by the **optimize-switchover-delay** or **optimize-hold-dead-delay** statement. For example, if you use the **optimize-hold-dead-delay** statement, you configure a time you think it is safe to wait before tearing down the old LSP instance after MBB. However, some routes might still be in the process of shifting to the new instance. Tearing down the old LSP instance prematurely results in one of the transit nodes dropping the traffic for those routes that have not shifted to the new LSP instance.

To avoid traffic loss, instead of using the **optimize-switchover-delay** statement, you can use MPLS-OAM (lsp ping), which confirms that the LSP data plane is established end-to-end. Instead of using the **optimize-hold-dead-delay** statement, you can use a feedback mechanism from the rpd infrastructure that confirms that all prefixes referring to the old LSP have been switched over. The feedback mechanism is sourced from the Tag library and relies on the routing protocol process (rpd) infrastructure to determine when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover.

The feedback mechanism is always in place, and it is optional. Configure the **optimize-adaptive-teardown** statement to have the feedback mechanism used during MBB switchover. This feature is not supported for RSVP point-to-multipoint (P2MP) LSP instances. Global configuration of the **optimize-adaptive-teardown** statement only affects the point-to-point LSPs that are configured in the system.

You only need to configure the **optimize-adaptive-teardown** statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). This feedback mechanism ensures that old paths are not torn down before all routes have been switched over to the new optimized paths. The global

configuration of this configuration statement affects only the point-to-point LSPs that are configured in the system.

```
optimize-adaptive-teardown {
  p2p:
}
```

You can include this statement at the **[edit protocols mpls]** hierarchy level.

Optimizing Signaled LSPs

Once an LSP has been established, topology or resources changes might, over time, make the path suboptimal. A new path might have become available that is less congested, has a lower metric, and traverses fewer hops. You can configure the router to recompute paths periodically to determine whether a more optimal path has become available.

If reoptimization is enabled, an LSP can be rerouted through different paths by constrained-path recomputations. However, if reoptimization is disabled, the LSP has a fixed path and cannot take advantage of newly available network resources. The LSP is fixed until the next topology change breaks the LSP and forces a recomputation.

Reoptimization is not related to failover. A new path is always computed when topology failures occur that disrupt an established path.

Because of the potential system overhead involved, you need to carefully control the frequency of reoptimization. Network stability might suffer when reoptimization is enabled. By default, the **optimize-timer** statement is set to 0 (that is, it is disabled).

LSP optimization is meaningful only when constrained-path LSP computation is enabled, which is the default behavior. For more information about constrained-path LSP computation, see "Disabling Constrained-Path LSP Computation" on page 390. Also, LSP optimization is only applicable to ingress LSPs, so it is only necessary to configure the **optimize-timer** statement on the ingress router. The transit and egress routers require no specific configuration to support LSP optimization (other than to have MPLS enabled).

To enable path reoptimization, include the **optimize-timer** statement:

```
optimize-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Once you have configured the **optimize-timer** statement, the reoptimization timer continues its countdown to the configured value even if you delete the **optimize-timer** statement from the configuration. The next optimization uses the new value. You can force the Junos OS to use a new value immediately by deleting the old value, committing the configuration, configuring the new value for the **optimize-timer** statement, and then committing the configuration again.

After reoptimization is run, the result is accepted only if it meets the following criteria:

1. The new path is not higher in IGP metric. (The metric for the old path is updated during computation, so if a recent link metric changed somewhere along the old path, it is accounted for.)

2. If the new path has the same IGP metric, it is not more hops away.

3. The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)

4. The new path does not worsen congestion overall.

   The relative congestion of the new path is determined as follows:

   a. The percentage of available bandwidth on each link traversed by the new path is compared to that for the old path, starting from the most congested links.

   b. For each current (old) path, the software stores the four smallest values for bandwidth availability for the links traversed in ascending order.

   c. The software also stores the four smallest bandwidth availability values for the new path, corresponding to the links traversed in ascending order.

   d. If any of the four new available bandwidth values are smaller than any of the corresponding old bandwidth availability values, the new path has at least one link that is more congested than the link used by the old path. Because using the link would cause more congestion, traffic is not switched to this new path.

   e. If none of the four new available bandwidth values is smaller than the corresponding old bandwidth availability values, the new path is less congested than the old path.

When all the above conditions are met, then:

5. If the new path has a lower IGP metric, it is accepted.

6. If the new path has an equal IGP metric and lower hop count, it is accepted.

7. If you choose **least-fill** as a load balancing algorithm, LSPs are load balanced as follows:

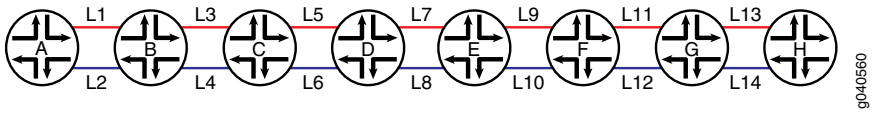
   a. The LSP is moved to a new path that is utilized at least 10% less than the current path. This might reduce congestion on the current path by only a small amount.

For example, if an LSP with 1 MB of bandwidth is moved off a path carrying a minimum of 200 MB, congestion on the original path is reduced by less than 1%.

b. For **random** or **most-fill** algorithms, this rule does not apply.

The following example illustrates how the **least-fill** load balancing algorithm works.

Figure 43: least-fill Load Balancing Algorithm Example



As shown in Figure 43 on page 439, there are two potential paths for an LSP to traverse from router A to router H, the odd links from L1 through L13 and the even links from L2 through L14. Currently, the router is using the even links as the active path for the LSP. Each link between the same two routers (for example, router A and router B) has the same bandwidth:

- L1, L2 = 10GE
- L3, L4 = 1GE
- L5, L6 = 1GE
- L7, L8 = 1GE
- L9, L10 = 1GE
- L11, L12 = 10GE
- L13, L14 = 10GE

The 1GE links are more likely to be congested. In this example, the odd 1GE links have the following available bandwidth:

- L3 = 41%
- L5 = 56%
- L7 = 66%
- L9 = 71%

The even 1GE links have the following available bandwidth:

- L4 = 37%
- L6 = 52%
- L8 = 61%
- L10 = 70%

Based on this information, the router would calculate the difference in available bandwidth between the odd links and the even links as follows:

- L4 - L3 = 41% - 37% = 4%
- L6 - L5 = 56% - 52% = 4%

- L8 - L7 = 66% - 61% = 5%
- L10 - L9 = 71% - 70% = 1%

The total additional bandwidth available over the odd links is 14% (4% + 4% + 5% + 1%). Since 14% is greater than 10% (the least-fill algorithm minimum threshold), the LSP is moved to the new path over the odd links from the original path using the even links.

8. Otherwise, the new path is rejected.

You can disable the following reoptimization criteria (a subset of the criteria listed previously):

- If the new path has the same IGP metric, it is not more hops away.
- The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
- The new path does not worsen congestion overall.
- If the new path has an equal IGP metric and lower hop count, it is accepted.

To disable them, either issue the **clear mpls lsp optimize-aggressive** command or include the **optimize-aggressive** statement:

```
optimize-aggressive;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Including the **optimize-aggressive** statement in the configuration causes the reoptimization procedure to be triggered more often. Paths are rerouted more frequently. It also limits the reoptimization algorithm to the IGP metric only.

Related Documentation

- Configuring Hot Standby of Secondary Paths for LSPs on page 462

Configuring the Smart Optimize Timer for LSPs

Because of network and router resource constraints, it is typically inadvisable to configure a short interval for the optimize timer. However, under certain circumstances, it might be

desirable to reoptimize a path sooner than would normally be provided by the optimize timer.

For example, an LSP is traversing a preferred path that subsequently fails. The LSP is then switched to a less desirable path to reach the same destination. Even if the original path is quickly restored, it could take an excessively long time for the LSP to use it again, because it has to wait for the optimize timer to reoptimize the network paths. For such situations, you might want to configure the smart optimize timer.

When you enable the smart optimize timer, an LSP is switched back to its original path so long as the original path has been restored within 3 minutes of going down. Also, if the original path goes down again within 60 minutes, the smart optimize timer is disabled, and path optimization behaves as it normally does when the optimize timer alone is enabled. This prevents the router from using a flapping link.

The smart optimize timer is dependant on other MPLS features to function properly. For the scenario described here in which an LSP is switched to an alternate path in the event of a failure on the original path, it is assumed that you have configured one or more of the MPLS traffic protection features, including fast reroute, link protection, and standby secondary paths. These features help to ensure that traffic can reach its destination in the event of a failure.

At the least, you must configure a standby secondary path for the smart optimize timer feature to work properly. Fast reroute and link protection are more temporary solutions to a network outage. A secondary path ensures that there is a stable alternate path in the event the primary path fails. If you have not configured any sort of traffic protection for an LSP, the smart optimize timer by itself does not ensure that traffic can reach its destination. For more information about MPLS traffic protection, see "MPLS and Traffic Protection" on page 378.

When a primary path fails and the smart optimize timer switches traffic to the secondary path, the router might continue to use the secondary path even after the primary path has been restored. If the ingress router completes a CSPF calculation, it might determine that the secondary path is the better path.

This might be undesirable if the primary path should be the active path and the secondary path should be used as a backup only. Also, if the secondary path is being used as the active path (even though the primary path has been reestablished) and the secondary path fails, the smart optimize timer feature will not automatically switch traffic back to the primary path. However, you can enable protection for the secondary path by configuring node and link protection or an additional standby secondary path, in which case, the smart optimize timer can be effective.

Specify the time in seconds for the smart optimize timer using the **smart-optimize-timer** statement:

```
smart-optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**

- **[edit logical-systems *logical-system-name* protocols mpls]**

Related Documentation

- Optimizing Signaled LSPs on page 437

Limiting the Number of Hops in LSPs

By default, each LSP can traverse a maximum of 255 hops, including the ingress and egress routers. To modify this value, include the **hop-limit** statement:

```
hop-limit number;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The number of hops can be from 2 through 255. (A path with two hops consists of the ingress and egress routers only.)

Configuring the Bandwidth Value for LSPs

Each LSP has a bandwidth value. This value is included in the sender's Tspec field in RSVP path setup messages. You can specify a bandwidth value in bits per second. If you configure more bandwidth for an LSP, it should be able to carry a greater volume of traffic. The default bandwidth is 0 bits per second.

A nonzero bandwidth requires that transit and egress routers reserve capacity along the outbound links for the path. The RSVP reservation scheme is used to reserve this capacity. Any failure in bandwidth reservation (such as failures at RSVP policy control or admission control) might cause the LSP setup to fail. If there is insufficient bandwidth on the interfaces for the transit or egress routers, the LSP is not established.

To specify a bandwidth value for a signaled LSP, include the **bandwidth** statement:

```
bandwidth bps;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth; this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

You set a sampling interval on an LSP configured with automatic bandwidth allocation. The average bandwidth is monitored during this interval. At the end of the interval, an attempt is made to signal a new path for the LSP with the bandwidth allocation set to

the maximum average value for the preceding sampling interval. If the new path is successfully established and the original path is removed, the LSP is switched over to the new path. If a new path is not created, the LSP continues to use its current path until the end of the next sampling interval, when another attempt is made to establish a new path. Note that you can set minimum and maximum bandwidth values for the LSP.

During the automatic bandwidth allocation interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Configuring Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth, and this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

At the end of the automatic bandwidth allocation time interval, the current maximum average bandwidth usage is compared with the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

NOTE: In calculating the value for Max AvgBW (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

If you have configured link and node protection for the LSP and traffic has been switched to the bypass LSP, the automatic bandwidth allocation feature continues to operate and take bandwidth samples from the bypass LSP. For the first bandwidth adjustment cycle, the maximum average bandwidth usage taken from the original link and node-protected LSP is used to resignal the bypass LSP if more bandwidth is needed. (Link and node protection are not supported on QFX Series switches.)

If you have configured fast-reroute for the LSP, you might not be able to use this feature to adjust the bandwidth. Because the LSPs use a fixed filter (FF) reservation style, when a new path is signaled, the bandwidth might be double-counted. Double-counting can prevent a fast-reroute LSP from ever adjusting its bandwidth when automatic bandwidth allocation is enabled. (Fast reroute is not supported on QFX Series switches.)

To configure automatic bandwidth allocation, complete the steps in the following sections:

- Configuring Automatic Bandwidth Allocation on LSPs on page 444
- Requesting Automatic Bandwidth Allocation Adjustment on page 450

NOTE: On the QFX10000 switches, you can only configure automatic bandwidth allocation at the **edit protocols mpls** hierarchy level. Logical systems are not supported.

Configuring Automatic Bandwidth Allocation on LSPs

To enable automatic bandwidth allocation on an LSP, include the **auto-bandwidth** statement:

```
auto-bandwidth (MPLS Tunnel) {
  adjust-interval seconds;
  adjust-threshold percent;
  adjust-threshold-overflow-limit number;
  adjust-threshold-underflow-limit number;
  maximum-bandwidth bps;
  minimum-bandwidth bps;
  minimum-bandwidth-adjust-interval
  minimum-bandwidth-adjust-threshold-change
  minimum-bandwidth-adjust-threshold-value
  monitor-bandwidth;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path *lsp-name*]
- **[edit logical-systems** *logical-system-name* **protocols mpls** label-switched-path *lsp-name*]

If an LSP has an automatic bandwidth configuration, you can disable automatic bandwidth adjustments on a particular path (either primary or secondary) by configuring a static bandwidth value and by disabling the CSPF computation (using the **no-cspf** statement).

For example:

```
user@host> show protocols mpls
label-switched-path primary-path {
  to 192.168.0.1;
  ldp-tunneling;
  optimize-timer 3571;
  least-fill;
  link-protection;
  adaptive;
  auto-bandwidth {
    adjust-interval 7177;
    adjust-threshold 5;
    minimum-bandwidth 1m;
```

```
    maximum-bandwidth 2500000000;
    adjust-threshold-overflow-limit 2;
    resignal-minimum-bandwidth;
  }
  primary primary-path;
  secondary secondary-path {
    bandwidth 0;
    no-cspf;
    priority 0 0;
  }
}
```

The statements configured at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level are optional and explained in the following sections:

- Configuring the Automatic Bandwidth Allocation Interval on page 445
- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446
- Configuring the Automatic Bandwidth Adjustment Threshold on page 447
- Configuring a Limit on Bandwidth Overflow and Underflow Samples on page 447
- Configuring Passive Bandwidth Utilization Monitoring on page 449

Configuring the Automatic Bandwidth Allocation Interval

At the end of the automatic bandwidth allocation interval, the automatic bandwidth computation and new path setup process is triggered.

NOTE: To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (**interval** statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (**adjust-interval** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level). See also "Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs" on page 451.

To specify the bandwidth reallocation interval in seconds for a specific LSP, include the **adjust-interval** statement:

```
adjust-interval seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]**

Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth

You can maintain the LSP's bandwidth between minimum and maximum bounds by specifying values for the **minimum-bandwidth** and **maximum-bandwidth** statements.

NOTE: For a label-swtiched path (LSP) that has both **bandwidth** and **minimum-bandwidth** for autobandwidth configured under the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the maximum bandwidth.

To specify the minimum amount of bandwidth allocated for a specific LSP, include the **minimum-bandwidth** statement:

```
minimum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

To specify the maximum amount of bandwidth allocated for a specific LSP, include the **maximum-bandwidth** statement:

```
maximum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

Configuring the Automatic Bandwidth Adjustment Threshold

Use the **adjust-threshold** statement to specify the sensitivity of the automatic bandwidth adjustment of an LSP to changes in bandwidth utilization. You can set the threshold for when to trigger automatic bandwidth adjustments. When configured, bandwidth demand for the current interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the specified **adjust-threshold** percentage, the LSP's bandwidth is adjusted to the current bandwidth demand.

For example, assume that the current bandwidth allocation is 100 megabits per second (Mbps) and that the percentage configured for the **adjust-threshold** statement is 15 percent. If the bandwidth demand increases to 110 Mbps, the bandwidth allocation is not adjusted. However, if the bandwidth demand increases to 120 Mbps (20 percent over the current allocation) or decreases to 80 Mbps (20 percent under the current allocation), the bandwidth allocation is increased to 120 Mbps or decreased to 80 Mbps, respectively.

To configure the threshold for automatic bandwidth adjustment, include the **adjust-threshold** statement:

```
adjust-threshold percent;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

Configuring a Limit on Bandwidth Overflow and Underflow Samples

The automatic bandwidth adjustment timer is a periodic timer which is triggered every adjust interval to determine whether any bandwidth adjustments are required on the LSP's active path. This interval is typically configured as a long period of time, usually hours. If, at the end of adjust interval, the change in bandwidth is above a certain adjust threshold, the LSP is resignaled with the new bandwidth.

During the automatic bandwidth adjustment interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Every statistics interval, the router samples the average bandwidth utilization of an LSP and if this has exceeded the current maximum average bandwidth utilization, the maximum average bandwidth utilization is updated.

During each sample period, the following conditions are also checked:

- Is the current average bandwidth utilization above the active bandwidth of the path?

- Has the difference between the average bandwidth utilization and the active bandwidth exceeded the adjust threshold (bandwidth utilization has changed significantly)?

If these conditions are true, it is considered to be one bandwidth overflow sample. Using the **adjust-threshold-overflow-limit** statement, you can define a limit on the number of bandwidth overflow samples such that when the limit is reached, the current automatic bandwidth adjustment timer is expired and a bandwidth adjustment is triggered. Once this adjustment is complete, the normal automatic bandwidth adjustment timer is reset to expire after the periodic adjustment interval.

To specify a limit on the number of bandwidth overflow samples before triggering an automatic bandwidth allocation adjustment, configure the **adjust-threshold-overflow-limit** statement:

```
adjust-threshold-overflow-limit number;
```

Similarly, if the current average bandwidth utilization is below the active bandwidth of the path by the configured adjusted threshold (meaning that bandwidth utilization has gone down significantly), the sample is considered to be an underflow sample. The adjusted (new signaling) bandwidth after an adjustment due to underflow is the maximum average bandwidth among the underflow samples. Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

You can specify a limit on the number of bandwidth underflow samples before triggering an automatic bandwidth allocation adjustment by configuring the **adjust threshold-underflow-limit** statement:

```
adjust-threshold-underflow-limit number;
```

These statements can be configured at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

You must configure the **adjust-threshold** and **minimum-bandwidth** statements whenever you configure the **adjust-threshold-underflow-limit** statement. You must configure the **adjust-threshold** and **maximum-bandwidth** statements whenever you configure the **adjust-threshold-overflow-limit** statement

- You must configure a nonzero value for the **adjust-threshold** statement if you configure the **adjust-threshold-overflow-limit** or **adjust-threshold-underflow-limit** statement.
- Any bandwidth increase or decrease below the value configured for the **adjust-threshold** statement does not constitute an overflow or underflow condition.

- To prevent unlimited increases in LSP bandwidth (to limit overflow beyond a certain bandwidth), you must also configure the **maximum-bandwidth** statement when you configure the **adjust-threshold-overflow-limit** statement.

The following describes the other aspects of the **adjust-threshold-overflow-limit** statement:

- It only applies to bandwidth overflows. If the bandwidth is decreasing, the normal automatic bandwidth adjustment interval is used.
- It does not affect manually triggered automatic bandwidth adjustment.
- It applies to single-class DiffServ-TE LSPs.
- Because the **adjust-threshold-overflow-limit** statement can trigger a bandwidth adjustment, it cannot be enabled at the same time as the **monitor-bandwidth** statement (for information about that statement, see "Configuring Passive Bandwidth Utilization Monitoring" on page 449).
- You cannot configure automatic bandwidth adjustments to occur more often than every 300 seconds. The **adjust-threshold-overflow-limit** statement is subject to the same minimum value with regard to the minimum frequency of adjustment allowed. Overflow condition based adjustments can occur no sooner than 300 seconds from the start of the overflow condition. Therefore it is required that:

  sample interval x adjust-threshold-overflow-limit >= 300s

  These values are checked during the commit operation. An error is returned if the value is less than 300 seconds.
- If you change the value of the **adjust-threshold-overflow-limit** statement on a working router, you can expect the following behavior:
  - If you increase the current value of the **adjust-threshold-overflow-limit** statement, the old value is replaced with the new one.
  - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is less than the new value, the old value is replaced with the new one.
  - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is greater than the new value, the adjustment timer is immediately expired and a bandwidth adjustment is initiated.

Configuring Passive Bandwidth Utilization Monitoring

Use the **monitor-bandwidth** statement to switch to a passive bandwidth utilization monitoring mode. In this mode, no automatic bandwidth adjustments are made, but the maximum average bandwidth utilization is continuously monitored and recorded.

To configure passive bandwidth utilization monitoring, include the **monitor-bandwidth** statement:

```
monitor-bandwidth;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

If you have configured an LSP with primary and secondary paths, the automatic bandwidth allocation statistics are carried over to the secondary path if the primary path fails. For example, consider a primary path whose adjustment interval is half complete and whose maximum average bandwidth usage is currently calculated as 50 Mbps. If the primary path suddenly fails, the time remaining for the next adjustment and the maximum average bandwidth usage are carried over to the secondary path.

Requesting Automatic Bandwidth Allocation Adjustment

For MPLS LSP automatic bandwidth allocation adjustment, the minimum value for the adjustment interval is 5 minutes (300 seconds). You might find it necessary to trigger a bandwidth allocation adjustment manually, for example in the following circumstances:

- When you are testing automatic bandwidth allocation in a network lab.
- When the LSP is configured for automatic bandwidth allocation in monitor mode (the **monitor-bandwidth** statement is included in the configuration as described in "Configuring Passive Bandwidth Utilization Monitoring" on page 449), and want to initiate an immediate bandwidth adjustment.

To use the **request mpls lsp adjust-autobandwidth** command, the following must be true:

- Automatic bandwidth allocation must be enabled on the LSP.
- The criteria required to trigger a bandwidth adjustment have been met (the difference between the adjust bandwidth and the current LSP path bandwidth is greater than the threshold limit).

A manually triggered bandwidth adjustment operates only on the active LSP path. Also, if you have enabled periodic automatic bandwidth adjustment, the periodic automatic bandwidth adjustment parameters (the adjustment interval and the maximum average bandwidth) are not reset after a manual adjustment.

For example, suppose the periodic adjust interval is 10 hours and there are currently 5 hours remaining before an automatic bandwidth adjustment is triggered. If you initiate a manual adjustment with the **request mpls lsp adjust-autobandwidth** command, the adjust timer is not reset and still has 5 hours remaining.

To manually trigger a bandwidth allocation adjustment, you need to use the **request mpls lsp adjust-autobandwidth** command. You can trigger the command for all affected LSPs on the router, or you can specify a particular LSP:

```
user@host> request mpls lsp adjust-autobandwidth
```

Once you execute this command, the automatic bandwidth adjustment validation process is triggered. If all the criteria for adjustment are met, the LSP's active path bandwidth is adjusted to the adjusted bandwidth value determined during the validation process.

Release History Table

Release	Description
14.1R9	Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure the device to collect statistics related to automatic bandwidth allocation by completing the following steps:

1. To collect statistics related to automatic bandwidth allocation, configure the **auto-bandwidth** option for the **statistics** statement at the **[edit protocols mpls]** hierarchy level. These settings apply to all LSPs configured on the router on which you have also configured the **auto-bandwidth** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level.

```
statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
  transit-statistics-polling;
}
```

2. Specify the ***filename*** for the files used to store the MPLS trace operation output using the **file** option. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.

3. Specify the maximum number of trace files using the **files *number*** option. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then

trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

4. Specify the interval for calculating the average bandwidth usage by configuring a time in seconds using the **interval** option. You can also set the adjustment interval on a specific LSP by configuring the **interval** option at the **[edit protocols mpls label-switch-path *label-switched-path-name* statistics]** hierarchy level.

   

   NOTE: To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (**interval** statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (**adjust-interval** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level).

5. To trace automatic bandwidth allocation, include the **autobw-state flag** for the MPLS **traceoptions** statement at the **[edit protocols mpls]** hierarchy level.

   The following configuration enables the MPLS traceoptions for automatic bandwidth allocation. The trace records are stored in a file called **auto-band-trace** (the filename is user configurable):

   ```
   [edit protocols mpls]
   traceoptions {
     file auto-band-trace size 10k files 10 world-readable;
     flag autobw-state;
   }
   ```

6. Using the **show log** command, you can display the automatic bandwidth allocation statistics file generated when you configure the auto-bandwidth (MPLS Statistics) statement. The following shows sample log file output taken from an MPLS statistics file named **auto-band-stats** on a router configured with an LSP named **E-D**. The log file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. Before **Oct 30 17:14:57**, the router triggered an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:16:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```

```

7. Issue the show mpls lsp autobandwidth command to display current information about automatic bandwidth allocation. The following shows sample output from the **show mpls lsp autobandwidth** command taken at about the same time as the log file shown previously:

```
user@host> show mpls lsp autobandwidth
Lspname               Last         Requested    Reserved     Highwater    AdjustTime LastAdjust
                      BW           BW           BW           mark         Left (sec)
E-D                  300bps      812.005bps  812bps      1.56801kbps 294 sec    Wed Oct 30 17:15:26 2013
```

8. Issue the **file show** command to display the MPLS trace file. You need to specify the file location and file name (the file is located in **/var/log/**. The following shows sample trace file output is taken from an MPLS trace file named **auto-band-trace.0.gz** on a router configured with an LSP named **E-D**. The trace file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. At **Oct 30 17:15:26**, the router triggers an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:15:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```

Configuring an LSP Across ASs

You can configure an LSP to traverse multiple areas in a network by including the **inter-domain** statement as a part of the LSP configuration. This statement allows the router to search for routes in the IGP database. You need to configure this statement on routers that might be unable to locate a path using intra-domain CSPF (by looking in the traffic engineering database (TED)). When you configure inter-area LSPs, the **inter-domain** statement is required.

Before you begin:

- Configure the device interfaces with family MPLS.
- Configure the device router ID and autonomous system number.
- Enable MPLS and RSVP on the router and transit interfaces.
- Configure your IGP to support traffic engineering.
- Set up an LSP from the ingress to the egress router.

To configure an LSP across multiple ASs on the ingress label-switched router (LER):

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set mpls interface all
user@LER# set mpls interface fxp0.0 disable
```

2. Enable RSVP on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set rsvp interface all
user@LER# set rsvp interface fxp0.0 disable
```

3. Configure the inter-area LSP.

```
[edit protocols]
user@LER# set mpls label-switched-path inter-area-LSP-name to
   egress-LER-ip-address
user@LER# set mpls label-switched-path inter-area-LSP-name inter-domain
```

4. Verify and commit the configuration.

```
[edit protocols]
user@LER# set rsvp interface ge-0/0/0.0
user@LER# set rsvp interface lo0.0
```

```
user@LER# set rsvp interface fxp0.0 disable
user@LER# set mpls statistics traffic-class-statistics
user@LER# set mpls label-switched-path R1-R2 to 20.0.0.1
user@LER# set mpls label-switched-path R1-R2 inter-domain
user@LER# set mpls interface ge-0/0/0.0
user@LER# set mpls interface lo0.0
user@LER# set mpls interface fxp0.0 disable
user@LER# set ospf traffic-engineering
user@LER# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@LER# set ospf area 0.0.0.0 interface lo0.0
```

Disabling Normal TTL Decrementing

By default, the time-to-live (TTL) field value in the packet header is decremented by 1 for every hop the packet traverses in the LSP, thereby preventing loops. If the TTL field value reaches 0, packets are dropped, and an Internet Control Message Protocol (ICMP) error packet is sent to the originating router.

If the normal TTL decrement is disabled, the TTL field of IP packets entering LSPs are decremented by only 1 on transiting the LSP, making the LSP appear as a one-hop router to diagnostic tools, such as **traceroute**. Decrementing the TTL field by 1 is done by the ingress router, which pushes a label on IP packets with the TTL field in the label initialized to 255. The label's TTL field value is decremented by 1 for every hop the MPLS packet traverses in the LSP. On the penultimate hop of the LSP, the router pops the label but does not write the label's TTL field value to the IP packet's TTL field. Instead, when the IP packet reaches the egress router, the IP packet's TTL field value is decremented by 1.

When you use **traceroute** to diagnose problems with an LSP from outside that LSP, **traceroute** sees the ingress router, even though the egress router performs the TTL decrement. The behavior of **traceroute** is different if it is initiated from the ingress router of the LSP. In this case, the egress router would be the first router to respond to **traceroute**.

You can disable normal TTL decrementing in an LSP so that the TTL field value does not reach 0 before the packet reaches its destination, thus preventing the packet from being dropped. You can also disable normal TTL decrementing to make the MPLS cloud appear as a single hop, thereby hiding the network topology.

There are two ways to disable TTL decrementing:

- On the ingress of the LSP, if you include the **no-decrement-ttl** statement, the ingress router negotiates with all downstream routers using a proprietary RSVP object, to ensure all routers are in agreement. If negotiation succeeds, the whole LSP behaves as one hop to transit IP traffic.

  ```
  no-decrement-ttl;
  ```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

NOTE: The RSVP object is proprietary to the Junos OS and might not work with other software. This potential incompatibility applies only to RSVP-signaled LSPs. When you include the **no-decrement-ttl** statement, TTL hiding can be enforced on a per-LSP basis.

- On the ingress router, you can include the **no-propagate-ttl** statement. The **no-propagate-ttl** statement applies to all LSPs, regardless of whether they are RSVP-signaled or LDP-signaled. Once set, all future LSPs traversing through this router behave as a single hop to IP packets. LSPs established before you configure this statement are not affected.

  ```
  no-propagate-ttl;
  ```

  You can include this statement at the following hierarchy levels:

  - **[edit protocols mpls]**
  - **[edit logical-systems *logical-system-name* protocols mpls]**

  The operation of the **no-propagate-ttl** statement is interoperable with other vendors' equipment. However, you must ensure that all routers are configured identically.

  To configure the TTL behavior for a single VRF routing instance, include the **no-vrf-propagate-ttl** or the **vrf-propagate-ttl** statement in the routing instance configuration at the [**edit routing-instances *instance-name***] hierarchy level. The **no-vrf-propagate-ttl** or the **vrf-propagate-ttl** statement overrides the behavior configured globally for the router. If the router is operating in default mode with normal TTL decrementing, the **no-vrf-propagate-ttl** overrides the global behavior for the routing instance on which the **no-vrf-propagate-ttl** statement is configured.

Configuring Adaptive LSPs

An LSP occasionally might need to reroute itself for these reasons:

- The continuous reoptimization process is configured with the **optimize-timer** statement.
- The current path has connectivity problems.
- The LSP is preempted by another LSP configured with the **priority** statement and is forced to reroute.
- The explicit-path information for an active LSP is modified, or the LSP's bandwidth is increased.

You can configure an LSP to be *adaptive* when it is attempting to reroute itself. When it is adaptive, the LSP holds onto existing resources until the new path is successfully established and traffic has been cut over to the new LSP. To retain its resources, an adaptive LSP does the following:

- Maintains existing paths and allocated bandwidths—This ensures that the existing path is not torn down prematurely and allows the current traffic to continue flowing while the new path is being set up.
- Avoids double-counting for links that share the new and old paths—Double-counting occurs when an intermediate router does not recognize that the new and old paths belong to the same LSP and counts them as two separate LSPs, requiring separate bandwidth allocations. If some links are close to saturation, double-counting might cause the setup of the new path to fail.

By default, adaptive behavior is disabled. You can include the **adaptive** statement in two different hierarchy levels.

If you specify the **adaptive** statement at the LSP hierarchy levels, the adaptive behavior is enabled on all primary/secondary paths of the LSP. This means both the primary and secondary paths share the same bandwidth on common links.

To configure adaptive behavior for all LSP paths, include the **adaptive** statement in the LSP configuration:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

If you specify the **adaptive** statement at the **[edit protocols mpls label-switched-path** ***lsp-name*** **(primary | secondary)** ***path-name*****]** hierarchy level, adaptive behavior is enabled only on the path on which it is specified. Bandwidth double-counting occurs between different paths. However, if you also have the **adaptive** statement configured at the **[edit protocols mpls label-switched-path** ***lsp-name*****]** hierarchy level, it overrides the adaptive behavior of each individual path.

To configure adaptive behavior for either the primary or secondary level, include the **adaptive** statement:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** **(**primary **|** secondary**)** ***path-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** **(**primary **|** secondary**)** ***path-name*****]**

Damping Advertisement of LSP State Changes

When an LSP changes from being up to being down, or from down to up, this transition takes effect immediately in the router software and hardware. However, when advertising LSPs into IS-IS and OSPF, you may want to damp LSP transitions, thereby not advertising the transition until a certain period of time has transpired (known as the hold time). In this case, if the LSP goes from up to down, the LSP is not advertised as being down until it has remained down for the hold-time period. Transitions from down to up are advertised into IS-IS and OSPF immediately. Note that LSP damping affects only the IS-IS and OSPF advertisements of the LSP; other routing software and hardware react immediately to LSP transitions.

To damp LSP transitions, include the **advertisement-hold-time** statement:

```
advertisement-hold-time seconds;
```

seconds can be a value from 0 through 65,535 seconds. The default is 5 seconds.

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Configuring Primary and Secondary LSPs

By default, an LSP routes itself hop-by-hop toward the egress router. The LSP tends to follow the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are “soft” in nature because they automatically re-route themselves whenever a change occurs in a routing table or in the status of a node or link.

To configure the path so that it follows a particular route, create a named path using the **path** statement, as described in “Creating Named Paths” on page 414. Then apply the named path by including the **primary** or **secondary** statement. A named path can be referenced by any number of LSPs.

To configure primary and secondary paths for an LSP, complete the steps in the following sections:

Configuring Primary and Secondary Paths for an LSP

The **primary** statement creates the primary path, which is the LSP’s preferred path. The **secondary** statement creates an alternative path. If the primary path can no longer reach the egress router, the alternative path is used.

To configure primary and secondary paths, include the **primary** and **secondary** statements:

```
primary path-name {
   ...
}
secondary path-name {
   ...
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

When the software switches from the primary to a secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable, but no sooner than the retry time specified in the **retry-timer** statement. (For more information, see "Configuring the Connection Between Ingress and Egress Routers" on page 419.)

You can configure zero or one primary path. If you do not configure a primary path, the first secondary path that is established is selected as the path.

You can configure zero or more secondary paths. All secondary paths are equal. The software does not attempt to switch among secondary paths. If the current secondary path is not available, the next one is tried in no particular order. To create a set of equal paths, specify secondary paths without specifying a primary path.

If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress router.

Configuring the Revert Timer for LSPs

For LSPs configured with both primary and secondary paths, it is possible to configure the revert timer. If a primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to a primary path. If during this time, the primary path experiences any connectivity problems or stability problems, the timer is restarted. You can configure the revert timer for both static and dynamic LSPs.

The Junos OS also makes a determination as to which path is the preferred path. The preferred path is the path that has not encountered any difficulty in the last revert timer period. If both the primary and secondary paths have encountered difficulty, neither path is considered preferred. However, if one of the paths is dynamic and the other static, the dynamic path is selected as the preferred path.

If you have configured BFD on the LSP, Junos OS waits until the BFD session comes up on the primary path before starting the revert timer counter.

The range of values you can configure for the revert timer is 0 through 65,535 seconds. The default value is 60 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the primary path to the secondary path, remains on the secondary path permanently (until the network operator intervenes or until the secondary path goes down).

You can configure the revert timer for all LSPs on the router at the **[edit protocols mpls]** hierarchy level or for a specific LSP at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level.

To configure the revert timer, include the **revert-timer** statement:

```
revert-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

Specifying the Conditions for Path Selection

When you have configured both primary and secondary paths for an LSP, you may need to ensure that only a specific path is used.

The **select** statement is optional. If you do not include it, MPLS uses an automatic path selection algorithm.

The **manual** and **unconditional** options do the following:

- **manual**—The path is immediately selected for carrying traffic as long as it is up and stable. Traffic is sent to other working paths if the current path is down or degraded (receiving errors). This parameter overrides all other path attributes except the **select unconditional** statement.
- **unconditional**—The path is selected for carrying traffic unconditionally, regardless of whether the path is currently down or degraded (receiving errors). This parameter overrides all other path attributes.

  Because the **unconditional** option switches to a path without regard to its current status, be aware of the following potential consequences of specifying it:

  - If a path is not currently up when you enable the **unconditional** option, traffic can be disrupted. Ensure that the path is functional before specifying the **unconditional** option.
  - Once a path is selected because it has the **unconditional** option enabled, all other paths for the LSP are gradually cleared, including the primary and standby paths. No path can act as a standby to an unconditional path, so signaling those paths serves no purpose.

For a specific path, the **manual** and **unconditional** options are mutually exclusive. You can include the **select** statement with the **manual** option in the configuration of only one of an LSP's paths, and the **select** statement with the **unconditional** option in the configuration of only one other of its paths.

Enabling or disabling the **manual** and **unconditional** options for the **select** statement while LSPs and their paths are up does not disrupt traffic.

To specify that a path be selected for carrying traffic if it is up and stable for at least the revert timer window, include the **select** statement with the **manual** option:

```
select manual;
```

To specify that a path should always be selected for carrying traffic, even if it is currently down or degraded, include the **select** statement with the **unconditional** option:

```
select unconditional;
```

You can include the **select** statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** **(**primary **|** secondary**)** ***path-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** **(**primary **|** secondary**)** ***path-name*****]**

Configuring Hot Standby of Secondary Paths for LSPs

By default, secondary paths are set up only as needed. To have the system maintain a secondary path in a hot-standby state indefinitely, include the **standby** statement:

```
standby;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** secondary**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** secondary**]**

The hot-standby state is meaningful only on secondary paths. Maintaining a path in a hot-standby state enables swift cutover to the secondary path when downstream routers on the current active path indicate connectivity problems. Although it is possible to configure the **standby** statement at the **[edit protocols mpls label-switched-path** ***lsp-name*** **primary** ***path-name*****]** hierarchy level, it has no effect on router behavior.

If you configure the **standby** statement at the following hierarchy levels, the hot-standby state is activated on all secondary paths configured beneath that hierarchy level:

- **[edit protocols mpls]**
- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

The hot-standby state has two advantages:

- It eliminates the call-setup delay during network topology changes. Call setup can suffer from significant delays when network failures trigger large numbers of LSP reroutes at the same time.

- A cutover to the secondary path can be made before RSVP learns that an LSP is down. There can be significant delays between the time the first failure is detected by protocol machinery (which can be an interface down, a neighbor becoming unreachable, a route becoming unreachable, or a transient routing loop being detected) and the time an LSP actually fails (which requires a timeout of soft state information between adjacent RSVP routers). When topology failures occur, hot-standby secondary paths can usually achieve the smallest cutover delays with minimal disruptions to user traffic.

When the primary path is considered to be stable again, traffic is automatically switched from the standby secondary path back to the primary path. The switch is performed no faster than twice the retry-timer interval and only if the primary path exhibits stability throughout the entire switch interval.

The drawback of the hot-standby state is that more state information must be maintained by all the routers along the path, which requires overhead from each of the routers.

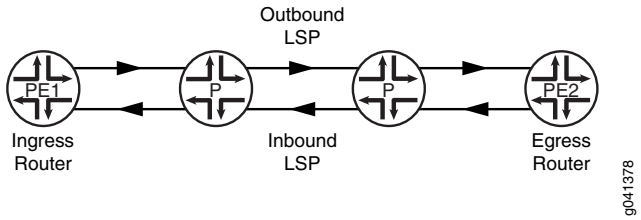
NOTE: When viewed with inet.3, the same LSP may appear to be shown twice as the active route (both primary and secondary), even though traffic actually is being forwarded over the primary path LSP only. This is normal output, and reflects only that the secondary standby path is available.

Configuring Corouted Bidirectional LSPs

A corouted bidirectional packet LSP is a combination of two LSPs sharing the same path between a pair of ingress and egress nodes, as shown in Figure 44 on page 463. It is established using the GMPLS extensions to RSVP-TE. This type of LSP can be used to carry any of the standard types of MPLS-based traffic, including Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. You can configure a single BFD session for the bidirectional LSP (you do not need to configure a BFD session for each LSP in each direction). You can also configure a single standby bidirectional LSP to provide a backup for the primary bidirectional LSP. Corouted bidirectional LSPs are supported for both penultimate hop popping (PHP) and ultimate hop popping (UHP).

High availability is available for bidirectional LSPs. You can enable graceful restart and nonstop active routing. Graceful restart and nonstop active routing are supported when the restarting router is the ingress, egress, or transit router for the bidirectional LSP.

Figure 44: Corouted Bidirectional LSP



To configure a corouted bidirectional LSP:

1. In configuration mode, configure the ingress router for the LSP and include the **corouted-bidirectional** statement to specify that the LSP be established as a corouted bidirectional LSP.

   The path is computed using CSPF and initiated using RSVP signaling (just like a unidirectional RSVP signaled LSP). Both the path to the egress router and the reverse path from the egress router are created when this configuration is committed.

   ```
   [edit protocols mpls]
   user@PE1# set label-switched-path sample-lsp corouted-bidirectional
   ```

2. (Optional) For a reverse path, configure an LSP on the egress router and include the **corouted-bidirectional-passive** statement to associate the LSP with another LSP.

   No path computation or signaling is used for this LSP since it relies on the path computation and signaling provided by the ingress LSP. You cannot configure both the **corouted-bidirectional** statement and the **corouted-bidirectional-passive** statement on the same LSP.

   ```
   [edit protocols mpls]
   user@PE1# set label-switched-path sample-lsp-reverse-path
     corouted-bidirectional-passive
   ```

   This statement also makes it easier to debug corouted bidirectional LSPs. If you configure the **corouted-bidirectional-passive** statement (again, on the egress router), you can issue ping mpls lsp-end-point, ping mpls ldp, ping mpls rsvp, traceroute mpls ldp, and traceroute mpls rsvp commands to test the corouted bidirectional LSP from the egress router.

3. Use the **show mpls lsp extensive** and the **show rsvp session extensive** commands to display information about the bidirectional LSP.

   The following shows output for the **show rsvp session extensive** command when run on an ingress router with a bidirectional LSP configured:

   user@PE1> show rsvp session extensive

   ```
   Ingress RSVP: 2 sessions

Configuring the Entropy Label for LSPs

The insertion of entropy labels for an LSP enables transit routers to load-balance MPLS traffic across ECMP paths or Link Aggregation groups using just the MPLS label stack as a hash input without having to rely on deep packet inspection. Deep packet inspection requires more of the router's processing power and different routers have differing deep-packet inspection capabilities.

To configure the entropy label for an LSP, complete the following steps:

1. On the ingress router, include the **entropy-label** statement at the **[edit protocols mpls labeled-switched-path *labeled-switched-path-name*]** hierarchy level or at the **[edit protocols mpls static-labeled-switched-path *labeled-switched-path-name* ingress]** hierarchy level. The entropy label is added to the MPLS label stack and can be processed in the forwarding plane.

   ```
   entropy-label;
   ```

   

   NOTE: This is only applicable for RSVP and static LSPs.

2. On the ingress router, you can configure an ingress policy for LDP-signaled LSPs:

   ```
   entropy-label {
     ingress-policy policy-name;
   }
   ```

   Configure the ingress policy at the **[edit policy-options]** hierarchy level:

   ```
   policy-options {
     policy-statement policy-name {
       term term-name {
         from {
           prefix-list prefix-list-name;
         }
         then actions;
       }
     }
   }
   ```

   The following shows an example of an entropy label ingress policy.

   ```
   policy-options {
     policy-statement entropy-policy {
       term no-insert-entropy-label {
         from {
           prefix-list no-entropy-label-fec;
         }
         then accept;
       }
   ```

```
  }
}
```

3. (Optional) By default, routers that support the pushing and popping of entropy labels are configured with the **load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the provider edge (PE) router from signaling the entropy label capability by configuring the **no-load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level.

```
[edit forwarding-options]
user@PE no-load-balance-label-capability;
```

Transit routers require no configuration. The presence of the entropy label indicates to the transit router to load balance based solely on the MPLS label stack.

Penultimate hop routers pop the entropy label by default.

Example: Configuring an Entropy Label for a BGP Labeled Unicast LSP

This example shows how to configure an entropy label for a BGP labeled unicast to achieve end-to-end load balancing using entropy labels. When an IP packet has multiple paths to reach its destination, Junos OS uses certain fields of the packet headers to hash the packet to a deterministic path. This requires an entropy label, a special load-balancing label that can carry the flow information. LSRs in the core simply use the entropy label as the key to hash the packet to the correct path. An entropy label can be any label value between 16 to 1048575 (regular 20-bit label range). Since this range overlaps with the existing regular label range, a special label called entropy label indicator (ELI) is inserted before the entropy label. ELI is a special label assigned by IANA with the value of 7.

BGP labeled unicasts generally concatenate RSVP or LDP LSPs across multiple IGP areas or multiple autonomous systems. RSVP or LDP entropy labels are popped at the penultimate hop node, together with the RSVP or LDP label. This feature enables the use of entropy labels at the stitching points to bridge the gap between the penultimate hop node and the stitching point, in order to achieve end-to-end entropy label load balancing for BGP traffic.

Requirements

This example uses the following hardware and software components:

- Seven MX Series routers with MPCs
- Junos OS Release 15.1 or later running on all the devices

Before you configure an entropy label for BGP labeled unicast, make sure you:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure RSVP.
5. Configure MPLS.

Overview

When BGP labeled unicasts concatenate RSVP or LDP LSPs across multiple IGP areas or multiple autonomous systems, RSVP or LDP entropy labels are popped at the penultimate hop node, together with the RSVP or LDP label. However, there are no entropy labels at the stitching points, that is, the routers between two areas. Therefore, the routers at the stitching points used the BGP labels to forward packets.

Beginning with Junos OS Release 15.1, you can configure an entropy label for BGP labeled unicast to achieve end-to-end entropy label load balancing. This feature enables the use of an entropy label at the stitching points in order to achieve end-to-end entropy label load balancing for BGP traffic. Junos OS allows the insertion of entropy labels at the BGP labeled unicast LSP ingress.

By default, routers that support entropy labels are configured with the **load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the signaling of entropy label capability by configuring the **no-load-balance-label-capability** at the **[edit forwarding-options]** hierarchy level.

```
[edit forwarding-options]
user@PE# no-load-balance-label-capability
```

NOTE: You can explicitly disable advertising entropy label capability at egress for routes specified in the policy with the **no-entropy-label-capability** option at the **[edit policy-options** policy-statement *policy name* **then]** hierarchy level.

```
[edit policy-options policy-statement policy-name then]
user@PE# no-entropy-label-capability
```

Topology

In Figure 45 on page 469 , Router PE1 is the ingress router and Router PE2 is the egress router. Routers P1 and P2 are the transit routers. Router ABR is the area bridge router between Area 0 and Area 1. LAG is configured on the provider routers for load balancing the traffic. Entropy label capability for BGP labeled unicast is enabled on the ingress Router PE1.

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring Router PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.5.0.1/24
user@PE1# set ge-0/0/0 unit 0 family iso
user@PE1# set ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:1/120
user@PE1# set ge-0/0/0 unit 0 family mpls

user@PE1# set ge-0/0/1 unit 0 family inet address 1.1.0.1/24
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6 address 2000::1:1:0:1/120
user@PE1# set ge-0/0/1 unit 0 family mpls

user@PE1# set ge-0/0/2 unit 0 family inet address 50.0.1.1/24
user@PE1# set ge-0/0/2 unit 0 family inet6 address 2000::1:34:0:2/120

user@PE1# set ge-0/0/3 vlan-tagging
user@PE1# set ge-0/0/3 unit 0 vlan-id 520
user@PE1# set ge-0/0/3 unit 0 family inet address 1.0.0.2/16
```

2. Configure the loopback interface.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.101.100/32 primary
```

3. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@PE1# set router-id 10.255.101.100
user@PE1# set autonomous-system 1
```

4. Configure RSVP protocol for all interfaces.

```
[edit protocols]
user@PE1# set protocols rsvp interface all
```

5. Enable MPLS on all the interfaces of Router PE1 and specify the LSP.

```
[edit protocols]
user@PE1# set mpls icmp-tunneling
user@PE1# set mpls no-cspf
user@PE1# set mpls label-switched-path r0-r2 to 10.255.102.102
user@PE1# set mpls label-switched-path r0-r2 entropy-label
user@PE1# set mpls interface all
```

6. Configure IBGP on the internal routers.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
user@PE1# set bgp group ibgp local-address 10.255.101.100
```

7. Enable entropy label capability for BGP labeled unicast for internal BGP group ibgp.

```
user@PE1# set bgp group ibgp family inet labeled-unicast entropy-label
user@PE1# set bgp group ibgp neighbor 10.255.102.102 family inet labeled-unicast
   rib inet.3
user@PE1# set bgp group ibgp neighbor 10.255.101.200 family inet-vpn unicast
```

8. Enable the OSPF protocol on all the interfaces of the area border router (ABR).

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

9. Define prefix lists to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-options prefix-list el-fec 10.255.101.200/32
user@PE1# set policy-options prefix-list el-fec-2 10.255.102.102/32
```

10. Define a policy EL to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-statement EL from prefix-list el-fec
user@PE1# set policy-statement EL then accept
```

11. Define another policy EL-2 to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-statement EL-2 from prefix-list el-fec-2
user@PE1# set policy-statement EL-2 then accept
```

12. Define a policy to export BGP routes to the OSPF routing table.

```
[edit policy-options ]
user@PE1# set policy-statement bgp-to-ospf from protocol bgp
user@PE1# set policy-statement bgp-to-ospf then accept
```

13. Define a policy to export OSPF routes to the BGP routing table.

```
[edit policy-options ]
user@PE1# set policy-statement ospf-to-bgp from protocol ospf
user@PE1# set policy-statement ospf-to-bgp then accept
```

14. Define a policy to export static routes to the BGP routing table.

```
[edit policy-options ]
user@PE1# set policy-statement stat-to-bgp from protocol static
user@PE1# set policy-statement stat-to-bgp then accept
```

15. Configure a VPN target for the VPN community.

```
[edit policy-options ]
user@PE1# set community VPN members target:100:1
```

16. Configure the Layer 3 VPN routing instance VPN-l3vpn.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn instance-type vrf
```

17. Assign the interfaces for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn interface ge-0/0/2.0
user@PE1# set VPN-l3vpn interface ge-0/0/3.0
```

18. Configure the route distinguisher for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn route-distinguisher 100.100.100.100:100
```

19. Configure a VPN routing and forwarding (VRF) target for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn vrf-target target:100:1
```

20. Configure a static route to Device CE1 using the Layer 3 VPN protocol for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn routing-options static route 5.0.0.0/16 next-hop 1.0.0.1
```

21. Export the BGP routes to the OSPF routing table for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn protocols ospf export bgp-to-ospf
```

22. Assign the OSPF interface for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn protocols ospf area 0.0.0.0 interface ge-0/0/2.0
```

Configuring Router P1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router P1:

NOTE: Repeat this procedure for Router P2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@P1# set ge-0/0/0 unit 0 family inet address 1.5.0.2/24
user@P1# set ge-0/0/0 unit 0 family iso
user@P1# set ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:2/120
user@P1# set ge-0/0/0 unit 0 family mpls

user@P1# set ge-0/0/2 unit 0 family inet address 1.1.0.2/24
user@P1# set ge-0/0/2 unit 0 family iso
user@P1# set ge-0/0/2 unit 0 family inet6 address 2000::1:1:0:2/120
user@P1# set ge-0/0/2 unit 0 family mpls

user@P1# set ge-0/0/1 gigether-options 802.3ad ae0

user@P1# set ge-0/0/3 gigether-options 802.3ad ae0
```

2. Configure link aggregation on the interfaces.

```
user@P1# set ae0 unit 0 family inet address 1.12.0.1/24
user@P1# set ae0 unit 0 family mpls
```

3. Configure the loopback interface.

```
[edit interfaces]
user@P1# set lo0 unit 0 family inet address 10.255.102.101/32 primary
```

4. Configure MPLS labels that the router uses for hashing the packets to its destination for load balancing.

```
[edit forwarding-options]
user@P1# set hash-key family mpls label-1
user@P1# set hash-key family mpls label-2
user@P1# set hash-key family mpls label-3
user@P1# set enhanced-hash-key family mpls no-payload
```

5. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@P1# set router-id 10.255.102.101
user@P1# set autonomous-system 1
```

6. Enable per packet load balancing.

```
[edit routing-options]
user@P1# set forwarding-table export pplb
```

7. Configure the RSVP protocol for all interfaces.

```
[edit protocols]
user@P1# set protocols rsvp interface all
```

8. Enable MPLS on all the interfaces of Router P1 and specify the LSP.

```
[edit protocols]
user@P1# set protocols mpls icmp-tunneling
user@P1# set protocols mpls interface all
```

9. Enable the OSPF protocol on all the interfaces of Router P1 excluding the management interface.

```
[edit protocols]
user@P1# set protocols ospf traffic-engineering
user@P1# set protocols ospf area 0.0.0.0 interface lo0.0 passive
user@P1# set protocols ospf area 0.0.0.0 interface fxp0.0 disable
```

```
user@P1# set protocols ospf area 0.0.0.0 interface all
user@P1# set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
user@P1# set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
```

10. Define a policy for per packet load balancing.

```
[edit policy-options]]
user@P1# set policy-statement pplb then load-balance per-packet
```

Configuring Router ABR

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router ABR:

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@ABR# set ge-0/0/0 gigether-options 802.3ad ae0

user@ABR# set ge-0/0/1 gigether-options 802.3ad ae1

user@ABR# set ge-0/0/2 gigether-options 802.3ad ae0

user@ABR# set ge-0/0/3 gigether-options 802.3ad ae1
```

2. Configure the loopback interface.

```
[edit interfaces]
user@ABR# set lo0 unit 0 family inet address 10.255.102.102/32 primary
```

3. Configure link aggregation on the interfaces.

```
[edit interfaces]
user@ABR# set ae0 unit 0 family inet address 1.12.0.2/24
user@ABR# set ae0 unit 0 family mpls
user@ABR# set ae1 unit 0 family inet address 1.23.0.1/24
user@ABR# set ae1 unit 0 family mpls
```

4. Configure MPLS labels that the router uses for hashing the packets to its destination for load balancing.

```
[edit forwarding-options]
```

```
user@ABR# set hash-key family mpls label-1
user@ABR# set hash-key family mpls label-2
user@ABR# set hash-key family mpls label-3
user@ABR# set enhanced-hash-key family mpls no-payload
```

5. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@ABR# set router-id 10.255.102.102
user@ABR# set autonomous-system 1
```

6. Enable per packet load balancing.

```
[edit routing-options]
user@ABR# set forwarding-table export pplb
```

7. Configure the RSVP protocol for all interfaces.

```
[edit protocols]
user@ABR# set protocols rsvp interface all
```

8. Enable MPLS on all the interfaces of Router P1 and specify the LSP.

```
[edit protocols]
user@ABR# set mpls icmp-tunneling
user@ABR# set mpls label-switched-path r2-r0 to 10.255.101.100
user@ABR# set mpls label-switched-path r2-r0 entropy-label
user@ABR# set mpls label-switched-path r2-r4 to 10.255.101.200
user@ABR# set mpls label-switched-path r2-r4 entropy-label
user@ABR# set mpls interface all
```

9. Configure IBGP on the internal routers.

```
[edit protocols ]
user@ABR# set bgp group ibgp type internal
user@ABR# set bgp group ibgp local-address 10.255.102.102
user@ABR# set bgp group ibgp family inet labeled-unicast rib inet.3
user@ABR# set bgp group ibgp neighbor 10.255.101.100 export send-inet3-R4
user@ABR# set bgp group ibgp neighbor 10.255.101.200 export send-inet3-R0
```

10. Enable the OSPF protocol on all the interfaces of ABR.

```
[edit protocols ]
user@ABR# set ospf traffic-engineering
user@ABR# set ospf area 0.0.0.0 interface lo0.0 passive
user@ABR# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@ABR# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@ABR# set ospf area 0.0.0.0 interface ae0.0
```

```
user@ABR# set ospf area 0.0.0.0 interface fxp0.0 disable
user@ABR# set ospf area 0.0.0.1 interface ge-0/0/3.0
user@ABR# set ospf area 0.0.0.1 interface ge-0/0/1.0
user@ABR# set ospf area 0.0.0.1 interface ae1.0
```

11. Define a policy to specify the routes with entropy label capability.

```
[edit policy-options ]
user@ABR# set policy-statement pplb then load-balance per-packet
user@ABR# set policy-statement send-inet3-R0 from route-filter 10.255.101.100/32
  exact
user@ABR# set policy-statement send-inet3-R0 then accept
user@ABR# set policy-statement send-inet3-R4 from route-filter 10.255.101.200/32
  exact
user@ABR# set policy-statement send-inet3-R4 then accept
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, **show forwarding options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@ABR# show interfaces

    then accept;
  }
```

Verification

Confirm that the configuration is working properly.

- Verifying That the Entropy Label Capability Is Being Advertised from Router PE2 on page 484
- Verifying That Router ABR Receives the Entropy Label Advertisement on page 485
- Verifying That the Entropy Label Flag Is Set on page 486

Verifying That the Entropy Label Capability Is Being Advertised from Router PE2

Purpose Verify that the entropy label capability path attribute is being advertised from the upstream Router PE2 at egress.

Action From operational mode, run the **show route 10.255.101.200 advertising-protocol bgp 10.255.102.102** command on Router PE2.

```
user@PE2> show route 10.255.101.200 advertising-protocol bgp 10.255.102.102

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
* 10.255.101.200/32 (1 entry, 1 announced)
 BGP group ibgp type Internal
     Route Label: 299920
     Nexthop: Self
     Flags: Nexthop Change
     MED: 2
     Localpref: 4294967294
     AS path: [1] I
     Entropy label capable
```

Meaning The output shows that the host PE2 with the IP address of 10.255.101.200 has the entropy label capability. The host is advertising the entropy label capability to its BGP neighbors.

Verifying That Router ABR Receives the Entropy Label Advertisement

Purpose Verify that Router ABR receives the entropy label advertisement at ingress from Router PE2.

Action From operational mode, run the **show route 10.255.101.200 receiving-protocol bgp 10.255.101.200** command on Router ABR.

```
user@ABR> show route 10.255.101.200 receiving-protocol bgp 10.255.101.200
inet.0: 63 destinations, 63 routes (63 active, 0 holddown, 0 hidden)

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
* 10.255.101.100/32 (1 entry, 1 announced)
     Accepted
     Route Label: 299920
     Nexthop: 10.255.102.102
     MED: 2
     Localpref: 4294967294
     AS path: I
     Entropy label capable

VPN-l3vpn.inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)

iso.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)

mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)

bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)

inet6.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)

VPN-l3vpn.inet6.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)

user@PE1> show route protocol bgp detail

                AS path: I
                Accepted
                Route Label: 299904
                Localpref: 4294967294
                Router ID: 10.255.102.102
VPN-l3vpn.inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
```

Meaning Router ABR receives the entropy label capability advertisement from its BGP neighbor PE2.

Verifying That the Entropy Label Flag Is Set

Purpose Verify that the entropy label flag is set for the label elements at the ingress.

Action From operational mode, run the **show route protocol bgp detail** command on Router PE1.

```
user@PE1> show route protocol bgp detail
inet.0: 64 destinations, 64 routes (64 active, 0 holddown, 0 hidden)

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
10.255.101.200/32 (1 entry, 1 announced)
        *BGP    Preference: 170/1
                Next hop type: Indirect, Next hop index: 0
                Address: 0xa533c10
                Next-hop reference count: 2
                Source: 10.255.102.102
                Next hop type: Router, Next hop index: 0
                Next hop: 1.1.0.2 via ge-0/0/1.0, selected
                Label-switched-path r0-r2
                Label operation: Push 299904, Push 300096(top)
                Label TTL action: prop-ttl, prop-ttl(top)
              Load balance label: Label 299904: Entropy label; Label 300096: None;

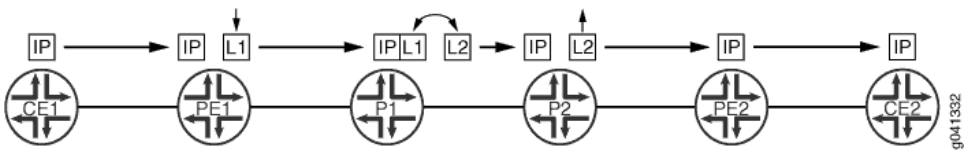
- *Understanding Entropy Label for BGP Labeled Unicast LSP*

Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (PHP). Figure 46 on page 487 illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

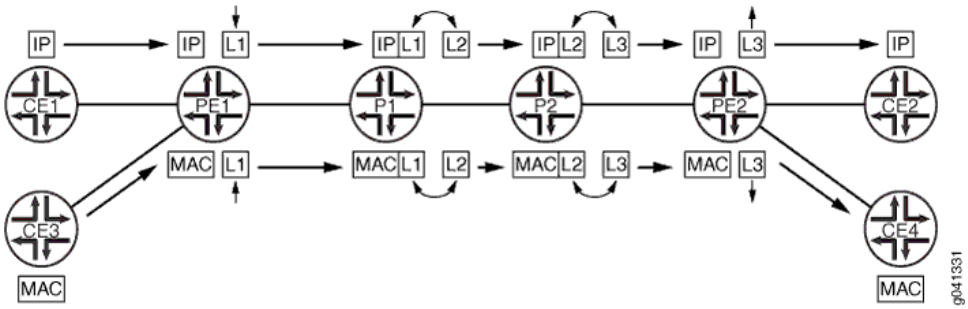
Figure 46: Penultimate-Hop Popping for an LSP



You can also configure ultimate-hop popping (UHP) (as shown in Figure 47 on page 488) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate- hop popping LSP, the penultimate router (Router P2 in Figure 47 on page 488) performs the standard

MPLS label swapping operation (in this example, label 2 for label 3) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

Figure 47: Ultimate-Hop Popping for an LSP



The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band OAM
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs
- Point-to-multipoint LSPs
- CCC
- **traceroute** command

For more information about UHP behavior, see Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a VT interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- Layer 2 VPNs and Layer 2 circuits—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the VC label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- Layer 3 VPN—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward the CE router. However, if you have configured the **vrf-table-label** statement for the Layer 3 VPN routing instance, the inner LSI label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

  NOTE: **UHP for Layer 3 VPNs configured with the vrf-table-label statement is supported on MX Series 5G Universal Routing Platforms only.**

- VPLS—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

  NOTE: **UHP for VPLS configured with the no-tunnel-service statement is supported on MX 3D Series routers only.**

- IPv4 over MPLS—A packet arrives at the PE router (egress of the UHP LSP) with one label (S=1). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route (S=1) points to the inet.0 routing table.
- IPv6 over MPLS—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the

inner label in the mpls.0 routing table redirects back to the mpls.0 routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the inet6.0 routing table.

- Enabling both PHP and UHP LSPs—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the **install-nexthop** statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the **ultimate-hop-popping** statement:

   ```
   ultimate-hop-popping;
   ```

   Include this statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the **[edit protocols mpls]** hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the router. You can also configure the **ultimate-hop-popping** statement under the equivalent **[edit logical-routers]** hierarchy levels.

   NOTE: When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a PathTear message along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).

   If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the **enhanced-ip** option for the **network-services** statement:

   ```
   network-services enhanced-ip;
   ```

   You configure this statement at the **[edit chassis]** hierarchy level. Once you have configured the **network-services** statement, you need to reboot the router to enable UHP behavior.

Configuring Static LSPs

To configure static LSPs, configure the ingress router and each router along the path up to and including the egress router.

To configure static MPLS, perform the following tasks:

- Configuring the Ingress Router for Static LSPs on page 491
- Configuring the Intermediate (Transit) and Egress Routers for Static LSPs on page 494
- Configuring a Bypass LSP for the Static LSP on page 497
- Configuring the Protection Revert Timer for Static LSPs on page 497
- Configuring Static Unicast Routes for Point-to-Multipoint LSPs on page 497

Configuring the Ingress Router for Static LSPs

The ingress router checks the IP address in the incoming packet's destination address field and, if it finds a match in the routing table, applies the label associated with that address to the packets. The label has forwarding information associated with it, including the address of the next-hop router, and the route preference and CoS values.

To configure static LSPs on the ingress router, include the **ingress** statement:

```
ingress {
  bandwidth bps;
  class-of-service cos-value;
  description string;
  install {
    destination-prefix <active>;
  }
  link-protection bypass-name name;
  metric metric;
  next-hop (address | interface-name | address/interface-name);
  no-install-to-address;
  node-protection bypass-name name next-next-label label;
  policing {
    filter filter-name;
    no-auto-policing;
  }
  preference preference;
  push out-label;
  to address;
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols mpls static-label-switched-path *static-lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]**

When you configure a static LSP on the ingress router, the **next-hop**, **push**, and **to** statements are required; the other statements are optional.

The configuration for a static LSP on the ingress router requires you to configure the following parts:

- Criteria for analyzing an incoming packet:
  - The **install** statement creates an LSP that handles IPv4 packets. All static MPLS routes created using the **install** statement are installed in inet.3 routing table, and the creating protocol is identified as static. This process is no different from creating static IPv4 routes at the **[edit routing-options static]** hierarchy level.
  - In the **to** statement, you configure the IP destination address to check when incoming packets are analyzed. If the address matches, the specified outgoing label (**push *out-label***) is assigned to the packet, and the packet enters an LSP. Manually assigned outgoing labels can have values from 0 through 1,048,575. Each prefix that you specify is installed as a static route in the routing table.
- The **next-hop** statement, which supplies the IP address of the next hop to the destination. You can specify this as the IP address of the next hop, the interface name (for point-to-point interfaces only), or as ***address/interface-name*** to specify an IP address on an operational interface. When the next hop is on a directly attached interface, the route is installed in the routing table. You cannot configure a LAN or nonbroadcast multiaccess (NBMA) interface as a next-hop interface.
- Properties to apply to the LSP (all are optional):
  - Bandwidth reserved for this LSP (bandwidth ***bps***)
  - Link protection and node protection to apply to the LSP (bypass ***bypass-name***, link-protection **bypass-name *name***, node-protection **bypass-name next-next-label *label***)
  - Metric value to apply to the LSP (metric)
  - Class-of-service value to apply to the LSP (class-of-service)
  - Preference value to apply to the LSP (preference)
  - Traffic policing to apply to the LSP (policing)
  - Text description to apply to the LSP (description)
  - Install or no-install policy (install or no-install-to-address)

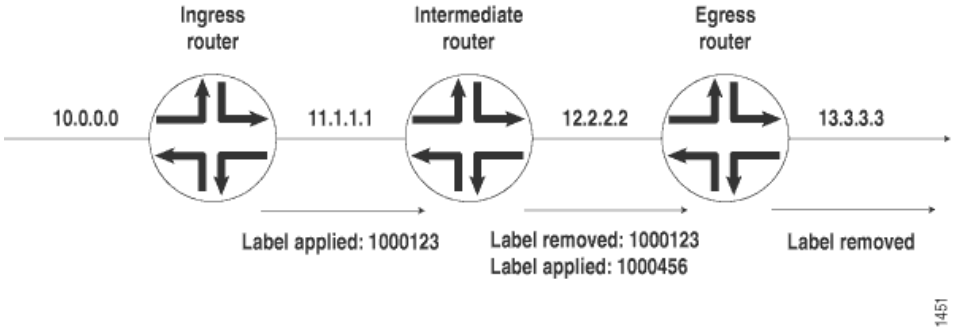
To determine whether a static ingress route is installed, use the command **show route table inet.3 protocol static**. Sample output follows. The **push** keyword denotes that a label is to be added in front of an IP packet.

```
10.0.0.0       *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0, push 1000123
```

Example: Configuring the Ingress Router

Configure the ingress router for a static LSP that consists of three routers (see Figure 48 on page 493).

Figure 48: Static MPLS Configuration



For packets addressed to **10.0.0.0**, assign label **1000123** and transmit them to the next-hop router at **11.1.1.1**:

```
[edit]
interfaces {
   so-0/0/0 {
      unit 0 {
         family mpls;
      }
   }
}
protocols {
   mpls {
      static-label-switched-path path1 {
         ingress {
            next-hop 11.1.1.1;
            to 10.0.0.0;
            push 1000123;
         }
      }
      interface so-0/0/0.0;
   }
}
routing-options {
   static {
      route 10.0.0.0/8 {
         static-lsp-next-hop path1;
      }
   }
```

To determine whether the static ingress route is installed, use the following command:

```
user@host> show route table inet.0 protocol static
```

Sample output follows. The **push 1000123** keyword identifies the route.

```
10.0.0.0/8       *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0.0, push 1000123
```

Configuring the Intermediate (Transit) and Egress Routers for Static LSPs

Intermediate (transit) and egress routers perform similar functions—they modify the label that has been applied to a packet. An intermediate router can change the label. An egress router removes the label (if the packet still contains a label) and continues forwarding the packet to its destination.

To configure static LSPs on intermediate and egress routers, include the **transit** statement:

```
static-label-switched-path lsp-name {
  transit incoming-label {
    bandwidth bps;
    description string;
    link-protection bypass-name name;
    next-hop (address | interface-name | address/interface-name);
    node-protection bypass-name name next-next-label label;
    pop;
    swap out-label;
  }
```

You can include these statements at the following hierarchy levels:

- **[edit protocols mpls static-label-switched-path *static-lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]**

For the **transit** statement configuration, the **next-hop** and **pop | swap** statements are required. The remaining statements are optional.

Each statement within the **transit** statement consists of the following parts:

- Packet label (specified in the **transit** statement)
- The **next-hop** statement, which supplies the IP address of the next hop to the destination. The address is specified as the IP address of the next hop, or the interface name (for point-to-point interfaces only), or ***address*** and ***interface-name*** to specify an IP address on an operational interface. When the specified next hop is on a directly attached interface, this route is installed in the routing table. You cannot configure a LAN or NBMA interface as a next-hop interface.
- Operation to perform on the labeled packet:
  - For egress routers, you generally just remove the packet's label altogether (**pop**) and continue forwarding the packet to the next hop. However, if the previous router removed the label, the egress router examines the packet's IP header and forwards the packet toward its IP destination.

  - For intermediate (transit) routers only, exchange the label for another label (**swap** ***out-label***). Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. Manually assigned outgoing labels can have values from 0 through 1,048,575.

- Label properties to apply to the packet (all are optional):

  - Bandwidth reserved for this route (bandwidth ***bps***).
  - Link-protection and node-protection to apply to the LSP (bypass ***bypass-name***, link-protection **bypass-name** ***name***, node-protection **bypass-name next-next-label** ***label***).
  - Text description to apply to the LSP (specified in the **description** statement).

The static routes are installed in the default MPLS routing table, mpls.0, and the creating protocol is identified as static. To verify that a static route is properly installed, use the command **show route table mpls.0 protocol static**. Sample output follows:

```
1000123            *[Static/5] 00:00:38
> to 12.2.2.2 via so-5/0/0.0, swap 1000456
```

You can configure a revert timer for a static LSP transiting an intermediate router. After traffic has been switched to a bypass static LSP, it is typically switched back to the primary static LSP when it comes back up. There is a configurable delay in the time (called the revert timer) between when the primary static LSP comes up and when traffic is reverted back to it from the bypass static LSP. This delay is needed because when the primary LSP comes back up, it is not certain whether all of the interfaces on the downstream node of the primary path have come up yet. You can display the revert timer value for an interface using the **show mpls interface detail** command. For more information, see "Configuring the Revert Timer for LSPs" on page 460.

Example: Configuring an Intermediate Router

For packets labeled **1000123** arriving on interface **so-0/0/0**, assign the label **1000456**, and transmit them to the next-hop router at **12.2.2.2**:

```
[edit]
interfaces {
   so-0/0/0 {
      unit 0 {
         family mpls;
      }
   }
}
protocols {
   mpls {
      static-label-switched-path path1 {
         transit 1000123 {
            next-hop 12.2.2.2;
            swap 1000456;
         }
```

```
    }
    interface so-0/0/0.0;
  }
}
```

To determine whether the static intermediate route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The **swap 1000456** keyword identifies the route.

```
1000123            *[Static/5] 00:01:48
> to 12.2.2.2 via so-0/0/0, swap 1000456
```

Example: Configuring an Egress Router

For packets labeled **1000456** arriving on interface **so-0/0/0**, remove the label and transmit the packets to the next-hop router at **13.3.3.3**:

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  mpls {
    static-label-switched-path path1 {
      transit 1000456 {
        next-hop 13.3.3.3;
        pop;
      }
    }
    interface so-0/0/0.0;
  }
}
```

To determine whether the static egress route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The **pop** keyword identifies the egress route.

```
1000456            *[Static/5] 00:01:48
> to 13.3.3.3 via so-0/0/0, pop
```

Configuring a Bypass LSP for the Static LSP

To enable a bypass LSP for the static LSP, configure the **bypass** statement:

```
bypass bypass-name {
  bandwidth bps;
  description string;
  next-hop (address | interface-name | address/interface-name);
  push out-label;
  to address;
}
```

Configuring the Protection Revert Timer for Static LSPs

For static LSPs configured with a bypass static LSP, it is possible to configure the protection revert timer. If a static LSP goes down and traffic is switched to the bypass LSP, the protection revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert back to the original static LSP.

The range of values you can configure for the protection revert timer is 0 through 65,535 seconds. The default value is 5 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the original static LSP to the bypass static LSP, remains on the bypass LSP permanently (until the network operator intervenes or until the bypass LSP goes down).

You can configure the protection revert timer for all LSPs on the router at the **[edit protocols mpls]** hierarchy level or for a specific LSP at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level.

To configure the protection revert timer for static LSPs include the **protection-revert-time** statement:

```
protection-revert-time seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

Configuring Static Unicast Routes for Point-to-Multipoint LSPs

You can configure a static unicast IP route with a point-to-multipoint LSP as the next hop. For more information about point-to-multipoint LSPs, see "Point-to-Multipoint LSPs Overview" on page 527, "Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs" on page 551, and "Configuring CCC Switching for Point-to-Multipoint LSPs" on page 1104.

To configure a static unicast route for a point-to-multipoint LSP, complete the following steps:

1. On the ingress PE router, configure a static IP unicast route with the point-to-multipoint LSP name as the next hop by including the **p2mp-lsp-next-hop** statement:

```
p2mp-lsp-next-hop point-to-multipoint-lsp-next-hop;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options static route *route-name*]**
- **[edit logical-systems *logical-system-name* routing-options static route *route-name*]**

2. On the egress PE router, configure a static IP unicast route with the same destination address configured in Step 1 (the address configured at the **[edit routing-options static route]** hierarchy level) by including the **next-hop** statement:

```
next-hop address;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options static route *route-name*]**
- **[edit logical-systems *logical-system-name* routing-options static route *route-name*]**

NOTE: CCC and static routes cannot use the same point-to-multipoint LSP.

For more information on static routes, see the *Junos OS Routing Protocols Library*.

The following **show route** command output displays a unicast static route pointing to a point-to-multipoint LSP on the ingress PE router where the LSP has two branch next hops:

```
user@host> show route 5.5.5.5 detail

inet.0: 29 destinations, 30 routes (28 active, 0 holddown, 1 hidden)
5.5.5.5/32 (1 entry, 1 announced)
        *Static Preference: 5
                Next hop type: Flood
                Next hop: via so-0/3/2.0 weight 1
                Label operation: Push 100000
                Next hop: via t1-0/1/1.0 weight 1
                Label operation: Push 100064
                State: <Active Int Ext>
                Local AS: 10458
                Age: 2:41:15
                Task: RT
                Announcement bits (2): 0-KRT 3-BGP.0.0.0.0+179
                AS path: I
```

Configuring Static Label Switched Paths for MPLS (CLI Procedure)

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress switch and each provider switch along the path up to and including the egress switch.

For the ingress switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575. Optionally, you can apply preference, class-of-service (CoS) values, node protection, and link protection to the packets.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575. Optionally, you can apply node protection and link protection to the packets.

For the egress switch, you generally just remove the label and continue forwarding the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure an LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)" on page 77.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

1. Configuring the Ingress PE Switch on page 499
2. Configuring the Provider and the Egress PE Switch on page 500

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the core interfaces:

   ```
   [edit]
   user@switch# set interfaces interface-name unit logical-unit-number family inet address address
   user@switch# set interfaces interface-name unit logical-unit-number family inet address address
   ```

2. Configure the name and the traffic rate associated with the LSP:

   ```
   [edit]
   user@switch# set protocols mpls static-label-switched-path lsp-name ingress bandwidth rate
   ```

3. Configure the next hop switch for the LSP:

   ```
   [edit]
   ```

```
user@switch# set protocols mpls static-label-switched-path lsp-name ingress next-hop
address-of-next-hop
```

4. Enable link protection on the specified static LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name ingress link-protection
bypass-name name
```

5. Specify the address of the egress switch for the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path path1 ingress to
address-of-egress-switch
```

6. Configure the new label that you want to add to the top of the label stack:

```
[edit]
user@switch# set protocols mpls static-label-switched-path path1 ingress push out-label
```

7. Optionally, configure the next hop address and the egress router address that you want to bypass, for the static LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name by bypass next-hop
address-of-next-hop
user@switch# set protocols mpls static-label-switched-path lsp-name by bypass to
address-of-the-egress-switch
user@switch# set protocols mpls static-label-switched-path lsp-name bypass push out-label
```

Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress provider edge switch:

1. Configure a transit static LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path path1 transit incoming-label
```

2. Configure the next hop switch for the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label
next-hop address-of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label
swap out-label
```

4. Only for the egress provider edge switch, remove the label at the top of the label stack:

NOTE: If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label
pop
```

Configuring Static Label Switched Paths for MPLS

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress PE switch and each provider switch along the path up to and including the egress PE switch.

For the ingress PE switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575.

The egress PE switch removes the label and forwards the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure a static LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches" on page 67.

NOTE: Do not configure LSPs at the **[edit protocols mpls label-switched-path]** hierarchy level on the PE switches.

- Configure one or more provider switches. See "Configuring MPLS on Provider Switches" on page 71.

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

1. Configuring the Ingress PE Switch on page 502
2. Configuring the Provider and the Egress PE Switch on page 502

Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for every core interface:

   ```
   [edit interfaces]
   user@switch# set interface-name unit logical-unit-number family inet address address
   ```

   NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure the name associated with the static LSP:

   ```
   [edit protocols mpls]
   user@switch# set static-label-switched-path lsp-name
   ```

3. Configure the next hop switch for the LSP:

   ```
   [edit protocols mpls]
   user@switch# set static-label-switched-path lsp-name ingress next-hop address-of-next-hop
   ```

4. Specify the address of the egress switch for the LSP:

   ```
   [edit protocols mpls]
   user@switch# set static-label-switched-path lsp-name ingress to address-of-egress-switch
   ```

5. Configure the new label that you want to add to the top of the label stack:

   ```
   [edit protocols mpls]
   user@switch# set static-label-switched-path lsp-name ingress push out-label
   ```

Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress PE switch:

1. Configure a transit static LSP:

   ```
   [edit protocols mpls]
   user@switch# set static-label-switched-path lsp-name transit incoming-label
   ```

2. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label next-hop
address-of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label swap out-label
```

4. Only for the egress PE switch, remove the label at the top of the label stack:

NOTE: If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label pop
```

Static Segment Routing Label Switched Path

You can create static segment routing label switched paths (LSPs) for MPLS networks. For more information, see the following topics:

- Understanding Static Segment Routing LSP in MPLS Networks on page 503
- Example: Configuring Static Segment Routing Label Switched Path on page 507

Understanding Static Segment Routing LSP in MPLS Networks

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Essentially, segments are provisioned on transit routers using the following two methods:

- First, by configuring static segment MPLS label switched paths (LSPs) at **[edit protocols mpls static-label-switched-path]** hierarchy level.
- Second, by using IGPs like ISIS and OSPF to manage segments and advertise segment labels.

The non-colored static segment routing LSPs are then configured on ingress routers at the **[edit protocols source-packet-routing sourc-routing-path]** hierarchy level. These

non-colored static segment routing LSPs refer to segment-lists which consists of the labels of the segments provisioned on the transit routers.

Segment routing leverages the source routing paradigm. A node steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress node to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack. Segment routing can be applied to the IPv6 architecture, with a new type of routing extension header. A segment is encoded as an IPv6 address. An ordered list of segments is encoded as an ordered list of IPv6 addresses in the routing extension header. The segment to process is indicated by a pointer in the routing extension header. Upon completion of a segment, the pointer is incremented. Static segment routing provisioning in MPLS networks supports static adjacency segments, prefix segment, and non-colored segment routing label switched paths. Static segment routing provisioning in an MPLS network involves segment provisioning, segment information distribution, and segment routing LSP provisioning.

Static Segment Routing Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique segment identifier(SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. A route for the SID label is then installed in the mpls.0 table. The next-hop of the route is obtained either through pops-and-forwards for an adjacency SID label, or through swaps-and-forwards for a prefix SID label or node SID label.

Junos OS allows static segment routing LSPs by configuring the **segment** statement at the **[edit protocols mpls static-label-switched-path *static-label-switched-path*]** hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the **static-label-range *static-label-range*** statement at the **[edit protocols mpls label-range]** hierarchy level. The default range of static label pool is 100000 through 1048575. The static segment LSP performs pop-and-forward label operation for adjacency segment or swap-and-forward label operation for prefix or node segment. For both the types of label operation, the static segment LSP has a next hop operation that specifies the remote IP address or the name of an outgoing interface. The interface name is only acceptable for point-to-point interface. For each static segment LSP, the SID label route

is installed in the mpls.0 table with the next hop as per the label operation and the outgoing interface. For an adjacency segment that uses pop-and-forward label operation, a clone route is installed in the mpls.0 table as well. The adjacency segment, prefix segment, and node segment are locally unprotected static segments.

Benefits of using Static Segment Routing of Label Switched Path

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

Non-Colored Static Segment Routing LSP

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

Segment List

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. For a segment routing LSP to be considered as non-colored static LSP, the first hop of the segment list has to be an IP address of an outgoing interface and the second to Nth hops can be SID labels. The number of SID labels in the segment list should not exceed the maximum segment list limit. By default, the maximum segment list limit is 5. You can configure the maximum segment list limit at the **[edit protocols source-packet-routing]** hierarchy level with a range of 2 through 5 SID labels.

Non-colored Segment Routing LSP

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the inet.3 routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1. A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may

specify a metric and a preference at **[edit protocols source-packet-routing source-routing-path *lsp-name*]** for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

Static Segment Routing LSP Provisioning

Junos OS currently has a limitation that the next hop cannot be built to push more than 5 labels. So, a segment list with more than 5 SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than 5, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed 5. You can configure the maximum segment list limit at **[edit protocols source-packet-routing]** hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to 5 SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label. The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring **no-ingress** statement at **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session. These non-colored segment routing LSPs may have binding segment ID (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

Limitations

- A segment-list is usable for non-colored static segment routing LSPs only if the first hop specifies an IP address. If the first hop specifies only as SID label, it cannot be used to resolve an outgoing interface, and a log message is displayed. If the first hop specifies both an IP address and a SID label, the SID label is simply ignored.
- A maximum of 8 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- The maximum depth of label stack that a next hop can push is 5. If any segment-list is configured with more labels then the configuration commit check fails with an error.

Example: Configuring Static Segment Routing Label Switched Path

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

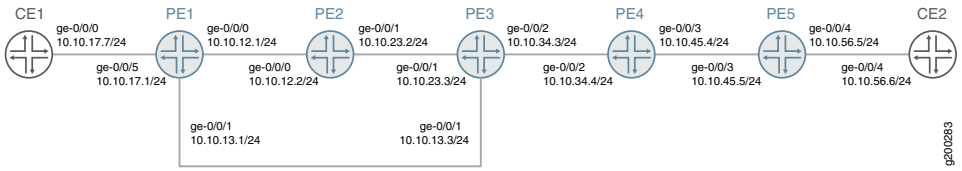
Overview

Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the **segment-list** statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure segment routing tunnel by configuring the **source-routing-path** statement at **[edit protocols source-packet-routing]** hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5 . Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

Figure 49: Static Segment Routing Label Switched Path



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring Device PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5

set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5

set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRIs in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
```

```
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
  ge-0/0/0 {
    unit 0 {
      family inet {
        address 55.1.12.1/24;
      }
      family mpls {
        maximum-labels 5;
      }
    }
  }
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 55.1.13.1/24;
      }

Configuring Device PE2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls

set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-0/0/0 {
   unit 0 {
      family inet {
         address 55.1.12.2/24;
      }
      family mpls;
   }
}
ge-0/0/1 {
   unit 0 {
      family inet {
         address 55.1.23.2/24;
      }
      family mpls;
   }
}
```

```
user@PE2# show protocols
mpls {
   static-label-switched-path adj-23 {
      segment {
         1000123;
         next-hop 55.1.23.3;
         pop;
      }
   }
   static-label-switched-path adj-21 {
      segment {
         1000221;
         next-hop 55.1.12.1;
         pop;
      }
   }
   interface ge-0/0/0.0;
   interface ge-0/0/1.0;
   label-range {
      static-label-range 1000000 1000999;
   }
}
ospf {
   area 0.0.0.0 {
      interface ge-0/0/0.0;
      interface ge-0/0/1.0;
   }
}
```

Verification

Confirm that the configuration is working properly.

Verifying Route Entry of Routing Table inet.3 of Router PE1

Purpose Verify the route entry of routing table inet.3 of router PE1.

Action From operational mode, enter the **show route table inet.3** command.

```
user@PE1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32   *[SPRING-TE/8] 03:09:26, metric 1
                   > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)

                       to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134,
Push 1000123(top)
```

Meaning The output displays the ingress routes of segment routing tunnels.

Verifying Route Table Entries of Routing Table mpls.0 of Router PE1

Purpose Verify the route entries of routing table mpls.0

Action From operational mode, enter the **show route table mpls.0** command.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 03:25:52, metric 1
                      Receive
1                  *[MPLS/0] 03:25:52, metric 1
                      Receive
2                  *[MPLS/0] 03:25:52, metric 1
                      Receive
13                 *[MPLS/0] 03:25:52, metric 1
                      Receive
16                 *[VPN/0] 03:25:52
                    > via lsi.0 (VRF1), Pop
1000999            *[SPRING-TE/8] 03:04:03, metric 1
                   > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)

                      to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134,
Push 1000123(top)
```

Meaning The output displays the SID labels of segment routing tunnels.

Verifying SPRING Traffic Engineered LSP of Router PE1

Purpose Verify SPRING traffic engineered LSPs on the ingress routers.

Action From operational mode, enter the **show spring-traffic-engineering overview** command.

```
user@PE1> show spring-traffic-engineering overview
Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
   < Not configured >
```

Meaning The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1

Purpose Verify SPRING traffic engineered LSPs on the ingress router.

Action From operational mode, enter the **show spring-traffic-engineering lsp detail** command.

```
user@PE1# show spring-traffic-engineering lsp detail
Name: lsp-15
To: 192.168.146.181
State: Up
  Path: sl-15-primary
  Outgoing interface: ge-0/0/1.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 3
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.13.3
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145
  Path: sl-15-backup
  Outgoing interface: ge-0/0/0.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 4
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.12.2
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000123
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 4 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

Meaning The output displays details of SPRING traffic engineered LSPs on the ingress router

Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2

Purpose Verify the routing table entries of routing table mpls.0 of router PE2.

Action From operational mode, enter the **show route table mpls.0** command.

```
user@PE2> show route table mpls.0
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 03:22:29, metric 1
                      Receive
1                  *[MPLS/0] 03:22:29, metric 1
                      Receive
2                  *[MPLS/0] 03:22:29, metric 1
                      Receive
13                 *[MPLS/0] 03:22:29, metric 1
                      Receive
1000123            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000123(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000221            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
1000221(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
```

Verifying the Status of Static MPLS LSP Segments of Router PE2

Purpose Verify the status of MPLS LSP segments of router PE2.

Action From operational mode, enter the **show mpls static-lsp** command.

```
user@PE2> show mpls static-lsp
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname                              SID-label       State
adj-21                               1000221         Up
adj-23                               1000123         Up
Total 2, displayed 2, Up 2, Down 0
```

Meaning The output displays the status of static MPLS LSP segments of router PE2.

Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.

Configuring Explicit-Path LSPs

If you disable constrained-path label-switched path (LSP) computation, as described in "Disabling Constrained-Path LSP Computation" on page 390, you can configure LSPs manually or allow the LSPs to follow the IGP path.

When explicit-path LSPs are configured, the LSP is established along the path you specified. If the path is topologically not feasible, either because the network is partitioned or insufficient resources are available along some parts of the path, the LSP will fail. No alternative paths can be used. If the setup succeeds, the LSP stays on the defined path indefinitely.

To configure an explicit-path LSP, follow these steps:

1. Configure the path information in a named path, as described in "Creating Named Paths" on page 414. To configure complete path information, specify every router hop between the ingress and egress routers, preferably using the **strict** attribute. To configure incomplete path information, specify only a subset of router hops, using the **loose** attribute in places where the path is incomplete.

   For incomplete paths, the MPLS routers complete the path by querying the local routing table. This query is done on a hop-by-hop basis, and each router can figure out only enough information to reach the next explicit hop. It might be necessary to traverse a number of routers to reach the next (loose) explicit hop.

   Configuring incomplete path information creates portions of the path that depend on the current routing table, and this portion of the path can reroute itself as the topology changes. Therefore, an explicit-path LSP that contains incomplete path information is not completely fixed. These types of LSPs have only a limited ability to repair themselves, and they tend to create loops or flaps depending on the contents of the local routing table.

2. To configure the LSP and point it to the named path, use either the **primary** or **secondary** statement, as described in "Configuring Primary and Secondary LSPs" on page 459.

3. Disable constrained-path LSP computation by including the **no-cspf** statement either as part of the LSP or as part of a **primary** or **secondary** statement. For more information, see "Disabling Constrained-Path LSP Computation" on page 390.
4. Configure any other LSP properties.

Using explicit-path LSPs has the following drawbacks:

- More configuration effort is required.
- Configured path information cannot take into account dynamic network bandwidth reservation, so the LSPs tend to fail when resources become depleted.
- When an explicit-path LSP fails, you might need to manually repair it.

Because of these limitations, we recommend that you use explicit-path LSPs only in controlled situations, such as to enforce an optimized LSP placement strategy resulting from computations with an offline simulation software package.

Example: Configuring an Explicit-Path LSP

On the ingress router, create an explicit-path LSP, and specify the transit routers between the ingress and egress routers. In this configuration, no constrained-path computation is performed. For the primary path, all intermediate hops are strictly specified so that its route cannot change. The secondary path must travel through router 14.1.1.1 first, then take whatever route is available to reach the destination. The remaining route taken by the secondary path is typically the shortest path computed by the IGP.

```

```

Configuring Static Adjacency Segment Identifier for Aggregate Ethernet Member Links Using Single-hop Static LSP

In a network where aggregate Ethernet (AE) bundles are in use, an aggregate link could be bundle of 'N' number of physical link. The traffic sent over these AE bundle interfaces are forwarded on any of the member links of an AE interface. The traffic can take any physical link based on the hash defined for load-balancing the traffic, which makes it difficult to isolate which link have gone bad or dropping the traffic.

One way to test the forwarding path available in the network, including member links of an AE interface, is by adding a single-hop static LSP with the next-hop pointing to specific member link of AE interface. The default label-operation for these static LSP must be pop and forward. When a packet hits these labeled routes, the packet is forwarded on to a specific member-link. A unique label is used to identify the member link thus these labels are referred as adjacency SID and these are statically provisioned.

You can control the flow of the packets in the network by constructing a label stack in controller, which includes the labels allocated by all transit static LSP. The OAM packets are crafted and injected into the network with entire label-stack.

When a packet hits this label route the label is popped and traffic is forwarded on the member link specified in the configuration. A destination MAC is chosen while forwarding the packet, the destination Mac is the aggregate interface MAC address (selected based on nexthop address configured).

When the member link goes down and aggregate interface is up then the route corresponding to that member link is deleted. When an aggregate interface goes down then all the routes corresponding to member links of the aggregate interface is deleted. When the child physical interface is LACP detached but the child physical interface is up, the labeled route for the child link is deleted. In the case of LACP detach, the member link is up and invalid forwarding state then the OAM packets is dropped in PFE when child physical interface is detached.

The static LSP configuration is extended to accommodate the member-link name. A new CLI statement **member-interface** is added under the transit configuration.

A static LSP label should be configured from a defined static label range. The following is a sample configuration of static LSP label:

user@host# show protocols mpls label-range static-label-range 1000000 1048575;

NOTE: The recommendation is to configure the default static label range (1000000-1048575) of Junos for the static LSP. If you wish to configure label-range other than the default static label range, then it can be done as multiple ranges can be configured.

The following is an example to configure single-hop static LSP for AE member link:

1. Define a static label range.

   user@host# set protocols mpls label-range static-label-range 1000000 1048575;

2. Create a static LSP for AE member link from the static label range.

   user@host# set protocols mpls static-label-switched-path statc-lsp transit 100001 pop next-hop 10.1.1.1 member-interface *interface-name*

In this configuration, a transit labelled router is installed in mpls.0 and pops the label and forwards the packet down the next-hop. The next-hop address is mandatory for broadcast interfaces (such as ge-, xe-, ae-) and the if-name is be used for p2p interfaces (such as so-). The address is required for broadcast interfaces because the next-hop IP address is needed to pick the destination MAC address. The source MAC address for the packet is the AE's MAC address.

The following are sample outputs to view the member link name in the next-hop output:

show mpls static-lsp extensive

```
user@host> show mpls static-lsp extensive
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
LSPname: static-lsp1, Incoming-label: 1000001
  Description: verify-static-lsp-behavior
  State: Up, Sub State: Traffic via primary but unprotected
  Nexthop: 10.2.1.1 Via ae0.0 -> ge-0/0/0
  LabelOperation: Pop

CHAPTER 15

Configuring Point-to-Multipoint LSPs

Point-to-Multipoint LSPs Overview

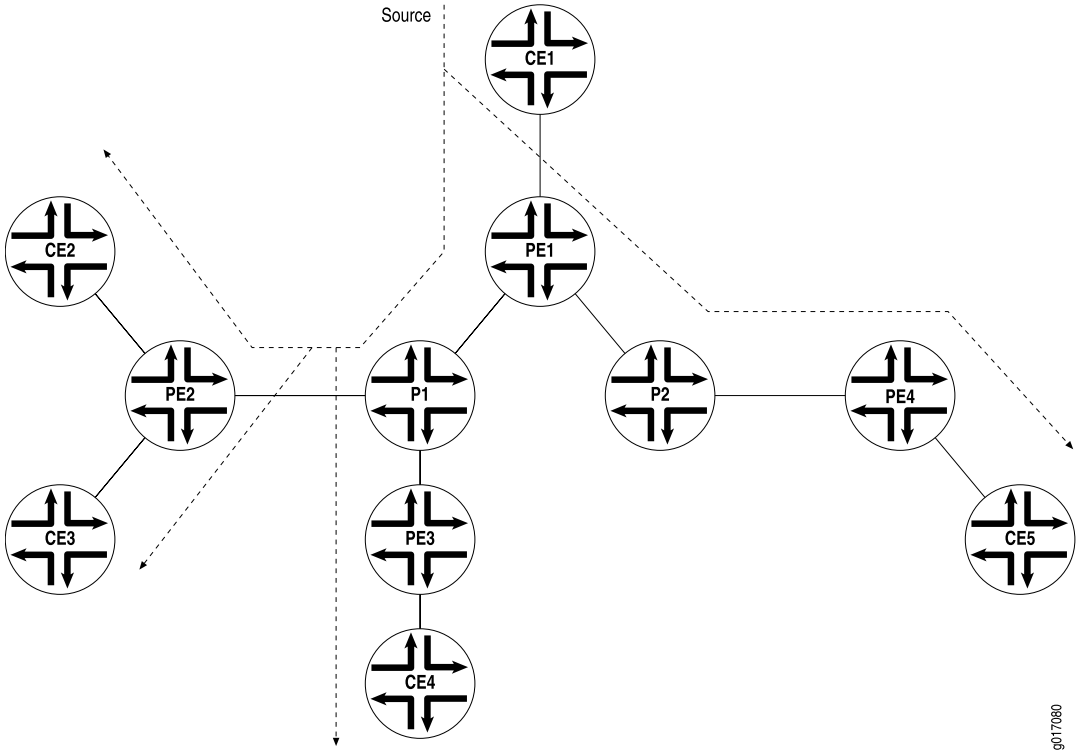
A point-to-multipoint MPLS LSP is an LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in Figure 50 on page 528. Router PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Router PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Router P1 replicates the packet and forwards it to Routers PE2 and PE3. Router P2 sends the packet to Router PE4.

This feature is described in detail in the Internet drafts draft-raggarwa-mpls-p2mp-te-02.txt (expired February 2004), *Establishing Point to Multipoint MPLS TE LSPs*, draft-ietf-mpls-rsvp-te-p2mp-02.txt, *Extensions to Resource Reservation Protocol-Traffic Engineering (RSVP-TE) for Point-to-Multipoint TE Label-Switched Paths (LSPs)*, and RFC 6388, *Label Distribution Protocol Extensions for*

Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths (only point-to-multipoint LSPs are supported).

Figure 50: Point-to-Multipoint LSPs



The following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP enables you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an egress router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any of the primary paths fail, traffic can be quickly switched to the bypass.
- You can configure branch LSPs either statically, dynamically, or as a combination of static and dynamic LSPs.
- You can enable graceful Routing Engine switchover (GRES) and graceful restart for point-to-multipoint LSPs at ingress and egress routers. The point-to-multipoint LSPs must be configured using either static routes or circuit cross-connect (CCC). GRES and graceful restart allow the traffic to be forwarded at the Packet Forwarding Engine based on the old state while the control plane recovers. Feature parity for GRES and

graceful restart for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

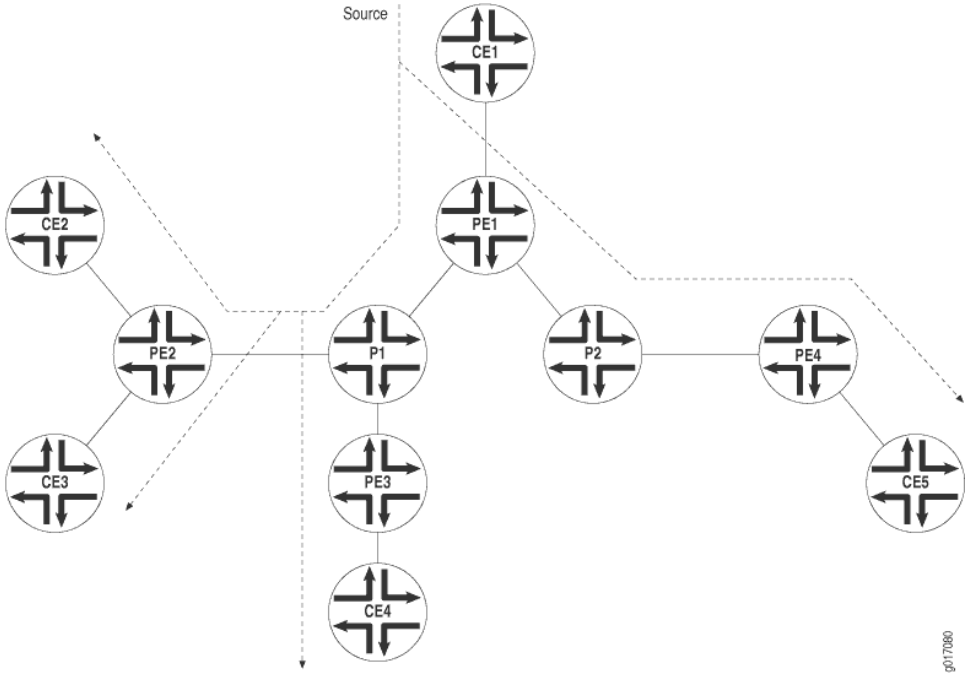
Understanding Point-to-Multipoint LSPs

A point-to-multipoint MPLS label-switched path (LSP) is an LDP-signaled or RSVP-signaled LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the inbound (ingress) router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in Figure 51 on page 529. Device PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Device PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Device P1 replicates the packet and forwards it to Routers PE2 and PE3. Device P2 sends the packet to Device PE4.

Figure 51: Point-to-Multipoint LSPs



Following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP allows you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an outbound (egress) router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any primary paths fail, traffic can be quickly switched to the bypass.
- You can configure subpaths either statically or dynamically.
- You can enable graceful restart on point-to-multipoint LSPs.

- Point-to-Multipoint LSP Configuration Overview on page 530

Point-to-Multipoint LSP Configuration Overview

To set up a point-to-multipoint LSP:

1. Configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers.
2. Specify a pathname on the primary LSP and this same path name on each branch LSP.

NOTE: By default, the branch LSPs are dynamically signaled by means of Constrained Shortest Path First (CSPF) and require no configuration. You can alternatively configure the branch LSPs as static paths.

Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP

This example shows how to configure a collection of paths to create an RSVP-signaled point-to-multipoint label-switched path (LSP).

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

In this example, multiple routing devices serve as the transit, branch, and leaf nodes of a single point-to-multipoint LSP. On the provider edge (PE), Device PE1 is the ingress node. The branches go from PE1 to PE2, PE1 to PE3, and PE1 to PE4. Static unicast routes on the ingress node (PE1) point to the egress nodes.

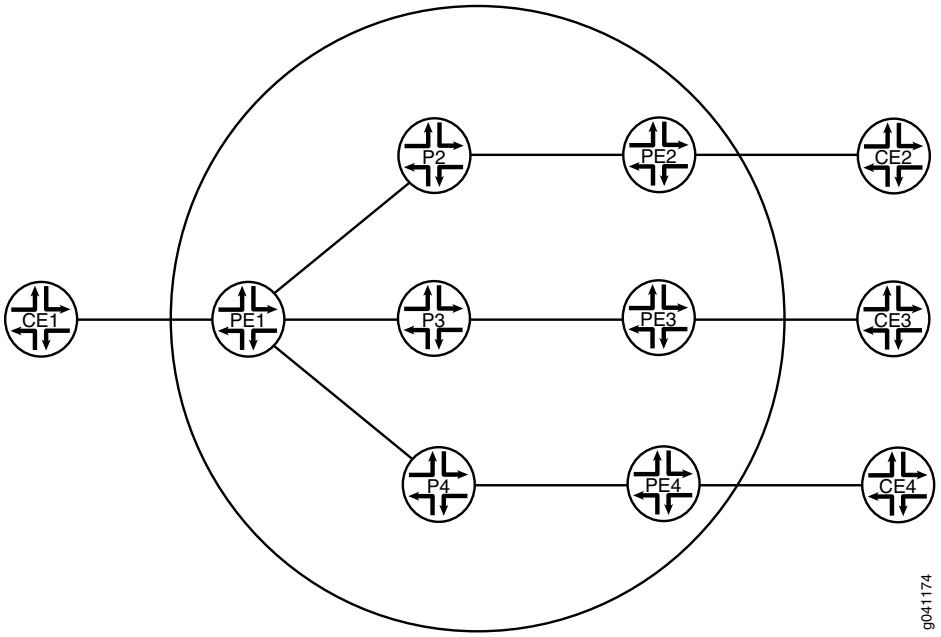
This example also demonstrates static routes with a next hop that is a point-to-multipoint LSP, using the p2mp-lsp-next-hop statement. This is useful when implementing filter-based forwarding.

NOTE: Another option is to use the lsp-next-hop statement to configure a regular point-to-point LSP to be the next hop. Though not shown in this example, you can optionally assign an independent preference and metric to the next hop.

Topology Diagram

Figure 52 on page 532 shows the topology used in this example.

Figure 52: RSVP-Signaled Point-to-Multipoint LSP



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device PE1

```
set interfaces ge-2/0/2 unit 0 description PE1-to-CE1

set routing-options static route 10.0.244.8/30 next-hop 10.0.104.9
```

Configuring the Ingress Label-Switched Router (LSR) (Device PE1)

Step-by-Step Procedure

To configure Device PE1:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit interfaces]
user@PE1# set ge-2/0/2 unit 0 description PE1-to-CE1
user@PE1# set ge-2/0/2 unit 0 family inet address 10.0.244.10/30
user@PE1# set fe-2/0/10 unit 1 description PE1-to-P2
user@PE1# set fe-2/0/10 unit 1 family inet address 2.2.2.1/24
user@PE1# set fe-2/0/10 unit 1 family mpls
```

```
user@PE1# set fe-2/0/9 unit 8 description PE1-to-P3
user@PE1# set fe-2/0/9 unit 8 family inet address 6.6.6.1/24
user@PE1# set fe-2/0/9 unit 8 family mpls
user@PE1# set fe-2/0/8 unit 9 description PE1-to-P4
user@PE1# set fe-2/0/8 unit 9 family inet address 3.3.3.1/24
user@PE1# set fe-2/0/8 unit 9 family mpls
user@PE1# set lo0 unit 1 family inet address 100.10.10.10/32
```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```
[edit protocols]
user@PE1# set rsvp interface fe-2/0/10.1
user@PE1# set rsvp interface fe-2/0/9.8
user@PE1# set rsvp interface fe-2/0/8.9
user@PE1# set rsvp interface lo0.1
user@PE1# set mpls interface fe-2/0/10.1
user@PE1# set mpls interface fe-2/0/9.8
user@PE1# set mpls interface fe-2/0/8.9
user@PE1# set mpls interface lo0.1
user@PE1# set ospf area 0.0.0.0 interface ge-2/0/2.0
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/10.1
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/9.8
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/8.9
user@PE1# set ospf area 0.0.0.0 interface lo0.1
```

3. Configure the MPLS point-to-multipoint LSPs.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 to 100.50.50.50
user@PE1# set mpls label-switched-path PE1-PE2 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE3 to 100.70.70.70
user@PE1# set mpls label-switched-path PE1-PE3 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE4 to 100.40.40.40
user@PE1# set mpls label-switched-path PE1-PE4 p2mp p2mp1
```

4. (Optional) Enable link protection on the LSPs.

   Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 link-protection
user@PE1# set mpls label-switched-path PE1-PE3 link-protection
user@PE1# set mpls label-switched-path PE1-PE4 link-protection
```

5. Enable MPLS to perform traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set mpls traffic-engineering bgp-igp
```

This causes the ingress routes to be installed in the inet.0 routing table. By default, MPLS performs traffic engineering for BGP only. You need to enable MPLS traffic engineering on the ingress LSR only.

6. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

7. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 100.10.10.10
```

8. Configure static IP unicast routes with the point-to-multipoint LSP name as the next hop for each route.

```
[edit routing-options]
user@PE1# set static route 5.5.5.0/24p2mp-lsp-next-hop p2mp1
user@PE1# set static route 7.7.7.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 4.4.4.0/24 p2mp-lsp-next-hop p2mp1
```

9. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

Configuring the Transit and Egress LSRs (Devices P2, P3, P4, PE2, PE3, and PE4)

Step-by-Step Procedure

To configure the transit and egress LSRs:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit]
user@P2# set interfaces fe-2/0/10 unit 2 description P2-to-PE1
user@P2# set interfaces fe-2/0/10 unit 2 family inet address 2.2.2.2/24

user@PE4# set protocols ospf area 0.0.0.0 interface lo0.4
```

3. Enable traffic engineering for OSPF.

```
[edit]
user@P2# set protocols ospf traffic-engineering
user@P3# set protocols ospf traffic-engineering
user@P4# set protocols ospf traffic-engineering
user@PE2# set protocols ospf traffic-engineering
user@PE3# set protocols ospf traffic-engineering
user@PE4# set protocols ospf traffic-engineering
```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

4. Configure the router IDs.

```
[edit]
user@P2# set routing-options router-id 100.20.20.20
user@P3# set routing-options router-id 100.60.60.60
user@P4# set routing-options router-id 100.30.30.30
user@PE2# set routing-options router-id 100.50.50.50
user@PE3# set routing-options router-id 100.70.70.70
user@PE4# set routing-options router-id 100.40.40.40
```

5. If you are done configuring the devices, commit the configuration.

```
[edit]
user@host# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Configuring Device CE1

Step-by-Step Procedure

To configure Device CE1:

1. Configure an interface to Device PE1.

```
[edit interfaces]
user@CE1# set ge-1/3/2 unit 0 family inet address 10.0.244.9/30
user@CE1# set ge-1/3/2 unit 0 description CE1-to-PE1
```

2. Configure static routes from Device CE1 to the three other customer networks, with Device PE1 as the next hop.

```
[edit routing-options]
user@CE1# set static route 10.0.104.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.134.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.224.8/30 next-hop 10.0.244.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-1/3/2 {
   unit 0 {
      family inet {
         address 10.0.244.9/30;
         description CE1-to-PE1;
      }
   }
}
```

```
user@CE1# show routing-options
static {
   route 10.0.104.8/30 next-hop 10.0.244.10;
   route 10.0.134.8/30 next-hop 10.0.244.10;
   route 10.0.224.8/30 next-hop 10.0.244.10;
}
```

Configuring Device CE2

Step-by-Step Procedure To configure Device CE2:

1. Configure an interface to Device PE2.

```
[edit interfaces]
user@CE2# set ge-1/3/3 unit 0 family inet address 10.0.224.9/30
user@CE2# set ge-1/3/3 unit 0 description CE2-to-PE2
```

2. Configure a static route from Device CE2 to CE1, with Device PE2 as the next hop.

```
[edit routing-options]
user@CE2# set static route 10.0.244.8/30 next-hop 10.0.224.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show interfaces
ge-1/3/3 {
   unit 0 {
      family inet {
         address 10.0.224.9/30;
         description CE2-to-PE2;
      }
   }
}
```

```
user@CE2# show routing-options
static {
   route 10.0.244.8/30 next-hop 10.0.224.10;
}
```

Configuring Device CE3

Step-by-Step Procedure To configure Device CE3:

1. Configure an interface to Device PE3.

```
[edit interfaces]
user@CE3# set ge-2/0/1 unit 0 family inet address 10.0.134.9/30
user@CE3# set ge-2/0/1 unit 0 description CE3-to-PE3
```

2. Configure a static route from Device CE3 to CE1, with Device PE3 as the next hop.

```
[edit routing-options]
user@CE3# set static route 10.0.244.8/30 next-hop 10.0.134.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE3# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE3# show interfaces
ge-2/0/1 {
   unit 0 {
      family inet {
```

```
        address 10.0.134.9/30;
        description CE3-to-PE3;
      }
    }
}
```

```
user@CE3# show routing-options
static {
  route 10.0.244.8/30 next-hop 10.0.134.10;
}
```

Configuring Device CE4

Step-by-Step Procedure

To configure Device CE4:

1. Configure an interface to Device PE4.

```
[edit interfaces]
user@CE4# set ge-3/1/3 unit 0 family inet address 10.0.104.10/30
user@CE4# set ge-3/1/3 unit 0 description CE4-to-PE4
```

2. Configure a static route from Device CE4 to CE1, with Device PE4 as the next hop.

```
[edit routing-options]
user@CE4# set static route 10.0.244.8/30 next-hop 10.0.104.9
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE4# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE4# show interfaces
ge-3/1/3 {
  unit 0 {
    family inet {
      address 10.0.104.10/30;
      description CE4-to-PE4;
    }
  }
}
```

```
user@CE4# show routing-options
static {
```

```
    route 10.0.244.8/30 next-hop 10.0.104.9;
}
```

Verification

Confirm that the configuration is working properly.

Verifying Connectivity

Purpose Make sure that the devices can ping each other.

Action Run the **ping** command from CE1 to the interface on CE2 connecting to PE2.

```
user@CE1> ping 10.0.224.9
PING 10.0.224.9 (10.0.224.9): 56 data bytes
64 bytes from 10.0.224.9: icmp_seq=0 ttl=61 time=1.387 ms
64 bytes from 10.0.224.9: icmp_seq=1 ttl=61 time=1.394 ms
64 bytes from 10.0.224.9: icmp_seq=2 ttl=61 time=1.506 ms
^C
--- 10.0.224.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.387/1.429/1.506/0.055 ms
```

Run the **ping** command from CE1 to the interface on CE3 connecting to PE3.

```
user@CE1> ping 10.0.134.9
PING 10.0.134.9 (10.0.134.9): 56 data bytes
64 bytes from 10.0.134.9: icmp_seq=0 ttl=61 time=1.068 ms
64 bytes from 10.0.134.9: icmp_seq=1 ttl=61 time=1.062 ms
64 bytes from 10.0.134.9: icmp_seq=2 ttl=61 time=1.053 ms
^C
--- 10.0.134.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.053/1.061/1.068/0.006 ms
```

Run the **ping** command from CE1 to the interface on CE4 connecting to PE4.

```
user@CE1> ping 10.0.104.10
PING 10.0.104.10 (10.0.104.10): 56 data bytes
64 bytes from 10.0.104.10: icmp_seq=0 ttl=61 time=1.079 ms
64 bytes from 10.0.104.10: icmp_seq=1 ttl=61 time=1.048 ms
64 bytes from 10.0.104.10: icmp_seq=2 ttl=61 time=1.070 ms
^C
--- 10.0.104.10 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.048/1.066/1.079/0.013 ms
```

Verifying the State of the Point-to-Multipoint LSP

Purpose Make sure that the ingress, transit, and egress LSRs are in the Up state.

Action Run the show mpls lsp **p2mp** command on all of the LSRs. Only the ingress LSR is shown here.

```
user@PE1> show mpls lsp p2mp
Ingress LSP: 1 sessions
P2MP name: p2mp1, P2MP branch count: 3
To              From            State Rt P     ActivePath       LSPname
100.40.40.40    100.10.10.10    Up     0 *                      PE1-PE4

Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs

A point-to-multipoint MPLS label-switched path (LSP) is an RSVP LSP with multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. For more information about point-to-multipoint LSPs, see "Point-to-Multipoint LSPs Overview" on page 527.

To configure a point-to-multipoint LSP, you need to configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers, as described in the following sections:

- Configuring the Primary Point-to-Multipoint LSP on page 552
- Configuring a Branch LSP for Point-to-Multipoint LSPs on page 552

Configuring the Primary Point-to-Multipoint LSP

A point-to-multipoint LSP must have a configured primary point-to-multipoint LSP to carry traffic from the ingress router. The configuration of the primary point-to-multipoint LSP is similar to a signaled LSP. See "Configuring the Ingress Router for MPLS-Signaled LSPs" on page 414 for more information. In addition to the conventional LSP configuration, you need to specify a path name for the primary point-to-multipoint LSP by including the **p2mp** statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

You can enable the optimization timer for point-to-multipoint LSPs. See "Optimizing Signaled LSPs" on page 437 for more information.

Configuring a Branch LSP for Point-to-Multipoint LSPs

The primary point-to-multipoint LSP sends traffic to two or more branch LSPs carrying traffic to each of the egress provider edge (PE) routers. In the configuration for each of these branch LSPs, the point-to-multipoint LSP path name you specify must be identical to the path name configured for the primary point-to-multipoint LSP. See "Configuring the Primary Point-to-Multipoint LSP" on page 552 for more information.

To associate a branch LSP with the primary point-to-multipoint LSP, specify the point-to-multipoint LSP name by including the **p2mp** statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

NOTE: Any change in any of the branch LSPs of a point-to-multipoint LSP, either due to a user action or an automatic adjustment made by the router, causes the primary and branch LSPs to be resignaled. The new point-to-multipoint LSP is signaled first before the old path is taken down.

The following sections describe how you can configure the branch LSP as a dynamically signaled path using Constrained Shortest Path First (CSPF), as a static path, or as a combination of dynamic and static paths:

- Configuring the Branch LSP as a Dynamic Path on page 553
- Configuring the Branch LSP as a Static Path on page 553

Configuring the Branch LSP as a Dynamic Path

By default, the branch LSP for a point-to-multipoint LSP is signaled dynamically using CSPF and requires no configuration.

When a point-to-multipoint LSP is changed, either by the addition or deletion of new destinations or by the recalculation of the path to existing destinations, certain nodes in the tree might receive data from more than one incoming interface. This can happen under the following conditions:

- Some of the branch LSPs to destinations are statically configured and might intersect with statically or dynamically calculated paths to other destinations.
- When a dynamically calculated path for a branch LSP results in a change of incoming interface for one of the nodes in the network, the older path is not immediately torn down after the new one has been signaled. This ensures that any data in transit relying on the older path can reach its destination. However, network traffic can potentially use either path to reach the destination.
- A faulty router at the ingress calculates the paths to two different branch destinations such that a different incoming interface is chosen for these branch LSPs on a router node common to these branch LSPs.

Configuring the Branch LSP as a Static Path

You can configure the branch LSP for a point-to-multipoint LSP as a static path. See "Configuring Static LSPs" on page 491 for more information.

Configuring Inter-Domain Point-to-Multipoint LSPs

An inter-domain P2MP LSP is a P2MP LSP that has one or more sub-LSPs (branches) that span multiple domains in a network. Examples of such domains include IGP areas and autonomous systems (ASs). A sub-LSP of an inter-domain P2MP LSP may be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source).

On the ingress node, a name is assigned to the inter-domain P2MP LSP and shared by all constituent sub-LSPs. Each sub-LSP is configured separately, with its own egress node and optionally an explicit path. The location of the egress node of the sub-LSP with respect to the ingress node determines whether the sub-LSP is intra-area, inter-area, or inter-AS.

Inter-domain P2MP LSPs can be used to transport traffic in the following applications in a multi-area or multi-AS network:

- Layer 2 broadcast and multicast over MPLS
- Layer 3 BGP/MPLS VPN
- VPLS

On each domain boundary node (ABR or ASBR) along the path of the P2MP LSP, the **expand-loose-hop** statement must be configured at the **[edit protocols mpls]** hierarchy

level so that CSPF can extend a loose-hop ERO (usually the first entry of the ERO list carried by RSVP Path message) towards the egress node or the next domain boundary node.

CSPF path computation for inter-domain P2MP LSPs:

- CSPF path computation is supported on each sub-LSP for inter-domain P2MP LSPs. A sub-LSP may be intra-area, inter-area, or inter-AS. CSPF treats an inter-area or inter-AS sub-LSP in the same manner as an inter-domain P2P LSP.
- On an ingress node or a domain boundary node (ABR or ASBR), CSPF can perform an Explicit Route Object (ERO) expansion per-RSVP query. The destination queried could be an egress node or a received loose-hop ERO. If the destination resides in a neighboring domain that the node is connected to, CSPF generates either a sequence of strict-hop EROs towards it or a sequence of strict-hop EROs towards another domain boundary node that can reach the destination.
- If RSVP fails to signal a path through a previously selected domain bounday node, RSVP attempts to signal a path through other available domain boundary nodes in a round-robin fashion.
- When a sub-LSP is added or removed to or from an inter-domain P2MP LSP, causing its path (branch) to be merged or pruned with or from the current P2MP tree, the paths being taken by the other sub-LSPs should not be affected, helping to prevent traffic disruption on those sub-LSPs.

Be aware of the following when deploying inter-domain P2MP LSPs in your network:

- Periodic path re-optimization is supported for inter-domain P2MP LSPs on ingress nodes. It can be turned on for an inter-domain P2MP LSP by configuring the **optimize-timer** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level with the same interval for every sub-LSP.
- Only link protection bypass LSPs are supported for inter-domain P2MP LSPs. To enable it for an inter-domain P2MP LSP, link-protection must be configured for all sub-LSPs and on all of the RSVP interfaces that the P2MP LSP might travel through.
- Only OSPF areas are supported for inter-domain P2MP LSPs. IS-IS levels are not supported.

Configuring Link Protection for Point-to-Multipoint LSPs

Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. When link protection is configured for an interface and a point-to-multipoint LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination.

To extend link protection to all of the paths used by a point-to-multipoint LSP, link protection must be configured on each router that each branch LSP traverses. If you enable link protection on a point-to-multipoint LSP, you must enable link protection on all of the branch LSPs.

The Internet draft draft-ietf-mpls-rsvp-te-p2mp-01.txt, *Extensions to RSVP-TE for Point to Multipoint TE LSPs*, describes link protection for point-to-multipoint LSPs.

To enable link protection on point-to-multipoint LSPs, complete the following steps:

1. Configure link protection on each branch LSP. To configure link protection, include the **link-protection** statement:

   ```
   link-protection;
   ```

   You can include this statement at the following hierarchy levels:

   - **[edit protocols mpls** label-switched-path ***branch-lsp-name*****]**
   - **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***branch-lsp-name*****]**

2. Configure link protection for each RSVP interface on each router that the branch LSP traverses. For information about how to configure link protection on RSVP interfaces, see *Configuring Link Protection on Interfaces Used by LSPs*.

For more information on how to configure link protection, see *Configuring Node Protection or Link Protection for LSPs*.

Configuring Graceful Restart for Point-to-Multipoint LSPs

You can configure graceful restart on point-to-multipoint LSPs. Graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not apparent to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers.

To enable graceful restart on a router handling point-to-multipoint LSP traffic, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems** ***logical-system-name*** **routing-options]**

The graceful restart configuration for point-to-multipoint LSPs is identical to that of point-to-point LSPs. For more information on how to configure graceful restart, see *Configuring RSVP Graceful Restart*.

Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs

You can control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to PIM islands situated downstream from the egress routers of the point-to-multipoint LSPs.

By configuring the **rpf-check-policy** statement, you can disable RPF checks for a source and group pair. You would typically configure this statement on the egress routers of a point-to-multipoint LSP, because the interface receiving the multicast traffic on a point-to-multipoint LSP egress router might not always be the RPF interface.

You can also configure a routing policy to act upon a source and group pair. This policy behaves like an import policy, so if no policy term matches the input data, the default policy action is "acceptance." An accept policy action enables RPF checks. A reject policy action (applied to all source and group pairs that are not accepted) disables RPF checks for the pair.

To configure a multicast RPF check policy for a point-to-multipoint LSP, specify the RPF check policy using the **rpf-check-policy** statement:

```
rpf-check-policy policy;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options multicast]**
- **[edit logical-systems *logical-system-name* routing-options multicast]**

You also must configure a policy for the multicast RPF check. You configure policies at the **[edit policy-options]** hierarchy level. For more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

NOTE: When you configure the **rpf-check-policy** statement, the Junos OS cannot perform RPF checks on incoming traffic and therefore cannot detect traffic arriving on the wrong interface. This might cause routing loops to form.

Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP

Configure a policy to ensure that an RPF check is not performed for sources with prefix **128.83/16** or longer that belong to groups having a prefix of **228/8** or longer:

```
[edit]
policy-options {
   policy-statement rpf-sg-policy {
      from {
         route-filter 228.0.0.0/8 orlonger;
         source-address-filter 128.83.0.0/16 orlonger;
      }
```

```
    then {
      reject;
    }
  }
}
```

Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs

You can configure one or more PE routers as part of a backup PE router group to enable ingress PE router redundancy. You accomplish this by configuring the IP addresses of the backup PE routers (at least one backup PE router is required) and the local IP address used by the local PE router.

You must also configure a full mesh of point-to-point LSPs between the primary and backup PE routers. You also need to configure BFD on these LSPs. See "Configuring BFD for RSVP-Signaled LSPs" on page 90 and *Configuring BFD for LDP LSPs* for more information.

To configure ingress PE router redundancy for point-to-multipoint LSPs, include the **backup-pe-group** statement:

```
backup-pe-group pe-group-name {
  backups [addresses];
  local-address address;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

After you configure the ingress PE router redundancy backup group, you must also apply the group to a static route on the PE router. This ensures that the static route is active (installed in the forwarding table) when the local PE router is the designated forwarder for the backup PE group. You can only associate a backup PE router group with a static route that also has the **p2mp-lsp-next-hop** statement configured. For more information, see "Configuring Static Unicast Routes for Point-to-Multipoint LSPs" on page 497.

Enabling Point-to-Point LSPs to Monitor Egress PE Routers

Configuring an LSP with the **associate-backup-pe-groups** statement enables it to monitor the status of the PE router to which it is configured. You can configure multiple backup PE router groups using the same router's address. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. The **associate-backup-pe-groups** statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to that address.

To allow an LSP to monitor the status of the egress PE router, include the **associate-backup-pe-groups** statement:

```
associate-backup-pe-groups;
```

This statement can be configured at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems *logical-system-name* protocols mpls** label-switched-path ***lsp-name*****]**

If you configure the **associate-backup-pe-groups** statement, you must configure BFD for the point-to-point LSP. For information about how to configure BFD for an LSP, see "Configuring BFD for MPLS IPv4 LSPs" on page 89 and *Configuring BFD for LDP LSPs*.

You also must configure a full mesh of point-to-point LSPs between the PE routers in the backup PE router group. A full mesh is required so that each PE router within the group can independently determine the status of the other PE routers, allowing each router to independently determine which PE router is currently the designated forwarder for the backup PE router group.

If you configure multiple LSPs with the **associate-backup-pe-groups** statement to the same destination PE router, the first LSP configured is used to monitor the forwarding state to that PE router. If you configure multiple LSPs to the same destination, make sure to configure similar parameters for the LSPs. With this configuration scenario, a failure notification might be triggered even though the remote PE router is still up.

Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases

In Junos OS Release 9.1 and earlier, Resv messages that include the S2L_SUB_LSP object are rejected by default. In Junos OS Release 9.2 and later, such messages are accepted by default. To ensure proper functioning of point-to-multipoint LSPs in a network that includes both devices running Junos OS Release 9.1 and earlier and devices running Junos 9.2 and later, you must include the **no-p2mp-sublsp** statement in the configuration of the devices running Junos 9.2 and later:

```
no-p2mp-sublsp;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

CHAPTER 16

Configuring Container LSPs

Dynamic Bandwidth Management Using Container LSP Overview

RSVP LSPs with the autobandwidth feature are increasingly deployed in networks to meet traffic engineering needs. However, the current traffic engineering solutions for point-to-point LSPs are inefficient in terms of network bandwidth utilization, mainly because the ingress routers originating the RSVP LSPs either try to fit the LSPs along a particular path without creating parallel LSPs, or do not interact with the other routers in the network and probe for additional available bandwidth.

This feature provides an ingress router with the capability of acquiring as much network bandwidth as possible by creating parallel LSPs dynamically.

Understanding RSVP Multipath Extensions

The RSVP multipath extensions proposed in the IETF [KOMPELLA-MLSP] allow the setup of traffic engineered multipath label-switched paths (container LSPs). The container LSPs, in addition to conforming to traffic engineering constraints, use multiple independent paths from a source to a destination, thereby facilitating load balancing of traffic. The multipath extensions require changes to the RSVP-TE protocol and allow for merging of labels at the downstream nodes (similar to LDP), which also helps in preserving forwarding resources.

The multipath extensions to RSVP provide the following benefits:

- Ease of configuration. Typically, multiple RSVP LSPs are configured for either load balancing or bin packing. With a container LSP, there is a single entity to provision, manage, and monitor LSPs. Changes in topology are handled easily and autonomously by the ingress LSP, by adding, changing, or removing member LSPs to rebalance traffic, while maintaining the same traffic engineering constraints.
- RSVP equal-cost multipath (ECMP) inherits the standard benefits of ECMP by absorbing traffic surges.
- Multipath traffic engineering allows for better and complete usage of network resources.
- Knowing the relationship among LSPs helps in computing diverse paths with constraint-based routing. It allows adjustment of member LSPs while other member LSPs continue to carry traffic.
- The intermediate routers have an opportunity to merge the labels of member LSPs. This reduces the number of labels that need to get added to the forwarding plane and in turn reduces the convergence time.

  If the number of independent ECMP paths is huge, label merging overcomes the platform limitations on maximum (ECMP) next hops. With point-to-point RSVP LSPs that require link or node protection, the next hops are doubled as each LSP is programmed with both primary and backup next hops. RSVP multipath (or ECMP) obviates the need for backup next hops.
- When there is a link failure, the router upstream to the link failure can distribute traffic from the failed link to the remaining ECMP branches, obviating the need for bypass LSPs. The bypass LSP approach not only requires more state when signaling backup LSPs, but also suffers from scaling issues that result in merge-point timing out a protected path state block (PSB) before point of local repair (PLR) gets a chance to signal the backup LSP.

Junos OS RSVP Multipath Implementation

In order to deploy RSVP multipath (ECMP) in a network, all the nodes through which ECMP LSPs pass must understand RSVP ECMP protocol extensions. This can be a challenge, especially in a multivendor networks.

Junos OS implements the RSVP multipath extensions without the need for protocol extensions. A single container LSP, which has the characteristics of ECMP and RSVP TE, is provisioned. A container LSP consists of several member LSPs and is set up between the ingress and egress routing device. Each member LSP takes a different path to the same destination. The ingress routing device is configured with all the required parameters to compute the RSVP ECMP LSP. The parameters configured to compute a set of RSVP point-to-point LSPs can be used by the ingress routing device to compute the container LSP as well.

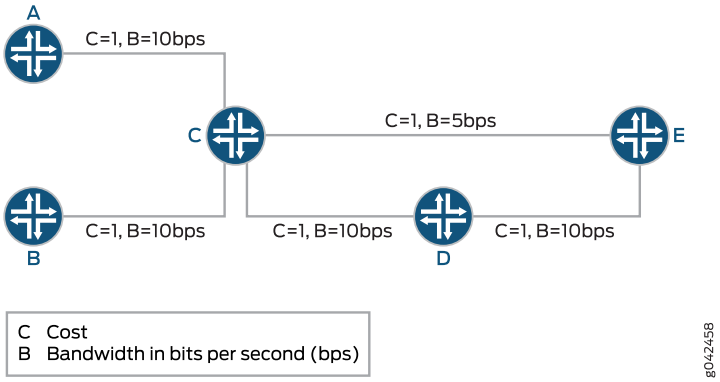
Current Traffic Engineering Challenges

The main challenge for traffic engineering is to cope with the dynamics of both topology and traffic demands. Mechanisms are needed that can handle traffic load dynamics in

scenarios with sudden changes in traffic demand and dynamically distribute traffic to benefit form available resources.

Figure 53 on page 561 illustrates a sample network topology with all the LSPs having the same hold and setup priorities, and admission control restricted on the ingress router. All the links are annotated with a tuple (cost and capacity).

Figure 53: Sample Topology



Some of the traffic engineering problems seen in Figure 53 on page 561 are listed here:

- **Bin Packing**

  This problem arises because of a particular order in which LSPs are signaled. The ingress routers might not be able to signal some LSPs with required demands although bandwidth is available in the network, leading to under-utilization of link capacity.

  For example, the following LSPs arrive in the sequence mentioned in Table 17 on page 562.

Table 17: LSP Sequence Order for Bin Packing

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	10	No ERO

The LSP originating at Router B is not routable as constraint-based routing fails to find a feasible path. However, if Router B is signaled first, both the LSPs are routable. Bin packing happens because of lack of visibility of individual per-LSP, per-device bandwidth demands at the ingress routing device.

Bin packing can also happen when there is no requirement for ordering of LSPs. For example, if there is an LSP with demand X and there are two different paths to the destination from the ingress router with available bandwidths Y1 and Y2, such that Y1 is less than X, Y2 is less than X, and Y1 plus Y2 is greater than or equal to X.

In this case, even though there are enough network resources in terms of available bandwidth to satisfy the aggregate LSP demand X, the LSP might not be signaled or re-optimized with the new demand. In Figure 53 on page 561, with container LSP support, the ingress B creates two LSPs each of size 5 when demand 10 is posed. One LSP is routed along B-C-E and another one along B-C-D-E.

- **Deadlock**

  Considering Figure 53 on page 561, the LSPs follow the sequence mentioned in Table 18 on page 562.

Table 18: LSP Sequence Order for Deadlock

Time	Source	Destination	Demand	ERO	Event
1	A	E	2	A-C-D-E	Constraint-based routing with RSVP signaling
2	B	E	2	B-C-D-E	Constraint-based routing with RSVP signaling
3	A	E	2 to 20	A-C-D-E	Constraint-based routing fails, no RSVP signaling

At time 3, the demand on LSP from A to E increases from 2 to 20. If autobandwidth is configured, the change does not get detected until the adjustment timer expires. In

the absence of admission control at A, the increased traffic demand might cause traffic to drop on other LSPs that share common links with the mis-behaving LSP.

This happens due to the following reasons:

- Lack of global state at all the ingress routers
- Signaling of mis-behaving demands
- Tearing down of mis-behaving demands

With container LSP configured, ingress A has more chances of splitting the load (even incrementally if not fully) across multiple LSPs. So, LSP from A is less likely to see prolonged traffic loss.

- **Latency Inflation**

  Latency inflation is caused by the autobandwidth and other LSPs parameters. Some of the other factors that contribute to latency inflation include:

  - LSP priority

    LSPs choose longer paths because shorter paths between data centers located in the same city can be congested. The bandwidth on the shorter paths can get exhausted by equal or higher priority LSPs. Due to periodic LSP optimization by autobandwidth, LSP can get rerouted to a higher delay path. When many LSPs undergo less than optimal path selection, they can potentially form a chain of dependencies. Modifing the LSP priorities dynamically is a workaround to the issue; however, dynamically adjusting LSP priorities to find shorter paths is a challenging task.

  - All or Nothing policy

    When the demand on an LSP increases and at least one of the links along the shorter path is close to its reservation limit, LSP optimization can force the LSP to move to a longer latency path. LSP has to traverse a long path even though the short path is capable of carrying most of the traffic.

  - Minimum and maximum bandwidth

    Minimum and maximum bandwidth specify the boundaries for LSP sizes. If minimum bandwidth is small, an LSP is more prone to autobandwidth adjustment because a small change in bandwidth is enough to cross the threshold limits. LSPs might reroute although bandwidth is available. On the other hand, if the minimum bandwidth is large, network bandwidth might be wasted. If the maximum bandwidth value is small, a large number of LSPs might be needed at the ingress router to accommodate the application demand. If the maximum bandwidth is large, the LSPs can grow larger in size. Such LSPs can suffer because of an all or nothing policy.

  - Autobandwidth adjustment threshold

    Bandwidth threshold dictates if LSPs need to be re-optimized and resized. If the value is small, LSPs are frequently re-optimized and rerouted. That might cause CPU spike because applications or protocols, such as BGP resolving over the LSPs, might keep the Routing Engine busy doing next-hop resolution. A large value might make an LSP immobile. With container LSP configured, an LSP is less likely to get subjected

to one or no policy. An ingress router originates multiple LSPs, although not all LSPs potentially traverse high latency paths.

- **Predictability**

  Service providers often want predictable behavior in terms of how LSPs get signaled and routed. Currently, without any global coordination, it is difficult to set up the same set of LSPs in a predictable way. Consider the two different orderings in Table 19 on page 564 and Table 20 on page 564. The ERO that an LSP uses depends on its signaling time.

Table 19: LSP Sequence Order for Predictability

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	5	B-C-E

Table 20: LSP Sequence Order for Predictability

Time	Source	Destination	Demand	ERO
1	B	E	5	B-C-E
2	A	E	5	A-C-D-E

Container LSP does not directly help LSPs find predictable EROs. If LSPs are getting rerouted because of an all or no policy without container LSP configured, such LSPs might see less churn if container LSPs are configured, because smaller LSPs have better chances of finding a shorter or same path.

Using Container LSP as a Solution

A container LSP can be used as a solution to the challenges faced by the current traffic engineering features. Considering Figure 53 on page 561, when the demand X on a container LSP increases with the network capacity (max-flow) being more than the demand, the following approaches come into effect with a container LSP:

- Accommodating the New Demand X on page 564
- Creating New LSPs to Meet Demand X on page 565
- Assigning Bandwidth to the New LSPs on page 565
- Controlling the LSP Paths on page 565

Accommodating the New Demand X

In the current implementation, autobandwidth attempts to re-signal an LSP with the new demand X and follows the all or nothing policy as mentioned earlier.

The container LSP approach computes several small (smaller than demand X) bandwidth LSPs such that the aggregate bandwidth is not less than X, and the ingress router performs

this adjustment periodically. One of the triggers to create new LSPs or to delete old LSPs can be changed in aggregate bandwidth. The ingress router then load-balances the incoming traffic across the newly created LSPs.

Creating New LSPs to Meet Demand X

Although the number of new LSPs created can be a maximum of the allowed configurable limit, there is not much benefit from these LSPs once the number of LSPs exceeds the number of possible diverse paths or equal-cost multipaths (ECMPs). The benefit of creating the smaller LSPs is seen when an ingress router uses the newly created LSPs for load-balancing traffic. This, however, depends on the network topology and state.

Creating multiple parallel LSPs by all the ingress routers in the network can lead to scaling issues at the transit routers. Thus, the number of new LSPs to be created depends on the size of the individual LSPs and the given aggregate demand, X in this case.

Assigning Bandwidth to the New LSPs

In general, there can be a number of heuristics to allocate bandwidths to the newly created LSPs. An ingress router can solve an optimization problem in which it can maximize a given utility function. The output of an optimization problem is assigning optimal bandwidth values. However, to solve an optimization problem, the number of newly created LSPs has to be fixed. Therefore, it is complex to optimize the number and size of each LSP. Thus, to simplify the problem, the same amount of bandwidth is assumed for all the newly created LSPs, and then the number of required LSPs is computed.

Controlling the LSP Paths

The flexibility to control the LSP paths is expressed in terms of the configuration for point-to-point LSPs and container LSPs. Controlling the LSP paths using the configuration parameters can be applied under two different aspects:

- Topology—There are no topology constraints with this feature. Each member LSP is treated like a point-to-point LSP and is re-optimized individually. An ingress router does not try to compute equal IGP cost paths for all its LSPs, but instead it computes paths for all the LSPs using current traffic engineering database information. While computing a path, constraint-based routing adheres to any constraints specified through the configuration, although there is no change in the constraint-based routing method for path computation.
- When to create a new LSP—When to create a new LSP can be explicitly specified. By default, an ingress router periodically computes the aggregate traffic rate by adding up the traffic rate of all the individual LSPs. Looking at the aggregate bandwidth and configuration, the ingress router recomputes the number of LSPs and the bandwidths of the LSPs. The new LSPs are then signaled or the existing LSPs are re-signaled with the updated bandwidth. Instead of looking at the instantaneous aggregate rate, the ingress routers can compute an average (of aggregates) over some duration by removing outlier samples (of aggregates). Managing the LSPs that remain outstanding and active by considering aggregate bandwidth is more scalable than creating the new LSPs based on the usage of a particular LSP. The intervals and thresholds can be configured to track the aggregate traffic and trigger adjustment. These dynamic LSPs co-exist and interoperate with per-LSP autobandwidth configuration.

Junos OS Container LSP Implementation

A container LSP is an ECMP TE LSP that acts like a container LSP consisting of one or more member LSPs. A point-to-point TE LSP is equivalent to a container LSP with a single member LSP. Member LSPs are added to the container LSP through a process called splitting, and removed from the container LSP through a process called merging.

Container LSP Terminology

The following terms are defined in the context of a container LSP:

- **Normalization**—An event occurring periodically when an action is taken to adjust the member LSPs, either to adjust their bandwidths, their number, or both. A normalization process is associated with a sampling process and periodically estimates aggregate utilization of a container LSP.
- **Nominal LSP**—The instance of a container LSP that is always present.
- **Supplementary LSP**—The instances or sub-LSPs of a container LSP, which are dynamically created or removed.

  Autobandwidth is run over each of the member LSPs, and each LSP is resized according to the traffic it carries and the autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by adding up the bandwidth across all the member LSPs.
- **Minimum signaling-bandwidth**—The minimum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the minimum-bandwidth defined under autobandwidth.
- **Maximum signaling-bandwidth** —The maximum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the maximum-bandwidth defined under autobandwidth.
- **Merging-bandwidth** —Specifies the lower bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage falls below this value, the ingress router merges the member LSPs at the time of normalization.
- **Splitting-bandwidth** —Specifies the upper bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage exceeds this value, the ingress router splits the member LSPs at the time of normalization.

- **Aggregate minimum-bandwidth** —Sum of merging-bandwidth of the current active member LSPs. This minimum bandwidth is different from the autobandwidth minimum-bandwidth.
- **Aggregate maximum-bandwidth**—Sum of the splitting-bandwidth of the current active member LSPs. This maximum bandwidth is different from the autobandwidth maximum-bandwidth.

LSP Splitting

Operational Overview

The LSP splitting mechanism enables an ingress router to create new member LSPs or to re-signal existing LSPs with different bandwidths within a container LSP when a demand X is placed on the container LSP. With LSP splitting enabled, an ingress router periodically creates a number of LSPs (by signaling new ones or re-signaling existing ones) to accommodate a new aggregate demand X. In the current implementation, an ingress router tries to find an LSP path satisfying a demand X and other constraints. If no path is found, either the LSP is not signaled or it remains up, but with the old reserved bandwidth.

Between two normalization events (splitting or merging), individual LSPs might get re-signaled with different bandwidths due to the autobandwidth adjustments. If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. There is no dynamic splitting in this case, as there is no dynamic estimation of aggregate bandwidth. The splitting adjustments with a specific bandwidth value can be manually triggered.

NOTE:

Be aware of the following considerations for LSP splitting:

- After LSP splitting, the ingress router continues to inject one forwarding adjacency. Forwarding adjacencies are not supported in IGP for this feature.
- Between two normalization events, two LSPs might have different bandwidths subjected to autobandwidth constraints.
- After LSPs are split (or merged), make-before-break uses the fixed filter (FF) style sharing unless the adaptive option is configured. However, two different LSPs do not do the shared explicit (SE) style sharing for this feature.
- When LSPs are re-signaled with modified bandwidths, some of the LSPs might not get signaled successfully, leading to failover options.

Operational Constraints

LSP splitting has the following operational constraints:

- LSP bandwidth—Although there are a number of ways to allocate bandwidth values to the LSPs, the Junos OS implementation supports only an equal-bandwidth allocation policy when normalization is done, wherein all the member LSPs are signaled or re-signaled with equal bandwidth.
- Number of LSPs—If an ingress router is configured to have a minimum number of LSPs, it maintains the minimum number of LSPs even if the demand can be satisfied with less than the minimum number of LSPs. In case the ingress router is unable to do constraint-based routing for computations on the sufficient number of LSPs or signal sufficient number of LSPs, the ingress router resorts to a number of failback options.

  By default, an incremental approach is supported as a fallback option (unless configured differently), where an ingress router makes attempts to bring up the sufficient number of LSPs, such that the new aggregate bandwidth exceeds the old aggregate bandwidth (and is as close to the desired demand as possible). The ingress router then load-balances traffic using the LSPs. The LSPs that could not be brought up are removed by the ingress router.

Supported Criteria

When a container LSP signals a member LSP, the member LSP gets signaled with minimum-signaling-bandwidth. Since each member LSP is configured with autobandwidth, between two normalization events, each LSP can undergo autobandwidth adjustment multiple times. As the traffic demand increases, the ingress router creates additional supplementary LSPs . All member LSPs are used for ECMP, so they should roughly have the same reserved bandwidth after normalization.

For example, if there are K LSPs signaled after normalization, each LSP is signaled with equal bandwidth B. The total aggregate bandwidth reserved is B.K, where B satisfies the following condition:

- Minimum signaling-bandwidth is less than or equal to B, which is turn is less than or equal to the maximum signaling-bandwidth

  (minimum-signaling-bandwidth ≤ B ≤ maximum-signaling-bandwidth)

Until the next normalization event, each member LSP undergoes several autobandwidth adjustments. After any autobandwidth adjustment, if there are N LSPs with reserved bandwidths bi, where i=1,2,.., N, each bi should satisfy the following the condition:

- Minimum bandwidth is less than or equal to bi, which in turn is less than or equal to the maximum bandwidth

  (minimum-bandwidth ≤ bi ≤ maximum-bandwidth)

Both the above-mentioned conditions are applicable for per member LSP (nominal and supplementary), and essentially have the reserved bandwidth to exist within a range.

Splitting Triggers

Every time the normalization timer expires, the ingress router decides if LSP splitting is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

Taking for example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP splitting are as follows:

- Absolute trigger—LSP splitting is performed when **New-Aggr-Bw** is greater than **Aggregate-maximum-bandwidth**.

  (**New-Aggr-Bw** > **Aggregate-maximum-bandwidth**)

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP splitting is performed when the difference in the bandwidth amount is off by a threshold.

  ([1-a] x **Current-Aggr-Bw** < **New-Aggr-Bw** < [1+a] x **Current-Aggr-Bw**, where 0 </= a </= 1)

  When **New-Aggr-Bw** is greater than or equal to [1+a] multiplied by **Current-Aggr-Bw**, the ingress routing device does not perform normalization, but instead LSP splitting is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

LSP Merging

Operational Overview

Junos OS supports two kinds of LSPs – CLI-configured LSPs and dynamically created LSPs. The CLI-configured LSPs are created manually and remain in the system until the configuration is modified. The dynamic LSPs are created dynamically by next generation MVPN, BGP virtual private LAN service (VPLS), or LDP, based on a template configuration, and are removed from the system when not used by any application for a certain duration. LSP merging follows a similar approach as dynamic LSPs.

LSP merging enables an ingress routing device to dynamically eliminate some member LSPs of the container LSP so less state information is maintained in the network. If an ingress router provisions several member LSPs between the ingress and egress routers, and there is an overall reduction in aggregate bandwidth (resulting in some LSPs being under-utilized), the ingress router distributes the new traffic load among fewer LSPs.

Although there are a number of ways to merge the member LSPs, Junos OS supports only overall-merge when normalization is being performed. An ingress router considers the aggregate demand and the minimum (or maximum) number of LSPs and revises the number of LSPs that should be active at an ingress routing device. As a result, the following can take place periodically as the normalization timer fires:

- Re-signaling some of the existing LSPs with updated bandwidth
- Creating new LSPs
- Removing some of the existing LSPs

Operational Constraints

If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. LSP merging does not happen because there is no dynamic estimation of aggregate bandwidth. However, a manual trigger for splitting and adjusting with a specific bandwidth value can be configured.

NOTE:

- Nominal LSPs are never deleted as part of LSP merging.
- Before deleting an LSP, the LSP is made inactive, so that traffic shifts to other LSPs before removing the LSP. This is because RSVP sends PathTear before deleting routes and next hops from the Packet Forwarding Engine.
- When member LSPs are re-signaled with modified bandwidth, it might happen that some LSPs do not get signaled successfully.

Merging Triggers

Every time the normalization timer expires, the ingress router decides if LSP merging is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

For example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP merging are as follows:

- Absolute trigger—LSP merging is performed when **New-Aggr-Bw** is less than **Aggregate-minimum-bandwidth**.

  (**New-Aggr-Bw** < **Aggregate-maximum-bandwidth**)

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP merging is performed when the difference in the bandwidth amount is off by a threshold.

  ([1-a] x **Current-Aggr-Bw** < **New-Aggr-Bw** < [1+a] x **Current-Aggr-Bw**, where 0 </= a </= 1)

When the **New-Aggr-Bw** value is less than or equal to [1+a] multiplied by the **Current-Aggr-Bw** value, the ingress routing device does not perform normalization, but instead LSP merging is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

Node and Link Protection

Junos OS supports the following mechanisms for node and link protection:

- Fast-reroute
- Link protection
- Node-link protection

Only one of the above-mentioned modes of protection can be configured on an ingress routing device at any given time. All member LSPs (nominal and supplementary) use the same mode of protection that is configured.

Naming Convention

While configuring a container LSP, a name is assigned to the LSP. The name of a nominal and a supplementary LSP is formed by adding the configured-name suffix and an auto-generated suffix to the name of the container LSP. The name of the container LSP is unique and is checked for accuracy during the configuration parsing. The container LSP name should uniquely identify parameters, such as the ingress and egress router names.

NOTE: A container LSP member LSP and a point-to-point LSP on an ingress routing device cannot have the same LSP name.

The container LSPs follow a number-based LSP naming convention. For example, if the nominal LSP's configured name is **bob** and the number of member LSPs is N, the member LSPs are named **bob-*<configured-suffix>*-1**, **bob-*<configured-suffix>*-2**, ..., and **bob-*<configured-suffix>*-N**.

After a normalization event, the number of member LSPs can change. For example, if the number of member LSPs increases from six to eight, then the ingress routing device keeps the first six LSPs named **bob-*<configured-suffix>*-1**, **bob-*<configured-suffix>*-2**, ..., and **bob-*<configured-suffix>*-6**. The two additional LSPs are named **bob-7** and **bob-8**. The original LSPs might need to be re-optimized if their signaled bandwidth changes.

Similarly, if the number of member LSPs reduces from eight to six, the ingress routing device re-signals the member LSPs in such as a way that the remaining active LSPs in the system are named **bob-*<configured-suffix>*-1**, **bob-*<configured-suffix>*-2**, ..., and **bob-*<configured-suffix>*-6**.

In the process of creating new LSPs, an RSVP LSP named **bob-*<configured-suffix>*-7** can be configured.

Normalization

Operational Overview

Normalization is an event that happens periodically. When it happens, a decision is made on the number of member LSPs that should remain active and their respective bandwidths in a container LSP. More specifically, the decision is made on whether new supplementary LSPs are to be created, or any existing LSPs are required to be re-signaled or deleted during the normalization event.

Between two normalization events, a member LSP can undergo several autobandwidth adjustments. A normalization timer, similar to re-optimization timer, is configured. The normalization timer interval should be no less than the adjustment interval or optimization timer.

NOTE: **Normalization is not triggered based on network events, such as topology changes.**

Operational Constraints

Normalization has the following operational constraints:

- Normalization happens only when none of the member LSPs are undergoing re-optimization or make-before-break. Normalization starts when all the member LSPs complete their ongoing make-before-break. If normalization is pending, new optimization should not be attempted until the normalization is complete.
- After normalization, an ingress routing device first computes a set of bandwidth-feasible paths using constraint-based routing computations. If enough constraint-based routing computed paths are not brought up with an aggregate bandwidth value that exceeds the desired bandwidth, several failover actions are taken.
- After a set of bandwidth-feasible paths are available, the ingress routing device signals those paths while keeping the original set of paths up with the old bandwidth values. The make-before-break is done with shared explicit (SE) sharing style, and when some of the LSPs do not get successfully re-signaled, a bounded number of retries is attempted for a specified duration. Only when all the LSPs are successfully signaled does the ingress router switch from the old instance of the container LSP to the newer instance. If all LSPs could not be successfully signaled, the ingress router keeps those instances of members that are up with higher bandwidth values.

  For example, if the bandwidth of an old instance of a member LSP (LSP-1) is 1G, the LSP is split into LSP-1 with bandwidth 2G and LSP-2 with bandwidth 2G. If the signaling of LSP-1 with bandwidth 2G fails, the ingress router keeps LSP-1 with bandwidth 1G and LSP-2 with bandwidth 2G.

When there is a signaling failure, the ingress routing device stays in the error state, where some LSPs have updated bandwidth values only if the aggregate bandwidth has increased. The ingress router makes an attempt to bring up those LSPs that could not be successfully signaled, resulting in minimum traffic loss.

- If an LSP goes down between two normalization events, it can increase the load on other LSPs that are up. In order to prevent overuse of other LSPs, premature normalization can be configured in case of LSP failure. LSPs can go down because of pre-emption or lack of node or link protection. It might not be necessary to bring up the LSPs that are down because the normalization process re-runs the constraint-based routing path computations.

Inter-Operation with Autobandwidth

Taking as an example, there is one nominal LSP named LSP-1 configured with the following parameters:

- Splitting-bandwidth and maximum-signaling-bandwidth of 1G
- Merging-bandwidth and minimum-signaling-bandwidth of 0.8G
- Autobandwidth

Normalization is performed differently in the following scenarios:

- Changes in Per-LSP Autobandwidth Adjustments on page 573
- Changes in Traffic Growth on page 575
- Computed Range and Configured Feasible Ranges on page 575

Changes in Per-LSP Autobandwidth Adjustments

Table 21 on page 573 illustrates how normalization splits and merges member LSPs as autobandwidth adjustments change per-LSP bandwidth with unconditional normalization.

Table 21: Normalization with Per-LSP Autobandwidth Adjustment Changes

Normalization Time	Current State	Events	Adjusted State
T0	No state.	Initialization	LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increases to 1.5G	• Multiple autobandwidth adjustments since T0 is possible. • The ingress router decides to split LSP-1 into two LSPs, and creates LSP-2.	LSP-1 = 0.8G LSP-2 = 0.8G
T2	LSP-1 usage increase to 2G LSP-2 usage increases to 0.9G (within limits)	• Aggregate bandwidth is 2.9G, which exceeds aggregate splitting maximum of 2G. • The ingress router decides to split LSP-1 into three LSPs, and creates LSP-3.	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Table 21: Normalization with Per-LSP Autobandwidth Adjustment Changes (continued)

Normalization Time	Current State	Events	Adjusted State
T3	LSP-3 usage increases to 1.5G	• Aggregate bandwidth is 3.5G with a maximum aggregate splitting of 3G. • The ingress router decides to split LSP-1 into four LSPs, and creates LSP-4.	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G LSP-4 = 1G
T4	LSP-2 usage drops to 0.5G	• Aggregate bandwidth is 3G. • The ingress router decides to merge LSP-1 and removes LSP-4.	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Because autobandwidth is configured on a per-LSP basis, every time there is an autobandwidth adjustment, the ingress router re-signals each LSP with **Max Avg Bw**.

Another approach to handling the changes in per-LSP autobandwidth adjustments is to not allow individual LSPs to run autobandwidth on the ingress router, but to run autobandwidth in passive (monitor) mode. This way, sampling is done at every statistics interval for member LSPs only, and normalization is performed for the container LSP alone instead of acting on individual LSPs adjustment timer expiry.

As a result, the number of re-signaling attempts and bandwidth fluctuations for a given member LSP is reduced. Only the computed bandwidth-values per-member LSP is used by the ingress router to find an aggregate bandwidth to be used during normalization. Configuring autobandwidth adjustment followed by normalization (adjustments and normalization intervals are comparable) can lead to considerable overhead because of re-signaling.

Taking the same example, and applying the second approach, LSP-1 goes from 0.8G to 1.5G and then back to 0.8G. If the normalization timer is of the same order as the adjustment interval, the ingress router leaves LSP-1 alone with its original 0.8G and only signals LSP-2 with 0.8G. This helps achieve the final result of normalization, thus avoiding the extra signaling attempt on LSP-1 with 1.5G at adjustment timer expiry.

Because member LSPs always use equal bandwidth, any adjustment done on member LSPs is undone. The member LSPs are re-signaled with reduced bandwidth when compared to the reserved capacity in adjustment trigger with normalization trigger. Therefore, avoiding adjustment trigger for member LSPs might be useful assuming that normalization and adjustment intervals are of the same order.

NOTE: We recommend that the normalization timer be higher than the autobandwidth adjustment interval and regular optimization duration, as the traffic trends are observed at a longer time scale and normalization is performed one-to-three times per day. An LSP can undergo optimization for the following reasons:

- Normal optimization
- Autobandwidth adjustment
- Normalization

Changes in Traffic Growth

Table 22 on page 575 illustrates how normalization is performed when traffic grows in large factor.

Table 22: Normalization with Traffic Growth

Normalization Time	Current State	Events	Adjusted State
T0	No state		LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increase to 3G	• Aggregate usage exceeds maximum splitting bandwidth • The ingress router decides to split LSP-1, and creates two more supplementary LSPs	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Having fewer LSPs is preferred over signaling four LSPs each with 0.8G bandwidth, unless there is a constraint on the minimum number of LSPs.

Computed Range and Configured Feasible Ranges

When an ingress router is configured with the minimum and maximum number of LSPs, and per LSP splitting-bandwidth and merging-bandwidth values, the bandwidth thresholds are used for splitting and merging. For this, the number of LSPs (N) should satisfy the following constraints:

```
minimum-member-lsps ≤ N ≤ maximum-member-lsps
```

At the time of normalization, based on the aggregate demand X:

```
[X/splitting-bandwidth] ≤ N ≤ [X/merging-bandwidth]
```

The above-mentioned constraints provide two ranges for N to work from. If the two ranges for N are overlapping, N will be selected from the overlapping interval (lowest possible N) to keep the number of LSPs small in the network.

Otherwise, if maximum-member-lsps is less than [X/splitting-bandwidth], the ingress router keeps (at maximum) the maximum-member-lsps in the system, and the bandwidth of each LSP is [X/maximum-member-lsps] or the maximum-signaling-bandwidth, whichever is less. It is possible that some LSPs might not get signaled successfully.

Similarly, if minimum-member-lsps is greater than [X/merging-bandwidth], the ingress router keeps (at minimum) the minimum-member-lsps in the system, and the bandwidth of each LSP is [X/minimum-member-lsps] or the minimum-signaling-bandwidth, whichever is less.

Taking as an example, normalization is performed as following in these cases:

- Case 1
  - minimum-member-lsps = 2
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 1G
  - splitting-bandwidth = 2.5G

  In this case, the ingress routing device signals four member LSPs each with a bandwidth of 2G.
- Case 2
  - minimum-member-lsps = 5
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 2.5G
  - splitting-bandwidth = 10G

  In this case, the ingress routing device signals five member LSPs each with a bandwidth of 2G. Here, the static configuration on the number of member LSPs takes precedence.
- Case 3
  - minimum-signaling-bandwidth = 5G
  - maximum-signaling-bandwidth = 40G
  - merging-bandwidth = 10G
  - splitting-bandwidth = 50G

  When a container LSP comes up, the nominal LSP is signaled with minimum-signaling-bandwidth. At the time of normalization, the new-aggregate-bandwidth is 100G. To find N and the bandwidth of each LSP, N should satisfy the following constraint:

  $100/50 \leq N \leq 100/10$, which gives $2 \leq N \leq 10$

Therefore, N is equal to:

- N = 2, bandwidth = min {100/2G, 40G} = 40G

  This option does not satisfy the new aggregate of 100G.

- N = 3, bandwidth = min {100/3G, 40G} = 33.3G

  This option makes the aggregate bandwidth equal to 100G.

In this case, the ingress routing device signals three LSPs each with a bandwidth of 33.3G.

NOTE: **The ingress router does not signal an LSP smaller than the minimum-signaling-bandwidth.**

Constraint-Based Routing Path Computation

Although there are no changes in the general constraint-based routing path computation, with a container LSP, there is a separate module that oversees the normalization process, schedules constraint-based routing events, and schedules switchover from an old instance to a new instance, when appropriate. An ingress routing device has to handle the constraint-based routing path computation periodically. When normalization occurs, an ingress router has to compute constraint-based routing paths, if the number of LSPs or the bandwidth of the LSPs needs to be changed.

For example, there are K LSPs at the ingress router with bandwidth values X-1, X-2, ..., and X-K. The current aggregate bandwidth value is Y, which is the sum of X-1 plus X-2 plus X-K. If there is a new demand of W, the ingress router first computes how many LSPs are required. If the ingress router only needs N LSPs (LSP-1, LSP-2, .., and LSP-N) each with bandwidth value B, the task of the constraint-based routing module is to provide a set of bandwidth-feasible LSPs that can accommodate the new aggregate demand which is not less than Y.

The ingress router then tries to see if the constraint-based routing paths can be computed successfully for all N LSPs. If the paths for all the LSPs are found successfully, the constraint-based routing module returns the set to the normalization module.

It is possible that the constraint-based routing computation is not successful for some LSPs. In this case, the ingress routing device takes the following action:

- If the configuration allows for incremental-normalization, implying if the ingress router has enough LSPs whose aggregate exceeds Y, the constraint-based routing module returns that set of paths.
- Whether increment-normalization is configured or not, if constraint-based routing paths could not be computed for a sufficient number of LSPs, the ingress router has to repeat the process of finding a new set of LSPs. Initially, the ingress router starts with the lowest value of N from the feasible region. Every time, the ingress router has to revise the number, it linearly increases it by 1. As a result, per LSP bandwidth becomes less and therefore, there is a greater chance of successful signaling. The process is

repeated for all feasible values of N (or some bounded number of times or duration as configured).

The ingress router signals the LSPs after successful computations of the constraint-based routing path computation. It might happen that when the LSPs are signaled, signaling of many LSPs fail. In addition to the constraint-based routing path computations to be successful, the RSVP signaling should also succeed, such that the new aggregate is not less than the old aggregate bandwidth.

Sampling

Sampling is important for normalization to function. With sampling configured, an ingress routing device is able to make a statistical estimate of the aggregate traffic demands. Every time the sampling timer fires, the ingress routing device can consider traffic rates on different LSPs and compute an aggregate bandwidth sample. This sampling timer is different from the statistics sampling done periodically by RSVP on all LSPs. The aggregate bandwidth is a sample to be used at the time of normalization. An ingress routing device can save past samples to compute an average (or some other statistical measure) and use it the next time normalization happens.

To remove any outlier samples, a sampling token is configured. In other words, from all the aggregate samples collected during the configured time, the bottom and top outliers are ignored before computing a statistical measure from the remaining samples.

The following two methods of computing an aggregate bandwidth value are supported:

- Average—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The average bandwidth value is computed from the remaining samples to be used during normalization.
- Max—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The maximum bandwidth value is picked from the remaining samples to be used during normalization.

The time duration, the number of past aggregate samples to store, the percentile value to determine, and the ignore outliers are user-configurable parameters.

Support for NSR, IPG-FA, and Static Routes

Starting with Junos OS Release 15.1, container label-switched paths (LSPs) provide support for nonstop active routing (NSR), IGP forwarding adjacency (FA), and static routes to address the requirements of wider business cases.

- NSR Support on page 578
- IPG-FA Support on page 580
- Static Route Support on page 581

NSR Support

A container LSP has the characteristics of ECMP and RSVP traffic engineering. Because a container LSP consists of several member LSPs between an ingress and an egress router, with each member LSP taking a different path to the same destination, the ingress router is configured with all the parameters necessary to compute an RSVP ECMP LSP.

These parameters along with the forwarding state information have to be synchronized between the master and backup Routing Engines to enable the support for nonstop active routing (NSR) for container LSPs. While some of the forwarding state information on the backup Routing Engine is locally built based on the configuration, most of it is built based on periodic updates from the master Routing Engine. The container LSPs are created dynamically using the replicated states on the backup Routing Engine.

By default, normalization occurs once in every 6 hours and during this time, a number of autobandwidth adjustments happen over each member LSP. A member LSP is resized according to the traffic it carries and the configured autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by summing up the bandwidth across all the member LSPs.

For RSVP point-to-point LSPs, a Routing Engine switchover can be under any one of the following:

- **Steady state**

  In the steady state, the LSP state is up and forwards traffic; however, no other event, such as the make-before-break (MBB), occurs on the LSP. At this stage, the RPD runs on both the Routing Engines, and the switchover event toggles between the master and backup Routing Engine. The backup Routing Engine has the LSP information replicated already. After the switchover, the new master uses the information of the replicated structure to construct the container LSP and en-queues the path (ERO) of LSP in the retrace mode. RSVP signals and checks if the path mentioned in the ERO is reachable. If the RSVP checks fail, then the LSP is restarted. If the RSVP checks succeed, the LSP state remains up.

- **Action leading to make-before-break (MBB)**

  A container LSP can be optimized with updated bandwidth, and this change is done in a MBB fashion. During an MBB process, there are two path instances for a given LSP, and the LSP switches from one instance to another. For every Routing Engine switchover, the path is checked to find out where in the MBB process the path is. If the path is in the middle of the MBB process, with the main instance being down and the re-optimized path being up, then MBB can switch over to the new instance. The **show mpls lsp extensive** command output, in this case, is as follows:

```
13 Dec  3 01:33:38.941 Make-before-break: Switched to new instance
   12 Dec  3 01:33:37.943 Record Route:  10.1.1.1
   11 Dec  3 01:33:37.942 Up
   10 Dec  3 01:33:37.942 Automatic Autobw adjustment succeeded: BW changes
from 100 bps to 281669 bps
    9 Dec  3 01:33:37.932 Originate make-before-break call
    8 Dec  3 01:33:37.931 CSPF: computation result accepted  10.1.1.1
    7 Dec  3 01:28:44.228 CSPF: ERO retrace was successful  10.1.1.1
    6 Dec  3 01:19:39.931 10.1.1.2 Down: mbb/reopt
    5 Dec  3 01:18:29.286 Up: mbb/reopt
    4 Dec  3 01:14:47.119 10.1.1.2 Down: mbb/reopt
    3 Dec  3 01:13:29.285 Up: mbb/reopt
    2 Dec  3 01:10:59.755 Selected as active path: selected by master RE
```

  A similar behavior is retained for member LSPs during bandwidth optimization.

A Routing Engine switchover under the steady state (when normalization is not in progress), keeps the container LSPs up and running without any traffic loss. Events, such as an MBB due to autobandwidth adjustments, link status being down, or double failure, in the steady state are similar to a normal RSVP point-to-point LSP.

If the container LSP is in the process of normalization, and the normalization event is triggered either manually or periodically, it goes through the computation and execution phase. In either of the cases, zero percent traffic loss is not guaranteed.

- Normalization in the computation phase

  During the computation phase, the master Routing Engine calculates the targeted member LSP count and bandwidth with which each member LSP should be re-signaled. The backup Routing Engine has limited information about the container LSP, such as the LSP name, LSP ID, current bandwidth of its member LSP, member LSP count, and the normalization retry count. If the switchover happens during the computation phase, then the backup Routing Engine is not aware of the targeted member LSP count and the bandwidth to be signaled. Since traffic statistics are not copied to the backup Routing Engine, it cannot compute the targeted member count and bandwidth. In this case, the new master Routing Engine uses the old data stored in the targeted member LSP count and the targeted bandwidth to signal the LSPs.

- Normalization in the execution phase

  During the execution phase, RSVP of the master Routing Engine tries to signal the LSPs with the newly calculated bandwidth. If the switchover occurs during the signaling of LSPs with greater bandwidth or during LSP splitting or merging, then the new master Routing Engine uses the information of the targeted member count and bandwidth value to be signaled with, to bring up the LSPs.

IPG-FA Support

A forwarding adjacency (FA) is a traffic engineering label-switched path (LSP) that is configured between two nodes and used by an interior gateway protocol (IGP) to forward traffic. By default, an IGP does not consider MPLS traffic-engineering tunnels between sites, for traffic forwarding. Forwarding adjacency treats a traffic engineering LSP tunnel as a link in an IGP topology, thus allowing the nodes in the network also to forward the IP traffic to reach the destination over this FA LSP. A forwarding adjacency can be created between routing devices regardless of their location in the network.

To advertise a container LSP as an IGP-FA, the LSP name needs to be configured either under IS-IS or OSPF. For example:

IS-IS

```
[edit]
protocols {
   isis {
      label-switched-path container-lsp-name;
   }
}
```

OSPF

```
[edit]
```

```
protocols {
   ospf {
      area 0.0.0.0 {
         label-switched-path container-lsp-name;
      }
   }
}
```

NOTE: The IGP-FA is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for FA.

Static Route Support

Static routes often include only one or very few paths to a destination and generally do not change. These routes are used for stitching services when policies and other protocols are not configured.

To advertise a container LSP as a static route, the LSP name needs to be configured under the static route configuration. For example:

Static Route

```
[edit]
routing-options {
   static {
      route destination {
         lsp-next-hop container-lsp-name;
      }
   }
}
```

NOTE: The static route support is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for static routing.

Configuration Statements Supported for Container LSPs

Table 23 on page 582 lists the MPLS LSP configuration statements that apply to RSVP LSP and a container LSP (nominal and supplementary).

The configuration support is defined using the following terms:

- Yes—The configuration statement is supported for this type of LSP.
- No—The configuration statement is not supported for this type of LSP.
- N/A—The configuration statement is not applicable for this type of LSP.

Table 23: Applicability of RSVP LSPs Configuration to a Container LSP

Configuration Statement	RSVP LSP (Ingress)	Member LSP (Ingress)
adaptive (Default: non-adaptive)	Yes	Yes
admin-down	Yes	Yes
admin-group	Yes	Yes
admin-groups-except	Yes	Yes
apply-groups	Yes	Yes
apply-groups-except	Yes	Yes
associate-backup-pe-groups	Yes	No
associate-lsp (No bidirectional support)	Yes	No
auto-bandwidth	Yes	Yes

standby (All LSPs are standby)	Yes	No
template	Yes	No
to	Yes	Yes
traceoptions	Yes	Yes
ultimate-hop-popping	Yes	Yes

Impact of Configuring Container LSPs on Network Performance

A container LSP is a container LSP that allows multiple member LSPs to co-exist and be managed as a bundle. The member LSPs are similar to independent point-to-point RSVP LSPs. As a result, resource consumption is similar to the sum of resources consumed by each point-to-point RSVP LSP. However, provisioning a container LSP is more efficient, as under-utilized member LSPs are dynamically removed, thus saving memory and CPU resources.

The container LSP features are dependent on the presence of a functional base MPLS RSVP implementation. As a result, a container LSP does not introduce any security considerations beyond the existing considerations for the base MPLS RSVP functionality. The categories of possible attacks and countermeasures are as follows:

- Interaction with processes and router configuration

  No new communication mechanisms with external hosts are required for a container LSP. Data arrives at the RSVP module through local software processes and router configuration, other than RSVP neighbor adjacency. Junos OS provides security controls on access to the router and router configuration.

- Communication with external RSVP neighbors

  RSVP signaled MPLS LSPs depend on the services of RSVP and IGP to communicate RSVP messages among neighboring routers across the network . Because the RSVP sessions involve communication outside of the local router, they are subject to many forms of attack, such as spoofing of peers, injection of falsified RSVP messages and route updates, and attacks on the underlying TCP/UDP transport for sessions. Junos OS provides countermeasures for such attack vectors.

- Resource limits and denial of service

  Junos OS provides several mechanisms through policers and filters to protect against denial-of-service attacks based on injecting higher than the expected traffic demands. At the MPLS LSP level, Junos OS allows operators to configure limits on the LSP

bandwidth and the number of LSPs. However, like point-to-point RSVP LSPs, container LSPs do not enforce limits on the volume of traffic forwarded over these LSPs.

Supported and Unsupported Features

Junos OS supports the following container LSP features:

- Equal-bandwidth-based LSP splitting mechanism
- Aggregate-bandwidth-based LSP splitting and merging in a make-before-break way
- LSP-number-based naming mechanism for dynamically created member LSPs
- Periodic sampling mechanisms to estimate aggregate bandwidth
- Interoperability with auto-bandwidth feature
- ECMP using the dynamically created LSPs
- LDP-tunneling on the dynamically created LSP
- Configuring container LSP using IGP shortcuts
- Aggregated Ethernet links
- Logical systems

Junos OS does **not** support the following container LSP functionality:

- Node and link disjoint paths for different LSPs between an ingress and an egress routing device
- Bandwidth allocation policy different from equal bandwidth policy at the normalization event
- Constraint-based routing path computation to find equal IGP cost paths for different LSPs
- RSVP objects, such as **MLSP_TUNNEL Sender Template**, and **MLSP_TUNNEL Filter Specification** defined in [KOMPELLA-MLSP]
- Change in topology as a trigger for LSP splitting and merging
- Change in topology and link failure as a trigger for normalization, unless member LSPs go down
- Egress protection on container LSP
- Container LSP as a backup LSP for IGP interface
- Container LSP as provider tunnel for multicast VPNs
- Dynamic LSPs for normalization
- CCC using container LSP
- Secondary paths for container LSP
- Bidirectional container LSP
- Policing

- Static routes using container LSPs as next hops on a best-effort basis
- External path computing entity, such as PCE
- Multichassis
- IPv6

Example: Configuring Dynamic Bandwidth Management Using Container LSP

This example shows how to enable dynamic bandwidth management by configuring container label-switched paths (LSPs) that enable load balancing across multiple point-to-point member LSPs.

Requirements

This example uses the following hardware and software components:

- Five routers that can be a combination of M Series, MX Series, or T Series routers, out of which two routers are provider edge (PE) routers and three routers are provider (P) routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - BGP
   - OSPF

Overview

Starting with Junos OS Release 14.2, a new type of LSP, called a container LSP, is introduced to enable load balancing across multiple point-to-point LSPs. A container

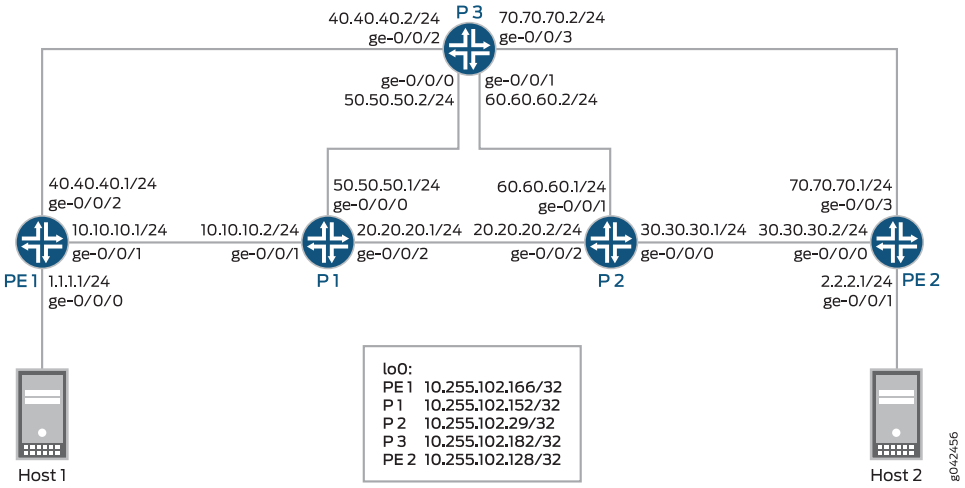
LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

Topology

Figure 54 on page 588 is a sample topology configured with container LSPs.

Figure 54: Dynamic Bandwidth Management Using Container LSP



In this example, Routers PE1 and PE2 are the PE routers connected to hosts Host1 and Host2, respectively. The core routers, Routers P1, and P2, and P3 connect to the PE routers.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

1. Configure the Router PE1 interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/24
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 40.40.40.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.102.166/32
user@PE1# set lo0 unit 0 family mpls
```

2. Configure the router ID and autonomous system number for Router PE1.

```
[edit routing-options]
user@PE1# set router-id 10.255.102.166
user@PE1# set autonomous-system 1234
```

3. Enable the policy to load-balance traffic.

```
[edit routing-options]
user@PE1# set forwarding-table export pplb
```

4. Enable RSVP on all Router PE1 interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
```

5. Enable MPLS on all the interfaces of Router PE1 (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

6. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
```

```
user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth
```

7. Configure the label-switched path (LSP) template parameters.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  adjust-interval 300
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  adjust-threshold 5
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  minimum-bandwidth 10m
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  maximum-bandwidth 10m
```

8. Configure a container LSP between Router PE1 and Router PE2, and assign the PE1-to-PE2-template1 LSP template.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 to
  10.255.102.128
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
  label-switched-path-template PE1-to-PE2-template1
```

9. Configure the container LSP parameters.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
  splitting-merging maximum-member-lsps 20

```

```
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
  splitting-merging sampling cut-off-threshold 1
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
  splitting-merging sampling use-percentile 90
```

10. Configure the BGP group, and assign the local and neighbor IP addresses.

```
[edit protocols]
user@PE1# set bgp group to-PE2 type internal
user@PE1# set bgp group to-PE2 local-address 10.255.102.166
user@PE1# set bgp group to-PE2 neighbor 10.255.102.128
user@PE1# set bgp group to-PE2 family inet-vpn unicast
user@PE1# set bgp group to-PE2 export direct
```

11. Enable OSPF on all the interfaces of Router PE1 (excluding the management interface) along with traffic engineering capabilities.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/2.0 metric 100
```

12. Configure the policy statement to load-balance traffic.

```
[edit policy-options]
user@PE1# set policy-statement direct term 1 from protocol direct
user@PE1# set policy-statement direct term 1 then accept
user@PE1# set policy-statement pplb then load-balance per-packet
```

13. Configure a routing instance on Router PE1, and assign the routing instance interface.

```
[edit routing-instances]
user@PE1# set vpn1 instance-type vrf
user@PE1# set vpn1 interface ge-0/0/0.0
```

14. Configure the route distinguisher, vrf target, and vrf-table label values for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 10.255.102.166:1
user@PE1# set vpn1 vrf-target target:1:1
user@PE1# set vpn1 vrf-table-label
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, **show policy-options**, and **show routing-options**

commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

```

Meaning At the expiry of the normalization timer, the container LSP is split into five member LSPs, each with 10 Mbps (minimum and maximum signaling bandwidth). As a result, the aggregate bandwidth is 50 Mbps.

Verifying the Container LSP Splitting Process

Purpose Verify the container LSP splitting process after normalization happens.

Action From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2

vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24         *[BGP/170] 00:12:14, localpref 100, from 10.255.102.128
                      AS path: I, validation-state: unverified
>to 10.10.10.2 via ge-0/0/1.0,label-switched-path PE1-PE2-container100-1
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-2
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-3
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-4
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-5
```

Meaning After LSP splitting, Router PE1 has injected the forwarding adjacency.

Verifying the Container LSP Statistics

Purpose Verify the container LSP statistics after normalization happens.

Action From operational mode, run the **show mpls container-lsp statistics** command.

```
user@PE1> show mpls container-lsp statistics
Ingress LSP: 1 sessions
Container LSP name                                State     Member LSP count
PE1-PE2-container-100                             Up                5
To              From            State     Packets            Bytes LSPname
10.255.102.128   10.255.102.166  Up   15166271       2062612856
PE1-PE2-container-100-1
10.255.102.128   10.255.102.166  Up   12289912       1671428032
PE1-PE2-container-100-2
10.255.102.128   10.255.102.166  Up   13866911       1885899896
PE1-PE2-container-100-3
10.255.102.128   10.255.102.166  Up   12558707       1707984152
PE1-PE2-container-100-4
10.255.102.128   10.255.102.166  Up   11512151       1565652536
PE1-PE2-container-100-5
```

Meaning Traffic is load-balanced across the newly created member LSPs.

Verifying the Container LSP Status with Decreased Bandwidth (Before Normalization)

Purpose Verify the status of the container LSP with decreased bandwidth before normalization happens.

Action From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 5
 Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 50Mbps, Sampled Aggregate bandwidth: 2.0215Mbps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
 BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 384 second(s)
---Output truncated---
```

Meaning Because normalization has not happened, the member LSP count remains at 5.

Verifying the Container LSP Status with Decreased Bandwidth (After Normalization)

Purpose Verify the status of the container LSP with decreased bandwidth after normalization happens.

Action From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
 Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 20Mbps, Sampled Aggregate bandwidth: 0bps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
 BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 397 second(s)
   22 Jun  5 22:30:37.094 Clear history and statistics: on container
(PE1-PE2-container-100)
   21 Jun  5 22:30:37.094 Delete member LSPs: PE1-PE2-container-100-3 through
PE1-PE2-container-100-5
   20 Jun  5 22:30:37.090 Normalize: container (PE1-PE2-container-100) into 2
members - each with bandwidth 10000000 bps
  19 Jun  5 22:30:37.090 Normalize: normalization with aggregate bandwidth 2037595
 bps
   18 Jun  5 22:30:37.090 Normalize: normalizaton with 2037595 bps
---Output truncated---
```

Meaning At the expiry of the normalization timer, the container LSP merging takes place because there is an overall reduction in bandwidth. The member LSPs are merged, and the member LSP count is 2 after normalization.

Verifying the Container LSP Merging Process

Purpose Verify the container LSP splitting process after normalization happens.

Action From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2

vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24         *[BGP/170] 01:09:45, localpref 100, from 10.255.102.128
                      AS path: I, validation-state: unverified
                    > to 10.10.10.2 via ge-0/0/1.0, label-switched-path
PE1-PE2-container-100-1
                      to 10.10.10.2 via ge-0/0/1.0, label-switched-path
PE1-PE2-container-100-2
```

Meaning After LSP merging, Router PE1 has deleted the merged member LSPs.

Verifying Failover Normalization

Purpose Verify load redistribution when traffic is sent at 35 Mbps and the link between Routers P1 and P2 is disabled. Arrival of PathErr on link failure triggers immediate normalization.

To enable failover normalization, include the **failover-normalization** configuration statement at the **[edit protocols mpls container-label-switched-path container-lsp-name splitting-merging normalization]** hierarchy level.

Action From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
```

```
Ingress LSP: 1 sessions
Container LSP name                                State     Member LSP count
PE1-PE2-container-100                              Up               2
To              From            State Rt P     ActivePath       LSPname
10.255.102.128   10.255.102.166  Up     0 *
PE1-PE2-container-100-1
10.255.102.128   10.255.102.166  Up     0 *
PE1-PE2-container-100-2
Total 2 displayed, Up 2, Down 0
```

After the ge-0/0/2 link between Routers P1 and P2 goes down, normalization is immediately triggered.

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
```

```
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 4

PathErr on member PE1-PE2-container-100-2
    4 Jun 5 19:28:20.308 Normalize: container (PE1-PE2-container-100) received
PathErr on member PE1-PE2-container-100-1
   3 Jun 5 19:27:48.574 Normalization complete: container (PE1-PE2-container-100)
 with 2 members
    2 Jun 5 19:27:28.644 Normalize: container (PE1-PE2-container-100) create 2
LSPs, min bw 10000000bps, member count 0
    1 Jun 5 19:27:28.644 Normalize: normalization with aggregate bandwidth 0 bps
----Output truncated----
```

Meaning Arrival of PathErr message on link failure triggers immediate normalization.

Verifying Incremental Normalization

Purpose Verify incremental normalization when enough bandwidth is not available.

On Router PE1, the RSVP interfaces static bandwidth is restricted to 22 Mbps each.

Action From operational mode, run the **show rsvp interface** command.

```
user@PE1> show rsvp interface
```

```
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
ge-0/0/2.0  Up         0   100%  22Mbps      22Mbps      0bps        21.4031Mbps
ge-0/0/1.0  Up         2   100%  22Mbps      12Mbps      10Mbps      21.7011Mbps
```

Before normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
```

```
Ingress LSP: 1 sessions
Container LSP name                                State     Member LSP count

Configuring Dynamic Bandwidth Management Using Container LSP

You can configure a container LSP to enable load balancing across multiple point-to-point LSPs dynamically. A container LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID and autonomous system number.
3. Configure the following protocols:
   - RSVP
   - BGP

     Configure a BGP group to peer device with remote provider edge (PE) device.

- OSPF

  Enable traffic engineering capabilities.

4. Configure a VRF routing instance.

To configure the PE device:

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

2. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file file-name
user@PE1# set mpls statistics file size size
user@PE1# set mpls statistics interval seconds
user@PE1# set mpls statistics auto-bandwidth
```

3. Configure the label-switched path (LSP) template parameters.

```
[edit protocols]
user@PE1# set mpls label-switched-path template-name template
user@PE1# set mpls label-switched-path template-name optimize-timer seconds
user@PE1# set mpls label-switched-path template-name link-protection
user@PE1# set mpls label-switched-path template-name adaptive
user@PE1# set mpls label-switched-path template-name auto-bandwidth
  adjust-interval seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth
  adjust-threshold seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth
  minimum-bandwidth mbps
user@PE1# set mpls label-switched-path template-name auto-bandwidth
  maximum-bandwidth mbps
```

4. Configure a container LSP between the two PE routers, and assign the LSP template.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name to
  remote-PE-ip-address
user@PE1# set mpls container-label-switched-path container-lsp-name
  label-switched-path-template template-name
```

5. Configure the container LSP parameters.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging maximum-member-lsps number
```

```
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging minimum-member-lsps number
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging splitting-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging merging-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging maximum-signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging minimum-signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging normalization normalize-interval seconds
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging normalization failover-normalization
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging normalization normalization-retry-duration seconds
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging normalization normalization-retry-limits number
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging sampling cut-off-threshold number
user@PE1# set mpls container-label-switched-path container-lsp-name
  splitting-merging sampling use-percentile number
```

6. Configure the policy statement to load-balance traffic.

```
[edit policy-options]
user@PE1# set policy-statement first-policy-name term 1 from protocol direct
user@PE1# set policy-statement first-policy-name term 1 then accept
user@PE1# set policy-statement second-policy-name then load-balance per-packet
```

NOTE: The policy to load-balance traffic should be assigned to the forwarding table configuration under the [edit routing-options] hierarchy level.

```
user@PE1# set forwarding-table export pplb
```

7. Verify and commit the configuration.

   For example:

```
[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth
```

```
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  adjust-interval 300
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  adjust-threshold 5
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  minimum-bandwidth 10m
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
  maximum-bandwidth 10m
user@PE1# set mpls label-switched-path PE1-PE2-template-1 template
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth
  adjust-interval 8000
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth
  minimum-bandwidth 5m
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth
  maximum-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100

CHAPTER 17

Configuring Pop-and-Forward LSPs

RSVP-TE Pop-and-Forward LSP Tunnels Overview

Pop-and-forward LSPs introduces the notion of pre-installed per traffic engineering link pop labels that are shared by RSVP-TE LSPs that traverse these links and significantly reducing the required forwarding plane state . A transit label-switching router (LSR) allocates a unique pop label per traffic engineering link with a forwarding action to pop the label and forward the packet over that traffic engineering link should the label appear at the top of the packet. These pop labels are sent back in the RESV message of the LSP at each LSR and further recorded in the record route object (RRO). The label stack is constructed from the recorded labels in the RRO and pushed by the ingress label edge router (LER), as each transit hop performs a pop-and-forward action on its label. The pop-and-forward tunnels enhances the RSVP-TE control plane feature benefits with the simplicity of the shared MPLS forwarding plane.

Benefits of RSVP-TE Pop-and-Forward LSP Tunnels

- **Scaling advantage of RSVP-TE**—Any platform-specific label space limit on an LSR is prevented from being a constraint to the control plane scaling on that interface.
- **Reduced forwarding plane state**—The transit labels on a traffic engineering link are shared across RSVP-TE tunnels traversing the link, and are used independent of the ingress and egress devices of the LSPs, thereby significantly reducing the required forwarding plane state.
- **Reduced transit data plane state**—Because the pop labels are allocated per traffic engineering link and shared across LSPs, the total label state in the forwarding plane is reduced to a function of the number of RSVP neighbors on that interface.

- **Faster LSP setup time**—The forwarding plane state is not programmed during the LSP setup and teardown. As a result, the control plane need not wait sequentially at each hop for the forwarding plane to be programmed prior to sending the label upstream in the RESV message, resulting in reduced LSP setup time.
- **Backward compatibility**—This allows backward compatibility with transit LSRs that provide regular labels in RESV messages. Labels can be mixed across transit hops in a single MPLS RSVP-TE LSP. Certain LSRs can use traffic engineering link labels and others can use regular labels. The ingress can construct a label stack appropriately based on what type of label is recorded from every transit LSR.

Pop-and-Forward LSP Tunnel Terminology

The following terminology is used in the implementation of RSVP-TE pop-and-forward LSP tunnels:

- **Pop label**—An incoming label at an LSR that is popped and forwarded over a specific traffic-engineering link to a neighbor.
- **Swap label**—An incoming label at an LSR that is swapped to an outgoing label and forwarded over a specific downstream traffic engineering link.
- **Delegation label**—An incoming label at an LSR that is popped. A new set of labels is pushed before the packet is forwarded.
- **Delegation hop**— A transit hop that allocates a delegation label.
- **Application label depth (AppLD)**—Maximum number of application or service labels (for example, VPN, LDP, or IPv6 explicit-null labels) that can be beneath the RSVP transport labels. It is configured on a per-node basis, and is equally applicable for all LSPs, and is neither signaled nor advertised.
- **Outbound label depth (OutLD)**—Maximum number of labels that can be pushed before a packet is forwarded. This is local to the node, and is neither signaled nor advertised.
- **Additional transport label depth (AddTLD)**—Maximum number of other transport labels that can be added (for example, bypass label). This is a per-LSP parameter that is neither signaled or advertised. The value is discerned by checking if the LSP has been signaled with link protection (AddTLD=1) or without link protection (AddTLD=0).
- **Effective transport label depth (ETLD)**— Number of transport labels that the LSP hop can potentially send to its downstream hop. This value is signaled per LSP in the hop attributes subobject. The hop attributes subobject is added to the record route object (RRO) in the path message.

Pop-and-Forward LSP Tunnel Label and Signaling

Every traffic engineering link is allocated a pop label that is installed in the mpls.0 routing table with a forwarding action to pop the label and forward the packet over the traffic engineering link to the downstream neighbor of the RSVP-TE tunnel.

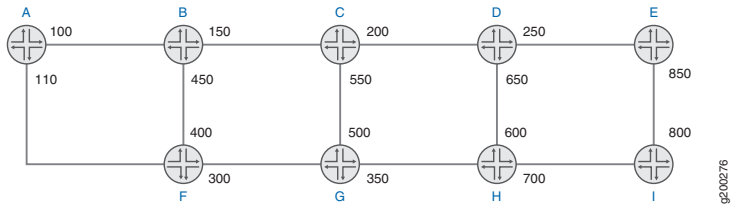
For pop-and-forward LSP tunnels, the pop label for the traffic engineering link is allocated when the first RESV message for a pop-and-forward transit LSP arrives over that traffic

engineering link. This is done to avoid preallocating pop labels and installing them in networks where pop-and-forward LSPs are not configured.

NOTE: For the pop-and-forward LSP tunnels to function effectively, we recommend that you configure the maximum-labels statement on all the interfaces in the RSVP-TE network.

Figure 55 on page 623 displays pop labels at all interfaces for neighboring devices.

Figure 55: Pop-and-Forward LSP Tunnel Labels



There are two pop-and-forward LSP tunnels—T1 and T2. Tunnel T1 is from Device A to Device E on path A-B-C-D-E. Tunnel T2 is from Device F to Device E on path F-B-C-D-E. Both the tunnels, T1 and T2, share the same traffic engineering links B-C, C-D, and D-E.

As RSVP-TE signals the setup of the pop-and-forward tunnel T1, the LSR D receives the RESV message from the egress E. Device D checks the next-hop traffic engineering link (D-E) and provides the pop label (250) in the RESV message for the tunnel. The label is sent in the label object and is also recorded in the label subobject (with the pop label bit set) carried in the RRO. Similarly, Device C provides the pop label (200) for the next-hop traffic engineering link C-D and Device B provides the pop label (150) for the next-hop traffic engineering link B-C. For the tunnel T2, the transit LSRs provide the same pop labels as described for tunnel T1.

Both the label edge routers (LERs), Device A and Device F, push the same stack of labels [150(top), 200, 250] for tunnels T1 and T2, respectively. The recorded labels in the RRO are used by the ingress LER to construct a stack of labels.

The pop-and-forward LSP tunnel labels are compatible with transit interfaces that use swap labels. Labels can be mixed across transit hops in a single MPLS RSVP-TE LSP, where certain LSRs can use pop labels and others can use swap labels. The ingress device constructs the appropriate label stack based on the label type recorded from every transit LSR.

Pop-and-Forward LSP Tunnel Label Stacking

Construction of Label Stack at the Ingress

The ingress LER checks the type of label received from each transit hop as recorded in the RRO in the RESV message and generates the appropriate label stack to use for the pop-and-forward tunnel.

The following logic is used by the ingress LER while constructing the label stack:

- Each RRO label subobject is processed starting with the label subobject from the first downstream hop.
- Any label provided by the first downstream hop is always pushed on the label stack. If the label type is a pop label, then any label from the succeeding downstream hop is also pushed on the constructed label stack.
- If the label type is a swap label, then any label from the succeeding downstream hop is not pushed on the constructed label stack.

Auto-Delegation of Label Stack

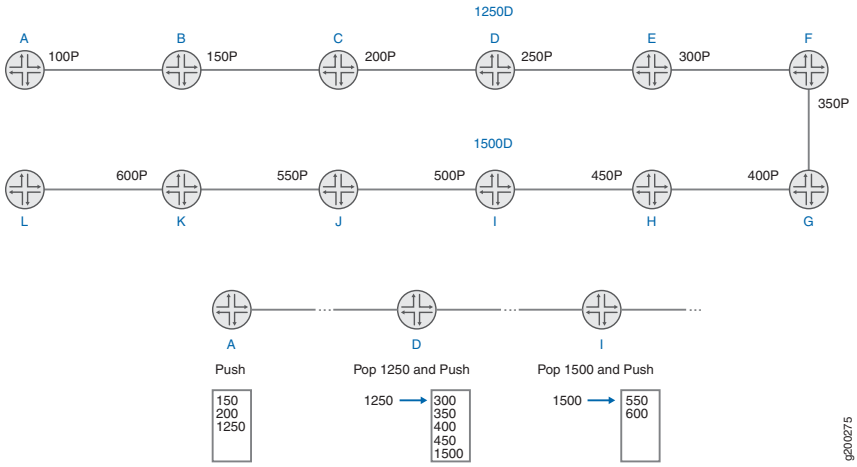
The ingress device runs the Constrained Shortest Path First (CSPF) to compute the path, and if the hop length is greater than the OutLD-AppLD-AddTLD, the ingress device cannot impose the entire label stack to reach the egress device.

When requesting RSVP-TE to signal the path, the ingress device always requests autodelegation for the LSP, where one or more transit hops automatically select themselves as delegation hops to push the label stack to reach the next delegation hop. Junos OS uses an algorithm based on the received Effective Transport Label-Stack Depth (ETLD), that each transit executes to decide whether it should autoselect itself as a delegation hop. This algorithm is based on the section on ETLD in the Internet draft draft-ietf-mpls-rsvp-shared-labels-00.txt (expires September 11 2017), *Signaling RSVP-TE Tunnels on a Shared MPLS Forwarding Plane*.

The label stack imposed by the ingress device delivers the packet up to the first delegation hop. Each delegation hop's label stack also includes the delegation label of the next delegation hop at the bottom of the stack.

Figure 56 on page 625 displays labels at every device interface, where Device D and Device I are delegation hops, *[Label]* P is the pop label, and *[Label]* D is the delegation label. The RSVP-TE pop-and-forward LSP tunnel is A-B-C-D-E-F-G-H-I-J-K-L. Delegation label 1250 represents (300, 350, 400, 450, 1500); Delegation label 1500 represents (550, 600).

Figure 56: Pop-and-Forward LSP Tunnel Pop and Delegation Labels



In this approach, for the tunnel, the ingress LER Device A pushes (150, 200, 1250). At LSR Device D, the delegation label 1250 gets popped and labels 300, 350, 400, 450, and 1500 get pushed. At LSR Device I, the delegation label 1500 gets popped and the remaining set of labels (550, 600) get pushed. In Junos OS, the pop and push action occurs as a swap to the bottom label of the outgoing stack and push the remaining labels.

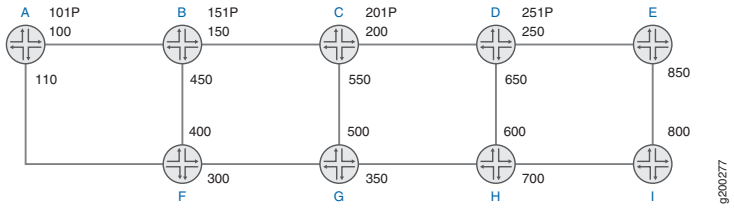
A delegation label and the LSP segment that it covers can be shared by multiple pop-and-forward LSPs. A LSP delegation segment consist of an ordered set of hops (IP addresses and labels) as seen in the RESV RRO. The delegation label (and the segment that it covers) is not owned by a particular LSP, but can be shared. When all LSPs using a delegation label are deleted, the delegation label (and route) is deleted.

Pop-and-Forward LSP Tunnel Link Protection

To provide link protection at a point of local repair (PLR) with a pop-and-forward data plane, the LSR allocates a separate pop label for the traffic engineering link that is used for the RSVP-TE tunnels that request link protection from the ingress device. No signaling extensions are required to support link protection for the RSVP-TE tunnels over the pop-and-forward data plane.

Figure 57 on page 625 displays pop labels at every device interface; labels marked with P are pop labels that offer link protection for the traffic-engineering link.

Figure 57: Pop-and Forward LSP Tunnel Link Protection



At each LSR, link-protected pop labels can be allocated for each traffic engineering link, and a link-protecting facility bypass LSP (which is not a pop-and-forward LSP, but rather a normal bypass LSP) can be created to protect the traffic engineering link. These labels can be sent in the RESV message by the LSR for LSPs requesting link protection over the specific traffic engineering link. Because the facility bypass terminates at the next hop (merge point), the incoming pop label on the packet at the PLR is what the merge point expects.

For example, LSR Device B can install a facility bypass LSP for the link-protected pop label 151. When the traffic engineering link B-C is up, LSR Device B pops 151 and sends the packet to C. If the traffic engineering link B-C is down, the LSR can pop 151 and send the packet through the facility backup to Device C.

RSVP-TE Pop-and-Forward LSP Tunnel Supported and Unsupported Features

Junos OS supports the following features with RSVP-TE pop-and-forward LSP tunnels:

- Pop labels per RSVP neighbor for unprotected LSP.
- Pop labels per RSVP neighbor for LSPs requesting link protection using facility bypass
- Autodelegation of LSP segment.
- Mixed label mode, where certain transit LSRs do not support pop-and-forward LSP tunnels
- LSP ping and traceroute
- All existing CSPF constraint.
- Load balancing of traffic between pop-and-forward LSPs and regular point-to-point RSVP-TE LSP.
- Autobandwidth, LDP tunneling, and TE++ container LSP.
- Aggregated Ethernet interface.
- Virtual platforms support, such as Juniper Networks vMX Virtual Router.
- 64-bit support
- Logical systems

Junos OS does not support the following functionality for RSVP-TE pop-and-forward LSP tunnels:

- Node link protection
- Detour protection for MPLS fast reroute
- Point-to-multipoint LSPs.
- Switch-away LSP.
- Generalized MPLS (GMPLS) LSPs (including bidirectional LSPs, associated LSPs, VLAN user-to-network interface [UNI] and so on)
- IP Flow Information Export (protocol) (IPFIX) inline flow sampling for MPLS template

- RFC 3813, *Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)*
- IPv4 Explicit-null (Inserting label 0 at the bottom of the label stack is not supported. If there are service labels beneath the RSVP-TE pop-and-forward label stack, because the penultimate hop for the LSP copies the EXP value to the service label, this can allow continuity of class of service (CoS) across the MPLS forwarding plane).
- Ultimate-hop popping (UHP)
- Graceful Routing Engine switchover (GRES)
- Nonstop active routing (NSR)

CHAPTER 20

Understanding MPLS Traffic Engineering

MPLS and Traffic Engineering

Traffic engineering allows you to control the path that data packets follow, bypassing the standard routing model, which uses routing tables. Traffic engineering moves flows from congested links to alternate links that would not be selected by the automatically computed destination-based shortest path. With traffic engineering, you can:

- Make more efficient use of expensive long-haul fibers.
- Control how traffic is rerouted in the face of single or multiple failures.

- Classify critical and regular traffic on a per-path basis.

The core of the traffic engineering design is based on building label-switched paths (LSPs) among routers. An LSP is connection-oriented, like a virtual circuit in Frame Relay or ATM. LSPs are not reliable: Packets entering an LSP do not have delivery guarantees, although preferential treatment is possible. LSPs also are similar to unidirectional tunnels in that packets entering a path are encapsulated in an envelope and switched across the entire path without being touched by intermediate nodes. LSPs provide fine-grained control over how packets are forwarded in a network. To provide reliability, an LSP can use a set of primary and secondary paths.

LSPs can be configured for BGP traffic only (traffic whose destination is outside of an autonomous system [AS]). In this case, traffic within the AS is not affected by the presence of LSPs. LSPs can also be configured for both BGP and interior gateway protocol (IGP) traffic; therefore, both intra-AS and inter-AS traffic is affected by the LSPs.

This section discusses the following topics:

MPLS Traffic Engineering and Signaling Protocols Overview

Traffic engineering facilitates efficient and reliable network operations while simultaneously optimizing network resources and traffic performance. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) to a potentially less congested physical path across a network. To support traffic engineering, besides source routing, the network must do the following:

- Compute a path at the source by taking into account all the constraints, such as bandwidth and administrative requirements.
- Distribute the information about network topology and link attributes throughout the network once the path is computed.
- Reserve network resources and modify link attributes.

When transit traffic is routed through an IP network, MPLS is often used to engineer its passage. Although the exact path through the transit network is of little importance to either the sender or the receiver of the traffic, network administrators often want to route traffic more efficiently between certain source and destination address pairs. By adding a short label with specific routing instructions to each packet, MPLS switches packets from router to router through the network rather than forwarding packets based on next-hop lookups. The resulting routes are called *label-switched paths (LSPs)*. LSPs control the passage of traffic through the network and speed traffic forwarding.

You can create LSPs manually, or through the use of signaling protocols. Signaling protocols are used within an MPLS environment to establish LSPs for traffic across a transit network. Junos OS supports two signaling protocols—LDP and the Resource Reservation Protocol (RSVP).

MPLS traffic engineering uses the following components:

- MPLS LSPs for packet forwarding
- IGP extensions for distributing information about the network topology and link attributes
- Constrained Shortest Path First (CSPF) for path computation and path selection
- RSVP extensions to establish the forwarding state along the path and to reserve resources along the path

Junos OS also supports traffic engineering across different OSPF regions.

Traffic Engineering Capabilities

The task of mapping traffic flows onto an existing physical topology is called *traffic engineering*. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide more efficient use of available aggregate bandwidth and long-haul fiber by ensuring that subsets of the network do not become overutilized while other subsets of the network along potential alternate paths are underutilized.

- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservices Internet.

Components of Traffic Engineering

In the Junos® operating system (OS), traffic engineering is implemented with MPLS and RSVP. Traffic engineering is composed of four functional components:

- Packet Forwarding Component on page 646
- Information Distribution Component on page 647
- Path Selection Component on page 648
- Signaling Component on page 649

Configuring Traffic Engineering for LSPs

When you configure an LSP, a host route (a 32-bit mask) is installed in the ingress router toward the egress router; the address of the host route is the destination address of the LSP. The **bgp** option for the **traffic engineering** statement at the **[edit protocols mpls]** hierarchy level is enabled by default (you can also explicitly configure the **bgp** option), allowing only BGP to use LSPs in its route calculations. The other **traffic-engineering** statement options allow you to alter this behavior in the master routing instance. This functionality is not available for specific routing instances. Also, you can enable only one of the **traffic-engineering** statement options (**bgp**, **bgp-igp**, **bgp-igp-both-ribs**, or **mpls-forwarding**) at a time.

NOTE: **Enabling or disabling any of the traffic-engineering statement options causes all the MPLS routes to be removed and then reinserted into the routing tables.**

You can configure OSPF and traffic engineering to advertise the LSP metric in summary link-state advertisements (LSAs) as described in the section "Advertising the LSP Metric in Summary LSAs" on page 642.

The following sections describe how to configure traffic engineering for LSPs:

- Using LSPs for Both BGP and IGP Traffic Forwarding on page 641
- Using LSPs for Forwarding in Virtual Private Networks on page 641
- Using RSVP and LDP Routes for Forwarding but Not Route Selection on page 641
- Advertising the LSP Metric in Summary LSAs on page 642

Using LSPs for Both BGP and IGP Traffic Forwarding

You can configure BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers by including the **bgp-igp** option for the **traffic-engineering** statement. The **bgp-igp** option causes all inet.3 routes to be moved to the inet.0 routing table.

On the ingress router, include **bgp-igp** option for the **traffic-engineering** statement:

```
traffic-engineering bgp-igp;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

NOTE: The bgp-igp option for the traffic-engineering statement cannot be configured for VPN). VPNs require that routes be in the inet.3 routing table.

Using LSPs for Forwarding in Virtual Private Networks

VPNs require that routes remain in the inet.3 routing table to function properly. For VPNs, configure the **bgp-igp-both-ribs** option of the **traffic-engineering** statement to cause BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers. The **bgp-igp-both-ribs** option installs the ingress routes in both the inet.0 routing table (for IPv4 unicast routes) and the inet.3 routing table (for MPLS path information).

On the ingress router, include the **traffic-engineering bgp-igp-both-ribs** statement:

```
traffic-engineering bgp-igp-both-ribs;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

When you use the **bgp-igp-both-ribs** statement, the routes from the inet.3 table get copied into the inet.0 table. The copied routes are LDP-signaled or RSVP-signaled, and are likely to have a lower preference than other routes in inet.0. Routes with a lower preference are more likely to be chosen as the active routes. This can be a problem because routing policies only act upon active routes. To prevent this problem, use the **mpls-forwarding** option instead.

Using RSVP and LDP Routes for Forwarding but Not Route Selection

If you configure the **bgp-igp** or **bgp-igp-both-ribs** options for the **traffic-engineering** statement, high-priority LSPs can supersede IGP routes in the inet.0 routing table. IGP routes might no longer be redistributed since they are no longer the active routes.

If you configure the **mpls-forwarding** option for the **traffic-engineering** statement, LSPs are used for forwarding but are excluded from route selection. These routes are added to both the inet.0 and inet.3 routing tables. LSPs in the inet.0 routing table are given a low preference when the active route is selected. However, LSPs in the inet.3 routing table are given a normal preference and are therefore used for selecting forwarding next hops.

When you activate the **mpls-forwarding** option, routes whose state is **ForwardingOnly** are preferred for forwarding even if their preference is lower than that of the currently active route. To examine the state of a route, execute a **show route detail** command.

To use LSPs for forwarding but exclude them from route selection, include the **mpls-forwarding** option for the **traffic-engineering** statement:

```
traffic-engineering mpls-forwarding;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

When you configure the **mpls-forwarding** option, IGP shortcut routes are copied to the inet.0 routing table only.

Unlike the **bgp-igp-both-ribs** option, the **mpls-forwarding** option allows you to use the LDP-signaled and RSVP-signaled routes for forwarding, and keep the BGP and IGP routes active for routing purposes so that routing policies can act upon them.

For example, suppose a router is running BGP and it has a BGP route of 10.10.10.1/32 that it needs to send to another BGP speaker. If you use the **bgp-igp-both-ribs** option, and your router also has a label-switched-path (LSP) to 10.10.10.1, the MPLS route for 10.10.10.1 becomes active in the inet.0 routing table. This prevents your router from advertising the 10.10.10.1 route to the other BGP router. On the other hand, if you use the **mpls-forwarding** option instead of the **bgp-igp-both-ribs** option, the 10.10.10.1/32 BGP route is advertised to the other BGP speaker, and the LSP is still used to forward traffic to the 10.10.10.1 destination.

Advertising the LSP Metric in Summary LSAs

You can configure MPLS and OSPF to treat an LSP as a link. This configuration allows other routers in the network to use this LSP. To accomplish this goal, you need to configure MPLS and OSPF traffic engineering to advertise the LSP metric in summary LSAs.

For MPLS, include the **traffic-engineering bgp-igp** and **label-switched-path** statements:

```
traffic-engineering bgp-igp;
label-switched-path lsp-name {
   to address;
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

For OSPF, include the **lsp-metric-into-summary** statement:

```
lsp-metric-into-summary;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols ospf traffic-engineering shortcuts]**
- **[edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts]**

For more information about OSPF traffic engineering, see the *Junos OS Routing Protocols Library*.

Enabling Interarea Traffic Engineering

The Junos OS can signal a contiguous traffic-engineered LSP across multiple OSPF areas. The LSP signaling must be done using either nesting or contiguous signaling, as described in RFC 4206, *Label-Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*. However, contiguous signaling support is limited to just basic signaling. Reoptimization is not supported with contiguous signaling.

The following describes some of the interarea traffic engineering features:

- Interarea traffic engineering can be enabled when the loose-hop area border routers (ABRs) are configured on the ingress router using CSPF for the Explicit Route Object (ERO) calculation within an OSPF area. ERO expansion is completed on the ABRs.
- Interarea traffic engineering can be enabled when CSPF is enabled, but without ABRs specified in the LSP configuration on the ingress router (ABRs can be automatically designated).
- Differentiated Services (DiffServ) traffic engineering is supported as long as the class type mappings are uniform across multiple areas.

To enable interarea traffic engineering, include the **expand-loose-hop** statement in the configuration for each LSP transit router:

```
expand-loose-hop;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Enabling Inter-AS Traffic Engineering for LSPs

Generally, traffic engineering is possible for LSPs that meet the following conditions:

- Both ends of the LSP are in the same OSPF area or at the same IS-IS level.
- The two ends of the LSP are in different OSPF areas within the same autonomous system (AS). LSPs that end in different IS-IS levels are not supported.
- The two ends of an explicit-path LSP are in different OSPF ASs and the autonomous system border routers (ASBRs) are configured statically as the loose hops supported on the explicit-path LSP. For more information, see "Configuring Explicit-Path LSPs" on page 522.

Without statically defined ASBRs on LSPs, traffic engineering is not possible between one routing domain, or AS, and another. However, when the ASs are under the control of single service provider, it is possible in some cases to have traffic engineered LSPs span the ASs and dynamically discover the OSPF ASBRs linking them (IS-IS is not supported with this feature).

Inter-AS traffic engineered LSPs are possible as long as certain network requirements are met, none of the limiting conditions apply, and OSPF passive mode is configured with EBGP. Details are provided in the following sections:

- Inter-AS Traffic Engineering Requirements on page 644
- Inter-AS Traffic Engineering Limitations on page 645
- Configuring OSPF Passive TE Mode on page 645

Inter-AS Traffic Engineering Requirements

The proper establishment and functioning of inter-AS traffic engineered LSPs depend on the following network requirements, all of which must be met:

- All ASs are under control of a single service provider.
- OSPF is used as the routing protocol within each AS, and EBGP is used as the routing protocol between the ASs.
- ASBR information is available inside each AS.
- EBGP routing information is distributed by OSPF, and an IBGP full mesh is in place within each AS.
- Transit LSPs are *not* configured on the inter-AS links, but *are* configured between entry and exit point ASBRs on each AS.
- The EBGP link between ASBRs in different ASs is a direct link and must be configured as a passive traffic engineering link under OSPF. The remote link address itself, not the loopback or any other link address, is used as the remote node identifier for this passive link. For more information about OSPF passive traffic engineering mode configuration, see "Configuring OSPF Passive TE Mode" on page 645.

In addition, the address used for the remote node of the OSPF passive traffic engineering link must be the same as the address used for the EBGP link. For more information about OSPF and BGP in general, see the *Junos OS Routing Protocols Library*.

Inter-AS Traffic Engineering Limitations

Only LSP hierarchical, or nested, signaling is supported for inter-AS traffic engineered LSPs. Only point-to-point LSPs are supported (there is no point-to-multipoint support).

In addition, the following limitations apply. Any one of these conditions is sufficient to render inter-AS traffic engineered LSPs impossible, even if the above requirements are met.

- The use of multihop BGP is not supported.
- The use of policers or topologies that prevent BGP routes from being known inside the AS is not supported.
- Multiple ASBRs on a LAN between EBGP peers are not supported. Only one ASBR on a LAN between EBGP peers is supported (others ASBRs can exist on the LAN, but cannot be advertised).
- Route reflectors or policies that hide ASBR information or prevent ASBR information from being distributed inside the ASs are not supported.
- Bidirectional LSPs are not supported (LSPs are unidirectional from the traffic engineering perspective).
- Topologies with both inter-AS and intra-AS paths to the same destination are not supported.

In addition, several features that are routine with all LSPs are not supported with inter-AS traffic engineering:

- Admin group link colors are not supported.
- Secondary standby is not supported.
- Reoptimization is not supported.
- Crankback on transit routers is not supported.
- Diverse path calculation is not supported.
- Graceful restart is not supported.

These lists of limitations or unsupported features with inter-AS traffic engineered LSPs are not exhaustive.

Configuring OSPF Passive TE Mode

Ordinarily, interior routing protocols such as OSPF are not run on links between ASs. However, for inter-AS traffic engineering to function properly, information about the inter-AS link, in particular, the address on the remote interface, must be made available inside the AS. This information is not normally included either in EBGP reachability messages or in OSPF routing advertisements.

To flood this link address information within the AS and make it available for traffic engineering calculations, you must configure OSPF passive mode for traffic engineering

on each inter-AS interface. You must also supply the remote address for OSPF to distribute and include in the traffic engineering database.

To configure OSPF passive mode for traffic engineering on an inter-AS interface, include the **passive** statement for the link at the **[edit protocols ospf area *area-id* interface *interface-name*]** hierarchy level:

```
passive {
   traffic-engineering {
      remote-node-id ip-address; /* IP address at far end of inter-AS link */
   }
}
```

OSPF must be properly configured on the router. The following example configures the inter-AS link **so-1/1/0** to distribute traffic engineering information with OSPF within the AS. The remote IP address is **192.168.207.2**.

```
[edit protocols ospf area 0.0.0.0]
interface so-1/1/0 {
   unit 0 {
      passive {
         traffic-engineering {
            remote-node-id 192.168.207.2;
         }
      }
   }
}
```

Packet Forwarding Component

The packet forwarding component of the Junos traffic engineering architecture is MPLS, which is responsible for directing a flow of IP packets along a predetermined path across a network. This path is called a *label-switched path (LSP)*. LSPs are simplex; that is, the traffic flows in one direction from the head-end (ingress) router to a tail-end (egress) router. Duplex traffic requires two LSPs: one LSP to carry traffic in each direction. An LSP is created by the concatenation of one or more label-switched hops, allowing a packet to be forwarded from one router to another across the MPLS domain.

When an ingress router receives an IP packet, it adds an MPLS header to the packet and forwards it to the next router in the LSP. The labeled packet is forwarded along the LSP by each router until it reaches the tail end of the LSP, the egress router. At this point the MPLS header is removed, and the packet is forwarded based on Layer 3 information such as the IP destination address. The value of this scheme is that the physical path of the LSP is not limited to what the IGP would choose as the shortest path to reach the destination IP address.

This section discusses the following topics:

- Packet Forwarding Based on Label Swapping on page 647
- How a Packet Traverses an MPLS Backbone on page 647

Related Documentation

- Components of Traffic Engineering on page 640

Packet Forwarding Based on Label Swapping

The packet forwarding process at each router is based on the concept of label swapping. This concept is similar to what occurs at each Asynchronous Transfer Mode (ATM) switch in a permanent virtual circuit (PVC). Each MPLS packet carries a 4-byte encapsulation header that contains a 20-bit, fixed-length label field. When a packet containing a label arrives at a router, the router examines the label and copies it as an index to its MPLS forwarding table. Each entry in the forwarding table contains an interface-inbound label pair mapped to a set of forwarding information that is applied to all packets arriving on the specific interface with the same inbound label.

How a Packet Traverses an MPLS Backbone

This section describes how an IP packet is processed as it traverses an MPLS backbone network.

At the entry edge of the MPLS backbone, the IP header is examined by the ingress router. Based on this analysis, the packet is classified, assigned a label, encapsulated in an MPLS header, and forwarded toward the next hop in the LSP. MPLS provides a high degree of flexibility in the way that an IP packet can be assigned to an LSP. For example, in the Junos traffic engineering implementation, all packets arriving at the ingress router that are destined to exit the MPLS domain at the same egress router are forwarded along the same LSP.

Once the packet begins to traverse the LSP, each router uses the label to make the forwarding decision. The MPLS forwarding decision is made independently of the original IP header: the incoming interface and label are used as lookup keys into the MPLS forwarding table. The old label is replaced with a new label, and the packet is forwarded to the next hop along the LSP. This process is repeated at each router in the LSP until the packet reaches the egress router.

When the packet arrives at the egress router, the label is removed and the packet exits the MPLS domain. The packet is then forwarded based on the destination IP address contained in the packet's original IP header according to the traditional shortest path calculated by the IP routing protocol.

Information Distribution Component

Traffic engineering requires detailed knowledge about the network topology as well as dynamic information about network loading. To implement the information distribution component, simple extensions to the IGPs are defined. Link attributes are included as part of each router's link-state advertisement. IS-IS extensions include the definition of new type length values (TLVs), whereas OSPF extensions are implemented with opaque link-state advertisements (LSAs). The standard flooding algorithm used by the link-state IGPs ensures that link attributes are distributed to all routers in the routing domain. Some of the traffic engineering extensions to be added to the IGP link-state advertisement

include maximum link bandwidth, maximum reserved link bandwidth, current bandwidth reservation, and link coloring.

Each router maintains network link attributes and topology information in a specialized traffic engineering database. The traffic engineering database is used exclusively for calculating explicit paths for the placement of LSPs across the physical topology. A separate database is maintained so that the subsequent traffic engineering computation is independent of the IGP and the IGP's link-state database. Meanwhile, the IGP continues its operation without modification, performing the traditional shortest-path calculation based on information contained in the router's link-state database.

Related Documentation

- Components of Traffic Engineering on page 640

Path Selection Component

After network link attributes and topology information are flooded by the IGP and placed in the traffic engineering database, each ingress router uses the traffic engineering database to calculate the paths for its own set of LSPs across the routing domain. The path for each LSP can be represented by either a strict or loose explicit route. An explicit route is a preconfigured sequence of routers that should be part of the physical path of the LSP. If the ingress router specifies all the routers in the LSP, the LSP is said to be identified by a strict explicit route. If the ingress router specifies only some of the routers in the LSP, the LSP is described as a loose explicit route. Support for strict and loose explicit routes allows the path selection process to be given broad latitude whenever possible, but to be constrained when necessary.

The ingress router determines the physical path for each LSP by applying a Constrained Shortest Path First (CSPF) algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. Input into the CSPF algorithm includes:

- Topology link-state information learned from the IGP and maintained in the traffic engineering database
- Attributes associated with the state of network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color) that are carried by IGP extensions and stored in the traffic engineering database
- Administrative attributes required to support traffic traversing the proposed LSP (such as bandwidth requirements, maximum hop count, and administrative policy requirements) that are obtained from user configuration

As CSPF considers each candidate node and link for a new LSP, it either accepts or rejects a specific path component based on resource availability or whether selecting the component violates user policy constraints. The output of the CSPF calculation is an explicit route consisting of a sequence of router addresses that provides the shortest path through the network that meets the constraints. This explicit route is then passed to the signaling component, which establishes the forwarding state in the routers along the LSP.

Related Documentation
- Components of Traffic Engineering on page 640

Offline Path Planning and Analysis

Despite the reduced management effort resulting from online path calculation, an offline planning and analysis tool is still required to optimize traffic engineering globally. Online calculation takes resource constraints into account and calculates one LSP at a time. The challenge with this approach is that it is not deterministic. The order in which LSPs are calculated plays a critical role in determining each LSP's physical path across the network. LSPs that are calculated early in the process have more resources available to them than LSPs calculated later in the process because previously calculated LSPs consume network resources. If the order in which the LSPs are calculated is changed, the resulting set of physical paths for the LSPs also can change.

An offline planning and analysis tool simultaneously examines each link's resource constraints and the requirements of each LSP. Although the offline approach can take several hours to complete, it performs global calculations, compares the results of each calculation, and then selects the best solution for the network as a whole. The output of the offline calculation is a set of LSPs that optimizes utilization of network resources. After the offline calculation is completed, the LSPs can be established in any order because each is installed according to the rules for the globally optimized solution.

Signaling Component

An LSP is not known to be workable until it is actually established by the signaling component. The signaling component, which is responsible for establishing LSP state and distributing labels, relies on a number of extensions to RSVP:

- The Explicit Route object allows an RSVP path message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The explicit route can be either strict or loose.
- The Label Request object permits the RSVP path message to request that intermediate routers provide a label binding for the LSP that it is establishing.
- The Label object allows RSVP to support the distribution of labels without changing its existing mechanisms. Because the RSVP Resv message follows the reverse path of the RSVP path message, the Label object supports the distribution of labels from downstream nodes to upstream nodes.

Flexible LSP Calculation and Configuration

Traffic engineering involves mapping traffic flow onto a physical topology. You can determine the paths online using constraint-based routing. Regardless of how the physical path is calculated, the forwarding state is installed across the network through RSVP.

The Junos OS supports the following ways to route and configure an LSP:

- You can calculate the full path for the LSP offline and individually configure each router in the LSP with the necessary static forwarding state. This is analogous to the way some Internet service providers (ISPs) configure their IP-over-ATM cores.
- You can calculate the full path for the LSP offline and statically configure the ingress router with the full path. The ingress router then uses RSVP as a dynamic signaling protocol to install a forwarding state in each router along the LSP.
- You can rely on constraint-based routing to perform dynamic online LSP calculation. You configure the constraints for each LSP; then the network itself determines the path that best meets those constraints. Specifically, the ingress router calculates the entire LSP based on the constraints and then initiates signaling across the network.
- You can calculate a partial path for an LSP offline and statically configure the ingress router with a subset of the routers in the path; then you can permit online calculation to determine the complete path.

  For example, consider a topology that includes two east-west paths across the United States: one in the north through Chicago and one in the south through Dallas. If you want to establish an LSP between a router in New York and one in San Francisco, you can configure the partial path for the LSP to include a single loose-routed hop of a router in Dallas. The result is an LSP routed along the southern path. The ingress router uses CSPF to compute the complete path and RSVP to install the forwarding state along the LSP.
- You can configure the ingress router with no constraints whatsoever. In this case, normal IGP shortest-path routing is used to determine the path of the LSP. This configuration does not provide any value in terms of traffic engineering. However, it is easy and might be useful in situations when services such as virtual private networks (VPNs) are needed.

In all these cases, you can specify any number of LSPs as backups for the primary LSP, thus allowing you to combine more than one configuration approach. For example, you might explicitly compute the primary path offline, set the secondary path to be constraint-based, and have the tertiary path be unconstrained. If a circuit on which the primary LSP is routed fails, the ingress router notices the outage from error notifications received from a downstream router or by the expiration of RSVP soft-state information. Then the router dynamically forwards traffic to a hot-standby LSP or calls on RSVP to create a forwarding state for a new backup LSP.

Link-State Distribution Using BGP Overview

- Supported and Unsupported Features on page 658
- BGP Link-State Extensions for Source Packet Routing in Networking (SPRING) on page 658

Role of an Interior Gateway Protocol

An interior gateway protocol (IGP) is a type of protocol used for exchanging routing information between devices within an autonomous system (AS). Based on the method of computing the best path to a destination, the IGPs are divided into two categories:

- Link-state protocols—Advertise information about the network topology (directly connected links and the state of those links) to all routers using multicast addresses and triggered routing updates until all the routers running the link-state protocol have identical information about the internetwork. The best path to a destination is calculated based on constraints such as maximum delay, minimum available bandwidth, and resource class affinity.

  OSPF and IS-IS are examples of link-state protocols.

- Distance vector protocols—Advertise complete routing table information to directly connected neighbors using a broadcast address. The best path is calculated based on the number of hops to the destination network.

  RIP is an example of a distance vector protocol.

As the name implies, the role of an IGP is to provide routing connectivity within or internal to a given routing domain. A routing domain is a set of routers under common administrative control that share a common routing protocol. An AS can consist of multiple routing domains, where IGP functions to advertise and learn network prefixes (routes) from neighboring routers to build a route table that ultimately contains entries for all sources advertising reachability for a given prefix. IGP executes a route selection algorithm to select the best path between the local router and each destination, and provides full connectivity among the routers making up a routing domain.

In addition to advertising internal network reachability, IGPs are often used to advertise routing information that is external to that IGP's routing domain through a process known as route redistribution. Route redistribution is the process of exchanging routing information among distinct routing protocols to tie multiple routing domains together when intra-AS connectivity is desired.

Limitations of an Interior Gateway Protocol

While each individual IGP has its own advantages and limitations, the biggest limitations of IGP in general are performance and scalability.

IGPs are designed to handle the task of acquiring and distributing network topology information for traffic engineering purposes. While this model has served well, IGPs have inherent scaling limitations when it comes to distributing large databases. IGPs can autodetect neighbors, with which they acquire intra-area network topology information. However, the link-state database or a traffic engineering database has the scope of a single area or AS, thereby limiting applications, such as end-to-end traffic engineering, the benefit of having external visibility to make better decisions.

For label-switched networks, such as MPLS and Generalized MPLS (GMPLS), most existing traffic engineering solutions work in a single routing domain. These solutions do not work when a route from the ingress node to the egress node leaves the routing area or AS of the ingress node. In such cases, the path computation problem becomes complicated because of the unavailability of the complete routing information throughout the network. This is because service providers usually choose not to leak routing information beyond the routing area or AS for scalability constraints and confidentiality concerns.

Need for Spanning Link-State Distribution

One of the limitations of IGP is its inability to span link-state distribution outside a single area or AS. However, spanning link-state information acquired by an IGP across multiple areas or ASs has the following needs:

- LSP path computation—This information is used to compute the path for MPLS LSPs across multiple routing domains, for example an inter-area TE LSP.
- External path computing entities—External path computing entities, such as Application Layer Traffic Optimization (ALTO) and Path Computation Elements (PCE), perform path computations based on the network topology and current state of connections within the network, including traffic engineering information. This information is typically distributed by IGPs within the network.

  However, because the external path computing entities cannot extract this information from the IGPs, they perform network monitoring to optimize network services.

Using BGP as a Solution

Overview

To meet the needs for spanning link-state distribution across multiple domains, an exterior gateway protocol (EGP) is required to collect link-state and traffic engineering information from an IGP area, share it with external component, and use it for computing paths for interdomain MPLS LSPs.

BGP is a standardized EGP designed to exchange routing and reachability information between autonomous systems (ASs). BGP is a proven protocol that has better scaling properties because it can distribute millions of entries (for example, VPN prefixes) in a scalable fashion. BGP is the only routing protocol in use today that is suited to carry all of the routes in the Internet. This is largely because BGP runs on top of TCP and can make use of TCP flow control. In contrast, the internal gateway protocols (IGPs) do not have flow control. When IGPs have too much route information, they begin to churn. When BGP has a neighboring speaker that is sending information too quickly, BGP can throttle down the neighbor by delaying TCP acknowledgments.

Another benefit of BGP is that it uses type, length, value (TLV) tuples and network layer reachability information (NLRI) that provide seemingly endless extensibility without the need for the underlying protocol to be altered.

The distribution of link-state information across domains is regulated using policies to protect the interests of the service provider. This requires a control over the topology distribution using policies. BGP with its implemented policy framework serves well in the interdomain route distribution. In Junos OS, BGP is completely policy driven. The operator must explicitly configure neighbors to peer with and explicitly accept routes into BGP. Furthermore, routing policy is used to filter and modify routing information. Thus, routing policies provide complete administrative control over the routing tables.

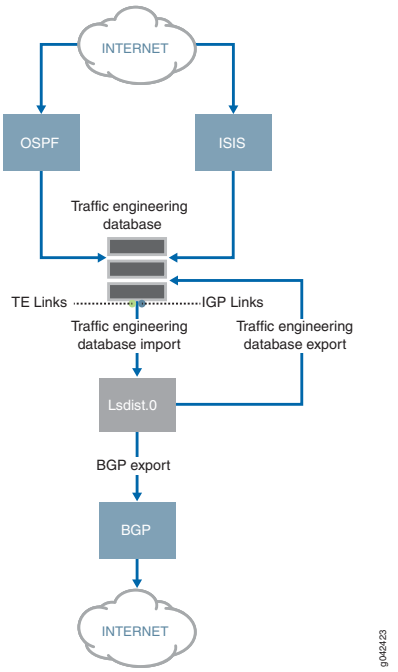
Although, within an AS, both IGP-TE and BGP-TE provide the same set of information, BGP-TE has better scaling characteristics that are inherited from the standard BGP protocol. This makes BGP-TE a more scalable choice for acquiring multi-area/multi-AS topology information.

By using BGP as a solution, the IGP-acquired information is used for distribution into BGP. The ISPs can selectively expose this information with other ISPs, service providers, and content distribution networks (CDNs) through normal BGP peering. This allows for aggregation of the IGP-acquired information across multiple areas and ASs, such that an external path computing entity can access the information by passively listening to a route reflector.

Implementation

In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. To install IGP topology information into traffic engineering database, use the **set igp-topology** configuration statement at the **[edit protocols isis traffic-engineering]** and **[edit protocols ospf traffic-engineering]** hierarchy levels. The mechanism to distribute link-state information using BGP includes the process of advertising the traffic engineering database into BGP-TE (import), and installing entries from BGP-TE into the traffic engineering database (export).

Figure 58: Junos OS Implementation of BGP Link-State Distribution



Traffic Engineering Database Import

To advertise the traffic engineering database into BGP-TE, the link and node entries in the traffic engineering database are converted in the form of routes. These converted routes are then installed by the traffic engineering database on behalf of the corresponding IGP, into a user-visible routing table called **lsdist.0**, on conditions subject to route policies. The procedure of leaking entries from the traffic engineering database into **lsdist.0** is called traffic engineering database import as illustrated in Figure 58 on page 654.

There are polices to govern the traffic engineering database import process. By default, no entries are leaked from the traffic engineering database into the **lsdist.0** table.

Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table as illustrated in Figure 58 on page 654. Prior to Junos OS Release 17.4R1, the traffic engineering database only exported RSVP-TE topology information. Now you can monitor both IGP and traffic engineering topology information. The BGP-LS reads IGP entries from lsdist.0 and advertises these entries to the BGP peers. To import IGP topology information into BGP-LS from lsdist.0, use the **set bgp-ls** configuration

statement at the **[edit protocols mpls traffic-engineering database import igp-topology]** hierarchy level.

Traffic Engineering Database Export

BGP can be configured to export or advertise routes from the **lsdist.0** table, subject to policy. This is common for any kind of route origination in BGP. In order to advertise BGP-TE into the traffic engineering database, BGP needs to be configured with the BGP-TE address family, and an export policy that selects routes for redistribution into BGP.

BGP then propagates these routes like any other NLRI. BGP peers that have the BGP-TE family configured and negotiated receive BGP-TE NLRIs. BGP stores the received BGP-TE NLRIs in the form of routes in the **lsdist.0** table, which is the same table that stores locally originated BGP-TE routes. The BGP-installed routes in **lsdist.0** are then distributed to other peers like any other route. Thus, the standard route selection procedure applies to BGP-TE NLRIs received from multiple speakers.

To achieve interdomain TE, the routes in **lsdist.0** are leaked into the traffic engineering database through a policy. This process is called traffic engineering database export as illustrated in Figure 58 on page 654.

There are polices to govern the traffic engineering database export process. By default, no entries are leaked from the **lsdist.0** table into the traffic engineering database.

NOTE: For SDN applications, such as PCE and ALTO, the BGP-TE advertised information cannot leak into the traffic engineering database of a router. In such cases, an external server that peers with the routers using BGP-TE is used to move topology information up into the sky/orchestration system that spans the network. These external servers can be deemed as BGP-TE consumers, where they receive BGP-TE routes, but do not advertise them.

Assigning Credibility Values

Once the entries are installed in the traffic engineering database, the BGP-TE learned information is made available for CSPF path computation. The traffic engineering database uses a protocol preference scheme that is based on credibility values. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value. BGP-TE has the capability to advertise information learned from multiple protocols at the same time, and so in addition to the IGP-installed entries in the traffic engineering database, there can be BGP-TE installed entries that correspond to more than one protocol. The traffic engineering database export component creates a traffic engineering database protocol and credibility level for each protocol that BGP-TE supports. These credibility values are configurable in the CLI.

The credibility order for the BGP-TE protocols is as follows:

- Unknown—80
- OSPF—81

- ISIS Level 1—82
- ISIS Level 2—83
- Static—84
- Direct—85

Cross-Credibility Path Computation

After you assign credibility values, each credibility level is treated as an individual plane. The Constrained Shorted Path First algorithm starts with the highest assigned credibility to the lowest, finding a path within that credibility level.

With BGP-TE, it is essential to compute paths across credibility levels to compute inter-AS paths. For example, different credibility settings are seen on a device from area 0 that computes the path through area 1, because area 0 entries are installed by OSPF, and area 1 entries are installed by BGP-TE.

To enable path computation across credibility levels, include the **cross-credibility-cspf** statement at the **edit protocols mpls**, **[edit protocols mpls label-switched-path *lsp-name*]**, and **[edit protocols rsvp]** hierarchy levels. At the **[edit protocols rsvp]** hierarchy level, enabling **cross-credibility-cspf** impacts bypass LSPs and loose hop expansion in transit.

Configuring **cross-credibility-cspf** enables path computation across credibility levels using the Constrained Shortest Path First algorithm, wherein the constraint is not performed on a credibility-by-credibility basis, but as a single constraint ignoring the assigned credibility values.

BGP-TE NLRIs and TLVs

Like other BGP routes, BGP-TE NLRIs can also be distributed through a route reflector that speaks BGP-TE NLRI. Junos OS implements the route reflection support for the BGP-TE family.

The following is a list of supported NLRIs:

- Link NLRI
- Node NLRI
- IPv4 Prefix NLRI (receive and propagate)
- IPv6 Prefix NLRI (receive and propagate)

NOTE: Junos OS does not provide support for the route-distinguisher form of the above NRLIs.

The following is a list of supported fields in link and node NLRIs:

- Protocol-ID—NLRI originates with the following protocol values:
  - ISIS-L1
  - ISIS-L2

    - OSPF
- Identifier—This value is configurable. By default, the identifier value is set to **0**.
- Local/Remote node descriptor—These include:
    - Autonomous system
    - BGP-LS Identifier—This value is configurable. By default, the BGP-LS identifier value is set to **0**
    - Area-ID
    - IGP router-ID
- Link descriptors (Only for link NLRI)—This includes:
    - Link Local/Remote Identifiers
    - IPv4 interface address
    - IPv4 neighbor address
    - IPv6 neighbor/interface address—The IPv6 neighbor and interface addresses are not originated, but only stored and propagated when received.
    - Multi-topology ID—This value is not originated, but stored and propagated when received.

The following is a list of supported LINK_STATE attribute TLVs:

- Link attributes:
    - Administrative group
    - Max link bandwidth
    - Max reservable bandwidth
    - Unreserved bandwidth
    - TE default metric
    - SRLG
    - The following TLVs, which are not originated, but only stored and propagated when received:
        - Opaque link attributes
        - MPLS protocol mask
        - Metric
        - Link protection type
        - Link name attribute
- Node attributes:

- IPv4 Router-ID
- Node flag bits—Only the overload bit is set.
- The following TLVs, which are not originated, but only stored and propagated when received:
  - Multi-topology
  - OSPF-specific node properties
  - Opaque node properties
  - Node name
  - IS-IS area identifier
  - IPv6 Router-ID
- Prefix attributes—These TLVs are stored and propagated like any other unknown TLVs.

Supported and Unsupported Features

Junos OS supports the following features with link-state distribution using BGP:

- Advertisement of multiprotocol assured forwarding capability
- Transmission and reception of node and link-state BGP and BGP-TE NLRIs
- Nonstop active routing for BGP-TE NLRIs
- Policies

Junos OS does **not** support the following functionality for link-state distribution using BGP:

- Aggregated topologies, links, or nodes
- Route distinguisher support for BGP-TE NLRIs
- Multi-topology identifiers
- Multi-instance identifiers (excluding the default instance ID 0)
- Advertisement of the link and node area TLV
- Advertisement of MPLS signaling protocols
- Importing node and link information with overlapping address

BGP Link-State Extensions for Source Packet Routing in Networking (SPRING)

- Source Packet Routing in Networking (SPRING) on page 659
- Flow of BGP Link-State SPRING Data on page 659
- Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING on page 661

Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers. BGP typically learns the link-state information from IGP and distributes it to BGP peers. Besides BGP, the SDN controller can get link-state information directly from IGP if the controller is a part of an IGP domain. However, BGP link-state distribution provides a scalable mechanism to export the topology information. BGP link-state extensions for SPRING is supported on interdomain networks.

Source Packet Routing in Networking (SPRING)

SPRING is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to decide the actual path it must take. SPRING engages IGPs, such as IS-IS and OSPF, for advertising network segments. Network segments can represent any instruction, topological or service-based. Within IGP topologies, IGP segments are advertised by the link-state routing protocols. There are two types of IGP segments:

Adjacency segment—A one-hop path over a specific adjacency between two nodes in the IGP

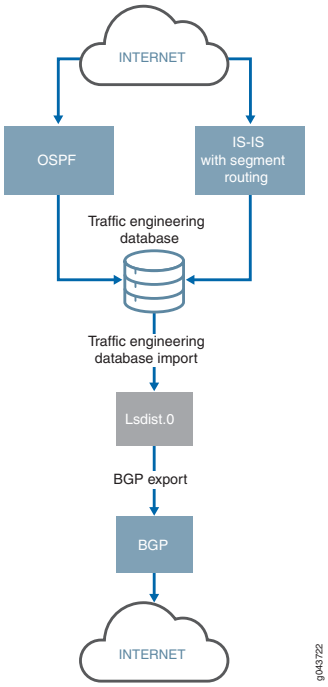
Prefix segment—A multi-hop, equal-cost, multipath-aware shortest-path to a prefix, as per the state of the IGP topology

When SPRING in enabled in a BGP network, BGP link-state address family learns the SPRING information from the IGP link-state routing protocols and advertises segments in the form of segment identifiers (SIDs). BGP link-state address family has been extended to carry SIDs and other SPRING-related information to BGP peers. The route reflector can steer a packet through a desired set of nodes and links by prepending the packet with an appropriate combination of tunnels. This feature allows BGP link-state address family to also advertise the SPRING information to BGP peers.

Flow of BGP Link-State SPRING Data

Figure 59 on page 660 depicts the data flow of BGP link-state SPRING data that IS-IS pushes to the traffic engineering database.

Figure 59: BGP Link-State Source Packet Routing in Networking (SPRING)



- IGP pushes the SPRING attributes to the traffic engineering database.
- SPRING capabilities and algorithm information are carried forward as node attributes into the traffic engineering database.
- Adjacent SID and LAN adjacent SID information are carried as link attributes.
- Prefix SID or node-SID information is carried as prefix attributes.
- A new set or a change to existing attributes triggers IGP updates to the traffic engineering database with new data.
- RSVP is a prerequisite for link attributes.

CAUTION: **If traffic engineering is disabled at the IGP level, none of the attributes are pushed to the traffic engineering database.**

- All parameters in the BGP traffic engineering NLRI, including the link, node, and prefix descriptors are derived from entries in the traffic engineering database.
- The traffic engineering database imports route entries into the **lsdist.0** routing table from IGP subject to policy.
- The default policy of BGP is to export routes, which are known to BGP only. You configure an export policy for non-BGP routes in the **lsdis.0** routing table. This policy advertises an entry learned from the traffic engineering database.

NOTE: Currently, OSPF does not push SPRING information to the BGP link-state address family. IS-IS is the only IGP that pushes SPRING information to the BGP link-state address family.

Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING

BGP link-state with SPRING supports the following attributes and type, length, and values (TLVs) that are originated, received, and propagated in the network:

Node attributes

- Segment routing Capabilities
- Segment routing Algorithm

Link attributes

- Adjacent-SID
- LAN Adjacent-SID

Prefix descriptors

- IP reachability information

Prefix attributes

- Prefix SID

The following list supports TLVs that are not originated, but only received and propagated in the network:

Prefix descriptors

- Multitopology ID
- OSPF route type

Prefix attributes

- Range
- Binding SID

Junos OS does not support the following features with BGP link-state with SPRING extensions:

- IPv6 prefix origination
- Multitopology identifiers
- Traffic engineering database export for SPRING parameters

- New TLVs with tcpdump (existing TLVs are also not supported).
- SPRING over IPv6

Release History Table

Release	Description
17.4R1	Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table
17.2R1	Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers.

Example: Configuring Link State Distribution Using BGP

This example shows how to configure BGP to carry link-state information across multiple domains, which is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Requirements

This example uses the following hardware and software components:

- Four routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - BGP

- IS-IS
- OSPF

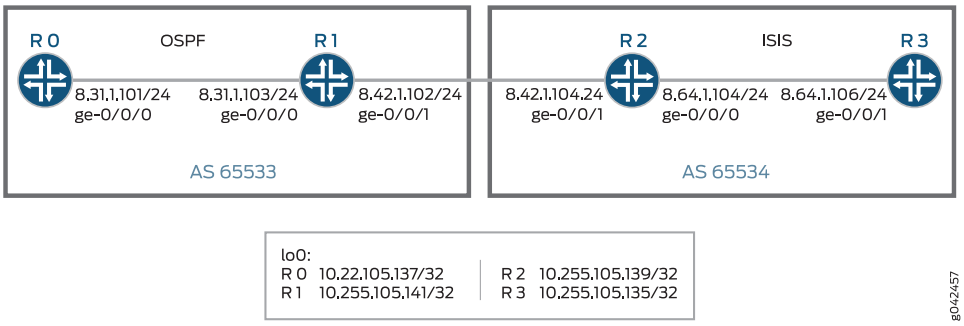
Overview

Starting with Junos OS Release 14.2, a new mechanism to distribute topology information across multiple areas and autonomous systems (ASs) is introduced by extending the BGP protocol to carry link -state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS label-switched paths (LSPs) spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

Topology

Figure 60: Link-State Distribution Using BGP



In Figure 60 on page 663, Routers R0 and R1 and Routers R2 and R3 belong to different autonomous systems. Routers R0 and R1 run OSPF, and Routers R2 and R3 run IS-IS.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R1:

1. Configure the Router R1 interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 8.31.1.103/24
user@R1# set ge-0/0/0 unit 0 family iso
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set ge-0/0/1 unit 0 family inet address 8.42.1.102/24
user@R1# set ge-0/0/1 unit 0 family iso
user@R1# set ge-0/0/1 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.255.105.141/32
```

2. Configure the router ID and autonomous system of Router R1.

```
[edit routing-options]
user@R1# set router-id 10.255.105.141
user@R1# set autonomous-system 65533
```

3. Enable RSVP on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
```

5. Configure the BGP group for Router R1 to peer with Router R0, and assign the local address and neighbor address.

```
[edit protocols]
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp neighbor 10.255.105.137
```

6. Include the BGP-TE signaling network layer reachability information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@R1# set bgp group ibgp family traffic-engineering unicast
```

7. Enable export of policy nlri2bgp on Router R1.

```
[edit protocols]
user@R1# set bgp group ibgp export nlri2bgp
```

8. Configure the BGP group for Router R1 to peer with Router R2, and assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
```

9. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp family traffic-engineering unicast
```

10. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
```

11. Enable OSPF on the interface connecting Router R1 to Router R0 and on the loopback interface of Router R1, and enable traffic engineering capabilities.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
```

12. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
  remote-node-id 8.42.1.104
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
  remote-node-router-id 10.255.105.139
```

13. Configure policies to accept traffic from BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then accept
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
ge-0/0/0 {

  }
}
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R2:

1. Configure the Router R2 interfaces.

```
[edit interfaces]
user@R2# set ge-0/0/0 unit 0 family inet address 8.64.1.104/24
user@R2# set ge-0/0/0 unit 0 family iso
user@R2# set ge-0/0/0 unit 0 family mpls
user@R2# set ge-0/0/1 unit 0 family inet address 8.42.1.104/24
user@R2# set ge-0/0/1 unit 0 family iso
user@R2# set ge-0/0/1 unit 0 family mpls
user@R2# set lo0 unit 0 family inet address 10.255.105.139/32
user@R2# set lo0 unit 0 family iso
```

2. Configure the router ID and autonomous system of Router R2.

```
[edit routing-options]
user@R2# set router-id 10.255.105.139
user@R2# set autonomous-system 65534
```

3. Enable RSVP on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set rsvp interface all
user@R2# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set mpls interface all
user@R2# set mpls interface fxp0.0 disable
```

5. Enable import of traffic engineering database parameters using the ted2nlri policy.

```
[edit protocols]
user@R2# set mpls traffic-engineering database import policy ted2nlri
```

6. Configure the BGP group for Router R2 to peer with Router R1.

```
[edit protocols]
user@R2# set bgp group ebgp type external
```

7. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp family traffic-engineering unicast
```

8. Assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp peer-as 65533
user@R2# set bgp group ebgp neighbor 8.42.1.102
```

9. Enable export of policy nlri2bgp on Router R2.

```
[edit protocols]
user@R2# set bgp group ebgp export nlri2bgp
```

10. Enable IS-IS on the interface connecting Router R2 with Router R3 and the loopback interface of Router R2.

```
[edit protocols]
user@R2# set isis level 1 disable
user@R2# set isis interface ge-0/0/0.0
user@R2# set isis interface lo0.0
```

11. Enable only IS-IS advertising on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5501.8181
user@R2# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.102
```

12. Configure traffic engineering capability on Router R2.

```
[edit protocols]
user@R2# set ospf traffic-engineering
```

13. Enable only OSPF advertisements on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
  remote-node-id 8.42.1.102
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
  remote-node-router-id 10.255.105.141
```

14. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
ge-0/0/0 {
   unit 0 {
      family inet {
         address 8.64.1.104/24;
      }
      family iso;
      family mpls;
   }
}
ge-0/0/1 {
   unit 0 {
      family inet {
         address 8.42.1.104/24;
      }
      family iso;
      family mpls;
   }
}
lo0 {
```

```
    unit 0 {
      family inet {
        address 10.255.105.139/32;
      }
      family iso;
    }
}
```

```
user@R2# show routing-options
router-id 10.255.105.139;
autonomous-system 65534;
```

```
user@R2# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    traffic-engineering {
        database {
            import {
                policy ted2nlri;
            }
        }
    }
    interface all;
    interface fxp0.0 {
        disable;
    }
}
bgp {
    group ebgp {
        type external;
        family traffic-engineering {
            unicast;
        }
        export nlri2bgp;
        peer-as 65533;
        neighbor 8.42.1.102;
    }
}
isis {
    level 1 disable;
    interface ge-0/0/0.0;
    interface ge-0/0/1.0 {
        passive {
            remote-node-iso 0102.5501.8181;
            remote-node-id 8.42.1.102;
        }
    }
    interface lo0.0;
}
```

```
ospf {
   traffic-engineering;
   area 0.0.0.0 {
      interface ge-0/0/1.0 {
         passive {
            traffic-engineering {
               remote-node-id 8.42.1.102;
               remote-node-router-id 10.255.105.141;
            }
         }
      }
   }
}
```

```
user@R2# show policy-options
policy-statement accept-all {
   from family traffic-engineering;
   then accept;
}
policy-statement nlri2bgp {
   term 1 {
      from family traffic-engineering;
      then {
         accept;
      }
   }
}
policy-statement ted2nlri {
   term 1 {
      from protocol [ isis ospf ];
      then accept;
   }
   term 2 {
      then reject;
   }
}
```

Verification

Verify that the configuration is working properly.

- Verifying the BGP Summary Status on page 674
- Verifying the MPLS LSP Status on page 675
- Verifying the lsdist.0 Routing Table Entries on page 676
- Verifying the Traffic Engineering Database Entries on page 679

Verifying the BGP Summary Status

Purpose Verify that BGP is up and running on Routers R0 and R1.

Action From operational mode, run the **show bgp summary** command.

```
user@R0> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
lsdist.0
                      10         10          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
10.255.105.141        65533         20         14       0      79        5:18
Establ
  lsdist.0: 10/10/10/0
```

From operational mode, run the **show bgp summary** command.

```
user@R1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
lsdist.0
                      10         10          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
8.42.1.104            65534         24         17       0      70        6:43
Establ
  lsdist.0: 10/10/10/0
10.255.105.137        65533         15         23       0      79        6:19
Establ
  lsdist.0: 0/0/0/0
```

Meaning Router R0 is peered with Router R1.

Verifying the MPLS LSP Status

Purpose Verify the status of the MPLS LSP on Router R0.

Action From operational mode, run the **show mpls lsp** command.

```
user@R0> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
10.255.105.135  10.255.105.137  Up     0 *                      to-R3-inter-as
Total 1 displayed, Up 1, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The MPLS LSP from Router R0 to Router R3 is established.

Verifying the lsdist.0 Routing Table Entries

Purpose Verify the lsdist.0 routing table entries on Routers R0, R1, and R2.

Action From operational mode, run the **show route table lsdist.0** command.

```
user@R0> show route table lsdist.0
lsdist.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Release History Table

Release	Description
17.1R1	Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

Related Documentation

- Link-State Distribution Using BGP Overview on page 650

Configuring Link State Distribution Using BGP

You can enable distribution of topology information across multiple areas and autonomous systems (ASs) by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
   - RSVP
   - MPLS
   - IS-IS
   - OSPF

To enable link-state distribution using BGP:

1. Configure an internal BGP group, and assign the local address and neighbor address for the group.

   ```
   [edit protocols]
   user@R1# set bgp group internal-group-name type internal
   user@R1# set bgp group internal-group-name local-address ip-address
   user@R1# set bgp group internal-group-name neighbor ip-address
   ```

2. Include the BGP-TE signaling network layer reachability information (NLRI) to the internal BGP group.

   ```
   [edit protocols]
   user@R1# set bgp group internal-group-name family traffic-engineering unicast
   ```

3. Enable export of policy on the device.

   ```
   [edit protocols]
   user@R1# set bgp group internal-group-name export second-policy-name
   ```

4. Configure an external BGP group, and assign the local address and neighbor autonomous system to the group.

```
[edit protocols]
user@R1# set bgp group external-group-name type external
user@R1# set bgp group external-group-name neighbor ip-address local-address
  ip-address
user@R1# set bgp group external-group-name neighbor ip-address peer-as as-number
```

5. Include the BGP-TE signaling NLRI to the external BGP group.

```
[edit protocols]
user@R1# set bgp group external-group-name family traffic-engineering unicast
```

6. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit policy-options
```

7. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement policy-name from family traffic-engineering
user@R1# set policy-statement policy-name then accept
user@R1# set policy-statement bgp-import-policy term 1 from family traffic-engineering
user@R1# set policy-statement bgp-import-policy term 1 then next-hop self
user@R1# set policy-statement bgp-import-policy term 1 then accept
```

8. On the remote connecting device, configure policy to accept the OSPF and IS-IS traffic.

```
[edit policy-options]
user@R2# set policy-statement bgp-export-policy term 1 from protocol isis
user@R2# set policy-statement bgp-export-policy term 1 from protocol ospf
user@R2# set policy-statement bgp-export-policy term 1 then accept
user@R2# set policy-statement bgp-export-policy term 2 then reject
```

9. Verify and commit the configuration.

   For example:

```
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp family traffic-engineering unicast
user@R1# set bgp group ibgp export nlri2bgp
user@R1# set bgp group ibgp neighbor 10.255.105.137
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp family traffic-engineering unicast
```

```
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
  remote-node-id 8.42.1.104
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
  remote-node-router-id 10.255.105.139
```

```
[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then next-hop self
user@R1# set policy-statement nlri2bgp term 1 then accept
```

```
[edit]
user@R1# commit
commit complete
```

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then next-hop self
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

```

Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages

An essential element of RSVP-based traffic engineering is the traffic engineering database. The traffic engineering database contains a complete list of all network nodes and links participating in traffic engineering, and a set of attributes each of those links can hold. (For more information about the traffic engineering database, see "Constrained-Path LSP Computation" on page 386.) One of the most important link attributes is bandwidth.

Bandwidth availability on links changes quickly as RSVP LSPs are established and terminated. It is likely that the traffic engineering database will develop inconsistencies relative to the real network. These inconsistencies cannot be fixed by increasing the rate of IGP updates.

Link availability can share the same inconsistency problem. A link that becomes unavailable can break all existing RSVP LSPs. However, its unavailability might not readily be known by the network.

When you configure the **rsvp-error-hold-time** statement, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

You can control the frequency of IGP updates by using the **update-threshold** statement. See *Configuring the RSVP Update Threshold on an Interface*.

This section discusses the following topics:

PathErr Messages

PathErr messages report a wide variety of problems by means of different code and subcode numbers. You can find a complete list of these PathErr messages in RFC 2205, *Resource Reservation Protocol (RSVP), Version 1, Functional Specification* and RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*.

When you configure the **rsvp-error-hold-time** statement, two categories of PathErr messages, which specifically represent link failures, are examined:

- Link bandwidth is low for this LSP: Requested bandwidth unavailable—code 1, subcode 2

  This type of PathErr message represents a global problem that affects all LSPs transiting the link. They indicate that the actual link bandwidth is lower than that required by the LSP, and that it is likely that the bandwidth information in the traffic engineering database is an overestimate.

  When this type of error is received, the available link bandwidth is reduced in the local traffic engineering database, affecting all future LSP computations.

- Link unavailable for this LSP:
  - Admission Control failure—code 1, any subcode except 2
  - Policy Control failures—code 2

- Service Preempted—code 12
- Routing problem—no route available toward destination—code 24, subcode 5

These types of PathErr messages are generally pertinent to the specified LSP. The failure of this LSP does not necessarily imply that other LSPs could also fail. These errors can indicate maximum transfer unit (MTU) problems, service preemption (either manually initiated by the operator or by another LSP with a higher priority), that a next-hop link is down, that a next-hop neighbor is down, or service rejection because of policy considerations. It is best to route this particular LSP away from the link.

Identifying the Problem Link

Each PathErr message includes the sender's IP address. This information is propagated unchanged toward the ingress router. A lookup in the traffic engineering database can identify the node that originated the PathErr message.

Each PathErr message carries enough information to identify the RSVP session that triggered the message. If this is a transit router, it simply forwards the message. If this router is the ingress router (for this RSVP session), it has the complete list of all nodes and links the session should traverse. Coupled with the originating node information, the link can be uniquely identified.

Configuring the Router to Improve Traffic Engineering Database Accuracy

To improve the accuracy of the traffic engineering database, configure the **rsvp-error-hold-time** statement. When this statement is configured, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages also are used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

To configure how long MPLS should remember RSVP PathErr messages and consider them in CSPF computation, include the **rsvp-error-hold-time** statement:

```
rsvp-error-hold-time seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The time can be a value from 1 to 240 seconds. The default is 25 seconds. Configuring a value of 0 disables the monitoring of PathErr messages.

Configuring DiffServ-Aware Traffic Engineering to Achieve Service Level Guarantees on an MPLS network

DiffServ-Aware Traffic Engineering Introduction

Differentiated Services (DiffServ)-aware traffic engineering provides a way to guarantee a specified level of service over an MPLS network. The routers providing DiffServ-aware traffic engineering are part of a differentiated services network domain. All routers participating in a differentiated services domain must have DiffServ-aware traffic engineering enabled.

To help ensure that the specified service level is provided, it is necessary to ensure that no more than the amount of traffic specified is sent over the differentiated services domain. You can accomplish this goal by configuring a policer to police or rate-limit the volume of traffic transiting the differentiated service domain. For more information about how to configure policers for label-switched paths (LSPs), see "Configuring Policers for LSPs" on page 98.

This feature can help to improve the quality of Internet services such as voice over IP (VoIP). It also makes it possible to better emulate an Asynchronous Transfer Mode (ATM) circuit over an MPLS network.

DiffServ-Aware Traffic Engineering Standards

The following RFCs provide information on DiffServ-aware traffic engineering and multiclass LSPs:

- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diff-Serv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diff-Serv-aware MPLS*

These RFCs are available on the IETF website at http://www.ietf.org/.

DiffServ-Aware Traffic Engineering Terminology

B

Bandwidth model The bandwidth model determines the values of the available bandwidth advertised by the interior gateway protocols (IGPs).

C

CAC Call admission control (CAC) checks to ensure there is adequate bandwidth on the path before the LSP is established. If the bandwidth is insufficient, the LSP is not established and an error is reported.

Class type — A collection of traffic flows that is treated equivalently in a differentiated services domain. A class type maps to a queue and is much like a class-of-service (CoS) forwarding class in concept. It is also known as a traffic class.

D

Differentiated Services — Differentiated Services make it possible to give different treatment to traffic based on the EXP bits in the MPLS header. Traffic must be marked appropriately and CoS must be configured.

Differentiated Services domain — The routers in a network that have Differentiated Services enabled.

DiffServ-aware traffic engineering — A type of constraint-based routing. It can enforce different bandwidth constraints for different classes of traffic. It can also do CAC on each traffic engineering class when an LSP is established.

M

MAM — The maximum allocation bandwidth constraint model divides the available bandwidth between the different classes. Sharing of bandwidth between the class types is not allowed.

Multiclass LSP — A multiclass LSP functions like a standard LSP, but it also allows you to reserve bandwidth from multiple class types. The EXP bits of the MPLS header are used to distinguish between class types.

R

RDM — The Russian dolls bandwidth constraint model makes efficient use of bandwidth by allowing the class types to share bandwidth.

T

Traffic engineering class — A paired class type and priority.

Traffic engineering class map — A map between the class types, priorities, and traffic engineering classes. The traffic engineering class mapping must be consistent across the Differentiated Services domain.

DiffServ-Aware Traffic Engineering Features

DiffServ-aware traffic engineering provides the following features:

- Traffic engineering at a per-class level rather than at an aggregate level
- Different bandwidth constraints for different class types (traffic classes)
- Different queuing behaviors per class, allowing the router to forward traffic based on the class type

In comparison, standard traffic engineering does not consider CoS, and it completes its work on an aggregate basis across all Differentiated Service classes.

DiffServ-aware traffic engineering provides the following advantages:

- Traffic engineering can be performed on a specific class type instead of at the aggregate level.
- Bandwidth constraints can be enforced on each specific class type.
- It forwards traffic based on the EXP bits.

This makes it possible to guarantee service and bandwidth across an MPLS network. With DiffServ-aware traffic engineering, among other services, you can provide ATM circuit emulation, VoIP, and a guaranteed bandwidth service.

The following describes how the IGP, Constrained Shortest Path First (CSPF), and RSVP participate in DiffServ-aware traffic engineering:

- The IGP can advertise the unreserved bandwidth for each traffic engineering class to the other members of the differentiated services domain. The traffic engineering database stores this information.
- A CSPF calculation is performed considering the bandwidth constraints for each class type. If all the constraints are met, the CSPF calculation is considered successful.
- When RSVP signals an LSP, it requests bandwidth for specified class types.

DiffServ-Aware Traffic Engineered LSPs

A DiffServ-aware traffic engineered LSP is an LSP configured to reserve bandwidth for one of the supported class types and to carry traffic for that class type. The following sections discuss this type of LSPs:

- DiffServ-Aware Traffic Engineered LSPs Overview on page 690
- DiffServ-Aware Traffic Engineered LSPs Operation on page 691

DiffServ-Aware Traffic Engineered LSPs Overview

A DiffServ-aware traffic engineered LSP is an LSP configured with a bandwidth reservation for a specific class type. This LSP can carry traffic for a single class type. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

The class type must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

For more information about topics related to LSPs and DiffServ-aware traffic engineering, see the following:

- For forwarding classes and class of service, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.
- For EXP bits, see "MPLS Label Allocation" on page 329.
- For differentiated services, see RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*.
- For information about how the IGPs and RSVP have been modified to support Differentiated Services-aware MPLS traffic engineering, see RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*.

DiffServ-Aware Traffic Engineered LSPs Operation

When configuring a DiffServ-aware traffic engineered LSP, you specify the class type and the bandwidth associated with it. The following occurs when an LSP is established with bandwidth reservation from a specific class type:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for an LSP, CSPF is used to ensure that the bandwidth constraints are met for the class type carried by the LSP at the specified priority level.

   CSPF also checks to ensure that the bandwidth model is configured consistently on each router participating in the LSP. If the bandwidth model is inconsistent, CSPF does not compute the path (except for LSPs from class type ct0).
3. Once a path is found, RSVP signals the LSP using the Classtype object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up.

An LSP that requires bandwidth from a particular class (except class type ct0) cannot be established through routers that do not understand the Classtype object. Preventing the use of routers that do not understand the Classtype object helps to ensure consistency throughout the Differentiated Services domain by preventing the LSP from using a router that cannot support Differentiated Services.

By default, LSPs are signaled with setup priority 7 and holding priority 0. An LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both LSPs configured for DiffServ-aware traffic engineering and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings (either by remarking the EXP settings or by assuming that the traffic arrived with the correct EXP settings from the upstream router).

Multiclass LSP Overview

A multiclass LSP is an LSP that can carry several class types. One multiclass LSP can be used to support up to four class types. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB)

associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

Once a multiclass LSP is configured, traffic from all of the class types can:

- Follow the same path
- Be rerouted along the same path
- Be taken down at the same time

Class types must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network.

You can unambiguously map a class type to a queue. On each node router, the CoS queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

The combination of a class type and a priority level forms a traffic engineering class. The IGPs can advertise up to eight traffic engineering classes for each link.

For more information about the EXP bits, see "MPLS Label Allocation" on page 329.

For more information about forwarding classes, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Multiclass LSPs

Multiclass LSPs function like standard LSPs, but they also allow you to configure multiple class types with guaranteed bandwidth. The EXP bits of the MPLS header are used to distinguish between class types. Multiclass LSPs can be configured for a variety of purposes. For example, you can configure a multiclass LSP to emulate the behavior of an ATM circuit. An ATM circuit can provide service-level guarantees to a class type. A multiclass LSP can provide a similar guaranteed level of service.

The following sections discuss multiclass LSPs:

Establishing a Multiclass LSP on the Differentiated Services Domain

The following occurs when a multiclass LSP is established on the differentiated services domain:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for a multiclass LSP, CSPF is used to ensure that the constraints are met for all the class types carried by the multiclass LSP (a set of constraints instead of a single constraint).

3. Once a path is found, RSVP signals the LSP using an RSVP object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up. The RSVP object is a hop-by-hop object. Multiclass LSPs cannot be established through routers that do not understand this object. Preventing routers that do not understand the RSVP object from carrying traffic helps to ensure consistency throughout the differentiated services domain by preventing the multiclass LSP from using a router that is incapable of supporting differentiated services.

By default, multiclass LSPs are signaled with setup priority 7 and holding priority 0. A multiclass LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both multiclass LSPs and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings.

Configuring Routers for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, include the **diffserv-te** statement:

```
diffserv-te {
  bandwidth-model {
    extended-mam;
    mam;
    rdm;
  }
  te-class-matrix {
    traffic-class {
      te number {
        priority priority;
        traffic-class ct number priority priority;
      }
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems** *logical-system-name* **protocols mpls]**

You must include the **diffserv-te** statement in the configuration on all routers participating in the Differentiated Services domain. However, you are not required to configure the traffic engineering class matrix (by including the **te-class-matrix** statement at the **[edit protocols mpls diffserv-te]** or **[edit logical-systems** *logical-system-name* **protocols mpls diffserv-te]** hierarchy level).

NOTE: To prevent the possibility of an incorrect configuration when migrating to Diffserv-aware traffic engineering, a policy control failure error might be triggered if there is conflict between the old LSPs and the newly configured TE-class matrix.

An old node might request an LSP with setup and hold priorities in such a way that the combination of the ct0 class and the priority does not match with the configured TE-class matrix. All LSPs on the router that are configured prior to configuring diffserv-aware traffic engineering are designated as being from class ct0.

The error appears in the RSVP tracing logs as a **Session preempted** error. For the router where the error originates, the error could appear as follows:

```
Jun 17 16:35:59 RSVP error for session 10.255.245.6(port/tunnel ID 31133)
  Proto 0: (class ct0, priority 2) is not a valid TE-class  Jun 17
16:35:59 RSVP originate PathErr 192.168.37.22->192.168.37.23 Session
preempted
```

For the router receiving the error, the error can appear as follows:

```
Jun 17 16:37:51 RSVP recv PathErr 192.168.37.22->192.168.37.23 Session
  preempted LSP to-f(2/31133)
```

To configure DiffServ-aware traffic engineering, complete the procedures in the following sections:

- Configuring the Bandwidth Model on page 694
- Configuring Traffic Engineering Classes on page 695
- Configuring Class of Service for DiffServ-Aware Traffic Engineering on page 697

Configuring the Bandwidth Model

You must configure a bandwidth model on all routers participating in the Differentiated Services domain. The bandwidth models available are MAM, extended MAM, and RDM:

- Maximum allocation bandwidth constraints model (MAM)—Defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.
- Extended MAM—A proprietary bandwidth model that behaves much like standard MAM. If you configure multiclass LSPs, you must configure the extended MAM bandwidth model.
- Russian-dolls bandwidth allocation model (RDM)—Makes efficient use of bandwidth by allowing the class types to share bandwidth. RDM is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

To configure a bandwidth model, include the **bandwidth-model** statement and specify one of the bandwidth model options:

```
bandwidth-model {
  extended-mam;
  mam;
  rdm;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** diffserv-te**]**
- **[edit logical-systems** *logical-system-name* **protocols mpls** diffserv-te**]**

NOTE: If you change the bandwidth model on an ingress router, all the LSPs enabled on the router are taken down and resignaled.

Configuring Traffic Engineering Classes

Configuring traffic engineering classes is optional. Table 24 on page 695 shows the default values for everything in the traffic engineering class matrix. The default mapping is expressed in terms of the default forwarding classes defined in the CoS configuration.

Table 24: Default Values for the Traffic Engineering Class Matrix

Traffic Engineering Class	Class Type	Queue	Priority
te0	ct0	0	7
te1	ct1	1	7
te2	ct2	2	7
te3	ct3	3	7
te4	ct0	0	0
te5	ct1	1	0
te6	ct2	2	0
te7	ct3	3	0

If you want to override the default mappings, you can configure traffic engineering classes 0 through 7. For each traffic engineering class, you configure a class type (or queue) from 0 through 3. For each class type, you configure a priority from 0 through 7.

To configure traffic engineering classes explicitly, include the **te-class-matrix** statement:

```
te-class-matrix {
   tenumber {
      priority priority;
      traffic-class {
         ctnumber priority priority;
      }
   }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** diffserv-te**]**
- **[edit logical-systems** *logical-system-name* **protocols mpls** diffserv-te**]**

The following example shows how to configure traffic engineering class **te0** with class type **ct1** and a priority of **4**:

```
[edit protocols mpls diffserv-te]
te-class-matrix {
   te0 traffic-class ct1 priority 4;
}
```

NOTE: If you explicitly configure a value for one of the traffic engineering classes, all the default values in the traffic engineering class matrix are dropped.

When you explicitly configure traffic engineering classes, you must also configure a bandwidth model; otherwise, the configuration commit operation fails.

Requirements and Limitations for the Traffic Engineering Class Matrix

When you configure a traffic engineering class matrix, be aware of the following requirements and limitations:

- A mapping configuration is local and affects only the router on which it is configured. It does not affect other systems participating in the differentiated services domain. However, for a Differentiated Services domain to function properly, you need to configure the same traffic engineering class matrix on all the routers participating in the same domain.
- When explicitly configuring traffic engineering classes, you must configure the classes in sequence (**te0**, **te1**, **te2**, **te3**, and so on); otherwise, the configuration commit operation fails.

The first traffic engineering class you configure must be **te0**; otherwise, the configuration commit operation fails.

Configuring Class of Service for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, you must also configure class of service. The following example illustrates a class-of-service configuration that would allocate 25 percent of the link bandwidth to each class:

```
class-of-service {
  interfaces {
    all {
      scheduler-map simple-map;
    }
  }
  scheduler-maps {
    simple-map {
      forwarding-class assured-forwarding scheduler simple_sched;
        forwarding-class best-effort scheduler simple_sched;
        forwarding-class network-control scheduler simple_sched;
      forwarding-class expedited-forwarding scheduler simple_sched;
    }
  }
  schedulers {
    simple_sched {
      transmit-rate percent 25;
      buffer-size percent 25;
    }
  }
}
```

For more information on how to configure class of service, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

LSP Bandwidth Oversubscription Overview

LSPs are established with bandwidth reservations configured for the maximum amount of traffic you expect to traverse the LSP. Not all LSPs carry the maximum amount of traffic over their links at all times. For example, even if the bandwidth for link A has been completely reserved, actual bandwidth might still be available but not currently in use. This excess bandwidth can be used by allowing other LSPs to also use link A, oversubscribing the link. You can oversubscribe the bandwidth configured for individual class types or specify a single value for all of the class types using an interface.

You can use oversubscription to take advantage of the statistical nature of traffic patterns and to permit higher utilization of links.

The following examples describe how you might use bandwidth oversubscription and undersubscription:

- Use oversubscription on class types where peak periods of traffic do not coincide in time.

- Use oversubscription of class types carrying best-effort traffic. You take the risk of temporarily delaying or dropping traffic in exchange for making better utilization of network resources.
- Give different degrees of oversubscription or undersubscription of traffic for the different class types. For instance, you configure the subscription for classes of traffic as follows:
  - Best effort—**ct0 1000**
  - Voice—**ct3 1**

When you undersubscribe a class type for a multiclass LSP, the total demand of all RSVP sessions is always less than the actual capacity of the class type. You can use undersubscription to limit the utilization of a class type.

The bandwidth oversubscription calculation occurs on the local router only. Because no signaling or other interaction is required from other routers in the network, the feature can be enabled on individual routers without being enabled or available on other routers which might not support this feature. Neighboring routers do not need to know about the oversubscription calculation, they rely on the IGP.

The following sections describe the types of bandwidth oversubscription available in the Junos OS:

- LSP Size Oversubscription on page 698
- LSP Link Size Oversubscription on page 698
- Class Type Oversubscription and Local Oversubscription Multipliers on page 699

LSP Size Oversubscription

For LSP size oversubscription, you simply configure less bandwidth than the peak rate expected for the LSP. You also might need to adjust the configuration for automatic policers. Automatic policers manage the traffic assigned to an LSP, ensuring that it does not exceed the configured bandwidth values. LSP size oversubscription requires that the LSP can exceed its configured bandwidth allocation.

Policing is still possible. However, the policer must be manually configured to account for the maximum bandwidth planned for the LSP, rather than for the configured value.

LSP Link Size Oversubscription

You can increase the maximum reservable bandwidth on the link and use the inflated values for bandwidth accounting. Use the **subscription** statement to oversubscribe the link. The configured value is applied to all class type bandwidth allocations on the link. For more information about link size oversubscription, see "Configuring the Bandwidth Subscription Percentage for LSPs" on page 702.

Class Type Oversubscription and Local Oversubscription Multipliers

Local oversubscription multipliers (LOMs) allow different oversubscription values for different class types. LOMs are useful for networks where the oversubscription ratio needs to be configured differently on different links and where oversubscription values are required for different classes. You might use this feature to oversubscribe class types handling best-effort traffic, but use no oversubscription for class types handling voice traffic. An LOM is calculated locally on the router. No information related to an LOM is signaled to other routers in the network.

An LOM is configurable on each link and for each class type. The per-class type LOM allows you to increase or decrease the oversubscription ratio. The per-class-type LOM is factored into all local bandwidth accounting for admission control and IGP advertisement of unreserved bandwidths.

The LOM calculation is tied to the bandwidth model (MAM, extended MAM, and Russian dolls) used, because the effect of oversubscription across class types must be accounted for accurately.

NOTE: All LOM calculations are performed by the Junos OS and require no user intervention.

The formulas related to the oversubscription of class types are described in the following sections:

- Class Type Bandwidth and the LOM on page 699
- LOM Calculation for the MAM and Extended MAM Bandwidth Models on page 700
- LOM Calculation for the Russian Dolls Bandwidth Model on page 700
- Example: LOM Calculation on page 701

Class Type Bandwidth and the LOM

The following formula expresses the relationship between the bandwidth of the class type and the LOM. The normalized bandwidth of the class type (N_B) is equal to the reserved bandwidth of the class type (R_B) divided by the LOM of the class type (L_C):

$$N_B = R_B / L_C$$

When calculating available bandwidth, you need to subtract the normalized bandwidth from the relevant bandwidth constraint.

NOTE: When using an LOM, values advertised for the available bandwidth might be larger than the bandwidth constraint values. However, the values advertised in the maximum link bandwidth advertisement are not affected by local oversubscription.

LOM Calculation for the MAM and Extended MAM Bandwidth Models

The following formulas show how the LOM is calculated for the MAM and extended MAM bandwidth models.

Unreserved TE-Class(i) = LOM*c* x [BC*c* – SUM (Normalized (CT*c*, q))] for q <= *p*

Or

Unreserved TE-Class(i) = (LOM*c* x BC*c*) – SUM (Reserved (CT*c*, q)) for q <= *p*

where:

- LOM*c*—LOM for class type *c*.
- BC*c*—Bandwidth constraint for class type *c*.
- CT*c*—Class type *c*.
- TE-Class(i) <–––> (CT*c* , preemption *p*) in the configured TE-Class mapping.

LOM Calculation for the Russian Dolls Bandwidth Model

The following formulas show how the LOM is calculated for the Russian dolls bandwidth model:

```
Unreserved TE-Class (i) = LOMc x MIN [

[ BCc - SUM ( Normalized (CTb, q) ) ] for q <= p and c <= b <= 7,
. . .
[ BC0 - SUM ( Normalized (CTb, q) ) ] for q <= p and 0 <= b <= 7,

]
```

where:

- **LOM*c***—LOM for class type ***c***.
- **BC*c***—Bandwidth constraint for class type ***c***.
- **TE-Class(i)** <– –>(**CT*c*** , preemption ***p***) in the configured TE-Class mapping.

Note that the impact of an LSP on the unreserved bandwidth of a class type does not depend only on the LOM for that class type—it also depends on the LOM for the class type of the LSP.

Example: LOM Calculation

The following example illustrates how an LOM calculation is made for four classes of traffic: **ct0**, **ct1**, **ct2**, and **ct3**.

The class types have been assigned the following values:

```
ct0 = 40
ct1 = 30
ct2 = 20
ct3 = 10
```

These class type values yield the following bandwidth constraints:

```
BC0 = (ct3 + ct2 + ct1 + ct0) = 100
BC1 = (ct3 + ct2 + ct1) = 60
BC2 = (ct3 + ct2) = 30
BC3 = (ct3) = 10
```

LSPs from class type **ct0** can take up to 100 percent of bandwidth on the link. LSPs from class type **ct1** can take up to 60 percent of the bandwidth on the link, and so on.

If you assume for this example that the class types have the following LOM values:

```
LOM(ct0) = 8
LOM(ct1) = 4
LOM(ct2) = 2
LOM(ct3) = 1
```

In the absence of any other reservation, LSPs from class type **ct0** can take up to 800 percent of the available bandwidth (**8 x 100 = 800**). In the absence of any other reservation, LSPs from class type **ct1** can take up to 240 percent of the available bandwidth (**4 x 60 = 240**). and so on.

The maximum amount of bandwidth that can be reserved is:

```
ct0 = LOM(ct0) x BC0 = 800
ct1 = LOM(ct1) x BC1 = 240
ct2 = LOM(ct2) x BC2 = 60
ct3 = LOM(ct3) x BC3 = 10
```

For the undersubscribed class type ct3, the maximum reservable bandwidth is the same as the bandwidth constraint. For the overbooked class types, these values are not the values of the bandwidth constraint-taking into account the oversubscription for each class type separately. The oversubscription per class type in the sum is not taken into account because ultimately the entire bandwidth constraint can be filled with the bandwidth reservation of just one class type, so you have to account for that class type's bandwidth oversubscription only.

When calculating the available bandwidth for **CT*c***, you need to express reservations from other classes as if they were from **CT*c***. The reservation from class **ct*x*** is normalized with the LOM of **ct*x***, but it is then multiplied by the LOM of **CT*c***.

For the previous example, assume that **LSP1** has class type **ct3** configured with bandwidth of **10** and a priority of **0**.

The values for the reservable bandwidth will be:

```
ct0 = 8 x (100 - 10) = 720
ct1 = 4 x min((100-10), (60-10)) = 200
ct2 = 2 x min((100-10), (60-10), (30-10)) = 40
ct3 = 1 x min((100-10), (60-10), (30-10), (10-10)) = 0
```

These numbers can be rationalized as follows: the normalized reservation is 10 percent. If this bandwidth came from class type ct0, it would be equivalent to an overbooked reservation of 80 percent. You can see that 720 percent (800 – 80 = 720) of the bandwidth remains available for other LSPs.

Configuring the Bandwidth Subscription Percentage for LSPs

By default, RSVP allows all of a class type's bandwidth (100 percent) to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

If you want to oversubscribe or undersubscribe all of the class types on an interface using the same percentage bandwidth, configure the percentage using the **subscription** statement:

```
subscription percentage;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

To undersubscribe or oversubscribe the bandwidth for each class type, configure a percentage for each class type (**ct0**, **ct1**, **ct2**, and **ct3**) option for the **subscription** statement. When you oversubscribe a class type, an LOM is applied to calculate the actual bandwidth reserved. See "Class Type Oversubscription and Local Oversubscription Multipliers" on page 699 for more information.

```
subscription {
    ct0 percentage;
    ct1 percentage;
    ct2 percentage;
    ct3 percentage;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

percentage is the percentage of class type bandwidth that RSVP allows to be used for reservations. It can be a value from 0 through 65,000 percent. If you specify a value greater than 100, you are oversubscribing the interface or class type.

The value you configure when you oversubscribe a class type is a percentage of the class type bandwidth that can actually be used. The default subscription value is 100 percent.

You can use the **subscription** statement to disable new RSVP sessions for one or more class types. If you configure a percentage of 0, no new sessions (including those with zero bandwidth requirements) are permitted for the class type.

Existing RSVP sessions are not affected by changing the subscription factor. To clear an existing session, issue the **clear rsvp session** command. For more information on the **clear rsvp session** command, see the CLI Explorer.

Constraints on Configuring Bandwidth Subscription

Be aware of the following issues when configuring bandwidth subscription:

- If you configure bandwidth constraints at the **[edit class-of-service interface *interface-name*]** hierarchy level, they override any bandwidth configuration you specify at the **[edit protocols rsvp interface *interface-name* bandwidth]** hierarchy level for Diffserv-TE. Also note that either of the CoS or RSVP bandwidth constraints can override the interface hardware bandwidth constraints.
- If you configure a bandwidth subscription value for a specific interface that differs from the value configured for all interfaces (by including different values for the **subscription** statement at the **[edit protocols rsvp interface *interface-name*]** and **[edit protocols rsvp interface all]** hierarchy levels), the interface-specific value is used for that interface.
- You can configure subscription for each class type only if you also configure a bandwidth model. If no bandwidth model is configured, the commit operation fails with the following error message:

```
user@host# commit check
[edit protocols rsvp interface all]
  'subscription'
RSVP: Must have a diffserv-te bandwidth model configured when configuring
subscription per traffic class.
error: configuration check-out failed
```

- You cannot include the **subscription** statement both in the configuration for a specific class type and the configuration for the entire interface. The commit operation fails with the following error message:

```
user@host# commit check
[edit protocols rsvp interface all]
  'subscription'
    RSVP: Cannot configure both link subscription and per traffic class
subscription.
error: configuration check-out failed
```

Configuring LSPs for DiffServ-Aware Traffic Engineering

You must configure the Differentiated Services domain (see "Configuring Routers for DiffServ-Aware Traffic Engineering" on page 693) before you can enable DiffServ-aware traffic engineering for LSPs. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in the LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the LSP to function properly.

NOTE: **You must configure either MAM or RDM as the bandwidth model when you configure DiffServ-aware traffic engineering for LSPs. See** **"Configuring the Bandwidth Model" on page 694**.

The actual data transmitted over this Differentiated Services domain is carried by an LSP. Each LSP relies on the EXP bits of the MPLS packets to enable DiffServ-aware traffic engineering. Each LSP can carry traffic for a single class type.

All the routers participating in the LSP must be Juniper Networks routers running Junos OS Release 6.3 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the DiffServ-aware traffic engineering LSP cannot traverse these routers.

NOTE: **You cannot simultaneously configure multiclass LSPs and DiffServ-aware traffic engineering LSPs on the same router.**

To enable DiffServ-aware traffic engineering for LSPs, you need to configure the following:

- Configuring Class of Service for the Interfaces on page 704
- Configuring IGP on page 705
- Configuring Traffic-Engineered LSPs on page 705
- Configuring Policing for LSPs on page 706
- Configuring Fast Reroute for Traffic-Engineered LSPs on page 706

Configuring Class of Service for the Interfaces

The existing class-of-service (CoS) infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to accomplish this are configured using the existing Junos OS CoS features.

NOTE: **The Junos OS does not support CoS on ATM interfaces.**

For information about how to configure CoS, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Configuring IGP

You can configure either IS-IS or OSPF as the IGP. The IS-IS and OSPF configurations for routers supporting LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

Configuring Traffic-Engineered LSPs

You configure an LSP by using the standard LSP configuration statements and procedures. To configure DiffServ-aware traffic engineering for the LSP, specify a class type bandwidth constraint by including the **bandwidth** statement:

```
label-switched-path lsp-name {
  bandwidth {
    ctnumber bps;
  }
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for this statement.

If you do not specify a bandwidth for a class type, **ct0** is automatically specified as the queue for the LSP. You can configure only one class type for each LSP, unlike multiclass LSPs.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

You can configure setup and holding priorities for an LSP, but the following restrictions apply:

- The combination of class and priority must be one of the configured traffic engineering classes. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.
- For migration issues, see Internet draft draft-ietf-tewg-diff-te-proto-07.txt.

Configuring Policing for LSPs

Policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each LSP.

For information about how to configure a policer for an LSP, see "Configuring Policers for LSPs" on page 98.

Configuring Fast Reroute for Traffic-Engineered LSPs

You can configure fast reroute for traffic engineered LSPs (LSPs carrying a single class of traffic). It is also possible to reserve bandwidth on the detour path for the class of traffic when fast reroute is enabled. The same class type number is used for both the traffic engineered LSP and its detour.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

You can configure the amount of bandwidth to reserve for detours using either the **bandwidth** statement or the **bandwidth-percent** statement. You can only configure one these statements at a time. If you do not configure either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path (the bandwidth guarantee will be lost if traffic is switched to the detour).

When you configure the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. For information, see "Configuring Fast Reroute" on page 381.

The **bandwidth-percent** statement allows you to specify the bandwidth of the detour path as a percentage of the bandwidth configured for the protected path. For example, if you configure 100 millions bps of bandwidth for the protected path and configure 20 for the **bandwidth-percent** statement, the detour path will have 20 million bps of bandwidth reserved for its use.

To configure the percent of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** fast-reroute**]**
- **[edit logical-systems** *logical-system-name* **protocols mpls** label-switched-path ***lsp-name*** fast-reroute**]**

Configuring Multiclass LSPs

A multiclass LSP is an LSP configured to reserve bandwidth for multiple class types and also carries the traffic for these class types. The differentiated service behavior is determined by the EXP bits.

You must configure the Differentiated Services domain (see "Configuring Routers for DiffServ-Aware Traffic Engineering" on page 693) before you can enable a multiclass LSP. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in a multiclass LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the multiclass LSP to function properly.

NOTE: **You must configure extended MAM as the bandwidth model when you configure multiclass LSPs. See** "Configuring the Bandwidth Model" on page 694.

All the routers participating in a multiclass LSP must be Juniper Networks routers running Junos OS Release 6.2 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the multiclass LSP cannot traverse these routers.

To enable multiclass LSPs, you need to configure the following:

- Configuring Class of Service for the Interfaces on page 707
- Configuring the IGP on page 708
- Configuring Class-Type Bandwidth Constraints for Multiclass LSPs on page 708
- Configuring Policing for Multiclass LSPs on page 709
- Configuring Fast Reroute for Multiclass LSPs on page 709

Configuring Class of Service for the Interfaces

The existing class-of-service infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to consistently mark traffic are configured with the existing Junos OS CoS features.

NOTE: **The Junos OS does not support ATM interfaces.**

For information about how to configure CoS, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Configuring the IGP

You can configure either IS-IS or OSPF. The IS-IS and OSPF configurations for routers supporting multiclass LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

Configuring Class-Type Bandwidth Constraints for Multiclass LSPs

You configure a multiclass LSP by using the standard LSP configuration statements and procedures. To configure an LSP as a multiclass LSP, specify the class type bandwidth constraints by including the **bandwidth** statement:

```
bandwidth {
   ct0 bps;
   ct1 bps;
   ct2 bps;
   ct3 bps;
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for these statements.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

For example, to configure 50 megabytes of bandwidth for class type 1 and 30 megabytes of bandwidth for class type 2, include the **bandwidth** statement as follows:

```
[edit protocols mpls]
label-switched-path traffic-class {
   bandwidth {
      ct1 50M;
      ct2 30M;
   }
}
```

You cannot configure a bandwidth for a class type and also configure a bandwidth at the **[edit protocols mpls label-switched-path *lsp-name* bandwidth]** hierarchy level. For example, the following configuration cannot be committed:

```
[edit protocols mpls]
label-switched-path traffic-class {
   bandwidth {
      20M;
      ct1 10M;
   }
```

```
}
```

You can configure setup and holding priorities for a multiclass LSP, but the following restrictions apply:

- The setup and holding priorities apply to all classes for which bandwidth is requested.
- The combination of class and priority must be one of the configured traffic engineering classes. The default traffic engineering class configuration results in multiclass LSPs that cannot preempt and cannot be preempted. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported for multiclass LSPs. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.

Configuring Policing for Multiclass LSPs

Policing allows you to control the amount of traffic forwarded through a particular multiclass LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each multiclass LSP. You can also enable automatic policing for multiclass LSPs.

For information about how to configure a policer for a multiclass LSP, see "Configuring Policers for LSPs" on page 98 and "Configuring Automatic Policers" on page 100.

Configuring Fast Reroute for Multiclass LSPs

You can enable fast reroute for multiclass LSPs. The bandwidth guarantees for the class types can be carried over to the detour path in case the primary path of the multiclass LSP fails. The same traffic class types configured for the primary multiclass LSP are also signaled for the detour LSP.

The bandwidth guarantee for the detour path is a percentage of the bandwidth configured for the class types of the primary path. For example, you configure a value of 50 percent for the detour path and the protected LSP carries traffic for class types CT0 through CT3. The detour path is signaled with the same class types (CT0 through CT3) but with 50 percent of the bandwidth configured for the protected LSP.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering, that all of the traffic class types needed are available, and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

The bandwidth percentage for fast reroute is signaled from the ingress router to the egress router. All of the intermediate devices must complete their own CSPF computations and signaling.

When you configure the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying by the bandwidth configured for the primary multiclass LSP. For information about how to configure the bandwidth for the multiclass LSP, see "Configuring Traffic-Engineered LSPs" on page 705.

To configure the percentage of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** fast-reroute**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** fast-reroute**]**

PART 6

MPLS Transport Profile

CHAPTER 22

Configuring Operation, Administration, and Maintenance (OAM) for MPLS

Configuring the MPLS Transport Profile for OAM

MPLS Transport Profile Overview

RFC 5654, *Requirements of an MPLS Transport Profile*, describes the requirements for the MPLS Transport Profile (MPLS-TP) that extends capabilities for Operation, Administration, and Maintenance (OAM) when MPLS is used for transport services and transport network operations. These capabilities help in troubleshooting and maintenance of a pseudowire or label-switched path (LSP).

MPLS-TP mechanisms for OAM contain two main components:

- Generic Associated Channel Label (GAL)—A special label that enables an exception mechanism that informs the egress label-switching router (LSR) that a packet it receives on an LSP belongs to an associated control channel or the control plane.
- Generic Associated Channel Header (G-Ach)—A special header field that identifies the type of payload contained in the MPLS label-switched paths (LSPs). G-Ach has the same format as a pseudowire associated control channel header.

For more information about MPLS-TP, see RFC 5654, *Requirements of an MPLS Transport Profile*. For specific information about GAL and G-Ach, see RFC 5586, *MPLS Generic Associated Channel*.

The following capabilities are supported in the Junos OS implementation of MPLS-TP:

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.

- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.

Example: Configuring the MPLS Transport Profile for OAM

This example shows how to configure the MPLS Transport Profile (MPLS-TP) for sending and receiving of OAM GAL and G-Ach messages across a label-switched path (LSP).

Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series, MX Series, and T Series routers
- Junos OS Release 12.1 or later running on the devices

Overview

Junos OS Release 12.1 and later support MPLS Transport Profile (MPLS-TP) Operation, Administration, and Maintenance (OAM) capabilities. MPLS-TP introduces new capabilities for OAM when MPLS is used for transport services and transport network operations. This includes configuring Generic Associated Channel Label (GAL) and Generic Associated Channel Header (G-Ach) for OAM messages.

This example shows how to configure MPLS-TP OAM capability to send and receive GAL and G-Ach OAM messages without IP encapsulation. In addition, it also shows how to associate two unidirectional RSVP label-switched paths (LSPs) between a pair of routers to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages.

Junos OS Release 12.1 and later support the following MPLS-TP capabilities:

- MPLS-TP OAM capability and the infrastructure required for MPLS applications to send and receive packets with GAL and G-Ach, without IP encapsulation.
- LSP-ping and Bidirectional Forwarding Detection (BFD) applications to send and receive packets using GAL and G-Ach, without IP encapsulation on transport LSPs.
- The association of two unidirectional RSVP LSPs, between a pair of routers, with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. The associated bidirectional LSP model is supported only for associating the primary paths. A single BFD session is established for the associated bidirectional LSP.

Junos OS Release 12.1 and later does not support the following MPLS-TP capabilities:

- Point-to-multipoint RSVP LSPs and BGP LSPs
- Loss Measurement and Delay Measurement

You can enable GAL and G-Ach OAM operation using the following configuration statements:

- **mpls-tp-mode**—Include this statement at the **[edit protocols mpls oam]** hierarchy level to enable GAL and G-Ach OAM operation, without IP encapsulation, on all LSPs in the MPLS network.

  ```
  [edit protocols mpls oam]
  mpls-tp-mode;
  ```

  Include this statement at the **[edit protocols mpls label-switched-path *lsp-name* oam]** hierarchy level to enable GAL and G-Ach OAM operation without IP encapsulation on a specific LSP in the network.

  ```
  [edit protocols mpls label-switched-path lsp-name oam]
  mpls-tp-mode;
  ```

  NOTE: Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the mpls-tp-mode statement. These additional channel types provide on-demand connectivity verification (CV) with and without IP/UDP encapsulation.

  - On-demand CV (0x0025)—This channel type is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.
  - IPv4 (0x0021)—This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

  The GACH-TLV is used along with the default LSPING channel type. As per RFC 7026, GACH-TLV is deprecated for 0x0021 and 0x0025 channel types.

  To configure a channel type for MPLS-TP, include the **lsping-channel-type *channel-type*** statement at the **[edit protocols mpls label-switched-path *lsp-name* oam mpls-tp-mode]** and **[edit protocols mpls oam mpls-tp-mode]** hierarchy levels.

- **associate-lsp *lsp-name* from *from-ip-address***—Include this statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level to configure associated bidirectional LSPs on the two ends of the LSP.

  ```
  [edit protocols mpls label-switched-path lsp-name ]
  associate-lsp lsp-name {
     from from-ip-address;
  ```

```
}
```

The **from** *from-ip-address* configuration for the LSP is optional. If omitted, it is derived from the **to** address of the ingress LSP configuration.

- **transit-lsp-association**—Include this statement at the **[edit protocols mpls]** hierarchy level to associate two LSPs at a transit router.

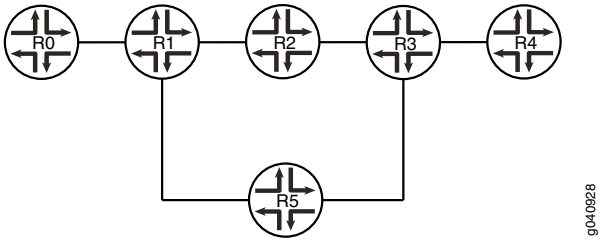
```
[edit protocols mpls]
transit-lsp-association transit-association-lsp-group-name {
   lsp-name-1 name-of-associated-lsp-1;
   from-1 address-of-associated-lsp-1;
   lsp-name-2 name-of-associated-lsp-2;
   from-2 address-of-associated-lsp-2;
}
```

The association of the LSPs in the transit nodes is useful for the return LSP path for TTL-expired LSP ping packets or traceroute.

In this example, R0 is the ingress router and R4 is the egress router. R1, R2, R3, and R5 are transit routers. The associated bidirectional LSP is established between the transit routers for sending and receiving the GAL and G-Ach OAM messages.

Figure 61 on page 716 shows the topology used in this example.

Figure 61: MPLS-TP OAM Associated Bidirectional LSPs



Configuration

CLI Quick Configuration

NOTE: This example shows the configuration on all devices and shows step-by-step procedures for configuring the ingress router, R0, and transit router R1. Repeat the step-by-step procedure described for the ingress router, R0, on the egress router, R4. Repeat the step-by-step procedure for the transit router, R1, on the other transit routers, R2, R3, and R5. Be sure to modify the appropriate interface names, addresses, and other parameters appropriately.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Configuring Device R0

Step-by-Step Procedure

To configure the ingress router, R0:

1. Configure the interfaces.

```
[edit interfaces]
user@R0# set ge-4/1/1 unit 0 family inet address 10.10.11.1/30
user@R0# set ge-4/1/1 unit 0 family iso
user@R0# set ge-4/1/1 unit 0 family inet6
user@R0# set ge-4/1/1 unit 0 family mpls
user@R0# set ge-5/0/0 unit 0 family inet address 10.10.10.1/30
user@R0# set ge-5/0/0 unit 0 family iso
user@R0# set ge-5/0/0 unit 0 family inet6
user@R0# set ge-5/0/0 unit 0 family mpls
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```

3. Configure an interior gateway protocol, such as OSPF.

```
[edit protocols ospf]
user@R0# set traffic-engineering
user@R0# set area 0.0.0.0 interface ge-5/0/0.0
user@R0# set area 0.0.0.0 interface ge-4/1/1.0
user@R0# set area 0.0.0.0 interface lo0.0 passive
```

4. Configure a signaling protocol, such as RSVP.

```
[edit protocols rsvp]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```

5. Configure the LSP.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 to 10.255.8.86
```

6. Enable GAL and G-Ach OAM operation without IP encapsulation on the LSPs.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 oam mpls-tp-mode
```

7. Configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 associate-lsp to-r0 from 10.255.8.86
```

8. After you are done configuring the device, commit the configuration.

```
[edit]
user@R0# commit
```

Results Confirm your configuration by issuing the **show interfaces** and **show protocols** commands.

```
user@R0# show interfaces
ge-4/1/1 {
   unit 0 {
      family inet {
         address 10.10.11.1/30;
      }

      }
   }
}
```

Configuring Device R1

Step-by-Step Procedure

To configure the transit router, R1:

1. Configure the interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/5 unit 0 family inet address 10.10.10.2/30
user@R1# set ge-0/0/5 unit 0 family iso
user@R1# set ge-0/0/5 unit 0 family inet6
user@R1# set ge-0/0/5 unit 0 family mpls
user@R1# set ge-0/2/2 unit 0 family inet address 10.10.12.2/30
user@R1# set ge-0/2/2 unit 0 family iso
user@R1# set ge-0/2/2 unit 0 family inet6
user@R1# set ge-0/2/2 unit 0 family mpls
user@R1# set ge-2/0/2 unit 0 family inet address 10.10.11.2/30
user@R1# set ge-2/0/2 unit 0 family iso
user@R1# set ge-2/0/2 unit 0 family inet6
user@R1# set ge-2/0/2 unit 0 family mpls
user@R1# set ge-1/0/2 unit 0 family inet address 10.10.13.2/30
user@R1# set ge-1/0/2 unit 0 family iso
user@R1# set ge-1/0/2 unit 0 family inet6
user@R1# set ge-1/0/2 unit 0 family mpls
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0
```

3. Configure an interior gateway protocol, such as OSPF.

```
[edit protocols ospf]
user@R1# set traffic-engineering
user@R1# set area 0.0.0.0 interface ge-0/0/5.0
user@R1# set area 0.0.0.0 interface ge-2/0/2.0
user@R1# set area 0.0.0.0 interface ge-1/0/2.0
user@R1# set area 0.0.0.0 interface ge-0/2/2.0 metric 100
user@R1# set area 0.0.0.0 interface lo0.0 passive
```

4. Configure a signaling protocol, such as RSVP.

```
[edit protocols rsvp]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0
```

5. Configure the association of the two LSPs on the transit router.

```
[edit protocols mpls]
user@R1# set transit-lsp-association trace1 lsp-name-1 r0-to-r4
user@R1# set transit-lsp-association trace1 from-1 10.255.8.207
user@R1# set transit-lsp-association trace1 lsp-name-2 r4-to-r0
user@R1# set transit-lsp-association trace1 from-2 10.255.8.86
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@R1# commit
```

Results Confirm your configuration by issuing the **show interfaces** and **show protocols** commands.

```

Configuring OAM Ingress Policies for LDP

Using the **ingress-policy** statement, you can configure an Operation, Administration, and Management (OAM) policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

You configure the OAM ingress policy at the **[edit policy-options]** hierarchy level. To configure an OAM ingress policy, include the **ingress-policy** statement:

```
ingress-policy ingress-policy-name;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ldp** oam**]**
- **[edit logical-systems** *logical-system-name* **protocols ldp** oam**]**

NOTE: ACX Series routers do not support **[edit logical-systems]** hierarchy level.

Tracing MPLS and LSP Packets and Operations

To trace MPLS and LSP packets and operations, include the **traceoptions** statement:

```
traceoptions {
   file filename <files number> <size size> <world-readable | no-world-readable>;
   flag flag;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can specify the following MPLS-specific flags in the MPLS **traceoptions** statement:

- **all**—Trace all operations.
- **connection**—Trace all circuit cross-connect (CCC) activity.
- **connection-detail**—Trace detailed CCC activity.
- **cspf**—Trace CSPF computations.
- **cspf-link**—Trace links visited during CSPF computations.
- **cspf-node**—Trace nodes visited during CSPF computations.
- **error**—Trace MPLS error conditions.
- **graceful-restart**—Trace MPLS graceful restart events.
- **lsping**—Trace LSP ping packets and return codes.
- **nsr-synchronization**—Trace nonstop routing (NSR) synchronization events.
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail.
- **state**—Trace all LSP state transitions.
- **static**—Trace static label-switched path.

When you configure trace options to track an MPLS LSP using the **cspf** option, the CSPF log displays information about the MPLS LSP using the term “generalized MPLS” (GMPLS). For example, a message in the CSPF log might state that the “link passes GMPLS constraints”. Generalized MPLS (GMPLS) is a superset of MPLS, so this message is normal and does not affect proper MPLS LSP operation.

For general information about tracing and global tracing options, see the *Junos OS Routing Protocols Library*.

CHAPTER 23

Configuring MPLS Pseudowires

Ethernet Pseudowire Overview

Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks. Ethernet or 802.3 PDUs are encapsulated within the pseudowire to provide a point-to-point Ethernet service. For the point-to-point Ethernet service, the following fault management features are supported:

- The IEEE 802.3ah standard for Operation, Administration, and Management (OAM). You can configure IEEE 802.3ah OAM link-fault management on Ethernet point-to-point direct links or links across Ethernet repeaters.

  Ethernet OAM link-fault management can be used for physical link-level fault detection and management. It uses a new, optional sublayer in the data link layer of the OSI model. Ethernet OAM can be implemented on any full-duplex point-to-point or emulated point-to-point Ethernet link. A system-wide implementation is not required; OAM can be deployed on particular interfaces of a router. Transmitted Ethernet OAM messages or OAM PDUs are of standard length, untagged Ethernet frames within the normal frame length limits in the range 64–1518 bytes.

- Ethernet connectivity fault management (CFM) to monitor the physical link between two routers.

- Connection protection using the continuity check protocol for fault monitoring . The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
- Path protection using the linktrace protocol for path discovery and fault verification . Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

Release History Table

Release	Description
14.1X53	Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks.

- *ATM Pseudowire Overview*

Example: Ethernet Pseudowire Base Configuration

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router
- Junos OS Release 12.2 or later

Overview of an Ethernet Pseudowire Base Configuration

The configuration shown here is the base configuration of an Ethernet pseudowire with Ethernet cross-connect for physical interface encapsulation on an ACX Series router. This configuration is for one provider edge router. To complete the configuration of an Ethernet pseudowire, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an Ethernet Pseudowire

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network

configuration, and then copy and paste the commands into the CLI at the [**edit**] hierarchy level:

```
set interfaces ge-0/1/1 encapsulation ethernet-ccc
set interfaces ge-0/1/1 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
set protocols mpls no-cspf
set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface ge-0/1/1.0 virtual-circuit-id
 1
```

NOTE: To configure an Ethernet pseudowire with 802.1Q tagging for cross-connect logical interface encapsulation, include the **vlan-ccc** statement at the [**edit interfaces ge-0/1/1 unit 0 encapsulation**] hierarchy level instead of the **ethernet-ccc** statement shown in this example.

Step-by-Step Procedure

1. Create two Gigabit Ethernet interfaces, set the encapsulation mode on one interface and MPLS on the other interface. Create the loopback (**lo0**) interface:

```
[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ge-0/1/1 encapsulation ethernet-ccc
user@host# set ge-0/1/1 unit 0
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

2. Enable the MPLS and RSVP protocols on the interface configured with MPLS—**ge-0/2/0.0**:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

3. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set protocols ldp interface ge-0/2/0.0
user@host# set protocols ldp interface lo0.0
```

4. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

5. Configure OSPF and enable traffic engineering on the MPLS interface—**ge-0/2/0.0**, and on the loopback (**lo0**) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

6. Uniquely identify a Layer 2 circuit for the Ethernet pseudowire:

```
[edit protocols]
user@host#  set l2circuit neighbor 40.1.1.1 interface ge-0/1/1.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
interfaces {
    ge-0/1/1 {
        encapsulation ethernet-ccc;
        unit 0;
    }
    ge-0/2/0 {
        unit 0 {
            family inet {
                address 20.1.1.2/24;
            }

Pseudowire Overview for ACX Series Universal Metro Routers

A pseudowire is a Layer 2 circuit or service, which emulates the essential attributes of a telecommunications service— such as a T1 line, over an MPLS packet-switched network. The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required degree of faithfulness for the given service definition. On the ACX Series routers, Ethernet, Asynchronous Transfer Mode (ATM), and time-division multiplexing (TDM) pseudowires are supported. The following pseudowire features are supported:

- Pseudowire transport service carrying Layer 1 and Layer 2 information over an IP and MPLS network infrastructure. Only similar end points are supported on the ACX Series—for example, T1 to T1, ATM to ATM, and Ethernet to Ethernet.

- Redundant pseudowires backup connections between PE routers and CE devices, maintaining Layer 2 circuits and services after certain types of failures. Pseudowire redundancy improves the reliability of certain types of networks (metro for example) where a single point of failure could interrupt service for multiple customers. The following pseudowire redundancy features are supported:
  - Maintenance of Layer 2 circuit services after certain types of failures with a standby pseudowire, which backs up the connection between PE routers and CE devices.
  - In case of failure, a protect interface, which backs up the primary interface. Network traffic uses the primary interface only so long as the primary interface functions. If the primary interface fails, traffic is switched to the protect interface.
  - Hot and cold standby enabling swift cut over to the backup or standby pseudowire.
- Ethernet connectivity fault management (CFM), which can be used to monitor the physical link between two routers. The following major features of CFM for Ethernet pseudowires only are supported:
  - Connection protection using the continuity check protocol for fault monitoring. The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
  - Path protection using the linktrace protocol for path discovery and fault verification. Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

Understanding Multisegment Pseudowire for FEC 129

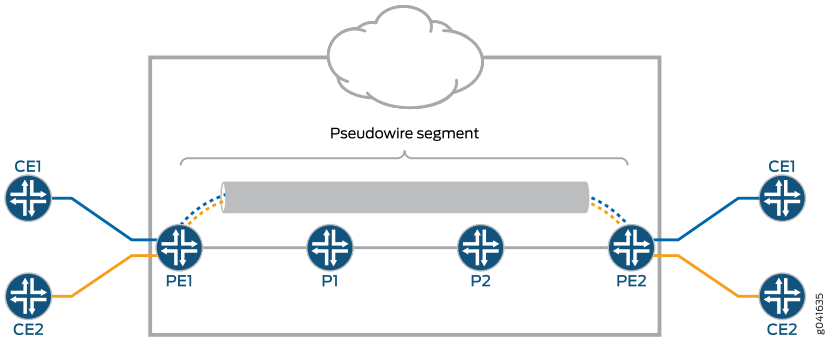
Understanding Multisegment Pseudowire

A pseudowire is a Layer 2 circuit or service that emulates the essential attributes of a telecommunications service, such as a T1 line, over an MPLS packet-switched network (PSN). The pseudowire is intended to provide only the minimum necessary functionality

to emulate the wire with the required resiliency requirements for the given service definition.

When a pseudowire originates and terminates on the edge of the same PSN, the pseudowire label is unchanged between the originating and terminating provider edge (T-PE) devices. This is called a single-segment pseudowire (SS-PW). Figure 62 on page 737 illustrates an SS-PW established between two PE routers. The pseudowires between the PE1 and PE2 routers are located within the same autonomous system (AS).

Figure 62: L2VPN Pseudowire

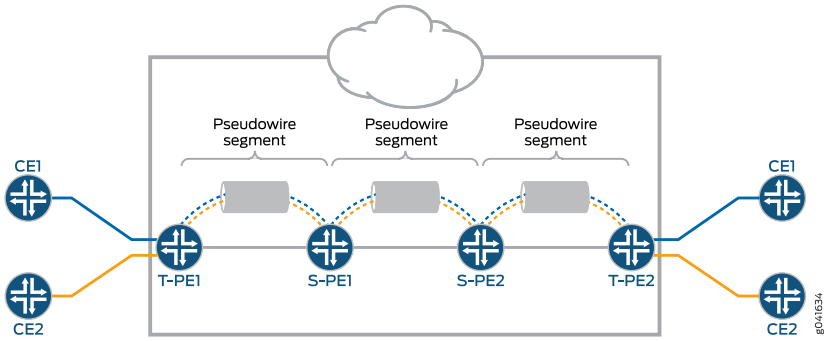


In cases where it is impossible to establish a single pseudowire from a local to a remote PE, either because it is unfeasible or undesirable to establish a single control plane between the two PEs, a multisegment pseudowire (MS-PW) is used.

An MS-PW is a set of two or more contiguous SS-PWs that are made to function as a single point-to-point pseudowire. It is also known as switched pseudowire. MS-PWs can go across different regions or network domains. A region can be considered as an interior gateway protocol (IGP) area or a BGP autonomous system that belongs to the same or different administrative domain. An MS-PW spans multiple cores or ASs of the same or different carrier networks. A Layer 2 VPN MS-PW can include up to 254 pseudowire segments.

Figure 63 on page 738 illustrates a set of two or more pseudowire segments that function as a single pseudowire. The end routers are called terminating PE (T-PE) routers, and the switching routers are called switching PE (S-PE) routers. The S-PE router terminates the tunnels of the preceding and succeeding pseudowire segments in an MS-PW. The S-PE router can switch the control and data planes of the preceding and succeeding pseudowire segments of the MS-PW. An MS-PW is declared to be up when all the single-segment pseudowires are up.

Figure 63: Multisegment Pseudowire



Using FEC 129 for Multisegment Pseudowire

Currently, there are two types of attachment circuit identifiers (AIIs) defined under FEC 129:

- Type 1 AII
- Type 2 AII

The support of an MS-PW for FEC 129 uses type 2 AII. A type 2 AII is globally unique by definition of RFC 5003.

Single-segment pseudowires (SS-PWs) using FEC 129 on an MPLS PSN can use both type 1 and type 2 AII. For an MS-PW using FEC 129, a pseudowire itself is identified as a pair of endpoints. This requires that the pseudowire endpoints be uniquely identified.

In the case of a dynamically placed MS-PW, there is a requirement for the identifiers of attachment circuits to be globally unique, for the purposes of reachability and manageability of the pseudowire. Thus, individual globally unique addresses are allocated to all the attachment circuits and S-PEs that make up an MS-PW.

Type 2 AII is composed of three fields:

- Global_ID—Global identification, which is usually the AS number.
- Prefix—IPv4 address, which is usually the router ID.
- AC_ID—Local attachment circuit, which is a user-configurable value.

Since type 2 AII already contains the T-PE's IP address and it is globally unique, from the FEC 129 pseudowire signaling point of view, the combination (AGI, SAII, TAII) uniquely identifies an MS-PW across all interconnected pseudowire domains.

Establishing a Multisegment Pseudowire Overview

An MS-PW is established by dynamically and automatically selecting the predefined S-PEs and placing the MS-PW between two T-PE devices.

When S-PEs are dynamically selected, each S-PE is automatically discovered and selected using the BGP autodiscovery feature, without the requirement of provisioning the FEC

129 pseudowire-related information on all the S-PEs. BGP is used to propagate pseudowire address information throughout the PSN.

Since there is no manual provisioning of FEC 129 pseudowire information on the S-PEs, the Attachment Group Identifier (AGI) and Attachment Individual Identifier (AII) are reused automatically, and choosing the same set of S-PEs for the pseudowire in both the forwarding and reverse direction is achieved through the active and passive role of each T-PE device.

- Active—The T-PE initiates an LDP label mapping message.
- Passive—The T-PE does not initiate an LDP label mapping message until it receives a label mapping message initiated by the active T-PE. The passive T-PE sends its label mapping message to the same S-PE from where it received the label mapping message originated from its active T-PE. This ensures that the same set of S-PEs are used in the reverse direction.

Pseudowire Status Support for Multisegment Pseudowire

Pseudowire Status Behavior on T-PE

The following pseudowire status messages are relevant on the T-PE:

- 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- 0x00000001—Generic nonforwarding fault code. This is set as the local fault code. The local fault code is set at the local T-PE, and LDP sends a pseudowire status TLV message with the same fault code to the remote T-PE.
- Fault codes are bit-wise OR'ed and stored as remote pseudowire status codes.

Pseudowire Status Behavior on S-PE

The S-PE initiates the pseudowire status messages that indicate the pseudowire faults. The SP-PE in the pseudowire notification message hints where the fault was originated.

- When a local fault is detected by the S-PE, a pseudowire status message is sent in both directions along the pseudowire. Since there are no attachment circuits on an S-PE, only the following status messages are relevant:
  - 0x00000008—Local PSN-facing pseudowire (ingress) receive fault.
  - 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- To indicate which SS-PW is at fault, an LDP SP-PE TLV is attached with the pseudowire status code in the LDP notification message. The pseudowire status is passed along from one pseudowire to another unchanged by the control plane switching function.
- If an S-PE initiates a pseudowire status notification message with one particular pseudowire status bit, then for the pseudowire status code an S-PE receives, the same bit is processed locally and not forwarded until the S-PE's original status error is cleared.

- An S-PE keeps only two pseudowire status codes for each SS-PW it is involved in – local pseudowire status code and remote pseudowire status code. The value of the remote pseudowire status code is the result of logic or operation of the pseudowire status codes in the chain of SS-PWs preceding this segment. This status code is incrementally updated by each S-PE upon receipt and communicated to the next S-PE. The local pseudowire status is generated locally based on its local pseudowire status.
- Only transmit fault is detected at the SP-PE. When there is no MPLS LSP to reach the next segment, a local transmit fault is detected. The transmit fault is sent to the next downstream segment, and the receive fault is sent to the upstream segment.
- Remote failures received on an S-PE are just passed along the MS-PW unchanged. Local failures are sent to both segments of the pseudowire that the S-PE is involved in.

Pseudowire TLV Support for MS-PW

MS-PW provides the following support for the LDP SP-PE TLV [RFC 6073]:

- The LDP SP-PE TLVs for an MS-PW include:
  - Local IP address
  - Remote IP address
- An SP-PE adds the LDP SP-PE TLV to the label mapping message. Each SP-PE appends the local LDP SP-PE TLV to the SP-PE list it received from the other segment.
- The pseudowire status notification message includes the LDP SP-PE TLV when the notification is generated at the SP-PE.

Supported and Unsupported Features

Junos OS supports the following features with MS-PW:

- MPLS PSN for each SS-PW that builds up the MS-PW.
- The same pseudowire encapsulation for each SS-PW in an MS-PW – Ethernet or VLAN-CCC.
- The generalized PWid FEC with T-LDP as an end-to-end pseudowire signaling protocol to set up each SS-PW.
- MP-BGP to autodiscover the two endpoint PEs for each SS-PW associated with the MS-PW.
- Standard MPLS operation to stitch two side-by-side SS-PWs to form an MS-PW.
- Automatic discovery of S-PE so that the MS-PW can be dynamically placed.
- Minimum provisioning of S-PE.
- Operation, administration, and maintenance (OAM) mechanisms, including end-to-end MPLS ping or end-to-any-S-PE MPLS ping, MPLS path trace, end-to-end VCCV, and Bidirectional Forwarding Detection (BFD).
- Pseudowire swithing point (SP) PE TLV for the MS-PW.

- Composite next hop on MS-PW.
- Pseudowire status TLV for MS-PW.

Junos OS does not support the following MS-PW functionality:

- Mix of LDP FEC 128 and LDP FEC 129.
- Static pseudowire where each label is provisioned statically.
- Graceful Routing Engine switchover.
- Nonstop active routing.
- Multihoming.
- Partial connectivity verification (originating from an S-PE) in OAM.

Related Documentation

- Example: Configuring a Multisegment Pseudowire on page 741
- *Example: Configuring FEC 129 BGP Autodiscovery for VPWS*

Example: Configuring a Multisegment Pseudowire

This example shows how to configure a dynamic multisegment pseudowire (MS-PW), where the stitching provider edge (S-PE) devices are automatically and dynamically discovered by BGP, and pseudowires are signaled by LDP using FEC 129. This arrangement requires minimum provisioning on the S-PEs, thereby reducing the configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Packet Transport Routers.
  - Two remote PE devices configured as terminating PEs (T-PEs).
  - Two S-PEs configured as:
    - Route reflectors, in the case of interarea configuration.
    - AS boundary routers or route reflectors, in the case of inter-AS configuration.

- Junos OS Release 13.3 or later running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure LDP.
5. Configure MPLS.

Overview

Starting with Junos OS Release 13.3, you can configure an MS-PW using FEC 129 with LDP signaling and BGP autodiscovery in an MPLS packet-switched network (PSN). The MS-PW feature also provides operation, administration, and management (OAM) capabilities, such as ping, traceroute, and BFD, from the T-PE devices.

To enable autodiscovery of S-PEs in an MS-PW, include the **auto-discovery-mspw** statement at the **[edit protocols bgp group *group-name* family l2vpn]** hierarchy level.

```
family l2vpn {
  auto-discovery-mspw;
}
```

The automatic selection of S-PE and dynamic setting up of an MS-PW rely heavily on BGP. BGP network layer reachability information (NLRI) constructed for the FEC 129 pseudowire to autodiscover the S-PE is called an MS-PW NLRI [draft-ietf-pwe3-dynamic-ms-pw-15.txt]. The MS-PW NLRI is essentially a prefix consisting of a route distinguisher (RD) and FEC 129 source attachment identifier (SAII). It is referred to as a BGP autodiscovery (BGP-AD) route and is encoded as **RD:SAII**.

Only T-PEs that are provisioned with type 2 AIIs initiate their own MS-PW NLRI respectively. Since a type 2 AII is globally unique, an MS-PW NLRI is used to identify a PE device to which the type 2 AII is provisioned. The difference between a type 1 AII and a type 2 AII requires that a new address family indicator (AFI) and subsequent address family identifier (SAFI) be defined in BGP to support an MS-PW. The proposed AFI and SAFI value pair used to identify the MS-PW NLRI is 25 and 6, respectively (pending IANA allocation).

The AFI and SAFI values support autodiscovery of S-PEs and should be configured on both T-PEs that originate the routes, and the S-PEs that participate in the signaling.

Figure 64 on page 743 illustrates an inter-area MS-PW setup between two remote PE routers—T-PE1 and T-PE2. The Provider (P) routers are P1 and P2, and the S-PE routers are S-PE1 and S-PE2. The MS-PW is established between T-PE1 and T-PE2, and all the devices belong to the same AS—AS 100. Since S-PE1 and S-PE2 belong to the same AS, they act as route reflectors and are also known as RR 1 and RR 2, respectively.

Figure 65 on page 743 illustrates an inter-AS MS-PW setup. The MS-PW is established between T-PE1 and T-PE2, where T-PE1, P1, and S-PE1 belong to AS 1, and S-PE2, P2, and T-PE2 belong to AS 2. Since S-PE1 and S-PE2 belong to different ASs, they are configured as ASBR routers and are also known as ASBR 1 and ASBR 2, respectively.

Figure 64: Interarea Multisegment Pseudowire

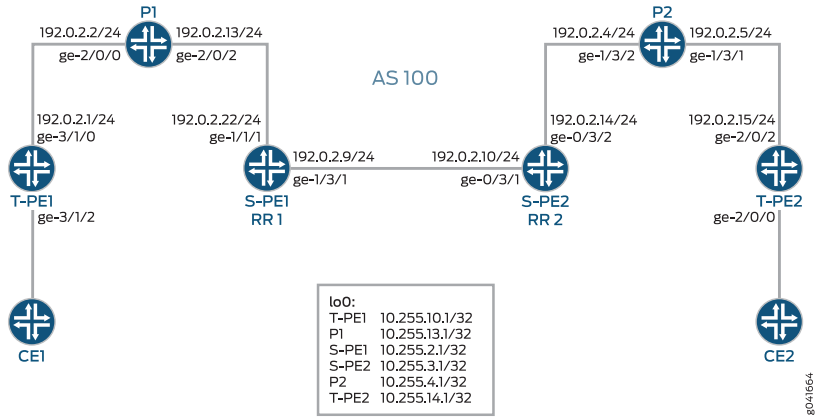


Figure 65: Inter-AS Multisegment Pseudowire

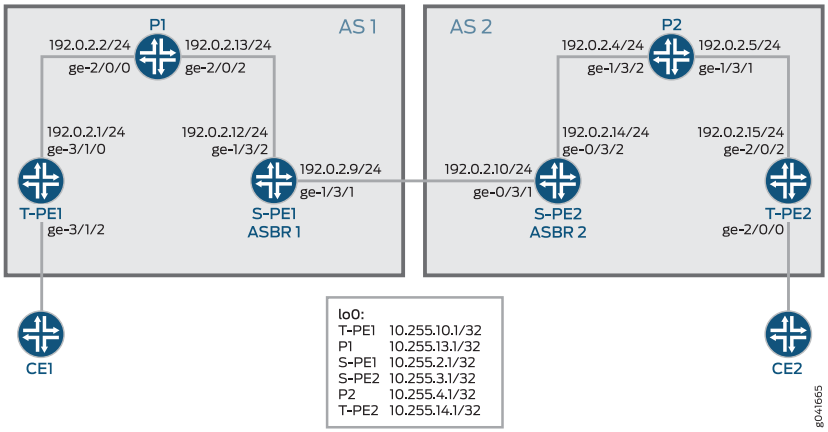

The following sections provide information about how an MS-PW is established in an interarea and inter-AS scenario.

Minimum Configuration Requirements on S-PE

In order to dynamically discover both ends of an SS-PW and set up a T-LDP session dynamically, the following is required:

- For interarea MS-PW, each S-PE plays both an ABR and BGP route reflector role.

  In the interarea case, as seen in Figure 64 on page 743, the S-PE plays a BGP route reflector role and reflects the BGP-AD route to its client. A BGP-AD route advertised by one T-PE eventually reaches its remote T-PE. Because of the next-hop-self set by each S-PE, the S-PE or T-PE that receives a BGP-AD route can always discover the

S-PE that advertises the BGP-AD in its local AS or local area through the BGP next hop.

- For inter-AS MS-PW, each S-PE plays either an ASBR or a BGP route reflector role.

  In an MS-PW, the two T-PEs initiate a BGP-AD route respectively. When the S-PE receives the BGP-AD route through either the IBGP session with the T-PE or through a regular BGP-RR, it sets the next-hop-self before re-advertising the BGP-AD route to one or more of its EBGP peers in the inter-AS case, as seen in Figure 65 on page 743.

- Each S-PE must set next-hop-self when re-advertising or reflecting a BGP-AD route for the MS-PW.

Active and Passive Role of T-PE

To ensure that the same set of S-PEs are being used for a MS-PW in both directions, the two T-PEs play different roles in terms of FEC 129 signaling. This is to avoid different paths being chosen by T-PE1 and T-PE2 when each S-PE is dynamically selected for an MS-PW.

When an MS-PW is signaled using FEC 129, each T-PE might independently start signaling the MS-PW. The signaling procedure can result in an attempt to set up each direction of the MS-PW through different S-PEs.

To avoid this situation, one of the T-PEs must start the pseudowire signaling (active role), while the other waits to receive the LDP label mapping before sending the respective pseudowire LDP label mapping message (passive role). When the MS-PW path is dynamically placed, the active T-PE (the Source T-PE) and the passive T-PE (the Target T-PE) must be identified before signaling is initiated for a given MS-PW. The determination of which T-PE assumes the active role is done based on the SAII value, where the T-PE that has a larger SAII value plays the active role.

In this example, the SAII values of T-PE1 and T-PE 2 are **800:800:800** and **700:700:700**, respectively. Since T-PE1 has a higher SAII value, it assumes the active role and T-PE2 assumes the passive role.

Directions for Establishing an MS-PW

The directions used by the S-PE for setting up the MS-PW are:

- Forwarding direction—From an active T-PE to a passive T-PE.

  In this direction, the S-PEs perform a BGP-AD route lookup to determine the next-hop S-PE to send the label mapping message.

- Reverse direction—From a passive T-PE to an active T-PE.

  In this direction, the S-PEs do not perform a BGP-AD route lookup, because the label mapping messages are received from the T-PEs, and the stitching routes are installed in the S-PEs.

In this example, the MS-PW is established in the forwarding direction from T-PE1 to T-PE2. When the MS-PW is placed from T-PE2 to T-PE1, the MS-PW is established in the reverse direction.

Autodiscovery and Dynamic Selection of S-PE

A new AFI and SAFI value is defined in BGP to support the MS-PWs based on type 2 AII. This new address family supports autodiscovery of S-PEs. This address family must be configured on both the TPEs and SPEs.

It is the responsibility of the Layer 2 VPN component to dynamically select the next S-PE to use along the MS-PW in the forwarding direction.

- In the forwarding direction, the selection of the next S-PE is based on the BGP-AD route advertised by the BGP and pseudowire FEC information sent by the LDP. The BGP-AD route is initiated by the passive T-PE (T-PE2) in the reverse direction while the pseudowire FEC information is sent by LDP from the active T-PE (T-PE1) in the forwarding direction.
- In the reverse direction, the next S-PE (S-PE2) or the active T-PE (T-PE1) is obtained by looking up the S-PE (S-PE1) that it used to set up the pseudowire in the forwarding direction.

Provisioning a T-PE

To support FEC 129 type 2 AII, the T-PE needs to configure its remote T-PE's IP address, a global ID, and an attachment circuit ID. Explicit paths where a set of S-PEs to use is explicitly specified on a T-PE is not supported. This eliminates the need to provision each S-PE with a type 2 AII.

Stitching an MS-PW

An S-PE performs the following MPLS label operations before forwarding the received label mapping message to the next S-PE:

1. Pops the MPLS tunnel label.
2. Pops the VC label.
3. Pushes a new VC label.
4. Pushes an MPLS tunnel label used for the next segment.

Establishing an MS-PW

After completing the necessary configuration, an MS-PW is established in the following manner:

1. The SAII values are exchanged between T-PE1 and T-PE2 using BGP.

   T-PE1 assumes the active T-PE role, because it is configured with a higher SAII value. T-PE2 becomes the passive T-PE.

2. T-PE1 receives the BGP-AD route originated by T-PE2. It compares the AII values obtained from T-PE2 in the received BGP-AD route against the AII values provisioned locally.

3. If the AII values match, T-PE1 performs a BGP-AD route lookup to elect the first S-PE (S-PE1).

4. T-PE1 sends an LDP label mapping message to S-PE1.

5. Using the BGP-AD route originated from T-PE2, and the LDP label mapping message received from T-PE1, S-PE1 selects the next S-PE (S-PE2) in the forwarding direction.

   To do this, S-PE1 compares SAII obtained from the BGP-AD route against the TAI from the LDP label mapping message.

6. If the AII values match, S-PE1 finds S-PE2 through the BGP next hop associated with the BGP-AD route.

7. The process of selecting S-PE goes on until the last S-PE establishes a T-LDP session with T-PE2. When T-PE2 receives the LDP label mapping message from the last S-PE (S-PE2), it initiates its own label mapping message and sends it back to S-PE2.

8. When all the label mapping messages are received on S-PE1 and S-PE2, the S-PEs install the stitching routes. Thus, when the MS-PW is established in the reverse direction, the S-PEs need not perform BGP-AD route lookup to determine its next hop as it did in the forwarding direction.

OAM Support for an MS-PW

After the MS-PW is established, the following OAM capabilities can be executed from the T-PE devices:

- Ping
  - End-to-End Connectivity Verification Between T-PEs

    If T-PE1, S-PEs, and T-PE2 support Control Word (CW), the pseudowire control plane automatically negotiates the use of the CW. Virtual Circuit Connectivity Verification (VCCV) Control Channel (CC) Type 3 will function correctly whether or not the CW is enabled on the pseudowire. However, VCCV Type 1, which is used for end-to-end verification only, is only supported if the CW is enabled.

The following is a sample:

```
user@T-PE1> ping mpls l2vpn fec129 instance instance-name local-id SAII of T-PE1
remote-pe-address address of T-PE2 remote-id TAII of T-PE2
```

or

```
user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface
```

- Partial Connectivity Verification from T-PE to Any S-PE

  To trace part of an MS-PW, the TTL of the pseudowire label can be used to force the VCCV message to pop out at an intermediate node. When the TTL expires, the S-PE can determine that the packet is a VCCV packet either by checking the CW or by checking for a valid IP header with UDP destination port 3502 (if the CW is not in use). The packet should then be diverted to VCCV processing.

  If T-PE1 sends a VCCV message with the TTL of the pseudowire label equal to 1, the TTL expires at the S-PE. T-PE1 can thus verify the first segment of the pseudowire.

  The VCCV packet is built according to RFC 4379. All the information necessary to build the VCCV LSP ping packet is collected by inspecting the S-PE TLVs. This use of the TTL is subject to the caution expressed in RFC 5085. If a penultimate LSR between S-PEs or between an S-PE and a T-PE manipulates the pseudowire label TTL, the VCCV message might not emerge from the MS-PW at the correct S-PE.

  The following is a sample:

  ```
  user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface bottom-label-ttl segment
  ```

  The **bottom-label-ttl** value is 1 for S-PE1 and 2 for S-PE2.

  The **bottom-label-ttl** statement sets the correct VC label TTL, so the packets are popped to the correct SS-PW for VCCV processing.

  

  NOTE: Junos OS supports VCCV Type 1 and Type 3 for the MS-PW OAM capability. VCCV Type 2 is not supported.

- Traceroute

  Traceroute tests each S-PE along the path of the MS-PW in a single operation similar to LSP trace. This operation is able to determine the actual data path of the MS-PW, and is used for dynamically signaled MS-PWs.

  ```
  user@T-PE1> traceroute mpls l2vpn fec129 interface CE1-facing interface
  ```

- Bidirectional Forwarding Detection

  Bidirectional Forwarding Detection (BFD) is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. In addition to fast forwarding path failure detection, BFD provides a consistent failure detection method for network administrators. The router or switch can be configured to log a system log (syslog) message when BFD goes down.

```
user@T-PE1> show bfd session extensive
```

Configuration

Configuring an Interarea MS-PW

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure T-PE1 in the interarea scenario:

NOTE: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```
[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@T-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.10:15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier
  800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0
  target-attachment-identifier 700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection
  minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (RR 1) in the interarea scenario:

NOTE: Repeat this procedure for the S-PE2 (RR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the S-PE1 interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for S-PE1.

```
[edit protocols]
user@S-PE1# set bgp group mspw type internal
```

6. Configure S-PE1 to act as a route reflector.

```
[edit protocols]
user@S-PE1# set bgp group mspw export next-hop-self
user@S-PE1# set bgp group mspw cluster 203.0.113.0
```

7. Assign local and neighbor addresses to the mspw group for S-PE1 to peer with T-PE1 and S-PE2.

```
[edit protocols]
user@S-PE1# set bgp group mspw local-address 10.255.2.1
user@S-PE1# set bgp group mspw neighbor 10.255.10.1 (to T-PE1)
user@S-PE1# set bgp group mspw neighbor 10.255.3.1 (to S-PE2)
```

8. Configure OSPF on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0
```

9. Configure LDP on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

10. Define the policy for enabling next-hop-self and accepting BGP traffic on S-PE1.

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
user@S-PE1# set policy-statement send-inet0 from protocol bgp
user@S-PE1# set policy-statement send-inet0 then accept
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```
user@T-PE1# show interfaces
ge-3/1/0 {
   unit 0 {
      family inet {
         address 192.0.2.1/24;
      }
      family mpls;
   }
}
ge-3/1/2 {
   encapsulation ethernet-ccc;
   unit 0;
}
lo0 {

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the T-PE1 router in the inter-AS scenario:

NOTE: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```
[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@T-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
```

```
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.10:15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier
  800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0
  target-attachment-identifier 700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection
  minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (ASBR 1) in the inter-AS scenario:

NOTE: Repeat this procedure for the S-PE2 (ASBR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure S-PE1 (ASBR 1) interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the IBGP group for S-PE1 (ASBR 1) to peer with T-PE1.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 type internal
```

6. Configure the IBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 local-address 10.255.2.1
user@S-PE1# set bgp group to_T-PE1 export next-hop-self
```

```
user@S-PE1# set bgp group to_T-PE1 neighbor 10.255.10.1
```

7. Configure the EBGP group for S-PE1 (ASBR 1) to peer with S-PE2 (ASBR 2).

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 type external
```

8. Configure the EBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 local-address 10.255.2.1
user@S-PE1# set bgp group to_S-PE2 peer-as 2
user@S-PE1# set bgp group to_S-PE2 neighbor 10.255.3.1 multihop ttl 1
```

9. Configure OSPF on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

10. Configure LDP on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

11. Define the policy for enabling next-hop-self on S-PE1 (ASBR 1).

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```
user@T-PE1# show interfaces
ge-3/1/0 {
   unit 0 {
      family inet {
         address 192.0.2.1/24;
      }
```

```
    family mpls;
  }
}
ge-3/1/2 {
  encapsulation ethernet-ccc;
  unit 0;
}

policy-statement next-hop-self {
    then {
        next-hop self;
    }
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the Routes

Purpose Verify that the expected routes are learned.

Action From operational mode, run the **show route** command for the **bgp.l2vpn.1**, **ldp.l2vpn.1**, **mpls.0**, and **ms-pw.l2vpn.1** routing tables.

From operational mode, run the **show route table bgp.l2vpn.1** command.

```
user@T-PE1> show route table bgp.l2vpn.1

bgp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.10.10:15:700:0.0.2.188:700/160 AD2
                   *[BGP/170] 16:13:11, localpref 100, from 10.255.2.1
                      AS path: 2 I, validation-state: unverified
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

From operational mode, run the **show route table ldp.l2vpn.1** command.

```
user@T-PE1> show route table ldp.l2vpn.1

ldp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2
                   *[LDP/9] 16:21:27
                      Discard
```

From operational mode, run the **show route table mpls.0** command.

```
user@T-PE1> show route table mpls.0

mpls.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
0                  *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
1                  *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
2                  *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
13                 *[MPLS/0] 1w6d 00:28:26, metric 1
                      Receive
299920             *[LDP/9] 1w5d 01:26:08, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Pop
299920(S=0)        *[LDP/9] 1w5d 01:26:08, metric 1
                    > to 203.0.113.2 via ge-3/1/0.0, Pop

ge-3/1/2.0         *[L2VPN/7] 16:22:33, metric2 1
                   > to 203.0.113.2 via ge-3/1/0.0, Push 300176, Push 300016(top)
 Offset: 252
```

From operational mode, run the **show route table ms-pw.l2vpn.1** command.

```
user@T-PE1> show route table ms-pw.l2vpn.1
```

```
ms-pw.l2vpn.1: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.10.10:15:700:0.0.2.188:700/160 AD2
                   *[BGP/170] 16:23:27, localpref 100, from 10.255.2.1
                      AS path: 2 I, validation-state: unverified
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300016
10.10.10.10:15:800:0.0.3.32:800/160 AD2
                   *[L2VPN/170] 1w5d 23:25:19, metric2 1
                      Indirect
10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2

                   *[LDP/9] 16:23:25
                      Discard
10.255.2.1:CtrlWord:5:100:15:800:0.0.3.32:800:700:0.0.2.188:700/304 PW2

                   *[L2VPN/7] 16:23:27, metric2 1
                    > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

Meaning The output shows all the learned routes, including the autodiscovery (AD) routes.

The AD2 prefix format is **RD:SAII-type2**, where:

- **RD** is the route distinguisher value.
- **SAII-type2** is the type 2 source attachment identifier value.

The PW2 prefix format is **Neighbor_Addr:C:PWtype:l2vpn-id:SAII-type2:TAII-type2**, where:

- **Neighbor_Addr** is the loopback address of neighboring S-PE device.
- **C** indicates if Control Word (CW) is enabled or not.
  - **C** is **CtrlWord** if CW is set.
  - **C** is **NoCtrlWord** if CW is not set.
- **PWtype** indicates the type of the pseudowire.
  - **PWtype** is **4** if it is in Ethernet tagged mode.
  - **PWtype** is **5** if it is Ethernet only.
- **l2vpn-id** is the Layer 2 VPN ID for the MS-PW routing instance.
- **SAII-type2** is the type 2 source attachment identifier value.
- **TAII-type2** is the type 2 target attachment identifier value.

Verifying the LDP Database

Purpose Verify the MS-PW labels received by T-PE1 from S-PE1 and sent from T-PE1 to S-PE1.

Action From operational mode, run the **show ldp database** command.

```
user@T-PE1> show ldp database
Input label database, 10.255.10.1:0--10.255.2.1:0
  Label     Prefix
      3      10.255.2.1/32
 300112      10.255.3.1/32
 300128      10.255.4.1/32
 299968      10.255.10.1/32
 299904      10.255.13.1/32

- **Remote PE**—Check if the T-PE1 loopback address is listed.
- **Negotiated PW status TLV**—Ensure that the value is **Yes**.
- **Pseudowire Switching Points**—Check if the switching points are listed from S-PE2 to S-PE1 and from S-PE1 to T-PE1.

Meaning MS-PW is established between T-PE1 and T-PE2 in the reverse direction.

Troubleshooting

To troubleshoot the MS-PW connection, see:

- Ping on page 784
- Bidirectional Forwarding Detection on page 785
- Traceroute on page 785

Ping

Problem How to check the connectivity between the T-PE devices and between a T-PE device and an intermediary device.

Solution Verify that T-PE1 can ping T-PE2. The **ping mpls l2vpn fec129** command accepts SAIs and TAIs as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters (**instance**, **local-id**, **remote-id**, **remote-pe-address**).

Checking Connectivity Between T-PE1 and T-PE2

```
user@T-PE1> ping mpls l2vpn fec129 instance FEC129-VPWS local-id 800:800:800
remote-pe-address 10.255.14.1 remote-id 700:700:700
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Checking Connectivity Between T-PE1 and S-PE2

```
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2 bottom-label-ttl 2
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Bidirectional Forwarding Detection

Problem How to use BFD to troubleshoot the MS-PW connection from the T-PE device.

Solution From operational mode, verify the **show bfd session extensive** command output.

```
user@T-PE1> show bfd session extensive

                                                Detect   Transmit

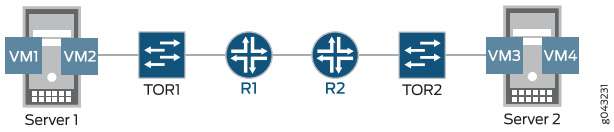
MPLS Stitching For Virtual Machine Connection

By using MPLS, the stitching feature of Junos OS provides connectivity between virtual machines that reside either on opposite sides of data center routers or in different data centers. An external controller, programmed in the data-plane, assigns MPLS labels to both virtual machines and servers. Then, the signaled MPLS labels are used between the data center routers, generating static link switched paths (LSPs), resolved over either BGP labeled unicast, RSVP or LDP, to provide the routes dictated by the labels.

When Would I Use Stitching?

There are several ways to connect virtual machines. One option when you have virtual machines on opposite sides of a router (or different data centers) is to use MPLS stitching. A typical topology for using MPLS stitching is shown in Figure 66 on page 786.

Figure 66: Virtual Machines on Either Side of Routers



The above topology consists of the following MPLS layers: VMs | Servers | ToRs | Router ..... Router | ToRs | Servers | VMs

NOTE: The label on the left is the top of the label stack.

How Does MPLS Stitching Work?

With stitching, the MPLS static allocation of labels demultiplexes incoming traffic onto any device/entity in the next layer in the direction of traffic flow. Essentially, there is a label hierarchy that picks up labels for the correct top-of-rack switch, server, and virtual machine that receives traffic. Static label assignments are done between the top-of-rack switches and the virtual machines.

For example, imagine that traffic is sent from VM1 to VM3 in Figure 66 on page 786. When traffic exits Server1, its label stack is L1 | L2 | L3 where:

- L1 represents the egress top-of-rack switch ToR1.
- L2 represents the physical server, Server2, towards which the egress-side ToR will forward the traffic.
- L3: represents the virtual machine on Server2 to which the Server2 should deliver the traffic.

Traffic arriving at ToR1 needs to be sent to ToR2. Since ToR1 and ToR2 are not directly connected, traffic must flow from ToR1 to ToR2 using label-switching starting on the outermost (top) label. Stitching has been added to static-LSP functionality to SWAP L1 to a l-BGP label that ToR2 advertises to ToR1. The label stack now must contain another label at the top to enable forwarding of the labeled packets between ToR1 and ToR2. An L-Top label is added if L-BGP is resolved over RSVP/LDP. If static LSP is resolved over L-BGP, then the top label is swapped with the L-BGP label and there is no L-Top label. When the traffic exits ToR1, the stack is: L-top | L-BGP | L2 | L3.

Traffic from ToR1 to ToR2 is then label switched over any signaled LSP.

When traffic arrives at ToR2, the top label is removed with PHP (popped) and the label stack becomes L-BGP | L2 | L3. Since L-BGP is a implicit null label, ToR2 pops the static LSP label L2 that corresponds to the egress server and then forwards the packet to the egress server using the static-LSP configuration on ToR2, which corresponds to a single-hop implicit-NULL LSP.

The outgoing stack becomes L3 and the next-hop is the egress server Server2.

When traffic arrives at the egress server Server2, Server2 pops L3 and delivers the packet to VM3.

How Do I Configure Stitching?

The new keyword **stitch** has been added under **transit** to resolve the remote next-hop. For example, instead of **set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 next-hop 10.9.82.47**, a top-of-rack switch redirects packets to another top-of-rack switch with **set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 stitch**. The show mpls static-lsp command has been extended to show the LSP state as 'InProgress' whenever the LSP is waiting for protocol next-hop resolution by resolver.

See the complete example for stitching at *Using MPLS Stitching with BGP to Connect Virtual Machines* for more information.

Which Switches Support Stitching?

See Feature Explorer for the list of switches that support the MPLS Stitching For Virtual Machine Connections feature.

Q&A

Q: Is link and node protection for the next-hop provided by MPLS stitching?
A: Link and node protection for the next-hop of transit LSP stitched to L-BGP LSP are not needed. That is provided by L-BGP LSP.

TDM Pseudowires Overview

A TDM pseudowire acts as Layer 2 circuit or service for T1 and E1 circuit signals across an MPLS packet-switched network. On ACX Series routers, you configure a TDM pseudowire with Structure-Agnostic Time Division Multiplexing (TDM) over Packet (SAToP) on the ACX Series built-in channelized T1 and E1 interfaces. When you configure a TDM pseudowire, the network between the customer edge (CE) routers appears transparent to the CE routers, making it seem that the CE routers are directly connected. With the SAToP configuration on the provider edge (PE) router's T1 and E1 interfaces, the interworking function (IWF) forms a payload (frame) that contains the CE router's T1 and E1 Layer 1 data and control word. This data is transported to the remote PE over the pseudowire. The remote PE removes all the Layer 2 and MPLS headers added in the network cloud and forwards the control word and the Layer 1 data to the remote IWF, which in turn forwards the data to the remote CE router.

- Ethernet Pseudowire Overview on page 731

Example: TDM Pseudowire Base Configuration

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router
- Junos OS Release 12.2 or later

Overview of a TDM Pseudowire Base Configuration

The configuration shown here is the base configuration of an TDM pseudowire with T1 framing on an ACX Series router. This configuration is for one provider edge router. To complete the TDM pseudowire configuration, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an TDM Pseudowire

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [**edit**] hierarchy level:

```
set chassis fpc 0 pic 0 framing t1
set interfaces ct1-0/0/0 no-partition interface-type t1
set interfaces t1-0/0/0 encapsulation satop
set interfaces t1-0/0/0 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
set protocols mpls no-cspf
set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id
 1
```

NOTE: To configure a TDM pseudowire with E1 framing, include the e1 statement at the [edit chassis fpc 0 pic 0 framing] hierarchy level instead of the t1 statement shown in this example.

Step-by-Step Procedure

1. Configure the framing format:

```
[edit]
user@host# edit chassis
[edit chassis]
user@host# set fpc 0 pic 0 framing t1
```

2. Create a T1 interface on a channelized T1 interface (**ct1**) and enable full channelization with the **no-partition** statement. On the logical T1 interface, set the Structure-Agnostic TDM over Packet (SAToP) encapsulation mode.

```
[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ct1-0/0/0 no-partition interface-type t1
user@host# set t1-0/0/0 encapsulation satop
user@host# set t1-0/0/0 unit 0
```

3. Create a Gigabit Ethernet interface and enable MPLS on that interface. Create the loopback (**lo0**) interface:

```
[edit interfaces]
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

4. Enable the MPLS and RSVP protocols on the MPLS interface—**ge-0/2/0.0**:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

5. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set ldp interface ge-0/2/0.0
user@host# set ldp interface lo0.0
```

6. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

7. Configure OSPF and enable traffic engineering on the MPLS interface—**ge-0/2/0.0**, and on the loopback (**lo0**) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Uniquely identify a Layer 2 circuit for the TDM pseudowire:

```
[edit protocols]
user@host#  set l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
chassis {
    fpc 0 {
        pic 0 {
            framing t1;
        }
    }
}
interfaces {
    ct1-0/0/0 {
        no-partition interface-type t1;
    }
    t1-0/0/0 {
        encapsulation satop;
        unit 0;
    }
    ge-0/2/0 {
        unit 0 {
            family inet {
                address 20.1.1.2/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 70.1.1.1/32;
            }
        }
    }
}
protocols {
    rsvp {
        interface ge-0/2/0.0;
    }
    mpls {
        no-cspf;
        label-switched-path PE1-to-PE2 {
            to 40.1.1.1;
        }
        interface ge-0/2/0.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ge-0/2/0.0;
            interface lo0.0 {
                passive;
            }
        }
    }
    ldp {
        interface ge-0/2/0.0;
        interface lo0.0;
```

```
    }
    l2circuit {
        neighbor 40.1.1.1 {
            interface t1-0/0/0.0 {
                virtual-circuit-id 1;
            }
        }
    }
}
```

Configuring Load Balancing for Ethernet Pseudowires

You can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

NOTE: This feature is supported only on M120, M320, MX Series, and T Series routers.

To configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires, include the **ether-pseudowire** statement at the **[edit forwarding-options hash-key family mpls payload]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ether-pseudowire;
    }
  }
}
```

NOTE: You must also configure either the **label-1** or the **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

You can also configure load balancing for Ethernet pseudowires based on IP information. This functionality provides support for load balancing for Ethernet cross-circuit connect (CCC) connections. To include IP information in the hash key, include the **ip** statement at the **[edit forwarding-options hash-key family mpls payload]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ip;
    }
  }
}
```

NOTE: You must also configure either the **label-1** or **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

You can configure load balancing for IPv4 traffic over Ethernet pseudowires to include only Layer 3 IP information in the hash key. To include only Layer 3 IP information, include the **layer-3-only** option at the **[edit forwarding-options family mpls hash-key payload ip]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ip {
        layer-3-only;
      }
    }
  }
}
```

NOTE: You must also configure either the **label-1** or **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

Configuring Load Balancing Based on MAC Addresses

The hash key mechanism for load-balancing uses Layer 2 media access control (MAC) information such as frame source and destination address. To load-balance traffic based on Layer 2 MAC information, include the **family multiservice** statement at the **[edit forwarding-options hash-key]** hierarchy level:

```
family multiservice {
  destination-mac;
  source-mac;
}
```

To include the destination-address MAC information in the hash key, include the **destination-mac** option. To include the source-address MAC information in the hash key, include the **source-mac** option.

NOTE: Any packets that have the same source and destination address will be sent over the same path.

NOTE: You can configure per-packet load balancing to optimize VPLS traffic flows across multiple paths.

NOTE: Aggregated Ethernet member links will now use the physical MAC address as the source MAC address in 802.3ah OAM packets.

NOTE: ACX Series routers do not support VPLS.

CHAPTER 24

Configuring Class-of-Service (CoS) for MPLS

Configuring Class of Service for MPLS LSPs

The following sections provide an overview of MPLS class of service (CoS) and describe how to configure the MPLS CoS value:

Class of Service for MPLS Overview

When IP traffic enters an LSP tunnel, the ingress router marks all packets with a CoS value, which is used to place the traffic into a transmission priority queue. On the router, for SDH/SONET and T3 interfaces, each interface has four transmit queues. The CoS value is encoded as part of the MPLS header and remains in the packets until the MPLS header is removed when the packets exit from the egress router. The routers within the

LSP utilize the CoS value set at the ingress router. The CoS value is encoded by means of the CoS bits (also known as the EXP or experimental bits). For more information, see "MPLS Label Allocation" on page 329.

MPLS class of service works in conjunction with the router's general CoS functionality. If you do not configure any CoS features, the default general CoS settings are used. For MPLS class of service, you might want to prioritize how the transmit queues are serviced by configuring weighted round-robin, and to configure congestion avoidance using random early detection (RED)..

Configuring the MPLS CoS Values

When traffic enters an LSP tunnel, the CoS value in the MPLS header is set in one of three ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. *Default MPLS EXP Classifier* explains the default MPLS CoS values, and summarizes how the CoS values are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.
- You set an MPLS EXP rewrite rule to override the default behavior.

To set a fixed CoS value on all packets entering the LSP, include the **class-of-service** statement:

```
class-of-service cos-value;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit protocols mpls label-switched-path *path-name*]**
- **[edit protocols mpls label-switched-path *path-name* primary *path-name*]**
- **[edit protocols mpls label-switched-path *path-name* secondary *path-name*]**
- **[edit protocols rsvp interface *interface-name* link-protection]**
- **[edit protocols rsvp interface *interface-name* link-protection bypass *destination*]**
- **[edit logical-systems *logical-system-name* protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* primary *path-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* secondary *path-name*]**

- **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]**
- **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *destination*]**

The CoS value set using the **class-of-service** statement at the **[edit protocols mpls]** hierarchy level supersedes the CoS value set at the **[edit class-of-service]** hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

The **class-of-service** statement at the **[edit protocols mpls label-switched-path]** hierarchy level assigns an initial EXP value for the MPLS shim header of packets in the LSP. This value is initialized at the ingress routing device only and overrides the rewrite configuration established for that forwarding class. However, the CoS processing (weighted round robin [WRR] and RED) of packets entering the ingress routing device is not changed by the **class-of-service** statement on an MPLS LSP. Classification is still based on the behavior aggregate (BA) classifier at the **[edit class-of-service]** hierarchy level or the multifield classifier at the **[edit firewall]** hierarchy level.

BEST PRACTICE: We recommend configuring all routing devices along the LSP to have the same input classifier for EXP, and, if a rewrite rule is configured, all routing devices should have the same rewrite configuration. Otherwise, traffic at the next LSR might be classified into a different forwarding class, resulting in a different EXP value being written to the EXP header.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that RED will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see *Managing Congestion Using RED Drop Profiles and Packet Loss Priorities*.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 25 on page 798 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in *Understanding How Forwarding Classes Assign Classes to Output Queues*.

Table 25: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only as they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

To configure class of service (CoS) for Multiprotocol Label Switching (MPLS) packets in a label-switched path (LSP):

1. Specify the CoS value

   If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value

For Ethernet interfaces installed on a T Series router or an M320 router with a peer connection to an M Series router or a T Series router, you can rewrite both MPLS CoS and IEEE 802.1p values to a configured value (the MPLS CoS values are also known as the EXP or experimental bits). Rewriting these values allows you to pass the configured value to the Layer 2 VLAN path. To rewrite both the MPLS CoS and IEEE 802.1p values, you must include the EXP and IEEE 802.1p rewrite rules in the class of service interface configuration. The EXP rewrite table is applied when you configure the IEEE 802.1p and EXP rewrite rules.

For information about how to configure the EXP and IEEE 802.1p rewrite rules, see *Rewriting Packet Headers to Ensure Forwarding Behavior*.

Related Documentation

- *Default MPLS EXP Classifier*

Configuring MPLS Rewrite Rules

You can apply a number of different rewrite rules to MPLS packets.

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

The following sections describe how you can apply rewrite rules to MPLS packets:

Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

In interprovider, carrier-of-carrier, and complex traffic engineering scenarios, it is sometimes necessary to push three labels on the next hop.

By default, on M Series routers except the M320, the top MPLS EXP label of an outgoing packet is not rewritten when you configure swap-push-push and triple-push operations. You can rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining the class of service (CoS) of an incoming MPLS or non-MPLS packet.

To push three labels on incoming MPLS packets, include the **exp-swap-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-swap-push-push default;
```

To push three labels on incoming non-MPLS packets, include the **exp-push-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-push-push-push default;
```

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Rewriting MPLS and IPv4 Packet Headers

You can apply a rewrite rule to MPLS and IPv4 packet headers simultaneously. This allows you to initialize MPLS EXP and IP precedence bits at LSP ingress. You can configure different rewrite rules depending on whether the traffic is VPN or non-VPN.

To rewrite MPLS and IPv4 packet headers, include the **protocol** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules exp *rewrite-rule-name*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp
  rewrite-rule-name]
protocol types;
```

Use the **protocol** statement to specify the types of MPLS packets and packet headers to which to apply the rewrite rule. The MPLS packet can be a standard MPLS packet or an MPLS packet with an IPv4 payload. Specify the type of MPLS packet by using the following options:

- **mpls-any**—Applies the rewrite rule to MPLS packets and writes the code point value to MPLS headers.
- **mpls-inet-both**—Applies the rewrite rule to VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series (except T4000 routers) and M320 routers. On M Series routers, except the M320, the **mpls-inet-both** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.
- **mpls-inet-both-non-vpn**—Applies the rewrite rule to any non-VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series and M320 routers. On M Series routers, except the M320, the **mpls-inet-both-non-vpn** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.

For a detailed example on how to configure rewrite rules for MPLS and IPv4 packets and for more information about how to configure class of service, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Configuring CoS Bits for an MPLS Network (CLI Procedure)

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Junos OS Class of Service Configuration Guide* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: **The CoS value set using the class-of-service statement at the [edit protocols mpls] hierarchy level supersedes the CoS value set at the [edit class-of-service] hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.**

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS (CLI Procedure)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using IP Over MPLS.

This task describes how to create a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE switch. It includes configuring a policer firewall filter and applying it to the customer-edge interface of the ingress PE switch. The policer firewall filter

ensures that the amount of traffic forwarded through the MPLS tunnel never exceeds the requested bandwidth allocation.

Before you begin, configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)" on page 77.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

This topic includes:

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

   ```
   [edit class-of-service]
   user@switch# set classifiers dscp classifier-name import default
   ```

2. Add a forwarding class to this custom DSCP classifier and specify a loss priority and code point:

   ```
   [edit class-of-service]
   user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class
   loss-priority loss-priority code-points code-point
   ```

3. Specify the values for the custom EXP rewrite rule, **e1**:

   ```
   [edit class-of-service]
   user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority
   loss-priority code-points code-point
   ```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

   ```
   [edit class-of-service]
   user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
   ```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the customer-edge-interface:

```
[edit firewall]
user@switch# set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
user@switch# set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
user@switch# set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family inet filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the customer-edge interface:

```
[edit interfaces]
user@switch# set ge-2/0/3 unit 0 family inet address 192.168.121.1/16 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect (CLI Procedure)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using MPLS over circuit-cross connect (CCC).

NOTE: On EX Series switches other than EX8200 switches, if you are using MPLS over CCC, you can use only one DSCP or IP precedence classifier and only one IEEE 802.1p classifier on the CCC interfaces.

This procedure is for creating a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE. It also includes enabling a policer on the label-switched path (LSP) of the ingress PE to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This topic includes:

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

   ```
   [edit class-of-service]
   user@switch# set classifiers dscp classifier-nameimport default
   ```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

   ```
   [edit class-of-service]
   user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class
   loss-priority loss-priority code-points code-point
   ```

3. Specify the values for the custom EXP rewrite rule, **e1**:

   ```
   [edit class-of-service]
   user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority
   loss-priority code-point code-point
   ```

4. Bind the DSCP classifier to the CCC interface:

   ```
   [edit ]
   user@switch# set class-of-service interfaces interface unit unit classifier classifier-name
   ```

5. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the policer, which will later be applied to the LSP:

   ```
   [edit firewall]
   set policer mypolicer if-exceeding bandwidth-limit 500m
   ```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

   ```
   [edit firewall policer]
   set mypolicer if-exceeding burst-size-limit 33553920
   ```

3. Discard traffic that exceeds the rate limits for this policer:

   ```
   [edit firewall policer]
   set mypolicer then discard
   ```

4. To reference the policer, configure a filter term that includes the policer action:

   ```
   [edit firewall]
   user@switch# set family any filter myfilter term t1 then policer mypolicer
   ```

5. Apply the filter to the LSP:

   ```
   [edit protocols mpls]
   set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
   ```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Configuring CoS on Provider Switches of an MPLS Network (CLI Procedure)

You can add class-of-service (CoS) components to your MPLS networks on EX Series switches to achieve end-to-end Differentiated Services to match your specific business requirements. The configuration of CoS components on the provider switches is the same regardless of whether the provider edge (PE) switches are using MPLS over CCC or IP over MPLS.

This task shows how to configure a custom EXP classifier and custom EXP rewrite rule on the provider switch.

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

   ```
   [edit class-of-service]
   user@switch# set classifiers exp exp1 import default
   ```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

   ```
   [edit class-of-service]
   user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority
   low code-points 010
   ```

3. Specify the values for the custom EXP rewrite rule, **e1**:

   ```
   [edit class-of-service]
   user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority
   low code-point 111
   ```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

   ```
   [edit class-of-service]
   user@switch# set class-of-service interfaces ge-0/0/2 unit 0 rewrite-rules exp e1
   ```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Understanding Using CoS with MPLS Networks on EX Series Switches

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. See *EX Series Switch Software Features Overview* for a complete list of the Junos OS MPLS features that are supported on specific EX Series switches.

Juniper Networks EX Series Ethernet Switches support Differentiated Service Code Point (DSCP) or IP precedence and IEEE 802.1p CoS classifiers on the customer-edge interfaces of the ingress provider edge (PE) switch. DSCP or IP precedence classifiers are used for Layer 3 packets. IEEE 802.1p is used for Layer 2 packets.

When a packet enters a customer-edge interface of the ingress PE switch, the switch associates the packet with a particular CoS servicing level before putting the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch. The CoS value that was embedded in the classifier is translated and encoded in the MPLS header by means of the EXP or experimental bits. EX Series switches enable a default EXP classifier and a default EXP rewrite rule. For more information about EXP classifiers and EXP rewrite rules, see EXP Classifiers and EXP rewrite Rules.

This topic includes:

EXP Classifiers and EXP rewrite Rules

EX Series switches enable a default EXP classifier and a default EXP rewrite rule. You can configure a custom EXP classifier and a custom EXP rewrite rule if you prefer. However, the switch supports only one type of EXP classifier (default or custom) and only one EXP rewrite rule (default or custom).

You do not bind the EXP classifier or the EXP rewrite rule to individual interfaces. The switch automatically and implicitly applies the default or the custom EXP classifier and the default or the custom EXP rewrite rule to the appropriate MPLS-enabled interfaces. Because rewrite rules affect only egress interfaces, the switch applies the EXP rewrite rule only to those MPLS interfaces that are transmitting MPLS packets (not to the MPLS interfaces that are receiving the packets).

After traversing the MPLS tunnel, the traffic flows out from the egress provider edge (PE) switch. Before the traffic leaves the egress interface, the egress PE switch copies the EXP bits from the MPLS header to the most significant bits in the original IP packet---

that is, to the IP precedence bits. Note that this is the default behavior only on Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis) that are configured for MPLS.

Guidelines for Using CoS Classifiers on CCCs

When you are configuring CoS for MPLS over circuit cross-connect (CCC), there are some additional guidelines, as follows:

- You *must* explicitly bind a CoS classifier to the CCC interface on the ingress PE switch.
- You *must* use the same DSCP, IP precedence, or IEEE 802.1p classifier on CCC interfaces. However, if the CCC interfaces are on the same switch, you cannot configure both a DSCP and an IP precedence classifier on these interfaces. Thus, if you configure one CCC interface to use a DSCP classifier DSCP1, you cannot configure another CCC interface to use another DSCP classifier DSCP2. All the CCC interfaces on the switch must use the same DSCP (or IP precedence) classifier and the same IEEE 802.1p classifier.
- You *cannot* configure one CCC interface to use a DSCP classifier and another CCC interface to use an IP precedence classifier, because these classifier types overlap.
- You *can* configure one CCC interface to use a DSCP classifier and another CCC interface to use IEEE 802.1p classifier.
- You *can* configure one CCC interface to use both a DSCP and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the DSCP classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.
- You *can* configure one CCC interface to use both an IP precedence and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the IP precedence classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.

NOTE: **These guidelines are not applicable to Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis).**

You can define multiple DSCP, IP precedence, and IEEE 802.1p classifiers for the non-CCC interfaces on a switch.

Using CoS Classifiers with IP over MPLS

When you are configuring CoS for IP over MPLS, the customer-edge interface uses the CoS configuration for the switch as the default. You do not have to bind a classifier to the customer-edge interface in this case. There are no restrictions on using multiple DSCP, IP precedence, and IEEE 802.1p classifiers on the same switch.

- You can modify the CoS classifier for a particular interface, but it is not required.

- You can configure a DSCP classifier, DSCP1 on the first interface, another DSCP classifier, DSCP2 on the second interface, and an IP precedence classifier on a third interface, and so forth.

Setting CoS Bits in an MPLS Header

When traffic enters an LSP tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service Feature Guide for Routing Devices and EX9200 Switches* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that random early detection (RED) will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

NOTE: **Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.**

Table 25 on page 798 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Table 26: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set

Table 26: MPLS CoS Values (continued)

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only while they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

NOTE: On EX8200 switches that run MPLS-based Layer 2 virtual private networks (VPNs):

- If you configure an LSP CoS, the EXP bits of the MPLS packet continue to use the same CoS values that are configured at the interface level.
- For Virtual Chassis, if the input and output interfaces are on different line cards, then the loss priority value that you configured on the first line card is not carried to the subsequent line cards. The loss priority for the outgoing traffic from the subsequent line cards is always set to low.

EXP Rewrite Rules

When traffic passes from the customer-edge interface to an MPLS interface, the DSCP, IP precedence, or IEEE 802.1p CoS classifier is translated into the EXP bits within the MPLS header. You cannot disable the default EXP rewrite rule, but you can configure your own custom EXP classifier and a custom EXP rewrite rule. You cannot bind the EXP classifier to individual MPLS interfaces; the switch applies it globally to all the MPLS-enabled interfaces on the switch.

Only one EXP rewrite rule (either default or custom) is supported on a switch. The switch applies it to all the egress interfaces on which MPLS is enabled.. This is, however, not the case with EX8200 switches. With EX8200 switches, you must explicitly apply the rewrite rule on each of the egress interfaces.

Policer

Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. During periods of congestion (when the total rate of queuing packets exceeds the rate of transmission), any new packets being sent to an interface can be dropped because there is no place to store them. You can configure a policer on the ingress PE switch to prevent this:

- If you are using MPLS over CCC, you bind the policer to the LSP. You cannot bind a policer to a CCC interface.
- If you are using IP over MPLS, you bind the policer to the **inet-family** customer-edge interface. You cannot bind a policer to the LSP when you are using IP over MPLS.

NOTE: You cannot configure LSP policers on EX8200 switches.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on EX Series switches. Default schedulers are provided for best-effort and network-control forwarding classes. If you are using assured-forwarding, expedited-forwarding, or any custom forwarding class, we recommend that you configure a scheduler to support that forwarding class. See *Understanding CoS Schedulers*.

- Configuring CoS on Provider Switches of an MPLS Network (CLI Procedure) on page 806

  Configuring CoS Bits for an MPLS Network (CLI Procedure) on page 801

Example: Combining CoS with MPLS on EX Series Switches

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. The CoS value is included within the MPLS label, which is passed through the network, enabling end-to-end CoS across the network.

MPLS services are often used to ensure better performance for low-latency applications such as VoIP and other business-critical functions. These applications place specific demands on a network for successful transmission. CoS gives you the ability to control the mix of bandwidth, delay, jitter, and packet loss while taking advantage of the MPLS labeling mechanism.

This example shows how to configure CoS on an MPLS network that is using a unidirectional circuit cross-connect (CCC) from the ingress provider edge (PE) switch to the egress PE switch. for the customer-edge interface of the ingress provider edge (PE) switch. It describes adding the configuration of CoS components to the ingress PE switch, the egress PE switch, and the core provider switches of the existing MPLS network.

Because of the unidirectional configuration, the DSCP classifier needs to be configured only on the ingress PE switch.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for EX Series switches
- Three EX Series switches

Before you configure CoS with MPLS, be sure you have:

Configured an MPLS network with two PE switches and one provider switch. See "Example: Configuring MPLS on EX8200 and EX4500 Switches" on page 48. This example assumes that an MPLS network has been configured using a cross circuit-connect (CCC).

Overview and Topology

This example describes adding custom classifiers and custom rewrite rules to switches in an MPLS network that is using MPLS over CCC.

It is a unidirectional configuration. Therefore, you need to configure custom classifiers and custom rewrite rules as follows:

- On the ingress PE switch: custom DSCP classifier and custom EXP rewrite rule
- On the egress PE switch: custom EXP classifier
- On the provider switch: customer EXP classifier and custom EXP rewrite rule

NOTE: You can also configure schedulers and shapers as needed. If you are using **assured-forwarding**, **expedited-forwarding**, or other custom forwarding classes, we recommend that you configure a scheduler to support that forwarding class. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

The example creates a custom DSCP classifier (**dscp1**) on the ingress PE switch and binds this classifier to the CCC interface. It includes configuration of a policer on the ingress PE switch. The policer is applied as a filter on the label-switched path (LSP) **lsp_to_pe2_ge1**(created in "Example: Configuring MPLS on EX8200 and EX4500 Switches" on page 48) to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This example creates a custom EXP rewrite rule (**exp1**) on the ingress PE switch, specifying a loss-priority and code point to be used for the expedited-forwarding class as the packet travels through the LSP. The switch applies this custom rewrite rule on the core interfaces **ge-0/0/5.0** and **ge-0/0/6.0**, which are the egress interfaces for this switch.

Table 27 on page 813 shows the CoS configuration components added to the ingress PE switch.

Table 27: CoS Configuration Components on the Ingress PE Switch

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Policing filter configured and applied to the LSP.	**policing filter mypolicer** **filter myfilter**	Name of the rate-limiting policer. Name of the filter, which refers to the policer
Custom DSCP classifier	**dscp1**	Specifies the name of the custom DSCP classifier
Custom EXP rewrite rule	**e1**	Name of the custom EXP rewrite rule.
Customer-edge interface	**ge-0/0/1.0**	Interface that receives packets from devices outside the network. The custom DSCP classifier must be specified on this CCC interface.
Core interfaces	**ge-0/0/5.0** and **ge-0/0/6.0**	Interfaces that transmit MPLS packets to other switches within the MPLS network. The EXP rewrite rule is applied implicitly to these interfaces.

Table 28 on page 813 shows the CoS configuration components added to the egress PE switch in this example.

Table 28: CoS Configuration Components of the Egress PE Switch

Property	Settings	Description
Remote provider edge switch hardware	EX Series switch	PE-2
Custom EXP classifier	**exp1**	Name of custom EXP classifier
Customer-edge interface	**ge-0/0/1.0**	Interface that transmits packets from this network to devices outside the network. No CoS classifier is specified for this interface. A scheduler can be specified.

Table 28: CoS Configuration Components of the Egress PE Switch (continued)

Property	Settings	Description
Core interfaces	**ge-0/0/7.0** and **ge-0/0/8.0**	Core interfaces on PE-2 that receive MPLS packets from the provider switch. The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.

Table 29 on page 814 shows the MPLS configuration components used for the provider switch in this example.

Table 29: CoS Configuration Components of the Provider Switch

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Custom EXP classifier	**exp1**	Name of the custom EXP classifier.
Custom EXP rewrite rule	**e1**	Name of the custom EXP rewrite rule.
Core interfaces receiving packets from other MPLS switches.	**ge-0/0/5.0** and **ge-0/0/6.0**	Interfaces that connect the provider switch to the ingress PE switch (PE-1). The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.
Core interfaces transmitting packets to other switches within the MPLS network.	**ge-0/0/7.0** and **ge-0/0/8.0**	Interfaces that transmit packets to the egress PE (PE-2). The EXP rewrite rule is applied implicitly on these interfaces. Schedulers can also be specified and will be applied to these interfaces.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the local PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]
set class-of-service classifiers dscp dscp1 import default
set class-of-service classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority low code-points 000111
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low code-point 111
set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
set firewall policer mypolicer if-exceeding bandwidth-limit 500m
set firewall policer mypolicer if-exceeding burst-size-limit 33553920
set firewall policer mypolicer then discard
set firewall family any filter myfilter term t1 then policer mypolicer
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3 policing filter myfilter
```

Step-by-Step Procedure

To configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the ingress PE switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority
low code-points 000111
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch#  set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority
low code-point 111
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit ]
user@switch#  set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
```

5. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

6. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

7. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

8. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch#  set family any filter myfilter term t1 then policer mypolicer
```

9. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

Results Display the results of the configuration:

```
  [edit]
   user@switch# show
class-of-service {
  classifiers {
    dscp dscp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 000111;
      }
    }
  }
  interfaces {
    ge-0/0/1 {
      unit 0 {
        classifiers {
          dscp dscp1;
        }
      }
    }
  }
rewrite-rules {
  exp e1 {
    forwarding-class expedited-forwarding {
      loss-priority low code-point 111;
    }
  }
  }
}
firewall {
  family any {
    filter myfilter {
      term t1 {
        then policer mypolicer;
      }
    }
  }
  policer mypolicer {
    if-exceeding {
      bandwidth-limit 500m;
      burst-size-limit 33553920;
    }
    then discard;
  }
}
```

Configuring the Remote PE Switch

CLI Quick Configuration To quickly configure a custom EXP classifier on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
set class-of-service classifiers exp exp1 import default
```

```
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Step-by-Step Procedure

To configure a custom EXP classifier on the egress PE switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

   ```
   [edit class-of-service]
   user@switch# set classifiers exp exp1 import default
   ```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

   ```
   [edit class-of-service]
   user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority
   low code-points 010
   ```

Results

Display the results of the configuration:

```
  [edit]
   user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 010;
      }
    }
```

Configuring the Provider Switch

CLI Quick Configuration

To quickly configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch, copy the following commands and paste them into the switch terminal window of the provider switch:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Step-by-Step Procedure

To configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

   ```
   [edit class-of-service]
   ```

```
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low code-point 111
```

Results Display the results of the configuration:

```
[edit]
 user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 010;
      }
    }
  }
  rewrite-rules {
    exp e1 {
      forwarding-class expedited-forwarding {
        loss-priority low code-point 111;
      }
    }
  }
}
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying That the Policer Firewall Filter Is Operational on page 818
- Verifying That the CoS Classifiers Are Going to the Right Queue on page 819
- Verifying the CoS Forwarding Table Mapping on page 823
- Verifying the Rewrite Rules on page 823

Verifying That the Policer Firewall Filter Is Operational

Purpose Verify the operational state of the policer that is configured on the ingress PE switch.

Action `user@switch>` **show firewall**

```
Filter: myfilter
Policers:
Name                                                Packets
mypolicer-t1                                              0
```

Meaning This output shows that the firewall filter **mypolicer** has been created.

Verifying That the CoS Classifiers Are Going to the Right Queue

Purpose Verify that the CoS classifiers are going to the right queue.

Action `user@switch>` **show class-of-service forwarding-table classifier**

```
Classifier table index: 7, # entries: 64, Table type: DSCP
Entry #   Code point   Forwarding-class #   PLP
   0        000000        0       0
   1        000001        0       0
   2        000010        0       0
   3        000011        0       0
   4        000100        0       0
   5        000101        0       0
   6        000110        0       0
   7        000111        0       0
   8        001000        0       0
   9        001001        0       0
  10        001010        0       0
  11        001011        0       0
  12        001100        0       0
  13        001101        0       0
  14        001110        0       0
  15        001111        0       0
  16        010000        0       0
  17        010001        0       0
  18        010010        0       0
  19        010011        0       0
  20        010100        0       0
  21        010101        0       0
  22        010110        0       0
  23        010111        0       0
  24        011000        0       0
  25        011001        0       0
  26        011010        0       0

48          110000          3          0
49          110001          3          0
50          110010          3          0
51          110011          3          0
52          110100          3          0
53          110101          3          0
54          110110          3          0
55          110111          3          0
56          111000          3          0
57          111001          3          0
58          111010          3          0
59          111011          3          0
60          111100          3          0
61          111101          3          0
62          111110          3          0
63          111111          3          0
```

Meaning This output shows that a new DSCP classifier has been created, index **9346**, on the ingress PE switch (PE-1).

Verifying the CoS Forwarding Table Mapping

Purpose For each logical interface, display either the table index of the classifier for a given code point type or the queue number (if it is a fixed classification) in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table classifier mapping

                        Table Index/
Interface      Index       Q num      Table type
ge-0/0/1.0        92        9346      DSCP
```

Meaning The results show that the new DSCP classifier, index number **9346**, is bound to interface **ge-0/0/1.0**.

Verifying the Rewrite Rules

Purpose Display mapping of the queue number and loss priority to code point value for each rewrite rule as it exists in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table rewrite-rule

Rewrite table index: 31, # entries: 4, Table type: DSCP
FC#     Low bits  State      High bits  State
0       000000  Enabled       000000  Enabled
1       101110  Enabled       101110  Enabled
2       001010  Enabled       001100  Enabled
3       110000  Enabled       111000  Enabled

Rewrite table index: 34, # entries: 4, Table type: IEEE 802.1
FC#     Low bits  State      High bits  State
0          000  Enabled          001  Enabled
1          010  Enabled          011  Enabled
2          100  Enabled          101  Enabled
3          110  Enabled          111  Enabled

Rewrite table index: 35, # entries: 4, Table type: IPv4 precedence
FC#     Low bits  State      High bits  State
0          000  Enabled          000  Enabled
1          101  Enabled          101  Enabled
2          001  Enabled          001  Enabled
3          110  Enabled          111  Enabled

Rewrite table index: 9281, # entries: 1, Table type: EXP
FC#     Low bits  State      High bits  State
1          111  Enabled          000  Disabled
```

Meaning This output shows that a new EXP classifier with the index number **9281** has been created.

Understanding CoS MPLS EXP Classifiers and Rewrite Rules

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion by applying packet classifiers and rewrite rules to the MPLS traffic. MPLS classifiers are global and apply to all interfaces configured as **family mpls** interfaces.

When a packet enters a customer-edge interface on the ingress provider edge (PE) switch, the switch associates the packet with a particular CoS servicing level before placing the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch to determine the CoS service level. The CoS value embedded in the classifier is translated and encoded in the MPLS header by means of the experimental (EXP) bits.

EXP classifiers map incoming MPLS packets to a forwarding class and a loss priority, and assign MPLS packets to output queues based on the forwarding class mapping. EXP classifiers are behavior aggregate (BA) classifiers.

EXP rewrite rules change (rewrite) the CoS value of the EXP bits in outgoing packets on the egress queues of the switch so that the new (rewritten) value matches the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

NOTE: On QFX5200, QFX5100, QFX3500, QF3600, and EX4600 switches, and on QFabric systems, there is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global EXP classifier applies to all MPLS traffic on interfaces configured as **family mpls**.

On QFX10000 switches, there is a no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure EXP classifiers and apply them to logical interfaces configured as **family mpls**. (You cannot apply classifiers to physical interfaces.). You can configure up to 64 EXP classifiers.

There is no default EXP rewrite rule. If you want to rewrite the EXP bit value at the egress interface, you must configure EXP rewrite rules and apply them to logical interfaces.

EXP classifiers and rewrite rules are applied only to interfaces that are configured as **family mpls** (for example, **set interfaces xe-0/0/35 unit 0 family mpls**.)

This topic includes:

EXP Classifiers

On QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, unlike DSCP and IEEE 802.1p BA classifiers, EXP classifiers are global to the switch and apply to all switch interfaces that are configured as **family mpls**. On QFX10000 switches, you apply EXP classifiers to individual logical interfaces, and different interfaces can use different EXP classifiers.

When you configure and apply an EXP classifier, MPLS traffic on all **family mpls** interfaces uses the EXP classifier, even on interfaces that also have a fixed classifier. If an interface has both an EXP classifier and a fixed classifier, the EXP classifier is applied to MPLS traffic and the fixed classifier is applied to all other traffic.

Also unlike DSCP and IEEE 802.1p BA classifiers, there is no default EXP classifier. If you want to classify MPLS traffic based on the EXP bits, you must explicitly configure an EXP classifier and apply it to the switch interfaces. Each EXP classifier has eight entries that correspond to the eight EXP CoS values (0 through 7, which correspond to CoS bits 000 through 111).

You can configure up to 64 EXP classifiers.

However, on QFX5200, QFX5100, EX4600, and legacy CLI switches, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure that classifier as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy level. All switch interfaces configured as **family mpls** use the global EXP classifier to classify MPLS traffic.

On these switches, only one EXP classifier can be configured as the global EXP classifier at any time. If you want to change the global EXP classifier, delete the global EXP classifier configuration (use the **user@switch# delete class-of-service system-defaults classifiers exp** configuration statement), then configure the new global EXP classifier.

QFX10000 switches do not support global EXP classifiers. You can configure one EXP classifier and apply it to multiple logical interfaces, or configure multiple EXP classifiers and apply different EXP classifiers to different logical interfaces.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. (Switches that have a default EXP classifier use the default classifier.) If no EXP classifier and no fixed classifier are applied to the interface, MPLS traffic is treated as best-effort traffic using the 802.1 default untrusted classifier. DSCP classifiers are not applied to MPLS traffic.

On QFX5200, QFX5100, EX4600, and legacy CLI switches, because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier.

NOTE: The switch uses only the outermost label of incoming EXP packets for classification.

NOTE: MPLS packets with 802.1Q tags are not supported.

EXP Rewrite Rules

As MPLS packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. EXP rewrite rules set the value of the EXP CoS bits within the header of the outgoing MPLS packet on **family mpls** interfaces. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table, and writes that CoS value into the packet header, replacing the old CoS value. EXP rewrite rules apply only to MPLS traffic.

EXP rewrite rules apply only to logical interfaces. You cannot apply EXP rewrite rules to physical interfaces.

There are no default EXP rewrite rules. If you want to rewrite the EXP value in MPLS packets, you must configure EXP rewrite rules and apply them to logical interfaces. If no rewrite rules are applied, all MPLS labels that are pushed have a value of zero (0). The EXP value remains unchanged on MPLS labels that are swapped.

You can configure up to 64 EXP rewrite rules, but you can only apply 16 EXP rewrite rules at any time on the switch. On a given logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

You can apply an EXP rewrite rule to an interface that has a DSCP, DSCP IPv6, or IEEE 802.1p rewrite rule. Only MPLS traffic uses the EXP rewrite rule. MPLS traffic does not use DSCP or DSCP IPv6 rewrite rules.

If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on the switch. Default schedulers are provided only for the best-effort, fcoe, no-loss, and network-control default forwarding classes. If you configure a custom forwarding class for MPLS traffic, you need to configure a scheduler to support that forwarding class and provide bandwidth to that forwarding class.

Related Documentation

- *Understanding Applying CoS Classifiers and Rewrite Rules to Interfaces*

Configuring Rewrite Rules for MPLS EXP Classifiers

You configure EXP rewrite rules to alter CoS values in outgoing MPLS packets on the outbound **family mpls** interfaces of a switch to match the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

To configure an EXP CoS rewrite rule, create the rule by giving it a name and associating it with a forwarding class, loss priority, and code point. This creates a rewrite table. After the rewrite rule is created, enable it on a logical **family mpls** interface. EXP rewrite rules can only be enabled on logical **family mpls** interfaces, not on physical interfaces or on interfaces of other family types. You can also apply an existing EXP rewrite rule on a logical interface.

NOTE: There are no default rewrite rules.

You can configure up to 64 EXP rewrite rules, but you can only use 16 EXP rewrite rules at any time on the switch. On a given **family mpls** logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

NOTE: To replace an existing rewrite rule on the interface with a new rewrite rule of the same type, first explicitly remove the existing rewrite rule and then apply the new rule.

To create an EXP rewrite rule for MPLS traffic and enable it on a logical interface:

1. Create an EXP rewrite rule:

```
user@switch# set class-of-service rewrite-rules exp rewrite-rule-name forwarding-class
forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

For example, to configure an EXP rewrite rule named **exp-rr-1** for a forwarding class named **mpls-1** with a loss priority of **low** that rewrites the EXP code point value to **001**:

```
user@switch# set class-of-service rewrite-rules exp exp-rr-1 forwarding-class mpls-1
loss-priority low code-points 001
```

2. Apply the rewrite rule to a logical interface:

```
user@switch # set class-of-service interfaces interface-name unit logical-unit rewrite-rules
exp rewrite-rule-name
```

For example, to apply a rewrite rule named **exp-rr-1** to logical interface **xe-0/0/10.0**:

```
user@switch# set class-of-service interfaces xe-0/0/10 unit 0 rewrite-rules exp exp-rr-1
```

NOTE: In this example, all forwarding classes assigned to port xe-0/0/10 must have rewrite rules. Do not mix forwarding classes that have rewrite rules with forwarding classes that do not have rewrite rules on the same interface.

Configuring CoS Bits for an MPLS Network

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service Feature Guide for Routing Devices and EX9200 Switches* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: **The CoS value set using the class-of-service statement at the [edit protocols mpls] hierarchy level supersedes the CoS value set at the [edit class-of-service] hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.**

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

Configuring a Global MPLS EXP Classifier

EXP packet classification associates incoming packets with a particular MPLS CoS servicing level. EXP behavior aggregate (BA) classifiers examine the MPLS EXP value in the packet header to determine the CoS settings applied to the packet. EXP BA classifiers allow you to set the forwarding class and loss priority of an MPLS packet based on the incoming CoS value.

You can configure up to 64 EXP classifiers, however, the switch uses only one MPLS EXP classifier as a global classifier, which is applied only on interfaces configured as **family mpls**. All **family mpls** switch interfaces use the global EXP classifier to classify MPLS traffic.

There is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global classifier applies to all MPLS traffic on all **family mpls** interfaces.

If a global EXP classifier is configured, MPLS traffic on **family mpls** interfaces uses the EXP classifier. If a global EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

To configure an MPLS EXP classifier using the CLI:

1. Create an EXP classifier and associate it with a forwarding class, a loss priority, and a code point:

   ```
   [edit class-of-service classifiers]
   user@switch# set (dscp | ieee-802.1 | exp) classifier-name forwarding-class
   forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
   ```

2. Apply the EXP classifier to the switch interfaces:

   ```
   [edit class-of-service]
   user@switch# set system-defaults classifiers exp classifier-name
   ```

CHAPTER 25

Configuring Generalized MPLS (GMPLS)

Introduction to GMPLS

Traditional MPLS is designed to carry Layer 3 IP traffic using established IP-based paths and associating these paths with arbitrarily assigned labels. These labels can be configured explicitly by a network administrator, or can be dynamically assigned by means of a protocol such as LDP or RSVP.

GMPLS generalizes MPLS in that it defines labels for switching varying types of Layer 1, Layer 2, or Layer 3 traffic. GMPLS nodes can have links with one or more of the following switching capabilities:

- Fiber-switched capable (FSC)
- Lambda-switched capable (LSC)

- Time-division multiplexing (TDM) switched-capable (TSC)
- Packet-switched capable (PSC)

Label-switched paths (LSPs) must start and end on links with the same switching capability. For example, routers can establish packet-switched LSPs with other routers. The LSPs might be carried over a TDM-switched LSP between SONET add/drop multiplexers (ADMs), which in turn might be carried over a lambda-switched LSP.

The result of this extension of the MPLS protocol is an expansion in the number of devices that can participate in label switching. Lower-layer devices, such as OXCs and SONET ADMs, can now participate in GMPLS signaling and set up paths to transfer data. A router can participate in signaling optical paths across a transport network.

Two service models determine the visibility that a client node (a router, for example) has into the optical core or transport network. The first is through a user-to-network interface (UNI), which is often referred to as the overlay model. The second is known as the peer model. Juniper Networks supports both models.

NOTE: **There is not necessarily a one-to-one correspondence between a physical interface and a GMPLS interface. If a GMPLS connection uses a nonchannelized physical connector, the GMPLS label can use the physical port ID. However, the label for channelized interfaces often is based on a channel or time slot. Consequently, it is best to refer to GMPLS labels as identifiers for a resource on a traffic engineering link.**

To establish LSPs, GMPLS uses the following mechanisms:

- An out-of-band control channel and a data channel—RSVP messages for LSP setup are sent over an out-of-band control network. Once the LSP setup is complete and the path is provisioned, the data channel is up and can be used to carry traffic. The Link Management Protocol (LMP) is used to define and manage the data channels between a pair of nodes. You can optionally use LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- RSVP-TE extensions for GMPLS—RSVP-TE is already designed to signal the setup of packet LSPs. This has been extended for GMPLS to be able to request path setup for various kinds of LSPs (nonpacket) and request labels like wavelengths, time slots, and fibers as label objects.
- Bidirectional LSPs—Data can travel both ways between GMPLS devices over a single path, so nonpacket LSPs are signaled to be bidirectional.

GMPLS Terms and Acronyms

F

Forwarding adjacency A forwarding path for sending data between GMPLS-enabled devices.

G

Generalized MPLS (GMPLS) An extension to MPLS that allows data from multiple layers to be switched over label-switched paths (LSPs). GMPLS LSP connections are possible between similar Layer 1, Layer 2, and Layer 3 devices.

GMPLS label Layer 3 identifiers, fiber port, time-division multiplexing (TDM) time slot, or dense wavelength-division multiplexing (DWDM) wavelength of a GMPLS-enabled device used as a next-hop identifier.

GMPLS LSP types The four types of GMPLS LSPs are:

- Fiber-switched capable (FSC)—LSPs are switched between two fiber-based devices, such optical cross-connects (OXCs) that operate at the level of individual fibers.
- Lambda-switched capable (LSC)—LSPs are switched between two DWDM devices, such as such as OXCs that operate at the level of individual wavelengths.
- TDM-switched capable (TDM)—LSPs are switched between two TDM devices, such as SONET ADMs.
- Packet-switched capable (PSC)—LSPs are switched between two packet-based devices, such as routers or ATM switches.

L

Link Management Protocol A protocol used to define a forwarding adjacency between peers and to maintain and allocate resources on the traffic engineering links.

T

Traffic engineering link A logical connection between GMPLS-enabled devices. Traffic engineering links can have addresses or IDs and are associated with certain resources or interfaces. They also have certain attributes (encoding-type, switching capability, bandwidth, and so on). The logical addresses can be routable, although this is not required because they are acting as link identifiers. Each traffic engineering link represents a forwarding adjacency between a pair of devices.

Supported GMPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for Generalized MPLS (GMPLS).

- RFC 3471, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Functional Description*

  Only the following features are supported:

  - Bidirectional LSPs (upstream label only)
  - Control channel separation
  - Generalized label (suggested label only)
  - Generalized label request (bandwidth encoding only)

- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions*

  Only Section 9, "Fault Handling," is supported.

- RFC 4202, *Routing Extensions in Support of Generalized Multi-Protocol Label Switching*

  Only interface switching is supported.

- RFC 4206, *Label Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*

- Internet draft draft-ietf-ccamp-gmpls-rsvp-te-ason-02.txt, *Generalized MPLS (GMPLS) RSVP-TE Signalling in support of Automatically Switched Optical Network (ASON)* (expires January 2005)

- Internet draft draft-ietf-ccamp-gmpls-sonet-sdh-08.txt, *Generalized Multi-Protocol Label Switching Extensions for SONET and SDH Control*

  Only S,U,K,L,M-format labels and SONET traffic parameters are supported.

- Internet draft draft-ietf-ccamp-lmp-10.txt, *Link Management Protocol (LMP)*

- Internet draft draft-ietf-ccamp-ospf-gmpls-extensions-12.txt, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching*

  The following sub-TLV types for the Link type, link, value (TLV) are not supported:

  - Link Local/Remote Identifiers (type 11)
  - Link Protection Type (type 14)
  - Shared Risk Link Group (SRLG) (type 16)

  The features described in Section 2 of the draft, "Implications on Graceful Restart," are also not supported.

  The Interface Switching Capability Descriptor (type 15) sub-TLV type is implemented, but only for packet switching.

- Internet draft draft-ietf-mpls-bundle-04.txt, *Link Bundling in MPLS Traffic Engineering*

- *Accessing Standards Documents on the Internet*

GMPLS Operation

The basic functionality of GMPLS requires close interaction between RSVP and LMP. It works in the following sequence:

1. LMP notifies RSVP of the new entities:
   - Traffic engineering link (forwarding adjacency)

- Resources available for the traffic engineering link
- Control peer

2. GMPLS extracts the LSP attributes from the configuration and requests RSVP to signal one or more specific paths, which are specified by the traffic engineering link addresses.
3. RSVP determines the local traffic engineering link, corresponding control adjacency and active control channel, and transmission parameters (such as IP destination). It requests that LMP allocate a resource from the traffic engineering link with the specified attributes. If LMP finds a resource matching the attributes, label allocation succeeds. RSVP sends a PathMsg hop by hop until it reaches the target router.
4. When the target router receives the PathMsg, RSVP again requests that LMP allocate a resource based on the signaled parameters. If label allocation succeeds, the router sends back a ResvMsg.
5. If the signaling is successful, a bidirectional optical path is provisioned.

GMPLS and OSPF

You can configure OSPF for GMPLS. OSPF is an interior gateway protocol (IGP) that routes packets within a single autonomous system (AS). OSPF uses link-state information to make routing decisions.

GMPLS and CSPF

GMPLS introduces extra constraints for computing paths for GMPLS LSPs that use CSPF. These additional constraints affect the following link attributes:

- Signal type (minimum LSP bandwidth)
- Encoding type
- Switching type

These new constraints are populated in the traffic engineering database with the exchange of an interface-switching capability descriptor type, length, value (TLV) through an IGP.

The ignored constraints that are exchanged through the interface switching capability descriptor include:

- Maximum LSP bandwidth
- Maximum transmission unit (MTU)

The CSPF path computation is the same as in non-GMPLS environments, except that the links are also limited by GMPLS constraints.

Each link can have multiple interface-switching capability descriptors. All the descriptors are checked before a link is rejected.

The constraints are checked in the following order:

1. The signal type configured for the GMPLS LSP signifies the amount of bandwidth requested. If the desired bandwidth is less than the minimum LSP bandwidth, the interface-switching descriptor is rejected.
2. The encoding type of the link for the ingress and the egress interfaces should match. The encoding type is selected and stored at the ingress node after all the constraints are satisfied by the link and is used to select the link on the egress node.
3. The switching type of the links of the intermediate switches should match that of the GMPLS LSP specified in the configuration.

GMPLS Features

The Junos OS includes the following GMPLS functionality:

- An out-of-band control plane makes it possible to signal LSP path setup.
- RSVP-TE extensions support additional objects beyond Layer 3 packets, such as ports, time slots, and wavelengths.
- The LMP protocol creates and maintains a database of traffic engineering links and peer information. Only the static version of this protocol is supported in the Junos OS. You can optionally configure LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- Bidirectional LSPs are required between devices.
- Several GMPLS label types that are defined in RFC 3471, *Generalized MPLS—Signaling Functional Description*, such as MPLS, Generalized, SONET/SDH, Suggested, and Upstream, are supported. Generalized labels do not contain a type field, because the nodes should know from the context of their connection what type of label to expect.
- Traffic parameters facilitate GMPLS bandwidth encoding and SONET/SDH formatting.
- Other supported attributes include interface identification and errored interface identification, user-to-network (UNI)-style signaling, and secondary LSP paths.

LMP Configuration Overview

You need to configure the Link Management Protocol (LMP) to define the data channel connection and the control channel connection between devices. Include the following statements at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
peer peer-name {
   address address;
   control-channel control-channel-name;
   lmp-control-channel control-channel-interface {
      remote-address ip-address;
   }
   lmp-protocol {
```

```
    hello-dead-interval milliseconds;
    hello-interval milliseconds;
    retransmission-interval milliseconds;
    retry-limit number;
    passive;
  }
  te-link te-link-name;
}
te-link te-link-name {
  disable;
  interface interface-name {
    disable;
    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
  }
  label-switched-path lsp-name;
  local-address ip-address;
  remote-address ip-address;
  remote-id id-number;
}
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

NOTE: Although you can include GMPLS configuration statements at the **[edit logical-systems *logical-system-name*]** hierarchy level, GMPLS is not supported on logical systems.

For information about configuring LMP, see the following sections:

- Configuring LMP Traffic Engineering Links on page 839
- Configuring LMP Peers on page 841
- Configuring RSVP and OSPF for LMP Peer Interfaces on page 846
- Configuring MPLS Paths for GMPLS on page 848
- Tracing LMP Traffic on page 848

Configuring LMP Traffic Engineering Links

An LMP traffic engineering link acts as a data channel connection between GMPLS devices.

To configure a traffic engineering link, include the **te-link** statement at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
te-link te-link-name {
```

```
    disable;
    interface interface-name {
      local-address ip-address;
      remote-address ip-address;
      remote-id id-number;
    }
    label-switched-path lsp-name;
    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
}
```

Complete the procedures in the following sections to configure an LMP traffic engineering link:

- Configuring the Local IP Address for Traffic Engineering Links on page 840
- Configuring the Remote IP Address for Traffic Engineering Links on page 840
- Configuring the Remote ID for Traffic Engineering Links on page 841

When you configure a traffic engineering link that contains interfaces for an LMP peer, you must also configure a control channel. However, no control channel is required for a traffic engineering link that contains an LSP. For information about configuring control channels, see "Configuring LMP Peers" on page 841.

Configuring the Local IP Address for Traffic Engineering Links

Use the **local-address** statement to configure the local IP address associated with the traffic engineering link.

We recommend that you configure an IP address subnet for your traffic engineering link addresses that is different from the subnet configured for your physical interfaces. This configuration enables you to identify which addresses are physical and which addresses belong to the traffic engineering link.

To configure the local IP address for the traffic engineering link, include the **local-address** statement:

```
te-link te-link-name {
  interface interface-name {
    local-address ip-address;
  }
  local-address ip-address;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the Remote IP Address for Traffic Engineering Links

You need to specify the address of the remote end of the data channel for each traffic engineering link. Use the **remote-address** statement to configure the remote IP address.

We recommend that you configure an IP address subnet for your traffic engineering link addresses that is different from the subnet configured for your physical interfaces. This enables you to identify which addresses are physical and which addresses belong to the traffic engineering link.

To configure the remote IP address for the traffic engineering link, include the **remote-address** statement:

```
te-link te-link-name {
  interface interface-name {
    remote-address ip-address;
  }
  remote-address ip-address;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the Remote ID for Traffic Engineering Links

The local ID for the traffic engineering link is automatically assigned by LMP. The port identifier and labels for the interfaces (resources) in the traffic engineering link are also assigned automatically. However, you need to explicitly configure the remote ID for the traffic engineering link and the remote ID traffic engineering link interface. The remote ID for the interface must be based on the post-ID assignment of the peer node. The remote IDs are needed for static mapping of remote labels to local labels.

Before you can obtain the remote IDs for the traffic engineering link and traffic engineering link interface on the peer node, you must first configure the LMP peer, as described in "Configuring LMP Peers" on page 841. Once you have configured the LMP peer, you can obtain the traffic engineering link local ID and interface local ID by issuing the **show link-management te-link** command. Once you have these IDs, you can configure them as the remote IDs on the peer node.

To configure the remote ID for a traffic engineering link and for the traffic engineering link interface, include the **remote-id** statement:

```
te-link te-link-name {
  interface interface-name {
    remote-id id-number;
  }
  remote-id id-number;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring LMP Peers

You need to configure network peers for GMPLS. A peer is a network device that your router communicates with when setting up the control and data channels. The peer is often an optical cross-connect (OXC).

To configure an LMP peer name, include the **peer** statement at the **[edit protocols link-management]** hierarchy level:

```
peer peer-name {
  address ip-address;
  control-channel control-channel-interface;
  lmp-control-channel control-channel-interface {
    remote-address ip-address;
  }
  lmp-protocol {
    hello-dead-interval milliseconds;
    hello-interval milliseconds;
    retransmission-interval milliseconds;
    retry-limit number;
    passive;
  }
  te-link te-link-name;
}
```

The following sections describe how to configure an LMP peer:

Configuring the ID for LMP Peers

To configure the LMP peer ID, include the **address** statement at the **[edit protocols link-management peer *peer-name*]** hierarchy level. The default value for the LMP peer ID is the loopback address.

```
[edit protocols link-management peer peer-name]
address ip-address;
```

Configuring the Interface for Control Channels Between LMP Peers

You must configure one or more control channels between the LMP peers. The control channels must travel across either a point-to-point link or a tunnel.

To configure the interface for the control channel, include the **control-channel** statement at the **[edit protocols link-management peer *peer-name*]** hierarchy level:

```
[edit protocols link-management peer peer-name]
```

```
control-channel [ interface-names ];
```

You can configure a generic routing encapsulation (GRE) interface (gre-x/y/z) for the control channel. This type of interface does not require a Tunnel PIC.

NOTE: You can configure GRE interfaces (gre-x/y/z) only for GMPLS control channels. GRE interfaces are not supported or configurable for other applications. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring the LMP Control Channel Interface for the Peer

In an environment that uses LMP to establish and maintain an LMP control channel between peers, you can configure a number of attributes associated with LMP. To configure the interface to be associated with the LMP control channel for the peer, include the **lmp-control-channel** statement:

```
lmp-control-channel control-channel-interface;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols link-management** peer *peer-name***]**
- **[edit logical-systems** *logical-system-name* **protocols link-management** peer *peer-name***]**

You can configure a GRE interface for the LMP control channel. This type of interface does not require a Tunnel PIC.

NOTE: You can configure GRE interfaces only for GMPLS control channels. GRE interfaces are not supported or configurable for other applications. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

When this LMP control channel interface comes up, the peers use LMP to negotiate channel parameters and configure the control channel.

The local peer repeatedly sends a Config message to the remote peer. The Config message contains the local control channel ID, the local peer's node ID, a message ID, and a CONFIG object that includes hello message attributes (the hello interval and the hello dead interval).

The channel is activated when the remote peer responds with a ConfigAck message. The remote peer does so only when its own configured hello interval and hello dead interval match the values in the received Config message or the default values. If these values do not match, the remote peer responds with a ConfigNack message. The local peer logs this event and resends the Config message until the message retry limit is reached. When the message retry limit is reached, the local peer logs that event and restarts the configuration process.

Configuring the Remote IP Address for LMP Control Channels

You need to specify the address of the remote end of the LMP control channel.

To configure the remote IP address for the LMP control channel, include the **remote-address** statement:

```
remote-address address;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols link-management** peer ***peer-name*** lmp-control-channel ***control-channel-interface*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols link-management** peer ***peer-name*** lmp-control-channel ***control-channel-interface*****]**

Configuring Hello Message Intervals for LMP Control Channels

Hello messages are exchanged between LMP peers to maintain the control channel after LMP has activated the control channel. The LMP control channel is considered to be up only when the hello negotiation is successful. Successful negotiation consists of the local peer sending a hello message to the remote peer and receiving a hello message in response.

The LMP peers continue to exchange hello messages after the LMP control channel is up in order to maintain the channel.

The hello interval specifies the interval between periodic hello messages. The hello dead interval specifies how long the local peer waits for a hello response before it declares the LMP control channel to be down. When the channel goes down, the local peer restarts the LMP control channel negotiation and configuration process.

You can specify a hello interval from 150 through 300,000 milliseconds. The default hello interval is 150 milliseconds.

You can specify a hello dead interval from 500 through 300,000 milliseconds. The default hello dead interval is 500 milliseconds.

To configure the attributes for hello messages exchanged between LMP peers, include the **hello-interval** and **hello-dead-interval** statements:

```
hello-dead-interval milliseconds;
hello-interval milliseconds;
```

You can configure these statements at the following hierarchy levels:

- **[edit protocols link-management** peer ***peer-name*** lmp-protocol**]**
- **[edit logical-systems** ***logical-system-name*** **protocols link-management** peer ***peer-name*** lmp-protocol**]**

When an LMP control channel comes up after a successful exchange of hello messages between LMP peers, LMP uses link property correlation to verify the traffic engineering and data link information on both sides of a link. To do so, the local peer sends a LinkSummary message for each traffic engineering link governed by the LMP control channel. The LinkSummary message contains information that characterizes the traffic engineering link and each data link in the traffic engineering link.

The local peer continues sending a LinkSummary message for each link until the remote peer responds with a LinkSummaryAck message or until the message retry limit is reached. When the message retry limit is reached, the local peer logs that event and restarts the link property correlation process.

When the remote peer receives a LinkSummary message, it examines its own link information. If this information agrees with that in the LinkSummary message, the remote peer responds with a LinkSummaryAck message. If the information is different, the remote peer responds with a LinkSummaryNack message.

Controlling Message Exchange for LMP Control Channels

You can configure message attributes that control the exchange of LMP Config and LinkSummary messages. The retransmission interval specifies the interval between resubmitted LMP messages. The retry limit specifies how many times LMP sends a message before restarting the process.

You can specify a retransmission interval from 500 through 300,000 milliseconds. The default retransmission interval is 500 milliseconds.

You can specify a retry limit from 3 through 1000 attempts. The default number of retry attempts is three.

To configure attributes governing the exchange of LMP messages between peers, include the **retransmission-interval** and **retry-limit** statements:

```
retransmission-interval milliseconds;
retry-limit number;
```

You can configure these statements at the following hierarchy levels:

- **[edit protocols link-management** peer ***peer-name*** lmp-protocol**]**
- **[edit logical-systems** ***logical-system-name*** **protocols link-management** peer ***peer-name*** lmp-protocol**]**

Preventing the Local Peer from Initiating LMP Negotiation

You can specify that the local peer does not initiate LMP negotiation. Instead, the local peer waits for the remote peer to configure the LMP control channel.

To configure the local peer to wait for the remote peer to configure the LMP control channel, include the **passive** statement:

```
passive;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols link-management** peer ***peer-name*** lmp-protocol**]**
- **[edit logical-systems** ***logical-system-name*** **protocols link-management** peer ***peer-name*** lmp-protocol**]**

Associating Traffic Engineering Links with LMP Peers

To specify the name of a traffic engineering link to be associated with this peer, include the **te-link** statement at the **[edit protocols link-management peer *peer-name*]** hierarchy level:

```
[edit protocols link-management peer peer-name]
te-link te-link-name;
```

For information about how to configure a traffic engineering link, see "Configuring LMP Traffic Engineering Links" on page 839.

Disabling the Traffic Engineering Link for LMP Peers

To disable a specific traffic engineering link, include the **disable** statement:

```
disable;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols link-management** te-link ***te-link-name***]
- **[edit logical-systems** ***logical-system-name*** **protocols link-management** te-link ***te-link-name***]

Configuring RSVP and OSPF for LMP Peer Interfaces

After you have configured the LMP peers as described in "Configuring LMP Peers" on page 841, add the peer interfaces to RSVP and OSPF. The peer interface name must match the peer name configured in LMP. Once the peer interfaces are added to the protocols, the traffic engineering link local and remote addresses can be signaled and advertised to peers like any other interface enabled for RSVP and OSPF. These addresses act as virtual interfaces for GMPLS.

NOTE: When adding the virtual peer interfaces to RSVP and OSPF, do not configure the corresponding physical control channel interface in either protocol. If you include the interface all statement, you must disable RSVP and OSPF protocols manually on the control channel interface.

To configure peer interfaces in RSVP and OSPF, complete the procedures in the following sections:

- Configuring RSVP Signaling for LMP Peer Interfaces on page 847
- Configuring OSPF Routing for LMP Peer Interfaces on page 847
- Configuring the Hello Interval for LMP Peer Interfaces on page 847

Configuring RSVP Signaling for LMP Peer Interfaces

To configure RSVP signaling for LMP peers, configure the LMP peer interface by including the **peer-interface** statement at the **[edit protocols rsvp]** hierarchy level:

```
[edit protocols rsvp]
peer-interface peer-interface-name {
   (aggregate | no-aggregate);
   authentication-key key;
   disable;
   hello-interval seconds;
   (reliable | no-reliable);
}
```

The statements configured at the **[edit protocols rsvp peer-interface *peer-interface-name*]** hierarchy level have the same functionality as the statements configured at the **[edit protocols rsvp interface *interface-name*]** hierarchy level.

Configuring OSPF Routing for LMP Peer Interfaces

To configure OSPF routing for LMP peers, configure the name of the LMP peer by including the **peer-interface** statement at the **[edit protocols ospf area *area-number*]** hierarchy level:

```
[edit protocols ospf area area-number]
peer-interface peer-interface-name {
   dead-interval seconds;
   disable;
   hello-interval seconds;
   retransmit-interval seconds;
   transit-delay seconds;
}
```

For information about how to configure OSPF statements, see the *Junos OS Routing Protocols Library*.

Configuring the Hello Interval for LMP Peer Interfaces

Hello packets are used to indicate to neighboring routers that the peer interface is still up and running. The hello interval must be the same for all routers on a shared logical IP network. You can specify a hello interval from 1 through 255 seconds. The default hello interval is normally 10 seconds. For nonbroadcast networks, the default hello interval is 120 seconds.

To specify how often the router sends hello packets out the peer interface, configure the **hello-interval** statement:

```
hello-interval seconds;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ospf area *area-number* peer-interface *peer-interface-name*]**
- **[edit logical-systems *logical-system-name* protocols ospf area *area-number* peer-interface *peer-interface-name*]**

Configuring MPLS Paths for GMPLS

As part of the configuration for GMPLS, you need to establish an MPLS path for each unique device connected through GMPLS. Configure the traffic engineering link remote address as the address at the **[edit protocols mpls path *path-name*]** hierarchy level. Constrained Shortest Path First (CSPF) is supported so you can choose either the **strict** or **loose** option with the address.

See "LMP Configuration Overview" on page 838 for information about how to obtain a traffic engineering link remote address.

To configure the MPLS path, include the **path** statement at the **[edit protocols mpls]** hierarchy level:

```
[edit protocols mpls]
path path-name {
  next-hop-address (strict | loose);
}
```

For information about how to configure MPLS paths, see "Creating Named Paths" on page 414.

Tracing LMP Traffic

To trace LMP protocol traffic, include the **traceoptions** statement at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory /var/log.

The following trace flags display the operations associated with the sending and receiving of various LMP messages:

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel

- **init**—Output from the initialization messages
- **packets**—Trace all packets other than hello packets on any LMP control channel
- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols
- **server**—Server processing operations
- **show**—Servicing operations for **show** commands
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

Each flag can carry one or more of the following flag modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

Configuring MPLS LSPs for GMPLS

To enable the proper GMPLS switching parameters, configure the label-switched path (LSP) attributes that are appropriate for your network connection. The default value for **switching-type** is **psc-1**, which is also appropriate for standard MPLS.

To configure the LSP attributes, include the **lsp-attributes** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name]
lsp-attributes {
  encoding-type type;
  gpid gpid;
  signal-bandwidth type;
  switching-type type;
}
```

If you include the **no-cspf** statement in the label-switched path configuration, you must also configure primary and secondary paths, or the configuration cannot be committed.

The following sections describe how to configure each of the LSP attributes for a GMPLS LSP:

- Configuring the Encoding Type on page 850
- Configuring the GPID on page 850
- Configuring the Signal Bandwidth Type on page 851

- Configuring GMPLS Bidirectional LSPs on page 851
- Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS on page 851

Configuring the Encoding Type

You need to specify the encoding type of the payload carried by the LSP. It can be any of the following:

- **ethernet**—Ethernet
- **packet**—Packet
- **pdh**—Plesiochronous digital hierarchy (PDH)
- **sonet-sdh**—SONET/SDH

The default value is **packet**.

To configure the encoding type, include the **encoding-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
encoding-type type;
```

Configuring the GPID

You need to specify the type of payload carried by the LSP. The payload is the type of packet underneath the MPLS label. The payload is specified by the generalized payload identifier (GPID).

You can specify the GPID with any of the following values:

- **hdlc**—High-Level Data Link Control (HDLC)
- **ethernet**—Ethernet
- **ipv4**—IP version 4 (default)
- **pos-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-scrambling-crc-32**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-32**—For interoperability with other vendors' equipment
- **ppp**—Point-to-Point Protocol (PPP)

To configure the GPID, include the **gpid** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
gpid gpid;
```

Configuring the Signal Bandwidth Type

The signal bandwidth type is the encoding used for path computation and admission control. To configure the signal bandwidth type, include the **signal-bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
signal-bandwidth type;
```

Configuring GMPLS Bidirectional LSPs

Because MPLS and GMPLS use the same configuration hierarchy for LSPs, it is helpful to know which LSP attributes control LSP functionality. Standard MPLS packet-switched LSPs are unidirectional, whereas GMPLS nonpacket LSPs are bidirectional.

If you use the default packet-switching type of **psc-1**, your LSP becomes unidirectional. To enable a GMPLS bidirectional LSP, you must select a non-packet-switching type option, such as **lambda**, **fiber**, or **ethernet**. Include the **switching-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
switching-type (lambda | fiber | ethernet);
```

Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS

By setting the A-bit in the Admin Status object. you can enable nonpacket GMPLS LSPs to establish paths through routers that run Junos. When an ingress router sends an RSVP PATH message with the Admin Status A-bit set, an external device (not a router running the Junos OS) can either perform a Layer 1 path setup test or help bring up an optical cross-connect.

When set, the A-bit in the Admin Status object indicates the administrative down status for a GMPLS LSP. This feature is used specifically by nonpacket GMPLS LSPs. It does not affect control path setup or data forwarding for packet LSPs.

Junos does not distinguish between the control path setup and data path setup. Other nodes along the network path use RSVP PATH signaling using the A-bit in a meaningful way.

To configure the Admin Status object for a GMPLS LSP, include the **admin-down** statement:

```
admin-down;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*****]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*****]**

Gracefully Tearing Down GMPLS LSPs

You can gracefully tear down nonpacket GMPLS LSPs. An LSP that is torn down abruptly, a common process in a packet-switched network, can cause stability problems in nonpacket-switched networks. To maintain the stability of nonpacket-switched networks, it might be necessary to tear down LSPs gracefully.

The following sections describe how to tear down GMPLS LSPs gracefully:

Temporarily Deleting GMPLS LSPs

You can gracefully tear down a GMPLS LSP using the **clear rsvp session gracefully** command.

This command gracefully tears down an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin Status object is signaled along the path to the endpoint of the LSP. During the second pass, the LSP is taken down. Using this command, the LSP is taken down temporarily. After the appropriate interval, the GMPLS LSP is resignaled and then reestablished.

The **clear rsvp session gracefully** command has the following properties:

- It only works on the ingress and egress routers of an RSVP session. If used on a transit router, it has the same behavior as the **clear rsvp session** command.
- It only works for nonpacket LSPs. If used with packet LSPs, it has the same behavior as the **clear rsvp session** command.

For more information, see the CLI Explorer.

Permanently Deleting GMPLS LSPs

When you disable an LSP in the configuration, the LSP is permanently deleted. By configuring the **disable** statement, you can disable a GMPLS LSP permanently. If the LSP being disabled is a nonpacket LSP, then the graceful LSP tear-down procedures that use the Admin Status object are used. If the LSP being disabled is a packet LSP, then the regular signaling procedures for LSP deletion are used.

To disable a GMPLS LSP, include the **disable** statement at any of the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**—Disable the LSP.
- **[edit protocols link-management** te-link ***te-link-name*]**—Disable a traffic engineering link.
- **[edit protocols link-management** te-link ***te-link-name*** interface ***interface-name*]**—Disable an interface used by a traffic engineering link.

Configuring the Graceful Deletion Timeout Interval

The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.

The ingress router initiates the graceful deletion procedure by sending the Admin Status object in the path message with the **D** bit set. The ingress router expects to receive an Resv message with the **D** bit set from the egress router. If the ingress router does not receive this message within the time specified by the graceful deletion timeout interval, it initiates a forced tear-down of the LSP by sending a PathTear message.

To configure the graceful deletion timeout interval, include the **graceful-deletion-timeout** statement at the **[edit protocols rsvp]** hierarchy level. You can configure a time between 1 through 300 seconds. The default value is 30 seconds.

```
graceful-deletion-timeout seconds;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

You can use the **show rsvp version** command to determine the current value configured for the graceful deletion timeout.

GMPLS RSVP-TE VLAN LSP Signaling Overview

Understanding GMPLS RSVP-TE Signaling

Signaling is the process of exchanging messages within the control plane to set up, maintain, modify, and terminate data paths (label-switched paths (LSPs)) in the data plane. Generalized MPLS (GMPLS) is a protocol suite that extends the existing control plane of MPLS to manage further classes of interfaces and to support other forms of label switching, such as time-division multiplexing (TDM), fiber (port), Lambda, and so on.

GMPLS extends intelligent IP/MPLS connections from Layer 2 and Layer 3 all the way to Layer 1 optical devices. Unlike MPLS, which is supported mainly by routers and switches, GMPLS can also be supported by optical platforms, including SONET/SDH, optical cross-connects (OXCs), and dense wave division multiplexing (DWDM).

In addition to labels, which are primarily used to forward data in MPLS, other physical entries, such as wavelengths, time slots, and fibers can be used as label objects to forward data in GMPLS, thereby leveraging the existing control plane mechanisms to signal different kinds of LSPs. GMPLS uses RSVP-TE to be able to request the other label objects to signal the various kinds of LSPs (nonpacket). Bidirectional LSPs and an out-of-band control channel and a data channel using the Link Management Protocol (LMP) are the other mechanisms that are used by GMPLS to establish LSPs.

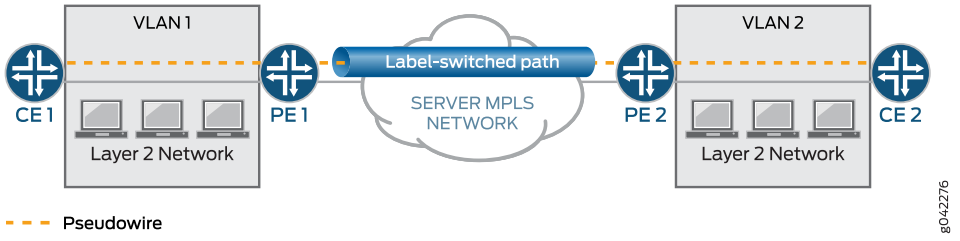
Need for GMPLS RSVP-TE VLAN LSP Signaling

The traditional Layer 2 point-to-point services use Layer 2 circuits and Layer 2 VPN technologies that are based on LDP and BGP. In the traditional deployment, the customer edge (CE) devices do not participate in the signaling of the Layer 2 service. The provider edge (PE) devices manage and provision the Layer 2 service to provide end-to-end connectivity between the CE devices.

One of the biggest challenges of having the PE devices provision the Layer 2 services for each Layer 2 circuit between a pair of CE devices is the network management burden on the provider network.

Figure 67 on page 854 illustrates how the Layer 2 service is set up and used by the CE routers in a LDP/BGP-based Layer 2 VPN technology. Two CE routers CE1 and CE2 are connected to a provider MPLS network through the PE routers PE1 and PE2 respectively. The CE routers are connected to the PE routers by Ethernet links. Routers CE1 and CE2 are configured with VLAN1 and VLAN2 logical Layer 3 interfaces, so they appear to be directly connected. Routers PE1 and PE2 are configured with Layer 2 circuit (pseudowire) to carry the Layer 2 VLAN traffic between the CE routers. The PE routers use packet MPLS LSPs within the provider MPLS network to carry the Layer 2 VLAN traffic.

Figure 67: Traditional Layer 2 Point-to-Point Services



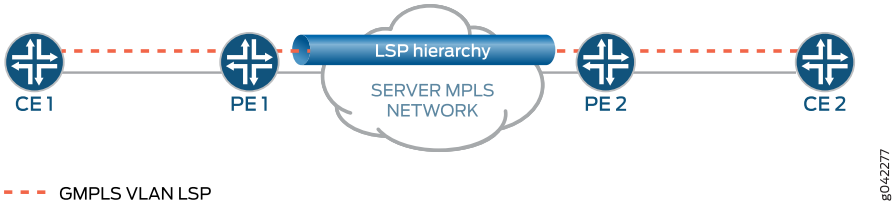
With the introduction of GMPLS-based VLAN LSP signaling, the need for the PE (also called server-layer) network to provision each individual Layer 2 connection between the CE (also called client) devices is minimized. The client router requests the server-layer router to which it is directly connected, for setting up the Layer 2 service to connect with a remote client router through GMPLS signaling.

The server-layer devices extend the signaling through the server-layer network to connect with the remote client routers. In the process, the server-layer device sets up the data plane for the Layer 2 service at the server-client border, and sets up the data plane for carrying the Layer 2 traffic within the server-layer network. With the Layer 2 service setup, the client routers can run IP/MPLS directly on top of the Layer 2 service and have IP/MPLS adjacency with each other.

In addition to reducing the provisioning activity needed on the server-layer devices, GMPLS signaling also provides the client routers with the flexibility of bringing up the Layer 2 circuits on an on-demand basis without depending on the server-layer administration for the provisioning of the Layer 2 service.

Using the same topology as in Figure 1, Figure 68 on page 855 illustrates how the Layer 2 service is set up and used by the client routers in GMPL RSVP-TE-based Layer 2 VPN technology.

Figure 68: GMPLS RSVP-TE VLAN LSP



In Figure 68 on page 855, instead of configuring a pseudowire to carry the Layer 2 VLAN traffic between the client routers, Routers PE1 and PE2 are configured with an IP-based communication channel and other GMPLS-specific configurations (identification of Ethernet links as TE-links) for allowing the exchange of GMPLS RSVP-TE signaling messages with the client routers. Routers CE1 and CE2 are also configured with an IP-based communication channel and relevant GMPLS configuration for exchanging the GMPLS RSVP-TE signaling messages with the server-layer routers. Routers CE1 and CE2 establish an IP/MPLS adjacency on top of this Layer 2 service.

GMPLS RSVP-TE VLAN LSP Signaling Functionality

Based on Figure 68 on page 855, the client router establishes the Layer 2 service in the server-layer network as follows:

1. Router CE1 initiates GMPLS RSVP-TE signaling with Router PE1. In this signaling message, Router CE1 indicates the VLAN on the Ethernet link for which it needs the Layer 2 service and the remote CE router, Router CE2, with which the VLAN should be connected.

   Router CE1 also indicates the remote PE router, Router PE2, to which Router CE2 is connected, and the exact Ethernet link connecting Router CE2 to Router PE2 on which the Layer 2 service is required in the signaling message.

2. Router PE1 uses the information from Router CE1 in the signaling message and determines the remote PE router, Router PE2, with which Router CE2 is attached.

Router PE1 then establishes a packet MPLS LSP (associated bidirectional) through the server-layer MPLS network for carrying the VLAN traffic and then passes the GMPLS RSVP-TE signaling message to Router PE2 using the LSP hierarchy mechanism.

3. Router PE2 propagates the GMPLS RSVP-TE signaling message to Router CE2 with the VLAN to be used on the PE2-CE2 Ethernet link.

4. Router CE2 responds with an acknowledgment to the GMPLS RSVP-TE signaling message to Router PE2. Router PE2 then propagates it to Router PE1, which in turn propagates it to Router CE1.

5. As part of this message propagation, Routers PE1 and PE2 set up the forwarding plane to enable bidirectional flow of VLAN Layer 2 traffic between Routers CE1 and CE2.

LSP Hierarchy with GMPLS RSVP-TE VLAN LSP

The Layer 2 service in GMPLS RSVP-TE VLAN LSP signaling is brought up using a hierarchy mechanism in which two different RSVP LSPs are created for the Layer 2 service:

- An end-to-end VLAN LSP that has state information at the client and server-layer routers.
- An associated bidirectional packet transport LSP that is present in the server-layer routers (PE and P) of the server-layer network.

The LSP hierarchy avoids sharing information about technology-specific LSP characteristics with the core nodes of the server-layer network. This solution cleanly separates the VLAN LSP state and the transport LSP state, and ensures that the VLAN LSP state is only present on the nodes (PE, CE) where it is needed.

Path Specification for GMPLS RSVP-TE VLAN LSP

The path for the GMPLS RSVP-TE LSP is configured as an Explicit Route Object (ERO) at the initiating client router. As this LSP traverses different network domains (initiating, terminating at client network, and traversing the server-layer network), the LSP setup falls under the category of an interdomain LSP setup. In an interdomain scenario, one network domain generally does not have full visibility into the topology of the other network domain. Hence, the ERO that gets configured at the initiating client router does not have full hop information for the server-layer portion. This feature requires that the ERO configured at the CE router has three hops, with the first hop being a strict hop identifying the CE1-PE1 Ethernet link, the second hop being a loose hop identifying the egress PE router (PE2), and the third hop being a strict hop identifying the CE2-PE2 Ethernet link.

GMPLS RSVP-TE VLAN LSP Configuration

The configuration required to set up a GMPLS VLAN LSP at the client and server routers uses the existing GMPLS configuration model with some extensions. The Junos OS GMPLS configuration model for nonpacket LSPs is targeted toward bringing the physical interfaces up and running through GMPLS RSVP-TE signaling, whereas signaling a GMPLS RSVP-TE

VLAN LSP aims at bringing up individual VLANs on top of a physical interface. The **ethernet-vlan** configuration statement under the **[edit protocols link-management te-link]** hierarchy enables this.

The client router has physical interfaces connected to a server network, and the server network provides a point-to-point connection between two client routers over the attached physical interfaces. The physical interface is brought into an operational state by GMPLS RSVP-TE as follows:

1. The client router maintains a routing or signaling adjacency with the server network node to which the physical interface is connected, typically through a control channel different from the physical interface, because the physical interface itself is brought up and running only after the signaling.
2. The client router and the server network node identify the physical interfaces connecting them using the TE-link mechanism.
3. The client router and the server network node use the TE-link identifier (IP address) as the GMPLS RSVP hop and the physical interface identifier as the GMPLS label values in the GMPLS RSVP-TE signaling messages to bring the physical interface into an operational state.

In the existing GMPLS configuration, the server and client network nodes use the **protocols link-management peer** ***peer-name*** configuration statement to specify the adjacent peer node. Because a client router can have one or more physical interfaces connected to the server network node, these physical interfaces are grouped and identified by an IP address through the **protocols link-management te-link** ***link-name*** configuration statement. The TE-link is assigned a local IP address, a remote IP address, and a list of physical interfaces. The TE-link is then associated with the **protocols link-management peer** ***peer-name*** **te-link** ***te-link-list*** configuration statement.

The out-of-band control channel that is required for exchanging signaling messages is specified using the **protocols link-management peer** ***peer-name*** **control-channel** ***interface-name*** configuration statement. The existence of the server or client network node is made visible to the RSVP and IGP (OSPF) protocols through the **peer-interface** ***interface-name*** configuration statement under the **[edit protocols rsvp]** and **[edit protocols ospf]** hierarchy levels.

In the existing GMPLS configuration, the label (upstream label and resv label) that is carried in the signaling message is an integer identifier that identifies the physical interface that is required to be brought up. As the label is used to identify the physical interface, the existing GMPLS configuration allows multiple interfaces to be grouped under a single TE-link. In the existing GMPLS configuration, there is sufficient information in the GMPLS RSVP-TE signaling message, such as TE-link address and label value, to identify the physical interface that is required to be brought up. In contrast, for GMPLS RSVP-TE VLAN LSP configuration, the VLAN ID value is used as the label in the signaling message.

In the GMPLS RSVP-TE VLAN LSP configuration, if multiple interfaces are allowed to be configured under a single TE-link, using VLAN ID as the label value in the signaling message can cause ambiguity as to which physical interface on which the VLAN has to be provisioned. Therefore, the TE-link is configured with the **ethernet-vlan** configuration

statement, if the number of physical interfaces that can be configured under the TE-link is restricted to only one.

In the existing GMPLS configuration, the bandwidth for a nonpacket LSP is a discrete quantity that corresponds to the bandwidth of the physical interface that needs to be brought up. So, the GMPLS LSP configuration does not allow any bandwidth to be specified, but allows the bandwidth to be specified only through the **signal-bandwidth** configuration statement under the **[protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level. In the GMPLS VLAN LSP configuration, bandwidth is specified similar to that of a packet LSP. In the GMPLS VLAN LSP configuration, the **bandwidth** option is supported and **signal-bandwidth** is not supported.

Associated Bidirectional Packet LSP

The GMPLS RSVP-TE VLAN LSP is carried on an associated bidirectional transport LSP within the server-layer network, which is a single-sided provisioned LSP. The transport LSP signaling is initiated as a unidirectional LSP from the source router to the destination router in the forward direction, and the destination router in turn initiates the signaling of the unidirectional LSP in the reverse direction back to the source router.

Make-Before-Break for Associated Bidirectional Packet and GMPLS RSVP-TE VLAN LSP

The make-before-break support for an associated bidirectional transport LSP follows a similar model, where the destination router for the forward direction of the bidirectional LSP does not perform any make-before-break operations on the reverse direction of the bidirectional LSP. It is the source router (initiator of the associated bidirectional LSP) that initiates the make-before-break newer instance of the associated bidirectional LSP, and the destination router in turn initiates the make-before-break newer instance in the other direction.

For instance, in Figure 68 on page 855, the unidirectional transport LSP is initiated from Router PE1 to Router PE2 in the forwarding direction, and in turn Router PE2 initiates the transport LSP to Router PE1 in the reverse direction. When a make-before-break instance occurs, only Router PE1 as the initiating client router can establish a new instance of the associated bidirectional LSP. Router PE2 in turn initiates the make-before-break newer instance in the reverse direction.

The make-before-break support for the associated bidirectional transport LSP is used only in scenarios where the transport LSP gets into a state of being locally protected due to link or node failure on the path of the LSP. The GMPLS RSVP-TE VLAN LSP uses the make-before-break mechanism for adjusting seamless bandwidth changes.

NOTE: Periodic re-optimization is not enabled for the associated bidirectional transport LSPs.

The newer make-before-break instance of the GMPLS VLAN LSP is supported under the following constraints:

- It should originate from the same client router as the older instance and be destined to the same client router as the older instance.
- It should use the same server-client links at both the server-client ends as the older instance.
- It should use the same VLAN label at the server-client links as the older instance.
- The GMPLS VLAN LSP should be configured as **adaptive** when the bandwidth change is initiated from the CLI, or else the current instance of the VLAN LSP is torn down and a new VLAN LSP instance is established.

The make-before-break operation for the GMPLS VLAN LSP on the server-layer edge router is rejected if these constraints are not met.

On the server-layer edge routers, when a make-before-break instance of the GMPLS VLAN LSP is seen, a completely new, separate associated bidirectional transport LSP is created to support this make-before-break instance. The existing associated bidirectional LSP (supporting the older instance) is not triggered to initiate a make-before-break instance at the transport LSP level. An implication of this choice (of initiating a new transport LSP) is that at the server-layer resource/bandwidth sharing does not happen when a make-before-break operation is performed for the GMPLS VLAN LSP.

Supported and Unsupported Features

Junos OS supports the following features with the GMPLS RSVP-TE VLAN LSP:

- Request for specific bandwidth and local protection for the VLAN LSP on the client router to the server-layer router.
- Nonstop active routing (NSR) support for the GMPLS VLAN LSP at the client routers, server-layer edge routers, and associated bidirectional transport LSP at the server-layer edge routers.
- Multichassis support.

Junos OS does **not** support the following GMPLS RSVP-TE VLAN LSP functionality:

- Graceful restart support for associated bidirectional packet LSP and GMPLS VLAN LSP.
- End-to-end path computation for GMPLS VLAN LSP using CSPF algorithm at the client router.
- Non-CSPF routing-based discovery of next-hop routers by the different client, server-layer edge routers.
- Automatic provisioning of the client Layer 3 VLAN interfaces upon the successful setup of the VLAN LSP at the client routers.
- MPLS OAM (LSP-ping, BFD).
- Packet MPLS applications, such as next-hop in static route and in IGP shortcuts.

- Local cross connect mechanism, where a client router connects to a remote client router which is connected to the same server router.
- Junos OS Services Framework.
- IPv6 support.
- Logical systems.
- Aggregated Ethernet/SONET/IRB interfaces at the server-client link.

Related Documentation

- Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling on page 860

Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling

This example shows how to configure GMPLS RSVP-TE VLAN LSP signaling on the client routers to enable one client router to connect with a remote client router through a server-layer network using the LSP hierarchy. This enables the client routers to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers
- Junos OS Release 14.2 or later running on the client routers and server-layer edge routers

Before you begin:

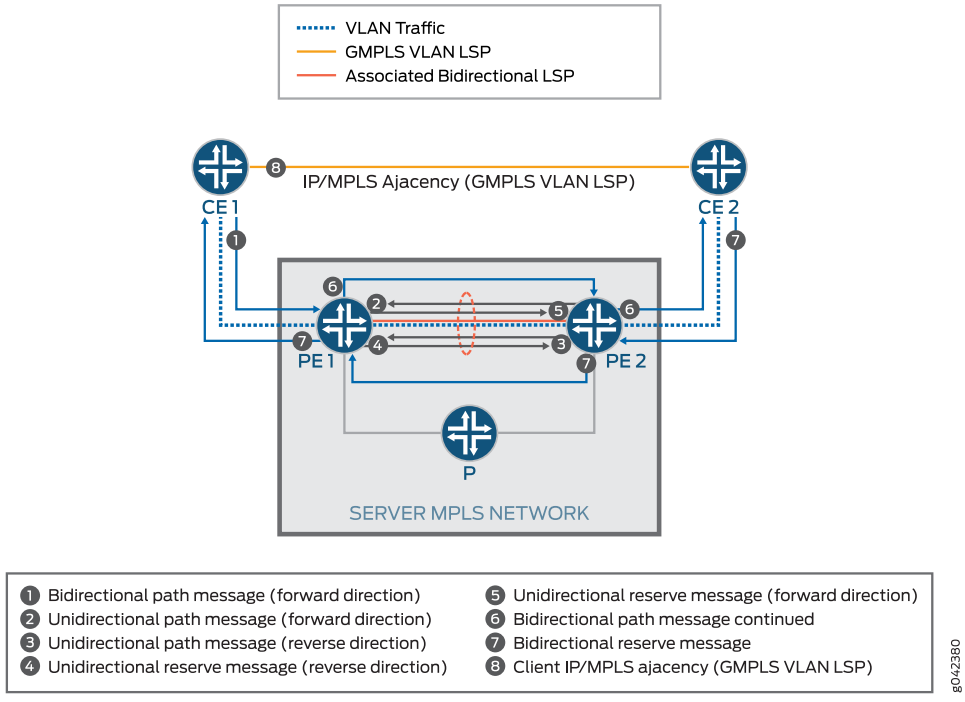
1. Configure the device interfaces.
2. Configure the interface-associated VLANs.
3. Configure the following routing protocols:
   - RSVP
   - MPLS
   - LMP

Overview

Starting with Junos OS Release 14.2, the Layer 2 services between two client routers across an external/third-party server-layer network are set up by the client routers on an on-demand basis through GMPLS RSVP-TE signaling. This feature provides the client routers the flexibility to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network. In traditional Layer 2 VPN technology based on LDP and BGP, the provider network handled the provisioning activity for each Layer 2 circuit established between two client routers.

Figure 69 on page 861 illustrates the setting up and signaling of the GMPLS VLAN LSP between two client routers, CE1 and CE2, across a server-layer network with two server-layer edge routers, PE1 and PE2, and one server-layer core router, P.

Figure 69: Setting Up a GMPLS VLAN LSP



The signaling of GMPLS VLAN LSP is executed as follows:

1. **Initiating GMPLS VLAN LSP at CE1**

   Router CE1 initiates the GMPLS VLAN LSP setup by sending the GMPLS RSVP-TE path message to Router PE1. The signaling between CE1 and PE1 is over an out-of-band

control channel, which is a separate control VLAN configured on the Ethernet link connecting the two routers.

The GMPLS RSVP-TE path message initiated by Router CE1 is used to perform the following:

a. Identify the Ethernet link on which the VLAN is active.

b. Abstract the Ethernet link as a TE-link and assign an IP address to identify the Ethernet link.

c. Allocate a VLAN ID from the pool of free VLANs managed by Router CE1 for every Ethernet link connecting Router PE1 to the identified Ethernet link.

   This VLAN ID can also be used for the GMPLS VLAN LSP at the CE2-PE2 Ethernet link.

d. Identify the VLAN for which the Layer 2 service is required to be set up using the allocated VLAN ID as the upstream label object and the upstream direction label value.

e. Include an ERO object that helps Router PE1 in establishing the VLAN LSP through the server-layer network to the remote client router, CE2. The ERO object in the path message includes three hops:

   - First hop—Strict hop identifying the initiating client-server Ethernet link, PE1-CE1.
   - Second hop—Loose hop identifying the remote server-layer router, PE2.
   - Third hop—Strict hop identifying the remote clinet-server Ethernet link, PE2-CE2.

f. Include the bandwidth required for the GMPLS VLAN LSP.

g. Include any local-protection required within the server-layer network for the VLAN LSP.

2. **Initiating Associated Bidirectional Transport LSP at PE1**

   After Router PE1 receives the path message from Router CE1, the message is validated to check the availability of the Ethernet link and VLAN ID. In the server-layer network, the Layer 2 services between the server-layer routers, PE1 and PE2, are provided at the data plane in a manner similar to Layer 2 circuits. Router PE1 brings up a transport LSP to Router PE2 and then extends the GMPLS VLAN LSP as a hierarchical LSP running on top of the PE1-PE2 transport LSP. The PE1-PE2 transport LSP is a packet LSP and is bidirectional in nature. This is because the GMPLS VLAN LSP is bidirectional and each server-layer router needs to be able to do the following:

   - Receive traffic from the server-client Ethernet link (for example, the PE1-CE1 link) and send it to the remote server-layer router, PE2.
   - Receive traffic from remote Router PE2 and send it on the PE1-CE1 Ethernet link.

For each GMPLS VLAN LSP, a packet transport LSP is set up within the server-layer network. The transport LSP is exclusively used to carry traffic of the GMPLS VLAN LSP for which it was created. The transport LSP is dynamically created at the time of receiving the GMPLS VLAN LSP; thus, no configuration is required to trigger its creation. The transport LSP established for the VLAN LSP inherits the bandwidth and the local-protection attributes from the VLAN LSP.

Router PE1 signals the PE1-PE2 transport LSP to Router PE2. Router PE1 determines the destination for the transport LSP from the loose hop specified in the ERO object of the GMPLS RSVP-TE path message from Router CE1 and then signals the VLAN LSP. However, if the PE1-PE2 transport LSP fails to establish, Router PE1 sends back a path error message to Router CE1, and the GMPLS VLAN LSP is not established as well.

3. **Setting Up the Associated Bidirectional Transport LSP Between the Server-Layer Routers**

   The associated bidirectional LSP between routers PE1 and PE2 consists of two unidirectional packet LSPs:

   - PE1-to-PE2
   - PE2-to-PE1

   Router PE1 initiates signaling of a unidirectional packet LSP to Router PE2. This unidirectional packet LSP constitutes the forward direction (PE1-to-PE2) of the associated bidirectional LSP, and the path message carries the Extended Association Object indicating this is a single-sided provisioning model. On receiving the path message for the LSP, Router PE2 responds with a Resv message and triggers the signaling of a unidirectional packet LSP to Router PE1 with the same path as (PE1-to-PE2) in the reverse direction. This unidirectional packet LSP uses the PE2-to-PE1 direction of the associated bidirectional LSP, and this path message carries the same Extended Association Object seen in the PE1-to-PE2 path message.

   When Router PE1 receives the Resv message for the PE1-to-PE2 unidirectional LSP and the path message for the PE2-to-PE1 unidirectional LSP, PE1 binds the PE1-to-PE2 and PE2-to-PE1 unidirectional LSPs by matching the Extended Association Objects carried in the respective path messages. For the path message for the PE2-to-PE1 unidirectional LSP, Router PE1 responds with the Resv Message. On receiving the Resv message for the PE1-to-PE2 LSP and the path message for the PE2-to-PE1 LSP, Router PE1 has established the associated bidirectional packet transport LSP.

4. **Setting Up the GMPLS VLAN LSP at Router PE1**

   After successfully establishing the transport LSP, Router PE1 triggers the signaling of the GMPLS VLAN LSP. Router PE1 sends the GMPLS RSVP-TE path message corresponding to the VLAN LSP directly to Router PE2, which is bidirectional in nature and includes the upstream label object.

   Router PE2 is not aware of the association between the transport LSP and the VLAN LSP. This association is indicated to Router PE2 by Router PE1.

5. **Setting Up the GMPLS VLAN LSP at Router PE2**

   On receiving the VLAN LSP path message from Router PE1, Router PE2 verifies the availability of the transport LSP. If the transport LSP is not available or the LSP setup is in progress, the VLAN LSP processing is put on hold. When the transport LSP is available, Router PE2 processes the VLAN LSP path message. The ERO object in this path message indicates that the next hop is a strict hop identifying the PE2-to-CE2 Ethernet link. The ERO object can indicate the VLAN ID to be used on the PE2-to-CE2 Ethernet link by Router PE2.

   Router PE2 appropriately allocates the VLAN ID to be sent as the upstream label in the VLAN LSP path message to Router CE2, and sends it through an out-of-band control channel.

6. **Processing the GMPLS VLAN LSP at Router CE2**

   On receiving the GMPLS RSVP-TE LSP from Router PE2, Router CE2 validates the availability of VLAN ID for allocation on the PE2-to-CE2 link. Router CE2 then allocates the VLAN ID for this VLAN LSP and sends back a Resv message to Router PE2 with the VLAN ID as the label object in the Resv message.

7. **Processing the GMPLS VLAN LSP at Router PE2**

   On receiving the Resv message from Router CE2, Router PE2 validates that the label object in the Resv message has the same VLAN ID as in the path message. Router PE2 then allocates a 20-bit MPLS label, which is included in the Resv message sent to Router PE1.

   Router PE2 then programs the forwarding plane with the entries to provide the Layer 2 service functionality.

   NOTE: For all the VLAN IDs that can be allocated as labels on the PE1-to-CE1 and PE2-CE2 Ethernet links, you must manually configure logical interfaces for circuit cross-connect (CCC) purposes on the server-layer edge routers and not for other families, such as IPv4, IPv6, or MPLS.

8. **Processing the GMPLS VLAN LSP at Router PE1**

   On receiving the Resv message for the VLAN LSP from Router PE2, Router PE1 sends a Resv message to Router CE1 with the same VLAN ID it received as the upstream label from Router CE1. Router PE1 programs the forwarding plane with the entries to provide the Layer 2 service functionality as Router PE2.

9. **Processing the GMPLS VLAN LSP at Router CE1**

   On receiving the Resv message from Router PE1, Router CE1 validates that the VLAN ID received in the Resv message matches the VLAN ID in the upstream label in the

path message it sent. This completes the setup of the GMPLS VLAN LSP from Router CE1 to Router CE2.

NOTE:

- The GMPLS VLAN LSP setup does not result in the addition of any forwarding plane entries at the client routers, CE1 and CE2. Only the server-layer routers, PE1 and PE2, add the forwarding plane entries for the GMPLS VLAN LSP.
- There is no routing information exchange between the client and the server-layer routers. The client and server-layer routers do not exchange their network topology information with each other.

10. **Accounting for Bandwidth of the GMPLS VLAN LSP**

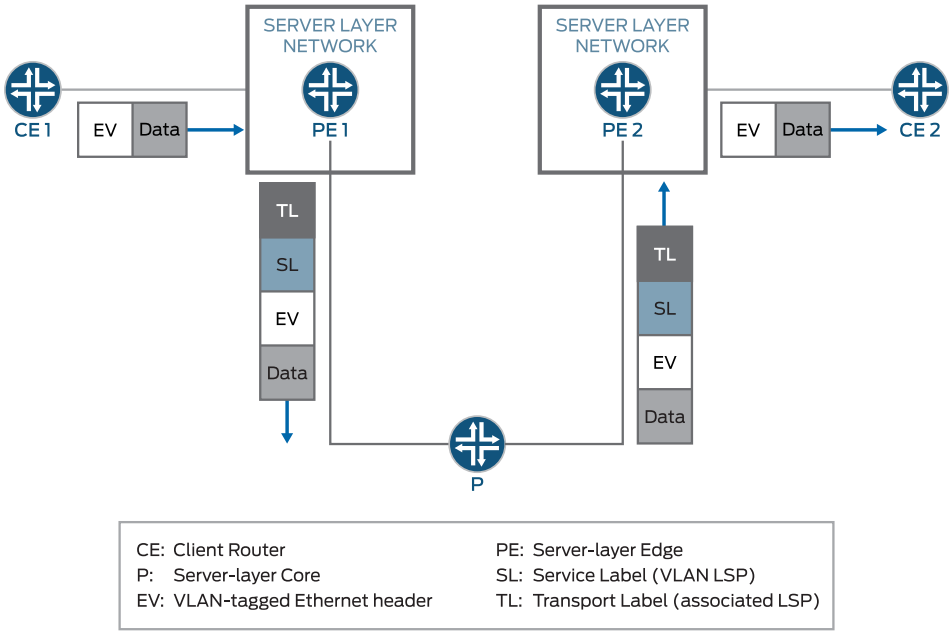
    On successfully setting up the GMPLS VLAN LSP, both the client and server-layer routers reduce the amount of available bandwidth on the server-client Ethernet links by the bandwidth amount allocated for the GMPLS VLAN LSP. This bandwidth accounting information is used for admission control purposes when additional GMPLS VLAN LSPs are brought up on the server-client Ethernet links.

11. **Using GMPLS VLAN LSP by the Client Routers**

    After successfully setting up the GMPLS VLAN LSP, the client routers – CE1 and CE2 – need to be manually configured with the VLAN logical interface on top of the server-client Ethernet links with the signaled VLAN ID. This logical interface needs to be configured with the IP address and needs to be included in the IGP protocol. As a result of this configuration, Routers CE1 and CE2 establish IGP adjacency and exchange data traffic over the Layer 2 service established through the GMPLS signaling.

    Figure 70 on page 866 illustrates the data traffic flow of the GMPLS VLAN LSP from Router CE1 to Router CE2 after the LSP setup is complete and the necessary CE1-to-CE2 IGP/MPLS adjacency has been established. The server-layer transport LSP originates from Router PE1, traverses a single server-layer core router, Router P, and reaches Router PE2. The server-layer transport LSP is shown as a penultimate-hop pop LSP, where Router P pops off the transport LSP label, and only the service label is present on the P-to-PE2 link.

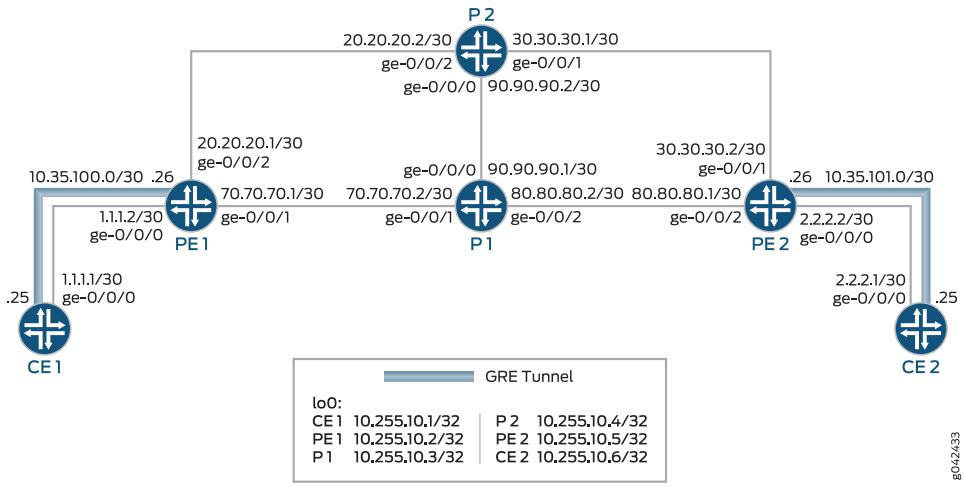
Figure 70: Data Traffic Flow of GMPLS VLAN LSP



Topology

In Figure 71 on page 866, GMPLS RSVP-TE VLAN LSP signaling is used to establish the Layer 2 services between the client routers, Router CE1 and Router CE2. The server routers, Router PE1 and Router PE2, have a GRE tunnel established with each of the directly connected client routers. Routers P1 and P2 are also server routers in the server-layer network.

Figure 71: Configuring GMPLS RSVP-TE VLAN LSP Signaling



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring the Client Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router CE1:

NOTE: Repeat this procedure for Router CE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router CE1 to Router PE1.

```
[edit interfaces]
user@CE1# set ge-0/0/0 vlan-tagging
```

2. Configure the control VLAN for the ge-0/0/0 interface.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 1 vlan-id 1
user@CE1# set ge-0/0/0 unit 1 family inet address 1.1.1.1/30
user@CE1# set ge-0/0/0 unit 1 family mpls
```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 10 vlan-id 10
user@CE1# set ge-0/0/0 unit 10 family inet address 10.10.10.1/24
user@CE1# set ge-0/0/0 unit 10 family mpls
```

4. Configure the GRE tunnel as the controlling interface for Router CE1.

```
[edit interfaces]
user@CE1# set gre unit 0 tunnel source 1.1.1.1
user@CE1# set gre unit 0 tunnel destination 1.1.1.2
```

```
user@CE1# set gre unit 0 family inet address 10.35.100.25/30
```

5. Configure the loopback interface of Router CE1.

```
[edit interfaces]
user@CE1# set lo0 unit 0 family inet address 10.255.10.1/32
```

6. Configure the loopback address of Router CE1 as its router ID.

```
[edit routing-options]
user@CE1# set router-id 10.255.10.1
```

7. Enable RSVP on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set rsvp interface all
user@CE1# set rsvp interface fxp0.0 disable
```

8. Configure the RSVP peer interface for Router CE1.

```
[edit protocols]
user@CE1# set rsvp peer-interface PE1
```

9. Disable automatic path computation for label-switched paths (LSPs).

```
[edit protocols]
user@CE1# set mpls no-cspf
```

10. Configure the LSP to connect Router CE1 to Router CE2.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 from 10.255.10.1
user@CE1# set mpls label-switched-path CE1-to-CE2 to 10.255.10.6
```

11. Configure the CE1-to-CE2 LSP attributes.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes switching-type
  ethernet-vlan
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes upstream-label
  vlan-id 10
user@CE1# set mpls label-switched-path CE1-to-CE2 bandwidth 100m
```

12. Configure the CE1-to-CE2 LSP path and path parameters.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 primary path1
user@CE1# set mpls path path1 10.35.1.2 strict
user@CE1# set mpls path path1 10.255.10.5 loose
user@CE1# set mpls path path1 10.36.1.1 strict
```

13. Enable MPLS on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set mpls interface all
user@CE1# set mpls interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@CE1# set link-management te-link link10 local-address 10.35.1.1
user@CE1# set link-management te-link link10 remote-address 10.35.1.2
```

15. Enable setting up of Layer 2 VLAN LSP on the link10 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link10 ethernet-vlan
```

16. Configure the Router CE1 interface as the member interface of the link10 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link10 interface ge-0/0/0
```

17. Configure Router PE1 as the Link Management Protocol (LMP) peer for Router CE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer PE1 address 10.255.10.2
user@CE1# set link-management peer PE1 control-channel gre.0
user@CE1# set link-management peer PE1 te-link link10
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-0/0/0 {
   vlan-tagging;
```

```
    unit 1 {
      vlan-id 1;
      family inet {
        address 1.1.1.1/30;
      }
      family mpls;
    }
    unit 10 {
      vlan-id 10;
      family inet {
        address 10.10.10.1/24;
      }
      family mpls;
    }
}
gre {
    unit 0 {
      tunnel {
        source 1.1.1.1;
        destination 1.1.1.2;
      }
      family inet {
        address 10.35.100.25/30;
      }
    }
}
lo0 {
    unit 0 {
      family inet {
        address 10.255.10.1/32;
      }
    }
}
```

```
user@CE1# show routing-options
router-id 10.255.10.1;
```

```
user@CE1# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
      disable;
    }
    peer-interface PE1;
}
mpls {
    no-cspf;
    label-switched-path CE1-to-CE2 {
      from 10.255.10.1;
      to 10.255.10.6;
      lsp-attributes {
        switching-type ethernet-vlan;
        upstream-label {
          vlan-id 10;
```

```
        }
      }
      bandwidth 100m;
      primary path1;
    }
    path path1 {
      10.35.1.2 strict;
      10.255.10.5 loose;
      10.36.1.1 strict;
    }
    interface all;
    interface fxp0.0 {
      disable;
    }
}
link-management {
    te-link link10 {
      local-address 10.35.1.1;
      remote-address 10.35.1.2;
      ethernet-vlan;
      interface ge-0/0/0;
    }
    peer PE1 {
      address 10.255.10.2;
      control-channel gre.0;
      te-link link10;
    }
}
```

Configuring the Server Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router PE1 to Router CE1.

```
[edit interfaces]
user@PE1# set ge-0/0/0 vlan-tagging
user@PE1# set ge-0/0/0 encapsulation flexible-ethernet-services
```

2. Configure the control VLAN for the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 1 vlan-id 1
user@PE1# ge-0/0/0 unit 1 family inet address 1.1.1.2/30
user@PE1# set ge-0/0/0 unit 1 family mpls
```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 10 encapsulation vlan-ccc
user@PE1# set ge-0/0/0 unit 10 vlan-id 10
```

4. Configure the interface connecting Router PE1 to the core routers (Router P1 and Router P2).

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 70.70.70.1/30
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 20.20.20.1/30
user@PE1# set ge-0/0/2 unit 0 family mpls
```

5. Configure the GRE tunnel as the controlling interface for Router PE1.

```
[edit interfaces]
user@PE1# set gre unit 0 tunnel source 1.1.1.2
user@PE1# set gre unit 0 tunnel destination 1.1.1.1
user@PE1# set gre unit 0 family inet address 10.35.100.26/30
```

6. Configure the loopback interface of Router PE1.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.10.2/32
```

7. Configure the loopback address of Router PE1 as its router ID.

```
[edit routing-options]
user@PE1# set router-id 10.255.10.2
```

8. Configure an associated bidirectional LSP, and enable unidirectional reverse LSP setup for single-sided provisioned forward LSP.

```
[edit protocols]
user@PE1# set rsvp associated-bidirectional-lsp single-sided-provisioning
```

9. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```

10. Configure the RSVP peer interface for Router PE1, and enable dynamic setup of bidirectional packet LSP for transporting nonpacket GMPLS LSP.

```
[edit protocols]
user@PE1# set rsvp peer-interface CE1 dynamic-bidirectional-transport
```

11. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

12. Configure OSPF with traffic engineering capabilities.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

13. Enable OSPF area 0 on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@PE1# set link-management te-link link1 local-address 10.35.1.2
user@PE1# set link-management te-link link1 remote-address 10.35.1.1
```

15. Enable setting up of a Layer 2 VLAN LSP for a specific range of VLANs on the link1 traffic engineering link.

```
[edit protocols]
user@PE1# set link-management te-link link1 ethernet-vlan vlan-id-range 1-1000
```

16. Configure the Router PE1 interface as the member interface of the link1 traffic engineering link.

```
[edit protocols]
```

```
user@CE1# set link-management te-link link1 interface ge-0/0/0
```

17. Configure Router CE1 as the LMP peer for Router PE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer CE1 address 10.255.10.1
user@CE1# set link-management peer CE1 control-channel gre.0
user@CE1# set link-management peer CE1 te-link link1
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
    vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 1 {
        vlan-id 1;
        family inet {
            address 1.1.1.2/30;
        }
        family mpls;
    }
    unit 10 {
        encapsulation vlan-ccc;
        vlan-id 10;
    }
}
ge-0/0/1 {
    unit 0 {
        family inet {
            address 70.70.70.1/30;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 20.20.20.1/30;
        }
        family mpls;
    }
}
gre {
    unit 0 {
        tunnel {
            source 1.1.1.2;
            destination 1.1.1.1;
```

```
    }
    family inet {
      address 10.35.100.26/30;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.10.2/32;
    }
  }
}
```

```
user@PE1# show routing-options
router-id 10.255.10.2;
```

```
user@PE1# show protocols
rsvp {
  associated-bidirectional-lsp single-sided-provisioning;
  interface all;
  interface fxp0.0 {
    disable;
  }

    }
  }
}
link-management {
  te-link link1 {
    local-address 10.35.1.2;
    remote-address 10.35.1.1;
    ethernet-vlan {
      vlan-id-range 1-1000;
    }
    interface ge-0/0/0;
  }
  peer CE1 {
    address 10.255.10.1;
```

```
    control-channel gre.0;
    te-link link1;
  }
}
```

Verification

Confirm that the configuration is working properly.

Verifying the Traffic Engineering Link Status on the Client Routers

Purpose Verify the status of the traffic engineering link configured between Router CE1 and Router CE2.

Action From operational mode, run the **show link-management** and the **show link-management te-link detail** commands.

```
user@CE1> show link-management
```

```
Peer name: PE1, System identifier: 50740
 State: Up, Control address: 10.255.10.2
 Hello interval: 150, Hello dead interval: 500
   Control-channel                  State
   gre.0                            Active
  TE links:
   link10

 TE link name: link10, State: Up
  Local identifier: 65075, Remote identifier: 0, Local address: 10.35.1.1, Remote
 address: 10.35.1.2, Encoding: Ethernet, Switching: EVPL, Minimum bandwidth: 0bps,

  Maximum bandwidth: 1000Mbps, Total bandwidth: 1000Mbps, Available bandwidth:
900Mbps
    Name                             State Local ID  Remote ID      Bandwidth
Used  LSP-name
    ge-0/0/0                         Up       54183          0       1000Mbps
Yes  CE1-to-CE2
```

```
user@CE1> show link-management te-link detail
```

```
TE link name: link10, State: Up
  Local identifier: 65075, Remote identifier: 0, Local address: 10.35.1.1, Remote
 address: 10.35.1.2, Encoding: Ethernet, Switching: EVPL, Minimum bandwidth: 0bps,

  Maximum bandwidth: 1000Mbps, Total bandwidth: 1000Mbps, Available bandwidth:
900Mbps
    Resource: ge-0/0/0, Type: IFD, System identifier: 137, State: Up, Local
identifier: 54183, Remote identifier: 0
    Total bandwidth: 1000Mbps, Unallocated bandwidth: 900Mbps
   Traffic parameters: Encoding: Ethernet, Switching: EVPL, Granularity: Unknown

    Maximum allocations: 4094, Number of allocations: 1, Unique allocations: 1,
In use: Yes
     LSP name: CE1-to-CE2, Local label: 10, Remote label: 10, Allocated bandwidth:
 100Mbps
```

```
user@CE2> show link-management
```

```
Peer name: PE2, System identifier: 50743
 State: Up, Control address: 10.255.10.5
 Hello interval: 150, Hello dead interval: 500
   Control-channel                  State
   gre.0                            Active
  TE links:
   link10

 TE link name: link10, State: Up
  Local identifier: 65075, Remote identifier: 0, Local address: 10.36.1.1, Remote
 address: 10.36.1.2, Encoding: Ethernet, Switching: EVPL, Minimum bandwidth: 0bps,

  Maximum bandwidth: 1000Mbps, Total bandwidth: 1000Mbps, Available bandwidth:
900Mbps
```

```
    Name                              State Local ID  Remote ID      Bandwidth
Used  LSP-name
    ge-0/0/0                          Up       54183          0       1000Mbps
Yes  CE1-to-CE2
```

Meaning The Link Management Protocol (LMP) peering has been established between the client routers, and the traffic engineering link is up on both Routers CE1 and CE2.

Verifying the RSVP Session Status on the Client Routers

Purpose Verify the status of the RSVP sessions between Router CE1 and Router CE2.

Action From operational mode, run the **show rsvp session** command.

```
user@CE1> show rsvp session
```

```
Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.6     10.255.10.1     Up      0  1 FF       -       10 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

```
user@CE2> show rsvp session
```

```
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.6     10.255.10.1     Up      0  1 FF      10        - CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The RSVP sessions are established between the ingress router, Router CE1, and the egress router, Router CE2.

Verifying the LSP Status on the Server Router

Purpose Verify the status of the MPLS LSP on Router PE1.

Action From operational mode, run the **show mpls lsp** command.

```
user@PE1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt P     ActivePath       LSPname
10.255.10.5     10.255.10.2     Up     0 *
vlan:0:10:8176:10.255.10.2->10.255.10.5 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.2     10.255.10.5     Up       0  1 FF       3        -
vlan:0:10:8176:10.255.10.2->10.255.10.5:rev
Total 1 displayed, Up 1, Down 0

Transit LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.255.10.6     10.255.10.1     Up      0  1 FF      10   299808 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0
```

Meaning The CE1-to-CE2 LSP is established, and the output displays the LSP attributes.

Verifying the CCC Entries in the MPLS Routing Table of the Server Routers

Purpose Verify the circuit cross-connect (CCC) interface entries in the MPLS routing table.

Action From operational mode, run the **show route table mpls.0** and the **show route forwarding-table ccc *ccc-interface*** commands.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
1                  *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
2                  *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
13                 *[MPLS/0] 1d 22:14:51, metric 1
                      Receive
299824             *[RSVP/7/1] 17:32:07, metric 1
                    > via ge-0/0/0.10, Pop
ge-0/0/0.10        *[RSVP/7/1] 17:32:07, metric 1
                   > to 20.20.20.2 via ge-0/0/2.0, label-switched-path CE1-to-CE2
```

```
user@PE1> show route forwarding-table ccc ge-0/0/0.10
Routing table: default.mpls
MPLS:
Destination        Type RtRef Next hop           Type Index    NhRef Netif
ge-0/0/0.10  (CCC) user     0 20.20.20.2       Push 299808, Push 299872(top)
 581     2 ge-0/0/2.0

Routing table: __mpls-oam__.mpls
MPLS:
Destination        Type RtRef Next hop           Type Index    NhRef Netif
default            perm     0                   dscd      534     1
```

Meaning The output displays the CCC interface that is the client-router-facing interface and the next-hop details for that interface.

Verifying End-to-End Connectivity

Purpose Verify the connectivity between Router CE1 and the remote client router, Router CE2.

Action From operational mode, run the **ping** command.

```
user@CE1> ping 10.10.10.2
PING 10.10.10.2 (10.10.10.2): 56 data bytes
64 bytes from 10.10.10.2: icmp_seq=0 ttl=64 time=15.113 ms
64 bytes from 10.10.10.2: icmp_seq=1 ttl=64 time=13.353 ms
64 bytes from 10.10.10.2: icmp_seq=2 ttl=64 time=13.769 ms
64 bytes from 10.10.10.2: icmp_seq=3 ttl=64 time=10.341 ms
64 bytes from 10.10.10.2: icmp_seq=4 ttl=64 time=12.597 ms
^C
--- 10.10.10.2 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max/stddev = 10.341/13.035/15.113/1.575 ms
```

Meaning The ping from Router CE1 to Router CE2 is successful.

MPLS BGP VPNs

CHAPTER 26

Configuring MPLS VPNs

MPLS VPN Overview

Virtual private networks (VPNs) are private networks that use a public network to connect two or more remote sites. Instead of dedicated connections between networks, VPNs use virtual connections routed (tunneled) through public networks that are typically service provider networks. VPNs are a cost-effective alternative to expensive dedicated lines. The type of VPN is determined by the connections it uses and whether the customer network or the provider network performs the virtual tunneling.

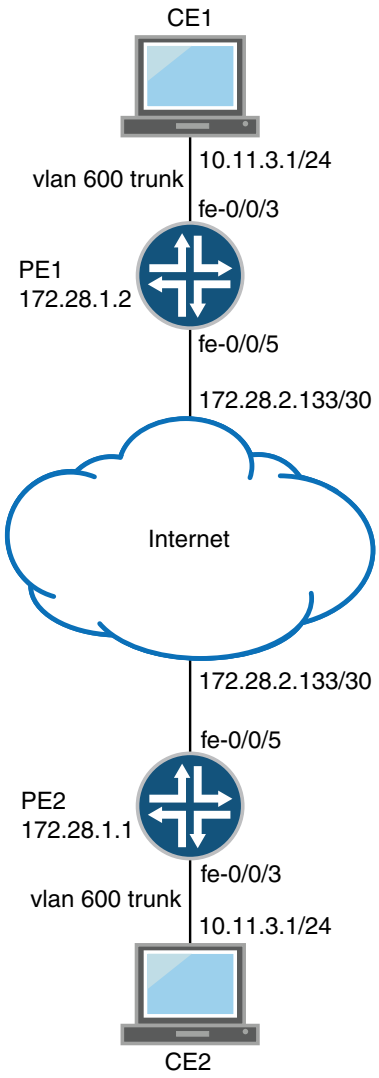
You can configure a router running Junos OS to participate in several types of VPNs. This topic discusses MPLS VPNs.

This topic contains the following sections:

MPLS VPN Topology

There are many ways to set up an MPLS VPN and direct traffic through it. Figure 72 on page 889 shows a typical MPLS VPN topology.

Figure 72: Typical VPN Topology



There are three primary types of MPLS VPNs: Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. All types of MPLS VPNs share certain components:

- The provider edge (PE) routers in the provider's network connect to the customer edge (CE) routers located at customer sites. PE routers support VPN and MPLS label functionality. Within a single VPN, pairs of PE routers are connected through a virtual tunnel, typically a label-switched path (LSP).
- Provider routers within the core of the provider's network are not connected to any routers at a customer site but are part of the tunnel between pairs of PE routers. Provider routers support LSP functionality as part of the tunnel support, but do not support VPN functionality.
- CE routers are the routers or switches located at the customer site that connect to the provider's network. CE routers are typically IP routers, but they can also be Asynchronous Transfer Mode (ATM), Frame Relay, or Ethernet switches.

All VPN functions are performed by the PE routers. Neither CE routers nor provider routers are required to perform any VPN functions.

MPLS VPN Routing

VPNs tunnel traffic as follows from one customer site to another customer site, using a public network as a transit network, when certain requirements are met:

1. Traffic is forwarded by standard IP forwarding from the CE routers to the PE routers.
2. The PE routers establish an LSP through the provider network.
3. The inbound PE router receives traffic, and it performs a route lookup. The lookup yields an LSP next hop, and the traffic is forwarded along the LSP.
4. The traffic reaches the outbound PE router, and the PE router pops the MPLS label and forwards the traffic with standard IP routing.

VRF Instances

A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The interfaces belong to the routing tables, and the routing protocol parameters control the information in the routing tables. In the case of MPLS VPNs, each VPN has a VPN routing and forwarding (VRF) instance.

A VRF instance consists of one or more routing tables, a derived forwarding table, the interfaces that use the forwarding table, and the policies and routing protocols that determine what goes into the forwarding table. Because each instance is configured for a particular VPN, each VPN has separate tables, rules, and policies that control its operation.

A separate VRF table is created for each VPN that has a connection to a CE router. The VRF table is populated with routes received from directly connected CE sites associated with the VRF instance, and with routes received from other PE routers in the same VPN.

Route Distinguishers

Because a typical transit network is configured to handle more than one VPN, the provider routers are likely to have multiple VRF instances configured. As a result, depending on the origin of the traffic and any filtering rules applied to the traffic, the BGP routing tables can contain multiple routes for a particular destination address. Because BGP requires that exactly one BGP route per destination be imported into the forwarding table, BGP must have a way to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs.

A route distinguisher is a locally unique number that identifies all route information for a particular VPN. Unique numeric identifiers allow BGP to distinguish between routes that are otherwise identical.

Each routing instance that you configure on a PE router must have a unique route distinguisher. There are two possible formats:

- ***as-number:number***, where ***as-number*** is an autonomous system (AS) number (a 2–byte value) in the range 1 through 65,535, and ***number*** is any 4–byte value. We recommend that you use an Internet Assigned Numbers Authority (IANA)-assigned, nonprivate AS number, preferably the ISP or the customer AS number.
- ***ip-address:number***, where ***ip-address*** is an IP address (a 4–byte value) and ***number*** is any 2–byte value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a public IP address in your assigned prefix range.

The route target defines which route is part of a VPN. A unique route target helps distinguish between different VPN services on the same router. Each VPN also has a policy that defines how routes are imported into the VRF table on the router. A Layer 2 VPN is configured with import and export policies. A Layer 3 VPN uses a unique route target to distinguish between VPN routes.

The PE router then exports the route in IBGP sessions to the other provider routers. Route export is governed by any routing policy that has been applied to the particular VRF table. To propagate the routes through the provider network, the PE router must also convert the route to VPN format, which includes the route distinguisher.

When the outbound PE router receives the route, it strips off the route distinguisher and advertises the route to the connected CE router, typically through standard BGP IPv4 route advertisements.

Understanding IPv6 Layer 3 VPNs

The interfaces between the PE and CE routers of a Layer 3 VPN can be configured to carry IP version 6 (IPv6) traffic. IP allows numerous nodes on different networks to interoperate seamlessly. IPv4 is currently used in intranets and private networks, as well as the Internet. IPv6 is the successor to IPv4, and is based for the most part on IPv4.

In the Juniper Networks implementation of IPv6, the service provider implements an MPLS-enabled IPv4 backbone to provide VPN service for IPv6 customers. The PE routers have both IPv4 and IPv6 capabilities. They maintain IPv6 VPN routing and forwarding (VRF) tables for their IPv6 sites and encapsulate IPv6 traffic in MPLS frames that are then sent into the MPLS core network.

IPv6 for Layer 3 VPNs is supported for BGP and for static routes.

IPv6 over Layer 3 VPNs is described in RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*.

Understanding Using MPLS-Based Layer 3 VPNs on Switches

On the QFX Series switches and on EX4600 switches, you can use MPLS-based Layer 3 virtual private networks (VPNs) to securely connect geographically diverse sites across an MPLS network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

A VPN uses a public telecommunications infrastructure, such as the Internet, to provide remote offices or individual users with secure access to their organization's network. VPNs are designed to provide the same level of performance and security as privately owned or leased networks but without the attendant costs.

This topic describes:

- MPLS-Based Layer 3 VPNs on page 892

MPLS-Based Layer 3 VPNs

In Junos OS, Layer 3 VPNs are based on RFC 4364, *BGP/MPLS IP Virtual Private Networks*. RFC 4364 defines a mechanism by which service providers can use their IP backbones to provide VPN services to their customers. A Layer 3 VPN is a set of sites that share common routing information and whose connectivity is controlled by a collection of policies. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone.

Customer networks, because they are private, can use either public or private addresses, as defined in RFC 1918, *Address Allocation for Private Internets*. When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the same private addresses used by other network users. BGP/MPLS VPNs solve this problem by adding a VPN identifier prefix to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and on the public Internet. In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only. Two different VPNs can use overlapping addresses. Each route within a VPN is assigned an MPLS label (for example, MPLS-ARCH, MPLS-BGP, or MPLS-ENCAPS). When BGP distributes a VPN route, it also distributes an MPLS label for that route. Before a customer data packet travels across the service provider's backbone, it is encapsulated along with the MPLS label that corresponds to the route within the customer's VPN that is the best match based on the packet's destination address. This MPLS packet is further encapsulated with another MPLS label or with an IP, so that it gets tunneled across the backbone to the egress provider edge (PE) switch. Thus, the backbone core switches do not need to know the VPN routes.

QFX5100 switches also support interprovider VPNs, and carrier-of-carriers VPNs. For more information, see "Understanding Interprovider and Carrier-of-Carriers VPNs" on page 1075

Configuring a BGP Session for MPLS VPNs (CLI Procedure)

NOTE: This section is valid for Layer 2 VPNs and Layer 3 VPNs, but not Layer 2 circuits.

To configure an IBGP session, perform the following steps on each PE router:

1. Configure BGP.

```
[edit]
user@host# edit protocols bgp group group-name
```

2. Set the BGP type to internal.

```
[edit protocols bgp group group-name]
user@host# set type internal
```

3. Specify the loopback interface.

```
[edit protocols bgp group group-name]
user@host# set local-address loopback-interface-ip-address
```

4. Set the Layer 2 or Layer 3 VPN family type to unicast.

```
[edit protocols bgp group group-name]
user@host# set family family-type unicast
```

Replace ***family-type*** with **l2vpn** for a Layer 2 VPN or **inet–vpn** for a Layer 3 VPN.

5. Enter the loopback address of the neighboring PE router.

```
[edit protocols bgp]
user@host# set neighbor ip-address
```

6. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)

To configure RSVP and OSPF:

1. Configure OSPF with traffic engineering support on the PE routers.

```
[edit]
user@host# edit protocols ospf traffic-engineering shortcuts
```

NOTE: You must configure the IGP at the **[edit protocols]** level, not within the routing instance at the **[edit routing-instances]** level.

2. Enable RSVP on interfaces that participate in the LSP. For PE routers, enable interfaces on the source and destination points. For provider routers, enable interfaces that connect the LSP between the PE routers.

```
[edit]
user@host# edit protocols rsvp interface interface-name
```

3. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring Routing Options for MPLS VPNs (CLI Procedure)

To configure routing options for a VPN:

1. Configure the AS number.

```
[edit]
user@host# set routing-options autonomous-system as-number
```

2. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Related Documentation

Configuring a Routing Instance for MPLS VPNs (CLI Procedure)

To configure a VPN routing instance on each PE router:

1. Create the routing instance.

```
[edit]
user@host# edit routing-instances routing-instance-name
```

2. Create a routing instance description. (This text appears in the output of the **show route instance detail** command.)

```
[edit routing-instances routing-instance-name]
user@host# set description "text"
```

3. Specify the instance type, either **l2vpn** for Layer 2 VPNs or **vrf** for Layer 3 VPNs.

```
[edit routing-instances routing-instance-name]
user@host# set instance-type instance-type
```

4. Specify the interface of the remote PE router.

```
[edit routing-instances routing-instance-name]
user@host# set interface interface-name
```

5. Specify the route distinguisher using one of the following commands:

```
[edit routing-instances routing-instance-name]
user@host# set route-distinguisheras-number:number
user@host# set route-distinguisher ip-address:number
```

6. Specify the policy for the Layer 2 VRF table.

```
[edit routing-instances routing-instance-name]
user@host# set vrf-import import-policy-name vrf-export export-policy-name
```

7. Specify the policy for the Layer 3 VRF table.

```
[edit routing-instances routing-instance-name]
user@host# set vrf-target target:community-id
```

Where *community-id* is either *as-number*:*number* or *ip-address*:*number*.

8. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Chained Composite Next Hops for Transit Devices for VPNs

The Juniper Networks PTX Series Packet Transport Routers, MX Series 5G Universal Routing Platforms with MIC and MPC interfaces, T4000 Core Routers, and QFX10000 switches are principally designed to handle large volumes of transit traffic in the core of large networks. Chained composite next hops help to facilitate this capability by allowing the router to process much larger volumes of routes. A chained composite next hop allows the router to direct sets of routes sharing the same destination to a common forwarding next hop, rather than having each route also include the destination. In the event that a network destination is changed, rather than having to update all of the routes sharing that destination with the new information, just the shared forwarding next hop is updated with the new information. The chained composite next hops continue to point to this forwarding next hop which now contains the new destination.

When the next hops for MPLS LSPs are created on the routers, the tag information corresponding to the inner-most MPLS label is extracted into a chained composite next hop. The chained composite next hop is stored in the ingress PFE. The chained composite next hop points to a next hop called the forwarding next hop that resides on the egress PFE. The forwarding next hop contains all of the other information (all of the labels except for the inner-most labels; and the IFA/IP information corresponding to the actual next hop node). Many chained composite next hops can share the same forwarding next hop. Additionally, separating the label from the forwarding next hop and storing it on the ingress PFE (within the chained composite next hop) helps to conserve egress PFE memory by reducing the number of rewrite strings stored on the egress PFE.

The support of chained composite next hops for directly connected Provider Edge (PE) routers varies from one platform to another.

On platforms containing only MPCs, such as PTX Series Packet Transport Routers, the MX80 router, the MX2020 router, and the QFX10000 switches, chained composite next hops are enabled by default for the following MPLS and VPN protocols and applications:

NOTE: Point-to-Multipoint LSPs and Layer 2 VPNs are not supported on the QFX10000 switches.

- Labeled BGP
- Layer 2 VPNs
- Layer 3 VPNs
- LDP
- MPLS
- Point-to-Multipoint LSPs
- RSVP
- Static LSPs

On MX Series 5G Universal Routing Platforms containing both DPC and MPC FPCs, chained composite next hops are disabled by default.

To enable chained composite next hops on the MX Series routers such as: MX80, MX240, MX480, MX960 and MX2020, the chassis must be configured to use the **enhanced-ip** option in network services mode.

On T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default.

To enable chained composite next hops on a T4000 router, the chassis must be configured to use the **enhanced-mode** option in network services mode.

For more information about configuring chassis network services, see the *Junos OS Administration Library*.

Understanding MPLS Layer 2 VPNs

In an MPLS Layer 2 VPN, traffic is forwarded to the provider edge (PE) router in Layer 2 format, carried by MPLS through an label-switched path (LSP) over the service provider

network, and then converted back to Layer 2 format at the receiving customer edge (CE) router.

Routing occurs on the customer routers, typically on the CE router. The CE router connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The PE router receiving the traffic sends it across the network to the PE router on the outbound side. The PE routers need no information about the customer's routes or routing topology, and need only to determine the virtual tunnel through which to send the traffic.

Implementing a Layer 2 VPN on the router is similar to implementing a VPN using a Layer 2 technology such as Asynchronous Transfer Mode (ATM) or Frame Relay.

Understanding Ethernet-over-MPLS (L2 Circuit)

Ethernet-over-MPLS allows sending Layer 2 (L2) Ethernet frames transparently over MPLS. Ethernet-over-MPLS uses a tunneling mechanism for Ethernet traffic through an MPLS-enabled Layer 3 core. It encapsulates Ethernet protocol data units (PDUs) inside MPLS packets and forwards the packets, using label stacking, across the MPLS network This technology has applications in service provider, enterprise and data center environments. For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network.

NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) routers. In contrast, each CCC requires a dedicated LSP.

- Ethernet-over-MPLS in Data Centers on page 898

Ethernet-over-MPLS in Data Centers

For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network. These data centers require L2 connectivity between them for the following reasons:

- To replicate the storage over Fiber Channel IP (FCIP). FCIP works only on the same broadcast domain.
- To run a dynamic routing protocol between the sites.
- To support High Availability clusters that interconnect the nodes hosted in the various data centers.

MPLS Layer 2 VPN Configuration Overview

To configure MPLS Layer 2 VPN functionality on a router running Junos OS, you must enable support on the provider edge (PE) router and configure the PE router to distribute routing information to other routers in the VPN, as explained in the following steps. However, because the tunnel information is maintained at both PE routers, neither the provider core routers nor the customer edge (CE) routers need to maintain any VPN information in their configuration databases.

To configure an MPLS Layer 2 VPN:

1. Determine all of the routers that you want to participate in the VPN, and then complete the initial configuration of their interfaces. See *Interfaces Feature Guide for Security Devices*.

2. For all of the routers in the VPN configuration, update the interface configurations to enable participation in the Layer 2 VPN. As part of the interface configuration, you must configure the MPLS address family for each interface that uses LDP or RSVP. See "Configuring Interfaces for Layer 2 VPNs (CLI Procedure)" on page 902.

3. For all of the routers in the VPN configuration, configure the appropriate protocols.

   a. MPLS—For PE routers and provider routers, use MPLS to advertise the Layer 2 VPN interfaces that communicate with other PE routers and provider routers.

   b. BGP and internal BGP (IBGP)—For PE routers, configure a BGP session to enable the routers to exchange information about routes originating and terminating in the VPN. (The PE routers use this information to determine which labels to use for traffic destined to the remote sites. The IBGP session for the VPN runs through the loopback address.) In addition, CE routers require a BGP connection to the PE routers. See "Configuring a BGP Session for MPLS VPNs (CLI Procedure)" on page 893.

   c. IGP and a signaling protocol—For PE routers, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but you cannot use them for interfaces between PE routers and CE routers.

      In addition, configure an IGP such as OSPF or static routes for PE routers to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

See "Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)" on page 931 and "Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)" on page 894.

4. For all of the routers in the VPN configuration, configure routing options. The only required routing option for VPNs is the AS number. You must specify it on each router involved in the VPN. See "Configuring Routing Options for MPLS VPNs (CLI Procedure)" on page 894.

5. For each PE router in the VPN configuration, configure a routing instance for each VPN. The routing instance should have the same name on each PE router. Each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP distinguish between potentially identical network layer reachable information [NLRI] messages received from different VPNs.) See "Configuring a Routing Instance for MPLS VPNs (CLI Procedure)" on page 895.

6. For each PE router in the VPN configuration, configure a VPN routing policy if you are not using a route target. Within the policy, describe which packets are sent and received across the VPN and specify how routes are imported into and exported from the router's VRF table. Each advertisement must have an associated route target that uniquely identifies the VPN for which the advertisement is valid. If the routing instance uses a policy for accepting and rejecting packets instead of a route target, you must specify the import and export routing policies and the community on each PE router. See "Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure)" on page 900.

Related Documentation

- Verifying an MPLS Layer 2 VPN Configuration on page 925

Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure)

These instructions show how to configure a Layer 2 VPN routing policy on the PE routers in the VPN.

After configuring an import routing policy for a Layer 2 VPN, configure an export routing policy for the Layer 2 VPN. Configure this export policy on the PE routers in the VPN. The export routing policy defines how routes are exported from the PE router routing table. An export policy is applied to routes sent to other PE routers in the VPN. The export policy must also evaluate all routes received over the routing protocol session with the CE router. The export policy must also contain a second term for rejecting all other routes.

To configure a Layer 2 VPN routing policy on a PE router:

1. Configure the import routing policy.

```
[edit]
user@host# edit policy-options policy-statement import-policy-name
```

2. Define the import policy's term for accepting packets.

```
[edit edit policy-options policy-statement import-policy-name]
user@host# set term term-name-accept from protocol bgp community
  community-name
user@host# set term term-name-accept then accept
```

3. Define the import policy's term for rejecting packets.

```
[edit edit policy-options policy-statement import-policy-name]
user@host# set term term-name-reject then reject
```

4. Configure the export routing policy.

```
[edit]
user@host# edit policy-options policy-statement export-policy-name
```

5. Define the export policy's term for accepting packets.

```
[edit policy-options policy-statement export-policy-name]
user@host# set term term-name-accept from community add community-name
user@host# set termterm-name-accept then accept
```

6. Define the export policy's term for rejecting packets.

```
[edit policy-options policy-statement export-policy-name]
user@host# set term term-name-reject from community add community-name
user@host# set term term-name-reject then reject
```

7. Define the export policy's community using one of the following commands.

```
[edit policy-options policy-statement export-policy-name]
user@host# community community-name target: as-number
user@host# community community-name target: ip-address:number
```

8. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring Interfaces for Layer 2 VPNs (CLI Procedure)

Configuring the router interfaces that participate in the VPN is similar to configuring them for other uses, with a few requirements for the VPN. Perform the following tasks for each interface involved in the VPN, except Layer 3 loopback interfaces, which do not require other configuration.

To configure an interface for an MPLS VPN:

1. Configure IPv4 on all of the routers' interfaces.

   - For all interfaces except loopback interfaces and Layer 2 VPN interfaces facing a CE router:

     ```
     [edit]
     user@host# edit interfaces interface-name unit logical_interface family inet address
       ipv4_address
     ```

   - For a loopback address on a Layer 2 configuration:

     ```
     [edit]
     user@host# edit interfaces lo0 unit logical_interface family inet address ipv4_address
       primary
     ```

   - For a Layer 2 VPN interface facing a CE router:

     ```
     [edit]
     user@host# set interfaces interface-name vlan-tagging encapsulation vlan-ccc unit
       logical_interface encapsulation vlan-ccc vlan-id id-number
     ```

2. Configure the MPLS address family on the PE router or provider router interfaces that communicate with other PE routers or provider routers (and not loopback addresses).

   ```
   [edit interfaces interface]
   user@host# set unit logical_interface family mpls
   ```

3. Configure encapsulation for the interfaces on the PE routers that communicate with the CE routers in Layer 2 VPNs and Layer 2 circuits. If multiple logical units are configured, the encapsulation type is needed at the interface level only. It is always required at the unit level.

   ```
   [edit interfaces interface]
   user@host# set encapsulation encapsulation_type
   user@host# set unit logical_interface encapsulation encapsulation_type
   ```

4. Enable protocol mpls on CE facing interface.

   ```
   [edit interfaces interface]
   user@host# set protocols mpls interface interface-name
   ```

5. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

- MPLS Layer 2 Circuit Configuration Overview on page 929

Configuring Ethernet over MPLS (L2 Circuit)

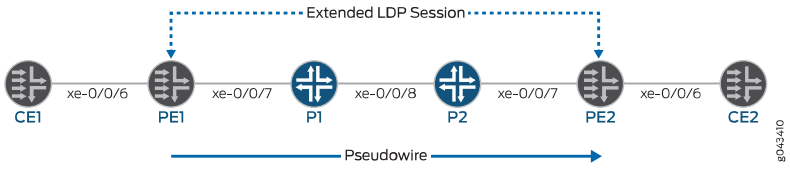
To implement Ethernet over MPLS, you must configure a Layer 2 circuit on the provider edge (PE) switches. No special configuration is required on the customer edge (CE) switches. The provider switches require MPLS and LDP to be configured on the interfaces that will be receiving and transmitting MPLS packets.

NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two PE switches. In contrast, each CCC requires a dedicated LSP.

This topic describes how to configure the PE switches to support Ethernet over MPLS. You must configure interfaces and protocols on both the local PE (PE1) and the remote PE (PE2) switches. The interface configuration varies depending upon whether the Layer 2 circuit is port-based or VLAN-based.

Figure 73 on page 903 shows an example of a Layer 2 circuit configuration.

Figure 73: Ethernet over MPLS Layer 2 Circuit



NOTE: This topic refers to the local PE switch as PE1 and the remote PE switch as PE2. It also uses interface names rather than variables to help clarify the connections between the switches. The loopback addresses of the switches are configured as follows:

- PE1: 1.1.1.1
- PE2: 4.4.4.4

Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

CAUTION: Configure MPLS networks with an MTU (maximum transmission unit) that is at least 12 bytes larger than the largest frame size that will be transported by the LSPs. If the size of a encapsulated packet on the ingress LSR exceeds the LSP MTU, that packet is dropped. If an egress LSR receives a packet on a VC LSP with a length (after the label stack and sequencing control word have been popped) that exceeds the MTU of the destination layer 2 interface, that packet is also dropped.

To configure the local PE switch (PE1) for a port-based layer 2 circuit (pseudo-wire):

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 4.4.4.4 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 4.4.4.4
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set rsvp interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

To configure the remote PE switch (PE2) for a port-based layer 2 circuit:

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

NOTE: On QFX Series switches, the L2 circuit CE facing interface does not support AE interfaces.

2. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch#set l2circuit neighbor 1.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch#set mpls label-switched-path PE2-to-PE1 to 1.1.1.1
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set rsvp interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit

To configure the local PE switch (PE1) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

NOTE: On QFX Series switches, the L2 circuit CE facing interface does not support AE interfaces.

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

NOTE: On QFX Series switches, L2 circuit CE facing interface does not support AE interfaces.

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 4.4.4.4 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 4.4.4.4
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set rsvp interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit

To configure the remote PE switch (PE2) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

NOTE: On QFX Series switches, the L2 circuit CE facing interface does not support AE interfaces.

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

NOTE: On QFX Series switches, L2 circuit CE facing interface does not support AE interfaces.

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch#set l2circuit neighbor 1.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch#set mpls label-switched-path PE2-to-PE1 to 1.1.1.1
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set rsvp interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Example: Configuring MPLS-Based Layer 2 VPNs

You can implement an MPLS-based Layer 2 virtual private network (VPN) using Junos OS routing devices to interconnect customer sites with Layer 2 technology. Layer 2 VPNs give customers complete control of their own routing. To support an MPLS-based Layer 2 VPN, you need to add components to the configuration of the two provider edge (PE) routing devices. You do not need to change the configuration of the provider devices.

This example shows how to configure an MPLS-based Layer 2 VPN.

NOTE: You can configure both an MPLS-based Layer 2 VPN and an MPLS-based Layer 3 VPN on the same device. However, you cannot configure the same customer edge interface to support both a Layer 2 VPN and a Layer 3 VPN. The core interfaces and the loopback interfaces are configured in the same way for Layer 2 VPNs and Layer 3 VPNs.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1 or later if you are using EX Series switches
- Two PE routing devices

Before you configure the Layer 2 VPN components, configure the basic components for an MPLS network:

- Configure two PE routing devices. See "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)" on page 77.
- Configure one or more provider devices. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: A Layer 2 VPN requires that the PE routing devices be configured using circuit cross-connect (CCC). The provider routing devices are configured in the same way for MPLS using CCC and for IP over MPLS.

Overview and Topology

A Layer 2 VPN provides complete separation between the provider's network and the customer's network—that is, the PE devices and the CE devices do not exchange routing information. Some benefits of a Layer 2 VPN are that it is private, secure, and flexible.

This example shows how to configure Layer 2 VPN components on the local and remote PE devices. This example does not include configuring a provider device, because there are no specific Layer 2 VPN components on the provider devices.

In the basic MPLS configuration of the PE devices using a circuit cross-connect (CCC), the PE devices are configured to use an interior gateway protocol (IGP), such as OSPF or IS-IS, as the routing protocol between the MPLS devices and LDP or RSVP as the signaling protocol. Traffic engineering is enabled. A label-switched path (LSP) is

configured within the **[edit protocols]** hierarchy. However, unlike the basic MPLS configuration using a CCC, you do not need to associate the LSP with the customer edge interface. When you are configuring a Layer 2 VPN, you must use BGP signaling. The BGP signaling automates the connections, so manual configuration of the association between the LSP and the customer edge interface is not required.

The following components must be added to the PE routing devices for an MPLS-based Layer 2 VPN:

- BGP group with **family l2vpn signaling**
- Routing instance using instance type **l2vpn**
- The physical layer encapsulation type (**ethernet**) must be specified on the customer edge interface and the encapsulation type must also be specified in the configuration of the routing instance.

Figure 74 on page 909 illustrates the topology of this MPLS-based Layer 2 VPN.

Figure 74: MPLS-Based Layer 2 VPN

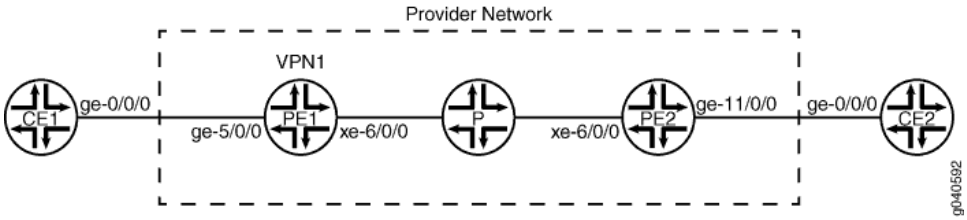

Table 30 on page 909 shows the settings of the customer edge interface on the local CE device.

Table 30: Local CE Routing Device in the MPLS-Based Layer 2 VPN Topology

Property	Settings	Description
Local CE routing device hardware	Routing device	CE1
Customer edge interface	**ge-0/0/0 unit 0** **family inet** **address 10.0.0.2/16**	Interface that connects CE1 to PE1.

Table 31 on page 909 shows the settings of the customer edge interface on the remote CE routing device.

Table 31: Remote CE Routing Device in the MPLS-Based Layer 2 VPN Topology

Property	Settings	Description
Remote CE routing device hardware	Routing device	CE2
Customer edge interface	**ge-0/0/0 unit 0** **family inet** **address 10.0.0.1/16**	Interface that connects CE2 to PE2.

Table 32 on page 910 shows the Layer 2 VPN components of the local PE routing device.

Table 32: Layer 2 VPN Components of the Local PE Routing Device

Property	Settings	Description
Local PE routing device hardware	Routing device	PE1
Customer edge interface	**ge-5/0/0** **encapsulation ethernet-ccc** **unit 0** **family ccc**	Connects PE1 to CE1. For the Layer 2 VPN, add **ethernet-ccc** as the physical layer encapsulation type. NOTE: The **family ccc** should already have been completed as part of the basic MPLS configuration of a PE routing device for circuit cross-connect. It is included here to show what was specified for that portion of the configuration.
Core interface	**xe-6/0/0 unit 0** **family inet address 10.0.0.60/16** **family iso** **family mpls**	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	**lo0 unit 0** **family inet address 192.0.2.0/24** **family iso address** **49.0001.2102.2021.0210.00**	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	**bgp**	Added for the Layer 2 VPN configuration.
Routing instance	**vpn1**	Added for the Layer 2 VPN configuration

Table 33 on page 910 shows the Layer 2 VPN components of the remote PE routing device.

Table 33: Layer 2 VPN Components of the Remote PE Routing Device

Property	Settings	Description
PE routing device hardware	Routing device	PE2

Table 33: Layer 2 VPN Components of the Remote PE Routing Device (continued)

Property	Settings	Description
Customer edge interface	**ge-11/0/0** **encapsulation ethernet-ccc unit 0** **family ccc**	Connects PE2 to CE2. For the Layer 2 VPN, add **ethernet-ccc** as the physical layer encapsulation type. NOTE: The **family ccc** should already have been completed as part of the basic MPLS configuration of a PE routing device for circuit cross-connect. It is included here to show what was specified for that portion of the configuration.
Core interface	**xe-6/0/0** **unit 0** **family inet** **address 10.2.0.61/16 family iso** **family mpls**	Connects PE2 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	**lo0 unit 0** **family inet address 192.0.2.3/24** **family iso address** **49.0001.2202.2022.0220.00**	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	**bgp**	Added for the Layer 2 VPN configuration.
Routing instance	**vpn1**	Added for the Layer 2 VPN configuration.

Configuring the Local PE Routing Device

CLI Quick Configuration

To quickly configure the Layer 2 VPN components on the local PE routing device, copy the following commands and paste them into the routing device terminal window:

```
[edit]
set interfaces ge-5/0/0 encapsulation ethernet-ccc
set protocols bgp group ibgp local-address 192.0.2.0 family l2vpn signaling
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 192.0.2.3
set routing-instances vpn1 instance-type l2vpn
set routing-instances vpn1 interface ge-5/0/0
set routing-instances vpn1 route-distinguisher 192.0.2.0:21
set routing-instances vpn1 vrf-target target:21:21
set routing-instances vpn1 protocols l2vpn encapsulation-type ethernet
set routing-instances vpn1 protocols l2vpn interface ge-5/0/0.0 description "BETWEEN PE1 AND CE1"
set routing-instances vpn1 protocols l2vpn site JE-V21 site-identifier 21 interface ge-5/0/0 remote-site-id 26
```

Step-by-Step Procedure

To configure the Layer 2 VPN components on the local PE routing device:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

```
[edit]
user@PE1# set interfaces ge-5/0/0 encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```
[edit protocols bgp]
user@PE1# set group ibgp local-address 192.0.2.0 family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@PE1# set group ibgp type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE routing device as the neighbor's address:

```
[edit protocols bgp]
user@PE1# set group ibgp neighbor 192.0.2.3/24
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@PE1# set vpn1 instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@PE1# set vpn1 interface ge-5/0/0
```

7. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 192.0.2.0:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@PE1# set vpn1 vrf-target target:21:21
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@PE1# set vpn1 protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@PE1# set vpn1 protocols interface ge-5/0/0.0 description "BETWEEN PE1 AND CE1"
```

11. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@PE1# set vpn1 protocols l2vpn site JE-V21 site-identifier 21remote-site-id 26
```

NOTE: The remote site ID (configured with the remote-site-id statement) corresponds to the site ID (configured with the site-identifier statement) configured on the other PE routing device.

Results Display the results of the configuration:

```
user@PE1# show
```

```
interfaces {
  ge-5/0/0 {
    encapsulation ethernet-ccc;
    unit 0 {
      family ccc;
    }
  }
  xe-6/0/0 {
    unit 0 {
      family inet {
        address 10.0.0.60/16;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 192.0.2.0/24;
      }
      family iso {
        address 49.0001.2102.2021.0210.00;
      }
    }
  }
protocols {
  rsvp {
```

```
    interface lo0.0;
    interface xe-0/0/6.0;
  }
  mpls {
    label-switched-path lsp_to_pe2 {
      to 192.0.2.3;
    }
  interface xe-0/0/6.0;
    bgp {
      group ibgp
      type internal
      local-address 192.0.2.0
      family l2vpn signaling
      unicast
    }
routing-instances {
  vpn1 {
    instance-type l2vpn;
    interface ge-5/0/0.0;
    route-distinguisher 192.0.2.0:21;
    vrf-target target:21:21;
    protocols {
      l2vpn {
        encapsulation-type ethernet;
        interface ge-5/0/0.0 {
          description "BETWEEN PE1 AND CE1";
        }
        site JE-V21 {
        site-identifier 21;
          interface ge-5/0/0.0 {
            remote-site-id 26;
          }
      }
    }
  }
}
```

Configuring the Remote PE Routing Device

CLI Quick Configuration

To quickly configure the Layer 2 VPN components on the remote PE routing device, copy the following commands and paste them into the routing device terminal window:

```
[edit]
set interfaces ge-11/0/0 encapsulation ethernet-ccc
set protocols bgp group ibgp local-address 192.0.2.3 family l2vpn signaling
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 192.0.2.0
set routing-instances vpn1 instance-type l2vpn
set routing-instances vpn1 interface ge-11/0/0
set routing-instances vpn1 route-distinguisher 192.0.2.0:21
set routing-instances vpn1 vrf-target target:21:21
set routing-instances vpn1 protocols l2vpn encapsulation-type ethernet
set routing-instances vpn1 protocols l2vpn interface ge-11/0/0.0 description "BETWEEN PE1 AND
CE1"
set routing-instances vpn1 protocols l2vpn site T26-VPN1 site-identifier 26 remote-site-id 21
```

Step-by-Step Procedure

To configure the Layer 2 VPN components on the remote PE routing device:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

```
[edit]
user@PE1# set interfaces ge-11/0/0 encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address as the **local-address** and specifying **family l2vpn signaling**:

```
[edit protocols bgp]
user@PE2# set group ibgp local-address 192.0.2.3 family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@PE2# set group ibgp type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE routing device as the neighbor's address:

```
[edit protocols bgp]
user@PE2# set group ibgp neighbor 192.0.2.0
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the **instance-type**:

```
[edit routing-instances]
user@PE2# set vpn1 instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@PE2# set vpn1 interface ge-11/0/0.0
```

7. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

```
[edit routing-instances]
user@PE2# set vpn1 route-distinguisher 192.0.2.0:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@PE2# set vpn1 vrf-target target:21:21
```

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@PE2# set vpn1 protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@PE1# set vpn1 protocols interface ge-11/0/0.0 description "BETWEEN PE1 AND CE1"
```

11. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@PE2# set vpn1 protocols l2vpn site T26-VPN1 site-identifier 26 remote-site-id 21
```

NOTE: The remote site ID (configured with the remote-site-id statement) corresponds to the site ID (configured with the site-identifier statement) configured on the other PE routing device.

Results Display the results of the configuration:

```
user@PE2# show
```

```
interfaces {
    ge-11/0/0 {
        encapsulation ethernet-ccc;
        unit 0 {
            family ccc;
        }
    }
    xe-6/0/0 {
        unit 0 {
            family inet {
                address 10.2.0.61/16;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 192.0.2.3/24;
            }
            family iso {
                address 49.0001.2202.2022.0220.00;
            }
        }
    }
protocols {
    rsvp {
        interface lo0.0;
        interface xe-0/0/6.0;
    mpls {
```

```
      label-switched-path lsp_to_pe1 {
        to 192.0.2.0;
      }
    interface xe-0/0/6.0;
      bgp {
        group ibgp
        type internal
        local-address 192.0.2.0
        family l2vpn signaling
        unicast
      }
routing-instances {
  vpn1 {
    instance-type l2vpn;
    interface ge-11/0/0.0;
    route-distinguisher 192.0.2.0:21;
    vrf-target target:21:21;
    protocols {
      l2vpn {
        encapsulation-type ethernet;
        interface ge-11/0/0.0 {
          description "BETWEEN PE1 AND CE1";
        }
        site T26-VPN1 {
          site-identifier 26;
          interface ge-11/0/0.0 {
            remote-site-id 21;
          }
        }
      }
    }
  }
}
```

Verification

To confirm that the MPLS-based Layer 2 VPN is working properly, perform these tasks:

- Verifying the Layer 2 VPN Connection on page 917
- Verifying the Status of MPLS Label-Switched Paths on page 918
- Verifying BGP Status on page 919
- Verifying the Status of the RSVP Sessions on page 919
- Verifying the Routes in the Routing Table on page 920
- Pinging the Layer 2 VPN Connections on page 921

Verifying the Layer 2 VPN Connection

Purpose Verify that the Layer 2 VPN connection is up.

Action `user@PE1>` **show l2vpn connections**

```
Layer-2 VPN connections:

Legend for connection status (St)
EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch     WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down    NP -- interface hardware not present
CM -- control-word mismatch      -> -- only outbound connection is up
CN -- circuit not provisioned    <- -- only inbound connection is up
OR -- out of range               Up -- operational
OL -- no outgoing label          Dn -- down
LD -- local site signaled down   CF -- call admission control failure
RD -- remote site signaled down  SC -- local and remote site ID collision
LN -- local site not designated  LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status  IL -- no incoming label
MM -- MTU mismatch               MI -- Mesh-Group ID not availble
BK -- Backup connection          ST -- Standby connection
PF -- Profile parse failure      PB -- Profile busy
RS -- remote site standby        SN -- Static Neighbor

Legend for interface status
Up -- operational
Dn -- down

Instance: vpn1
  Local site: JE-V21 (21)
    connection-site           Type  St     Time last up          # Up trans
    26                        rmt   Up     Apr 16 05:53:21 2010           1
      Remote PE: 192.0.2.3, Negotiated control-word: Yes (Null)
      Incoming label: 800000, Outgoing label: 800001
      Local interface: ge-5/0/0.0, Status: Up, Encapsulation: ETHERNET
```

Meaning The **St** field in the output shows that the Layer 2 VPN connection to **Remote PE** (**192.0.2.3**) is up.

Verifying the Status of MPLS Label-Switched Paths

Purpose Verify that the MPLS label-switched paths (ingress and egress) are up.

Action

```
user@PE1> show mpls lsp
Ingress LSP: 1 sessions

To              From            State Rt P     ActivePath       LSPname
192.0.2.3     192.0.2.0     Up     0 *                       lsp_to_pe2

Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions

To              From            State   Rt Style Labelin Labelout LSPname

192.0.2.0     192.0.2.3     Up       0  1 FF       3        - lsp_to_pe1

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The **State** field in the output shows that the Ingress LSP to **Remote PE** (**192.0.2.3**) is up, and the Egress LSP from the remote PE routing device to this PE routing device (**192.0.2.0**) is also up.

Verifying BGP Status

Purpose Verify that BGP is up.

Action

```
user@PE1> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
bgp.l2vpn.0            1          1          0          0          0          0
Peer                     AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
192.0.2.3              10         33         34       0       1       13:24 Establ

  bgp.l2vpn.0: 1/1/1/0
  vpn2.l2vpn.0: 1/1/1/0
```

Meaning The output shows that the remote PE routing device (**192.0.2.3**) is listed as the BGP peer and that a protocol session has been established. It also shows the number of packets received from the remote PE routing device (**33**) and the number of packets sent (**34**) to the remote PE routing device.

Verifying the Status of the RSVP Sessions

Purpose Verify that the RSVP sessions (ingress and egress) are up.

Action

```
user@PE1> show rsvp session
Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
192.0.2.3     192.0.2.0     Up       0  1 FF       -   462880 lsp_to_pe2
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
192.0.2.0     192.0.2.3     Up       0  1 FF       3        - lsp_to_pe1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The output shows that both the ingress RSVP session and the egress RSVP session are up.

Verifying the Routes in the Routing Table

Purpose On routing device PE 1, use the **show route table** command to verify that the routing table is populated with the Layer 2 VPN routes used to forward the traffic.

Action

```
user@PE1> show route table bgp.l2vpn.0

bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192:2:27:27/96
                   *[BGP/170] 00:13:55, localpref 100, from 192.0.2.3
                      AS path: I
                    > to 10.2.0.24 via ge-6/0/46.0, label-switched-path lsp_to_pe2
```

```
user@PE1> show route table vpn1.l2vpn.0

vpn1.l2vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192:2:27:27/96

                   *[BGP/170] 00:14:00, localpref 100, from 192.0.2.3
                      AS path: I

                    > to 10.2.0.24 via ge-6/0/46.0, label-switched-path lsp_to_pe2
192:2:28:27/96

                   *[L2VPN/170/-101] 00:15:55, metric2 1
                      Indirect
```

Meaning The command **show route table bgp.l2vpn.0** displays all Layer 2 VPN routes that have been created on this routing device. The command **show route table vpn1.l2vpn.0** shows the Layer 2 VPN routes that have been created for the routing instance **vpn1**.

Pinging the Layer 2 VPN Connections

Purpose Verify connectivity.

Action

```
user@PE1> ping mpls l2vpn interface xe-6/0/0.0 reply-mode ip-udp
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@PE1> ping mpls l2vpn instance vpn1 remote-site-id 26 local-site-id 21 detail
Request for seq 1, to interface 68, labels <800001, 100176>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 68, labels <800001, 100176>
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 68, labels <800001, 100176>
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 68, labels <800001, 100176>
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 68, labels <800001, 100176>
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Meaning The output shows that connectivity is established.

Understanding Using MPLS-Based Layer 2 and Layer 3 VPNs on EX Series Switches

On EX8200 and EX4500 switches, you can use MPLS-based Layer 2 and Layer 3 virtual private networks (VPNs) or MPLS Layer 2 circuits, allowing you to securely connect geographically diverse sites across an MPLS network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

A VPN uses a public telecommunications infrastructure, such as the Internet, to provide remote offices or individual users with secure access to their organization's network. VPNs are designed to provide the same level of performance and security as privately owned or leased networks but without the attendant costs.

This topic describes:

- MPLS-Based Layer 2 VPNs on page 923
- Layer 2 Circuits on page 923
- MPLS-Based Layer 3 VPNs on page 924
- Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN on page 924

MPLS-Based Layer 2 VPNs

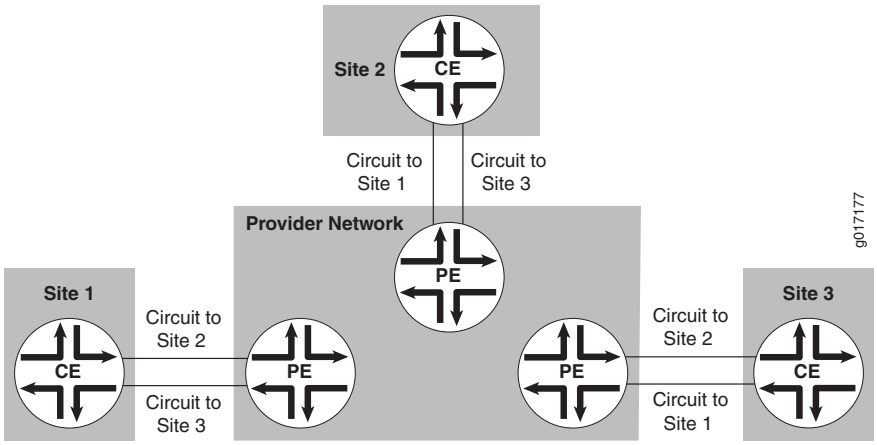
In an MPLS-based Layer 2 VPN, traffic is forwarded by the customer's customer edge (CE) switch (or router) to the service provider's provider edge (PE) switch in a Layer 2 format. It is carried by MPLS over the service provider's network and then converted back to Layer 2 format at the receiving site.

On a Layer 2 VPN, routing occurs on the customer's switches, typically on the CE switch. The CE switch connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The PE switch receiving the traffic sends it across the service provider's network to the PE switch connected to the receiving site. The PE switches do not store or process the customer's routes; the switches must be configured to send data to the appropriate tunnel.

For a Layer 2 VPN, customers must configure their own switches to carry all Layer 3 traffic. The service provider must detect only how much traffic the Layer 2 VPN will need to carry. The service provider's switches carry traffic between the customer's sites using Layer 2 VPN interfaces. The VPN topology is determined by policies configured on the PE switches.

Customers must know only which VPN interfaces connect to which of their own sites. Figure 75 on page 923 illustrates a full-mesh Layer 2 VPN in which each site has a VPN interface linked to each of the other customer sites. In a full-mesh topology between all three sites, each site requires two logical interfaces (one for each of the other CE routers or switches), although only one physical link is needed to connect each PE switch to each CE router or switch.

Figure 75: Layer 2 VPN Connecting CE Switches



Layer 2 Circuits

A Layer 2 circuit is a point-to-point Layer 2 connection that uses MPLS or another tunneling technology on the service provider's network. A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) switches. In contrast, each CCC requires a dedicated LSP.

The Junos OS implementation of Layer 2 circuits supports only the remote form of a Layer 2 circuit; that is, a connection from a local customer edge (CE) switch to a remote CE switch.

Packets are sent to the remote CE switch by means of an egress virtual private network (VPN) label advertised by the remote PE switch. The VPN label transits over either an RSVP or an LDP LSP (or other type) tunnel to the remote PE switch connected to the remote CE switch. LDP is the signaling protocol used for advertising VPN labels.

Return traffic sent from the remote CE switch to the local CE switch uses an ingress VPN label advertised by the local PE switch.

MPLS-Based Layer 3 VPNs

In a Layer 3 VPN, the routing occurs on the service provider's routers. Therefore, Layer 3 VPNs require more configuration on the part of the service provider, because the service provider's PE routers must store and process the customer's routes.

In the Junos OS, Layer 3 VPNs are based on RFC 4364, *BGP/MPLS IP Virtual Private Networks*. This RFC defines a mechanism by which service providers can use their IP backbones to provide Layer 3 VPN services to their customers. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone.

VPNs based on RFC 4364 are also known as BGP/MPLS VPNs because BGP is used to distribute VPN routing information across the provider's backbone, and MPLS is used to forward VPN traffic across the backbone to remote VPN sites.

Customer networks, because they are private, can use either public addresses or private addresses, as defined in RFC 1918, *Address Allocation for Private Internets*. When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the private addresses used by other network users. BGP/MPLS VPNs solve this problem by prefixing a VPN identifier to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and within the public Internet.

In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only. Two different VPNs can use overlapping addresses. Each route within a VPN is assigned an MPLS label (for example, MPLS-ARCH, MPLS-BGP, or MPLS-ENCAPS). When BGP distributes a VPN route, it also distributes an MPLS label for that route. Before a customer data packet travels across the service provider's backbone, it is encapsulated along with the MPLS label that corresponds to the route within the customer's VPN that is the best match based on the packet's destination address. This MPLS packet is further encapsulated with another MPLS label or with an IP, so that it gets tunneled across the backbone to the egress provider edge (PE) switch. Thus, the backbone core switches do not need to know the VPN routes.

Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN

The differences between Layer 2 VPNs and Laer 3 VPNS are summarized in Table 34 on page 925

Table 34: Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN

Layer 2 VPN	Layer 3 VPN
Customer sites appear to be on the same LAN even if geographically dispersed.	Service provider's technical expertise ensures efficient site-to-site routing. Service providers can provide additional value-added services through network convergence that encompasses voice, video, and data.
The service provider does not require information about the customer's network topology, policies, routing information, etc. The customer has complete control over policies and routing.	Customers must share information about their network topology. The service provider determines the policies and routing.
The CE switch forwards traffic to the service provider's PE switch in Layer 2 format.	The customer's CE switch must be configured to use BGP or OSPF to communicate with the service provider's PE switch to carry IP prefixes across the network. Other protocol packets are not supported.

Verifying an MPLS Layer 2 VPN Configuration

Purpose Verify the connectivity of MPLS Layer 2 VPNs using the **ping mpls** command. This command helps to verify that a VPN has been enabled by testing the integrity of the VPN connection between the PE routers. It does not test the connection between a PE router and CE router.

Action

- To ping an interface configured for the Layer 2 VPN on the PE router, use the following command:

  ping mpls l2vpn interface *interface-name*

- To ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier to test the integrity of the Layer 2 VPN connection (specified by identifiers) between the two PE routers, use the following command:

  ping mpls l2vpn instance *l2vpn-instance-name* **local-site-id** *local-site-id-number* **remote-site-id** *remote-site-id-number*

Related Documentation

- MPLS Layer 2 VPN Configuration Overview on page 899

Configuring an MPLS-Based Layer 2 VPN (CLI Procedure)

You can configure MPLS-based Layer 2 virtual private networks (VPNs) on EX8200 and EX4500 switches. Some benefits of a Layer 2 VPN are that it is private, secure and flexible. To configure Layer 2 VPN functionality in your MPLS network, you must configure Layer 2 VPN components on the local and remote provider edge (PE) switches.

NOTE: This topic shows how to add Layer 2 VPN components to a CCC configured on a simple interface. For information on combining Layer 2 VPN components with a tagged VLAN CCC, see "Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)" on page 1106 .

Before you configure the Layer 2 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)" on page 77.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: A Layer 2 VPN requires that the PE switches be configured using a circuit cross-connect (CCC).

Configure the Layer 2 VPN components on both PE switches. This procedure describes how to configure one PE switch. Repeat the procedure to configure the remote PE switch.

To configure Layer 2 VPN components on the PE switch:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

   NOTE: The customer edge interface is a simple interface.

   ```
   [edit]
   user@switch# set interfaces interface-name encapsulation ethernet-ccc
   ```

2. Configure BGP, specifying the loopback address of this PE switch as the local address and specifying **family l2vpn signaling**:

   ```
   [edit protocols bgp]
   user@switch# set local-address address family l2vpn signaling
   ```

3. Configure the BGP group, specifying the group name and **type internal**:

   ```
   [edit protocols bgp]
   ```

```
user@switch# set group group-name type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switch# set neighbor address
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@switch# set routing-instance-name instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
user@switch#  set routing-instances routing-instance-name interface interface-name
```

7. Configure the routing instance to use a route distinguisher:

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances musthave a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

```
user@switch#  set routing-instances routing-instance-name route-distinguisher
ip-address:number
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name vrf-target community
```

NOTE: If you configure the *community* option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols interface interface-name description text
```

11. Configure the routing instance protocols site:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn site site-name site-identifier
identifierremote-site-id identifier
```

NOTE: The remote site ID (configured with the remote-site-id statement) corresponds to the site ID (configured with the site-identifier statement) configured on the other PE switch.

Understanding MPLS Layer 2 Circuits

An MPLS Layer 2 circuit is a point-to-point Layer 2 connection that transports traffic by means of MPLS or another tunneling technology on the service provider network. The Layer 2 circuit creates a virtual connection to direct traffic between two customer edge (CE) routers across a service provider network. The main difference between a Layer 2 VPN and a Layer 2 circuit is the method of setting up the virtual connection. As with a leased line, a Layer 2 circuit forwards all packets received from the local interface to the remote interface.

Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router to the local CE router. All Layer 2 circuits using a particular remote PE router neighbor is identified by its IP address and is usually the endpoint destination for the label-switched path (LSP) tunnel transporting the Layer 2 circuit.

Each virtual circuit ID uniquely identifies the Layer 2 circuit among all the Layer 2 circuits to a specific neighbor. The key to identifying a particular Layer 2 circuit on a PE router is the neighbor address and the virtual circuit ID. Based on the virtual circuit ID and the neighbor relationship, an LDP label is bound to an LDP circuit. LDP uses the binding for sending traffic on that Layer 2 circuit to the remote CE router.

MPLS Layer 2 Circuit Configuration Overview

To configure an MPLS Layer 2 circuit:

1. Determine all of the routers that you want to participate in the circuit, and then complete the initial configuration of their interfaces. See the *Interfaces Feature Guide for Security Devices*.

2. For all of the routers in the circuit configuration, update the interface configurations to enable participation in the Layer 2 circuit.

   a. On the interface communicating with the other provider edge (PE) router, specify MPLS and IPv4, and include the IP address. For the loopback interface, specify **inet**, and include the IP address. For IPv4, designate the loopback interface as primary so it can receive control packets. (Because it is always operational, the loopback interface is best able to perform the control function.)

   b. On the PE router interface facing the customer edge (CE) router, specify a circuit cross-connect (CCC) encapsulation type. The type of encapsulation depends on the interface type. For example, an Ethernet interface uses **ethernet-ccc**. (The encapsulation type determines how the packet is constructed for that interface.)

   c. On the CE router interface that faces the PE router, specify **inet** (for IPv4), and include the IP address. In addition, specify a routing protocol such as Open Shortest Path First (OSPF), which specifies the area and IP address of the router interface.

   See "Configuring Interfaces for Layer 2 VPNs (CLI Procedure)" on page 902.

3. For all of the routers in the circuit configuration, configure the appropriate protocols.

   a. MPLS—For PE routers and provider routers, use MPLS to advertise the Layer 2 circuit interfaces that communicate with other PE routers and provider routers.

   b. BGP—For PE routers, configure a BGP session.

   c. IGP and a signaling protocol—For PE routers, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but cannot use them for interfaces between PE routers and CE routers.

      In addition, configure an IGP such as OSPF or static routes on the PE routers to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area

boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

See "Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)" on page 931 and "Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)" on page 894.

4. For all of the routers in the circuit configuration, configure routing options. The only required routing option for circuits is the autonomous system (AS) number. You must specify it on each router involved in the circuit. See "Configuring Routing Options for MPLS VPNs (CLI Procedure)" on page 894.

5. For PE routers, configure Layer 2 circuits on the appropriate interfaces. See "Configuring an MPLS Layer 2 Circuit (CLI Procedure)" on page 930.

Related Documentation

- Verifying an MPLS Layer 2 Circuit Configuration on page 930

Configuring an MPLS Layer 2 Circuit (CLI Procedure)

To configure a Layer 2 circuit on a PE router:

1. Enable a Layer 2 circuit on the appropriate interface.

```
[edit]
user@host# edit protocols l2circuit neighbor interface-name interface interface-name
```

2. Enter the circuit ID number.

```
[edit protocols l2circuit neighbor interface-name interface interface-name]
user@host# set virtual-circuit-id id-number
```

For **neighbor**, specify the local loopback address, and for **interface**, specify the interface name of the remote PE router.

3. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)

The following instructions show how to configure LDP and OSPF on PE routers and provider routers. Within the task, you specify which interfaces to enable for LDP. Perform this step on each PE router interface and provider router interface that communicates with other PE routers and provider routers. For OSPF, you configure at least one area on at least one of the router's interfaces. (An AS can be divided into multiple areas.) These instructions use the backbone area **0.0.0.0** and show how to enable traffic engineering for Layer 2 VPN circuits.

To configure LDP and OSPF:

1. Enable the ldp protocol.

   ```
   [edit]
   user@host# edit protocols ldp
   ```

   NOTE: You must configure the IGP at the **[protocols]** level of the configuration hierarchy, not within the routing instance at the **[routing-instances]** level of the configuration hierarchy.

2. Specify which interfaces to enable for LDP.

   ```
   [edit protocols ldp]
   user@host# edit interface interface-name
   ```

3. Configure OSPF for each interface that uses LDP.

   ```
   [edit]
   user@host# edit protocols ospf area 0.0.0.0 interface interface-name
   ```

4. (Layer 2 VPN circuits only) Enable traffic engineering.

```
[edit protocols ospf]
user@host# set traffic engineering
```

5. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring an MPLS-Based Layer 2 VPN (CLI Procedure)

You can configure MPLS-based Layer 2 virtual private networks (VPNs) on EX8200 and EX4500 switches. Some benefits of a Layer 2 VPN are that it is private, secure and flexible. To configure Layer 2 VPN functionality in your MPLS network, you must configure Layer 2 VPN components on the local and remote provider edge (PE) switches.

NOTE: This topic shows how to add Layer 2 VPN components to a CCC configured on a simple interface. For information on combining Layer 2 VPN components with a tagged VLAN CCC, see "Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)" on page 1106 .

Before you configure the Layer 2 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)" on page 77.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: A Layer 2 VPN requires that the PE switches be configured using a circuit cross-connect (CCC).

Configure the Layer 2 VPN components on both PE switches. This procedure describes how to configure one PE switch. Repeat the procedure to configure the remote PE switch.

To configure Layer 2 VPN components on the PE switch:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

   

   NOTE: The customer edge interface is a simple interface.

   ```
   [edit]
   user@switch# set interfaces interface-name encapsulation ethernet-ccc
   ```

2. Configure BGP, specifying the loopback address of this PE switch as the local address and specifying **family l2vpn signaling**:

   ```
   [edit protocols bgp]
   user@switch# set local-address address family l2vpn signaling
   ```

3. Configure the BGP group, specifying the group name and **type internal**:

   ```
   [edit protocols bgp]
   user@switch# set group group-name type internal
   ```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

   ```
   [edit protocols bgp]
   user@switch# set neighbor address
   ```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

   ```
   [edit routing-instances]
   user@switch# set routing-instance-name instance-type l2vpn
   ```

6. Configure the routing instance to apply to the customer edge interface:

   ```
   user@switch#  set routing-instances routing-instance-name interface interface-name
   ```

7. Configure the routing instance to use a route distinguisher:

   

   NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances musthave a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

   ```
   user@switch#  set routing-instances routing-instance-name route-distinguisher
   ip-address:number
   ```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name vrf-target community
```

NOTE: If you configure the *community* option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols interface interface-name description text
```

11. Configure the routing instance protocols site:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn site site-name site-identifier
identifierremote-site-id identifier
```

NOTE: The remote site ID (configured with the remote-site-id statement) corresponds to the site ID (configured with the site-identifier statement) configured on the other PE switch.

Understanding MPLS Layer 3 VPNs

An MPLS Layer 3 VPN operates at the Layer 3 level of the OSI model, the Network layer. The VPN is composed of a set of sites that are connected over a service provider's existing public Internet backbone. The sites share common routing information and the connectivity of the sites is controlled by a collection of policies.

In an MPLS Layer 3 VPN, routing occurs on the service provider's routers. The provider routers route and forward VPN traffic at the entry and exit points of the transit network. The service provider network must learn the IP addresses of devices sending traffic across

the VPN and the routes must be advertised and filtered throughout the provider network. As a result, Layer 3 VPNs require information about customer routes and a more extensive VPN routing and forwarding (VRF) policy configuration than a Layer 2 VPN. This information is used to share and filter routes that originate or terminate in the VPN.

The MPLS Layer 3 VPN requires more processing power on the provider edge (PE) routers than a Layer 2 VPN, because the Layer 3 VPN has larger routing tables for managing network traffic on the customer sites. Route advertisements originate at the customer edge (PE) routers and are shared with the inbound PE routers through standard IP routing protocols, typically BGP. Based on the source address, the PE router filters route advertisements and imports them into the appropriate VRF table.

The provider router uses OSPF and LDP to communicate with the PE routers. For OSPF, the provider router interfaces that communicate with the PE routers are specified, as well as the loopback interface. For the PE routers, the loopback interface is in passive mode, meaning it does not send OSPF packets to perform the control function.

MPLS Layer 3 VPN Configuration Overview

To configure MPLS Layer 3 VPN functionality on a router running Junos OS, you must enable support on the provider edge (PE) router and configure the PE router to distribute routing information to other routers in the VPN, as explained in the following steps. However, because the tunnel information is maintained at both PE routers, neither the provider core routers nor the customer edge (CE) routers need to maintain any VPN information in their configuration databases.

To configure an MPLS Layer 3 VPN:

1. Determine all of the routers that you want to participate in the VPN, and then complete the initial configuration of their interfaces. See the *Junos OS Interfaces Configuration Guide for Security Devices*.

2. For all of the routers in the VPN configuration, update the interface configurations to enable participation in the Layer 3 VPN. As part of the interface configuration, you must configure the MPLS address family for each interface that uses LDP or RSVP. See "Configuring Interfaces for Layer 2 VPNs (CLI Procedure)" on page 902.

3. For all of the routers in the VPN configuration, configure the appropriate protocols.

   a. MPLS—If you are using RSVP, use MPLS to advertise the Layer 3 VPN interfaces on the PE routers and provider routers that communicate with other PE routers and provider routers.

   b. BGP, EBGP, and internal BGP (IBGP)—For PE routers, configure a BGP session to enable the routers to exchange information about routes originating and terminating in the VPN. (The PE routers use this information to determine which labels to use

for traffic destined to the remote sites. The IBGP session for the VPN runs through the loopback address.) In addition, CE routers require a BGP connection to the PE routers. See "Configuring a BGP Session for MPLS VPNs (CLI Procedure)" on page 893.

c. IGP and a signaling protocol—For PE routers and provider, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but cannot use them for interfaces between PE routers and CE routers.

   In addition, configure an IGP such as OSPF or static routes on the PE routers in order to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

   See "Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)" on page 931 and "Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)" on page 894.

4. For all of the routers in the VPN configuration, configure routing options. The only required routing option for VPNs is the autonomous system (AS) number. You must specify it on each router involved in the VPN. See "Configuring Routing Options for MPLS VPNs (CLI Procedure)" on page 894.

5. For each PE router in the VPN configuration, configure a routing instance for each VPN. The routing instance should have the same name on each PE router. Each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP distinguish between potentially identical network layer reachable information [NLRI] messages received from different VPNs.) See "Configuring a Routing Instance for MPLS VPNs (CLI Procedure)" on page 895.

6. For CE routers, configure a routing policy. In addition, if you are not using a route target, configure a VPN routing policy for each PE router in the VPN configuration. Within the policy, describe which packets are sent and received across the VPN and specify how routes are imported into and exported from the router's VRF table. Each advertisement must have an associated route target that uniquely identifies the VPN for which the advertisement is valid. See "Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure)" on page 937.

- Verifying an MPLS Layer 3 VPN Configuration on page 937

Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure)

To configure a Layer 3 VPN routing policy on a CE router:

1. Configure the routing policy for the loopback interface.

```
[edit]
user@host# edit policy-options policy-statement policy-name
```

2. Define the term for accepting packets.

```
[edit policy-options policy-statement policy-name]
user@host# set term term-name-accept from protocol direct route-filter
   local-loopback-address/netmask exact
user@host# set termterm-name-accept then accept
```

3. Define the term for rejecting packets.

```
[edit policy-options policy-statement policy-name]
user@host# set termterm-name-reject then reject
```

4. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Related Documentation

- MPLS Layer 3 VPN Configuration Overview on page 935

Verifying an MPLS Layer 3 VPN Configuration

Purpose Verify the connectivity of MPLS Layer 3 VPNs using the **ping mpls** command. This command helps to verify that a VPN has been enabled by testing the integrity of the VPN connection between the source and destination routers. The destination prefix corresponds to a prefix in the Layer 3 VPN. However, ping tests only whether the prefix is present in a PE VRF table.

Action To a combination of a IPv4 destination prefix and a Layer 3 VPN name on the destination PE router, use the following command:

```
ping mpls l3vpn l3vpn-name prefix prefix count count
```

Example: Configuring MPLS-Based Layer 3 VPNs

You can implement an MPLS-based Layer 3 virtual private network (VPN) on QFX switches to interconnect sites for customers who want the service provider to handle all the Layer 3 routing functions. To support an MPLS-based Layer 3 VPN, you need to add components of the Layer 3 VPN to the configuration of the two provider edge (PE) switches. You do not need to change the configuration of the provider switches.

This example shows how to configure an MPLS-based Layer 3 VPN spanning two corporate sites:

Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.3 or later for the QFX Series
- Three QFX switches

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches" on page 67.
- Configure one or more provider switches. See "Configuring MPLS on Provider Switches" on page 71.

Overview and Topology

Layer 3 VPNs allow customers to leverage the service provider's technical expertise to ensure efficient site-to-site routing. The customer's customer edge (CE) switch uses a routing protocol such as BGP or OSPF to communicate with the service provider's provider edge (PE) switch to carry IP prefixes across the network. MPLS-based Layer 3 VPNs use only IP over MPLS; other protocol packets are not supported. This example includes two PE switches, PE1 and PE2.

In the basic MPLS configuration of the PE switches using IP over MPLS, the PE switches were configured to use OSPF as the routing protocol between the MPLS switches and RSVP as the signaling protocol. Traffic engineering was enabled. A label-switched path (LSP) was configured.

The following components must be added to the PE switches for an MPLS-based Layer 3 VPN:

- BGP group with **family inet-vpn unicast**

- Routing instance with instance type **vrf**

Figure 76 on page 939 shows the topology used in this example.

Figure 76: Configuring an MPLS-Based Layer 3 VPN

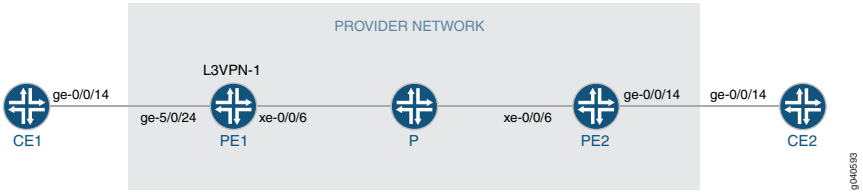

Table 35 on page 939 shows the settings of the customer edge interface on the local CE switch.

Table 35: Local CE Switch in the MPLS-Based Layer 3 VPN Topology

Property	Settings	Description
Local CE switch hardware	QFX switch	CE1
Customer edge interface	**ge-0/0/14 unit 0** **family inet** **address 51.51.0.14/16** protocols ospf interface ge-0/0/14	Interface that connects CE1 to PE1.

Table 36 on page 939 shows the settings of the customer edge interface on the remote CE switch.

Table 36: Remote CE Switch in the MPLS-Based Layer 3 VPN Topology

Property	Settings	Description
Remote CE switch hardware	QFX switch	CE2
Customer edge interface	**ge-0/0/14 unit 0** **family inet** **address 11.22.26.1/16** protocols ospf interface ge-0/0/14	Interface that connects CE2 to PE2.

Table 37 on page 939 shows the Layer 3 VPN components of the local PE switch.

Table 37: Layer 3 VPN Components of the Local PE Switch

Property	Settings	Description
Local PE switch hardware	QFX switch	PE1

Table 37: Layer 3 VPN Components of the Local PE Switch (continued)

Property	Settings	Description
Customer edge interface	**ge-5/0/24 unit 0** **family inet** **address 51.51.0.1/16**	Connects PE1 to CE1. NOTE: The **family inet** configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	**xe-0/0/6 unit 0** **family inet address 60.0.0.60/16** **family mpls**	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	**lo0 unit 0** **family inet address 21.21.21.21/32**	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	**bgp**	Added for the Layer 3 VPN configuration.
Routing instance	**L3VPN-1**	Added for the Layer 3 VPN configuration.

Table 38 on page 941 shows the Layer 3 VPN components of the remote PE switch.

Table 38: Layer 3 VPN Components of the Remote PE Switch

Property	Settings	Description
Remote PE switch hardware	QFX switch	PE2
Customer edge interface	**ge-0/0/14 unit 0** **family inet** **address 11.22.26.14/16**	Connects PE2 to CE2. For the Layer 3 VPN configuration, added **family mpls**. NOTE: The **family inet** configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	**xe-0/0/6 unit 0** **family inet address 60.2.0.60/16** **family mpls**	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	**lo0 unit 0** **family inet address 22.22.22.22/32**	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	**bgp**	Added for the Layer 3 VPN configuration.
Routing instances	**L3VPN-1**	Added for the Layer 3 VPN configuration.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the local PE switch, copy the following commands and paste them into the switch terminal window of PE1:

```
[edit]
set protocols bgp local-address 21.21.21.21 family inet-vpn unicast
set protocols bgp group PE1-PE2 type internal
set protocols bgp neighbor 22.22.22.22
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-5/0/24.0
set routing-instances L3VPN-1 protocols ospf interface ge-5/0/24.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label
```

```
set routing-options router-id 21.21.21.21
set routing-options autonomous-system 10
```

Step-by-Step Procedure

To configure the Layer 3 VPN components on the local PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

   ```
   [edit protocols bgp]
   user@switchPE1# set local-address 21.21.21.21 family inet-vpn unicast
   ```

2. Configure the BGP group, specifying the group name and type:

   ```
   [edit protocols bgp]
   user@switchPE1# set group PE1-PE2 type internal
   ```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

   ```
   [edit protocols bgp]
   user@switchPE1# set neighbor 22.22.22.22
   ```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 instance-type vrf
   ```

5. Configure a description for this routing instance:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
   ```

6. Configure the routing instance for the OSPF interface:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 protocols ospf interface ge-5/0/24.0
   ```

7. Configure the routing instance to use a route distinguisher:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 route-distinguisher 21:21
   ```

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances require a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-target target:21:21
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Library for Routing Devices*.

9. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-table-label
```

10. Configure the router ID and autonomous system (AS):

NOTE: We recommend that you explicitly configure the router identifier under the **[edit routing-options]** hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
user@switchPE1# set router-id 21.21.21.21 autonomous-system 10
```

Results Display the results of the configuration:

```
user@switchPE1> show configuration
```

```
interfaces {
    ge-5/0/24 {
        unit 0 {
            family inet {
                address 51.51.0.1/16;
            }
        }
    }
    xe-0/0/6 {
        unit 0 {
            family inet {
                address 60.0.0.60/16;
            }
            family mpls;
        }
    }
```

```

      interface ge-5/0/24.0
    }
  }
}
```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE2:

```
[edit]
set protocols bgp local-address 22.22.22.22 family inet-vpn unicast
set protocols bgp group PE1-PE2 type internal
set protocols bgp neighbor 21.21.21.21
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-0/0/14.0
set routing-instances L3VPN-1 protocols ospf interface ge-0/0/14.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
set routing-options router-id 22.22.22.22
set routing-options autonomous-system 10
```

Step-by-Step Procedure

To configure Layer 3 VPN components on the remote PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

   ```
   [edit protocols bgp]
   user@switchPE2# set local-address 22.22.22.22 family inet-vpn unicast
   ```

2. Configure the BGP group, specifying the group name and type:

   ```
   [edit protocols bgp]
   user@switchPE2# set group PE1-PE2 type internal
   ```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

   ```
   [edit protocols bgp]
   user@switchPE2# set neighbor 21.21.21.21
   ```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 instance-type vrf
   ```

5. Configure a description for this routing instance:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
   ```

6. Configure the routing instance to apply to the customer edge interface:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 interface ge-0/0/14.0
   ```

7. Configure the routing instance for the OSPF interface:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 protocols ospf interface ge-0/0/14.0
```

8. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 route-distinguisher 21:21
```

9. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-target target:21:21
```

10. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-tabel-label
```

11. Configure the router ID and autonomous system (AS):

```
[edit routing-options]
user@switchPE2# set router-id 22.22.22.22 autonomous-system 10
```

Results Display the results of the configuration:

```
user@switchPE2> show configuration
```

```
interfaces {
    ge-0/0/14 {
        unit 0 {
            family inet {

Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

This example shows how to configure Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

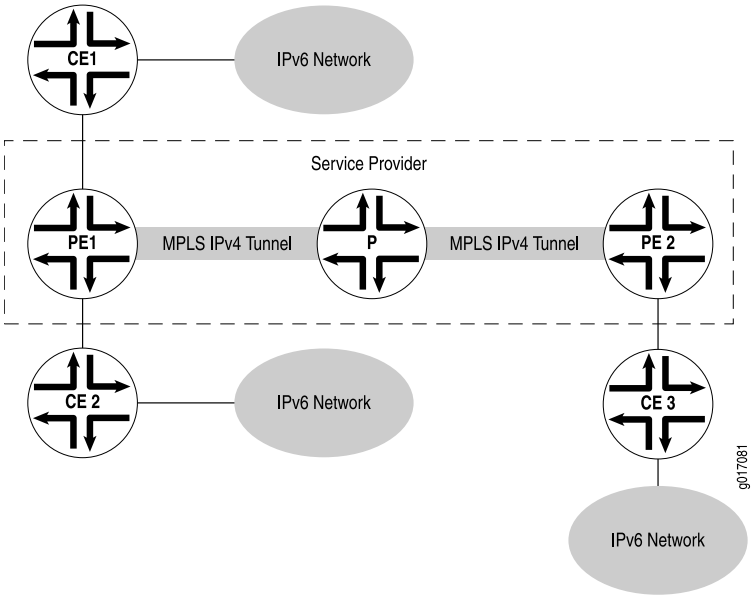
- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at **http://www.ietf.org/**.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In Figure 16 on page 282, PE1 and PE2 are dual-stack BGP routers or switches, meaning they have both IPv4 and IPv6 stacks. The PE devices link the IPv6 networks through the customer edge (CE) routers or switches to the IPv4 core network. The CE devices and the PE devices connect through a link layer that can carry IPv6 traffic. The PE devices use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

Figure 77: IPv6 Networks Linked by MPLS IPv4 Tunnels



The two PE devices are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE devices can learn the IPv6 routes from the CE devices connected to them using MP-BGP or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE device and CE device could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGP, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE devices always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE device is not a Juniper Networks routing or switching platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE devices to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The

penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 device in Figure 16 on page 282 receives an IPv6 packet from the CE1 device, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 device, then no labels need to be pushed and the packet is simply sent to the CE2 device. If the destination matches a prefix that was learned from the PE2 device, then the PE1 router pushes two labels onto the packet and sends it to the Provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the **family inet6** statement on all the CE router–facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.
- You enable IPv6 tunneling by including the **ipv6-tunneling** statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

  NOTE: **BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the labeled-unicast statement at the [edit protocols bgp family inet] hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the inet6.3 routing table.**

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the **explicit-null** statement in the BGP configuration.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device PE1

```
set interfaces xe-0/0/5 unit 2 family inet6 address ::10.1.1.2/126
set interfaces xe-0/0/5 unit 2 family mpls
set interfaces xe-0/0/6 unit 5 family inet address 10.1.1.5/30
set interfaces xe-0/0/6 unit 5 family inet6
set interfaces xe-0/0/6 unit 5 family mpls
set interfaces lo0 unit 2 family inet address 1.1.1.2/32

```

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
user@PE1# set xe-0/0/5 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set xe-0/0/5 unit 2 family mpls
user@PE1# set xe-0/0/6 unit 5 family inet address 10.1.1.5/30
user@PE1# set xe-0/0/6 unit 5 family inet6
user@PE1# set xe-0/0/6 unit 5 family mpls
user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface xe-0/0/5.2
user@PE1# set interface xe-0/0/6.5
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
```

```
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1
user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6
user@PE1# set group toPE2 neighbor 1.1.1.4
```

4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface xe-0/0/6.5
user@PE1# set interface lo0.2 passive
```

5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set rsvp interface xe-0/0/6.5
```

6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self
user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept
user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```

7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
xe-0/0/5 {
```

```
    unit 2 {
      family inet6 {
        address ::10.1.1.2/126;
      }
      family mpls;
    }
}
xe-0/0/6 {
    unit 5 {
      family inet {
        address 10.1.1.5/30;
      }
      family inet6;
      family mpls;
    }
}
lo0 {
    unit 2 {
      family inet {
        address 1.1.1.2/32;
      }
    }
}
```

```
user@R1# show policy-options
policy-statement next-hop-self {
    then {
      next-hop self;
    }
}
policy-statement send-bgp6 {
    from {
      family inet6;
      protocol bgp;
    }
    then accept;
}
policy-statement send-v6 {
    from {
      family inet6;
      protocol [ bgp direct ];
    }
    then accept;
}
```

```
user@R1# show protocols
mpls {
    ipv6-tunneling;
    interface xe-0/0/5.2;
    interface xe-0/0/6.5;
}
bgp {
    group toCE1 {
      type external;
```

```
    local-address ::10.1.1.2;
    family inet6 {
      unicast;
    }
    export send-bgp6;
    peer-as 1;
    neighbor ::10.1.1.1;
  }
  group toPE2 {
    type internal;
    local-address 1.1.1.2;
    family inet6 {
      labeled-unicast {
        explicit-null;
      }
    }
    export [ next-hop-self send-v6 ];
    neighbor 1.1.1.4;
  }
}
ospf {
  area 0.0.0.0 {
    interface xe-0/0/6.5;
    interface lo0.2 {
      passive;
    }
  }
}
rsvp {
  interface xe-0/0/6.5;
}
```

```
user@R1# show routing-options
router-id 1.1.1.2;
autonomous-system 2;
```

If you are done configuring the device, enter **commit** from configuration mode. Configure the other devices in the topology, as shown in "CLI Quick Configuration" on page 284.

Verification

Confirm that the configuration is working properly.

Verifying That the CE Devices Have Connectivity

Purpose Make sure that the tunnel is operating.

Action From operational mode, enter the **ping** command.

```
user@CE1> ping ::10.1.1.14
```

```
PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms
```

```
user@CE3> ping ::10.1.1.1
PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

Meaning The IPv6 CE devices can communicate over the core IPv4 network.

Related Documentation

Example: Configuring MPLS-Based Layer 3 VPNs on EX Series Switches

You can implement an MPLS-based Layer 3 virtual private network (VPN) on EX8200 and EX4500 switches to interconnect sites for customers who want the service provider to handle all the Layer 3 routing functions. To support an MPLS-based Layer 3 VPN, you need to add components of the Layer 3 VPN to the configuration of the two provider edge (PE) switches. You do not need to change the configuration of the provider switches.

NOTE: The core interfaces and the loopback interfaces are configured in the same way for Layer 2 VPNs and Layer 3 VPNs.

This example shows how to configure an MPLS-based Layer 3 VPN spanning two corporate sites:

Requirements

This example uses the following software and hardware components:

- Junos OS Release 11.1 or later for EX Series switches
- Three EX8200 switches

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)" on page 72.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: **A Layer 3 VPN requires that the PE switches be configured using IP over MPLS.**

Overview and Topology

Layer 3 VPNs allow customers to leverage the service provider's technical expertise to ensure efficient site-to-site routing. The customer's customer edge (CE) switch uses a routing protocol such as BGP or OSPF to communicate with the service provider's provider edge (PE) switch to carry IP prefixes across the network. MPLS-based Layer 3 VPNs use only IP over MPLS; other protocol packets are not supported. This example includes two PE switches, PE1 and PE2.

In the basic MPLS configuration of the PE switches using IP over MPLS, the PE switches were configured to use OSPF as the routing protocol between the MPLS switches and RSVP as the signaling protocol. Traffic engineering was enabled. A label-switched path (LSP) was configured.

NOTE: **A static path is not configured in this example.**

The following components must be added to the PE switches for an MPLS-based Layer 3 VPN:

- BGP group with **family inet-vpn unicast**
- Routing instance with instance type **vrf**

Figure 78 on page 959 illustrates the topology of this MPLS-based Layer 3 VPN.

Figure 78: MPLS-Based Layer 3 VPN

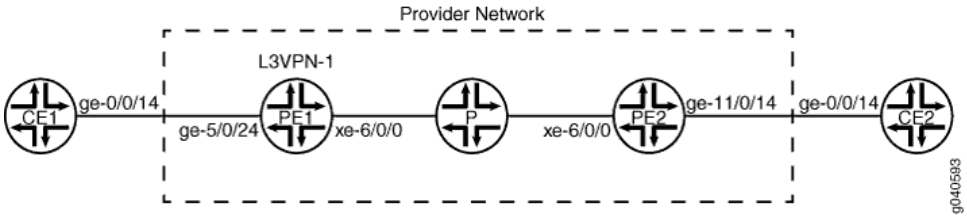

Table 35 on page 939 shows the settings of the customer edge interface on the local CE switch.

Table 39: Local CE Switch in the MPLS-Based Layer 3 VPN Topology

Property	Settings	Description
Local CE switch hardware	EX8200 switch	CE1
Customer edge interface	**ge-0/0/14 unit 0** **family inet** **address 51.51.0.14/16**	Interface that connects CE1 to PE1.

Table 36 on page 939 shows the settings of the customer edge interface on the remote CE switch.

Table 40: Remote CE Switch in the MPLS-Based Layer 3 VPN Topology

Property	Settings	Description
Remote CE switch hardware	EX8200 switch	CE2
Customer edge interface	**ge-0/0/14 unit 0** **family inet** **address 11.22.26.1/16**	Interface that connects CE2 to PE2.

Table 37 on page 939 shows the Layer 3 VPN components of the local PE switch.

Table 41: Layer 3 VPN Components of the Local PE Switch

Property	Settings	Description
Local PE switch hardware	EX8200 switch	PE1
Customer edge interface	**ge-5/0/24 unit 0** **family inet** **address 51.51.0.1/16**	Connects PE1 to CE1. NOTE: The **family inet** configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.

Table 41: Layer 3 VPN Components of the Local PE Switch (continued)

Property	Settings	Description
Core interface	**xe-6/0/0 unit 0** **family inet address 60.0.0.60/16** **family iso;** **family mpls**	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	**lo0 unit 0** **family inet address 21.21.21.21/32** **family iso address** **49.0001.2102.1021.0210.00**	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	**bgp**	Added for the Layer 3 VPN configuration.
Routing instance	**L3VPN-1**	Added for the Layer 3 VPN configuration.

Table 38 on page 941 shows the Layer 3 VPN components of the remote PE switch.

Table 42: Layer 3 VPN Components of the Remote PE Switch

Property	Settings	Description
Remote PE switch hardware	EX8200 switch	PE2
Customer edge interface	**ge-11/0/14 unit 0** **family inet** **address 11.22.26.14/16** **family mpls**	Connects PE2 to CE2. For the Layer 3 VPN configuration, added **family mpls**. NOTE: The **family inet** configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	**xe-6/0/0/ unit 0** **family inet address 60.2.0.60/16** **family iso** **family mpls**	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	**lo0 unit 0** **family inet address 22.22.22.22/32** **family iso address** **49.0001.2202.1022.0220.00**	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	**bgp**	Added for the Layer 3 VPN configuration.
Routing instances	**L3VPN-1**	Added for the Layer 3 VPN configuration.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the local PE switch, copy the following commands and paste them into the switch terminal window of PE1:

```
[edit]
set protocols bgp group ibgp local-address 21.21.21.21 family inet-vpn unicast
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 22.22.22.22
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-5/0/24.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
set routing-options router-id 21.21.21.21
```

```
set routing-options autonomous-system 10;
```

Step-by-Step Procedure

To configure the Layer 3 VPN components on the local PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

   ```
   [edit protocols bgp]
   user@switchPE1# set group ibgp local-address 21.21.21.21 family inet-vpn unicast
   ```

2. Configure the BGP group, specifying the group name and type:

   ```
   [edit protocols bgp]
   user@switchPE1# set group ibgp type internal
   ```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

   ```
   [edit protocols bgp]
   user@switchPE1# set group ibgp neighbor 22.22.22.22
   ```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 instance-type vrf
   ```

5. Configure a description for this routing instance:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
   ```

6. Configure the routing instance to use a route distinguisher:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 route-distinguisher 21:21
   ```

   NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances require a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

7. Configure the VPN routing and forwarding (VRF) target of the routing instance:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 vrf-target target:21:21
   ```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

8. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-table-label
```

9. Configure the router ID and autonomous system (AS):

NOTE: We recommend that you explicitly configure the router identifier under the **[edit routing-options]** hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
user@switchPE1# set router-id 21.21.21.21 autonomous-system 10
```

Results Display the results of the configuration:

```
user@switchPE1> vrf-table-label
```

```
interfaces {
    ge-5/0/24 {
        unit 0 {
            family inet {
                address 51.51.0.1/16;
            }
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 21.21.21.21/32;
            }
        }
    }
    xe-6/0/0 {
        unit 0 {
            family inet {
                address 60.0.0.60/16;
            }
            family iso;
```

```
      family mpls;
    }
  }
  protocols {
    mpls {
      label-switched-path 21-22 {
        from 21.21.21.21;
        to 22.22.22.22;
        no-cspf;
      }
      interface xe-6/0/0.0;
      interface lo0.0;
      bgp {
        group ibgp
        type internal
        local-address 21.21.21.21
        family inet-vpn
        unicast
      }
    ospf {
      traffic-engineering;
      area 0.0.0.0 {
        interface ge-5/0/24.0;
        interface lo0.0;
        interface xe-6/0/0.0;
      }
    }
  }
  routing-instances {
    L3VPN-1 {
      instance-type vrf;
      description "BETWEEN PE1 AND PE2";
      route-distinguisher 21:21;
      vrf-target target:21:21;
      vrf-table-label;
    }
  routing-options {
    router-id 21.21.21.21;
    autonomous-system 10;
```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE2:

```
[edit]
set protocols bgp group ibgp local-address 22.22.22.22 family inet-vpn unicast
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 21.21.21.21
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-11/0/14.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
```

```
set routing-options router-id 22.22.22.22;
set routing-options autonomous-system 10;
```

Step-by-Step Procedure

To configure Layer 3 VPN components on the remote PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

   ```
   [edit protocols bgp]
   user@switchPE2# set group ibgp local-address 22.22.22.22 family inet-vpn unicast
   ```

2. Configure the BGP group, specifying the group name and type:

   ```
   [edit protocols bgp]
   user@switchPE2# set group ibgp type internal
   ```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

   ```
   [edit protocols bgp]
   user@switchPE2# set group ibgp neighbor 21.21.21.21
   ```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 instance-type vrf
   ```

5. Configure a description for this routing instance:

   ```
   [edit routing-instances]
   user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
   ```

6. Configure the routing instance to apply to the customer edge interface:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 interface ge-11/0/14.0
   ```

7. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 route-distinguisher 21:21
   ```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

   ```
   [edit routing-instances]
   user@switchPE2# set L3VPN-1 vrf-target target:21:21
   ```

9. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.

   ```
   [edit routing-instances]
   ```

```
user@switchPE2# set L3VPN-1 vrf-tabel-label
```

10. Configure the router ID and autonomous system (AS):

```
[edit routing-options]
user@switchPE2# set router-id 22.22.22.22 autonomous-system 10
```

Results Display the results of the configuration:

```
user@switchPE2> show configuration
```

```
interfaces {
    ge-11/0/14 {
        unit 0 {
            family inet {
                address 11.22.26.14/16;
            }
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 22.22.22.22/32;
            }
        }
    }
    xe-6/0/0 {
        unit 0 {
            family inet {
                address 60.2.0.60/16;
            }
            family iso;
            family mpls;
        }
    }
    protocols {
        mpls {
            label-switched-path 22-21 {
                from 22.22.22.22;
                to 21.21.21.21;
                no-cspf;
            }
            interface xe-6/0/0.0;
            interface lo0.0;
            bgp {
                group ibgp
                type internal
                local-address 21.21.21.21
                family inet-vpn
                unicast
            }
        ospf {
            traffic-engineering;
```

```
        area 0.0.0.0 {
          interface ge-11/0/14.0;
          interface lo0.0;
          interface xe-6/0/0.0;
        }
      }
    }
    routing-instances {
      L3VPN-1 {
        instance-type vrf;
        description"BETWEEN PE1 AND PE2";
        route-distinguisher 21:21;
        vrf-target target:21:21;
        vrf-table-label;
      }
    routing-options {
      router-id 22.22.22.22;
      autonomous-system 10;
```

Verification

To confirm that the MPLS-based Layer 3 VPN is working properly, perform these tasks:

- Verifying Peering and Adjacency on page 967
- Verifying That the Local CE Switch Can Ping the Local PE Switch on page 968
- Verifying That the Local PE Switch Can Ping the Local CE Switch on page 968

Verifying Peering and Adjacency

Purpose Verify the peering and adjacency along the route from CE1 (the local CE switch or router) to CE2 (the remote CE switch or router), starting with checking the routing protocol adjacency on the local PE switch:

NOTE: Be sure to specify the name of the routing instance.

Action

```
user@switchPE1> show ospf neighbor instance L3VPN-1

Address    Interface   State ID         Pri Dead
51.51.0.14 ge-5/0/24.0 Full 21.21.21.21 128 38
```

Meaning The **Address** field shows the IP address of the customer edge interface that connects CE1 to PE1. The **Interface** field shows the interface name of the customer edge interface that connects PE1 to CE1. For our purposes, the **State** field is the most important. It shows a status of **Full**, indicating that neighboring routing devices are fully adjacent. These adjacencies appear in router-link and network-link advertisements. (The field **Pri** indicates

the priority of the neighbor to become the designated router. The field **Dead** indicates the number of seconds until the neighbor becomes unreachable.)

Verifying That the Local CE Switch Can Ping the Local PE Switch

Purpose Verify that the local CE switch can ping the local PE switch:

Action

```
user@switchCE1> ping 51.51.0.1
PING 51.51.0.1 (51.51.0.1): 56 data bytes
64 bytes from 51.51.0.1: icmp_seq=0 ttl=64 time=3.461 ms
64 bytes from 51.51.0.1: icmp_seq=1 ttl=64 time=3.543 ms
```

Meaning This command specified the IP address of the customer edge interface on PE1. The results indicate that CE1 is receiving packets from PE1.

Verifying That the Local PE Switch Can Ping the Local CE Switch

Purpose Verify that the local PE switch can ping the local CE switch:

Action

```
user@switchPE1> ping 51.51.0.14 routing-instance L3VPN-1
PING 51.51.0.14 (51.51.0.14): 56 data bytes
64 bytes from 51.51.0.14: icmp_seq=0 ttl=64 time=3.842 ms
64 bytes from 51.51.0.14: icmp_seq=1 ttl=64 time=3.736 ms
```

Meaning The results indicate a successful connection.

Related Documentation

- Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure) on page 72
- Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure) on page 81

Configuring an MPLS-Based Layer 3 VPN (CLI Procedure)

You can configure MPLS-based Layer 3 virtual private networks (VPNs) on EX8200 and EX4500 switches. Layer 3 VPNs leverage the service provider's technical expertise for site-to-site routing.

To configure Layer 3 VPN functionality in your MPLS network, you must enable Layer 3 VPN support on the local and remote provider edge (PE) switches as described in this task.

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See "Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)" on page 72.
- Configure one or more provider switches. See "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: A Layer 3 VPN requires that the PE switches be configured using IP over MPLS.

Configure the Layer 3 VPN components on both PE switches. This procedure describes how to configure one PE switch. Repeat the procedure to configure the remote PE switch.

NOTE: When you configure the remote PE switch, the information specified for the routing instance must be configured the same as the information specified for the routing instance on the local PE switch. You must also specify the same BGP group name. The following statements will have different values on the remote PE switch from those on the local PE switch:

- **local-address**
- **neighbor**

To configure an MPLS-based Layer 3 VPN on the PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying ***family*** **inet-vpn unicast**:

   ```
   [edit protocols bgp]
   user@switch# set local-address address family inet-vpn unicast
   ```

2. Configure the BGP group, specifying the group name and **type internal**:

   ```
   [edit protocols bgp]
   user@switch# set group group-name type internal
   ```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

   ```
   [edit protocols bgp]
   user@switch# set neighbor address
   ```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

   ```
   [edit]
   user@switch# set routing-instances routing-instance-name instance-type vrf
   ```

5. Configure a description for this routing instance:

   ```
   [edit]
   user@switch# set routing-instances routing-instance-name description text
   ```

6. Configure the routing instance to use a route distinguisher:

   NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances must have a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

   ```
   user@switch#  set routing-instances routing-instance-name route-distinguisher
   ip-address:number
   ```

7. Configure the VPN routing and forwarding (VRF) target of the routing instance:

   ```
   [edit routing-instances]
   user@switch# set routing-instance-name vrf-target community
   ```

   NOTE: If you configure the *community* option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

8. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.

   ```
   [edit routing-instances]
   user@switch# set routing-instance-name vrf-table-label
   ```

9. (Optional) Configure the routing options:

NOTE: We recommend that you configure the router identifier under the **[edit routing-options]** hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
user@switch# set router-id ip-address autonomous-system as-number
```

CHAPTER 27

Configuring CLNS VPNs

CLNS Overview

Connectionless Network Service (CLNS) is a Layer 3 protocol similar to IP version 4 (IPv4) for linking hosts (end systems) with routers (intermediate systems) in an Open Systems Interconnection (OSI) network. CLNS and its related OSI protocols, Intermediate System-to-Intermediate System (IS-IS) and End System-to-Intermediate System (ES-IS), are International Organization for Standardization (ISO) standards.

You can configure devices running Junos OS as provider edge (PE) routers within a CLNS network. CLNS networks can be connected over an IP MPLS network core using Border Gateway Protocol (BGP) and MPLS Layer 3 virtual private networks (VPNs). See RFC 2547, *BGP/MPLS VPNs*.

CLNS uses network service access points (NSAPs), similar to IP addresses found in IPv4, to identify end systems (hosts) and intermediate systems (routers). ES-IS enables the hosts and routers to discover each other. IS-IS is the interior gateway protocol (IGP) that carries ISO CLNS routes through a network.

For more information about CLNS, see the ISO 8473 standards.

- Understanding ES-IS for CLNS on page 975
- Understanding IS-IS for CLNS on page 978
- Understanding Static Routes for CLNS on page 981
- Understanding BGP for CLNS VPNs on page 983

CLNS Configuration Overview

To configure CLNS:

1. Configure the network interfaces. See the *Junos OS Interfaces Configuration Guide for Security Devices*.

2. If applicable, configure BGP and VPNs. See:
   - Example: Configuring BGP for CLNS VPNs on page 984
   - MPLS Layer 2 VPN Configuration Overview on page 899
   - MPLS Layer 3 VPN Configuration Overview on page 935
3. Configure a VPN routing instance. You typically configure ES-IS, IS-IS, and CLNS static routes using a VPN routing instance. See "Example: Configuring a VPN Routing Instance for CLNS" on page 986.

4. Configure one or more of the following protocols for CLNS (depending on your network).
   - ES-IS—If a device is a PE router within a CLNS island that contains any end systems, you must configure ES-IS on the device. If a CLNS island does not contain any end systems, you do not need to configure ES-IS on a device. See "Example: Configuring ES-IS for CLNS" on page 976.

     NOTE: ES-IS is enabled only if either ES-IS or IS-IS is configured on the router. ES-IS must not be disabled. If ES-IS is not explicitly configured, the interface sends and receives only intermediate system hello (ISH) messages. If ES-IS is explicitly configured and disabled, the interface does not send or receive ES-IS packets. If ES-IS is explicitly configured and not disabled, the interface sends and receives ISH messages as well as ES-IS packets.

     One of the interfaces that is configured for ES-IS must be configured with an ISO address for hello messages. The ISO address family must be configured on an interface to support ES-IS on that interface.

   - IS-IS—You can configure IS-IS to exchange CLNS routes within a CLNS island. See "Example: Configuring IS-IS for CLNS" on page 978.

NOTE: If you have a pure CLNS island—an island that does not contain any IP devices—you must disable IPv4 and IPv6 routing. Also, to export BGP routes into IS-IS, you must configure and apply an export policy.

- Static routes—If some devices in your network do not support IS-IS, you must configure CLNS static routes. You can use static routing with or without IS-IS. You might also consider using static routes if your network is simple. See "Example: Configuring Static Routes for CLNS When No IGP is Present" on page 981.
- BGP—See "Example: Configuring BGP for CLNS VPNs" on page 984.

NOTE: Many of the configuration statements used to configure CLNS and routing protocols can be included at different hierarchy levels in the configuration.

Understanding ES-IS for CLNS

End System-to-Intermediate System (ES-IS) is a protocol that resolves Layer 3 ISO network service access points (NSAP) to Layer 2 addresses. ES-IS has an equivalent role as Address Resolution Protocol (ARP) in IP version 4 (IPv4).

ES-IS provides the basic interaction between Connectionless Network Service (CLNS) hosts (end systems) and routers (intermediate systems). ES-IS allows hosts to advertise NSAP addresses to other routers and hosts attached to the network. Those routers can then advertise the address to the rest of the network by using Intermediate System-to-Intermediate System (IS-IS). Routers use ES-IS to advertise their network entity title (NET) to hosts and routers that are attached to that network.

ES-IS routes are exported to Layer 1 IS-IS by default. You can also export ES-IS routes into Layer 2 IS-IS by configuring a routing policy. ES-IS generates and receives end system hello (ESH) hello messages when the protocol is configured on an interface. ES-IS is a resolution protocol that allows a network to be fully ISO integrated at both the network layer and the data layer.

The resolution of Layer 3 ISO NSAPs to Layer 2 subnetwork point of attachments (SNPAs) by ES-IS is equivalent to ARP within an IPv4 network. If a device is a provider edge (PE) router within a CLNS island that contains any end systems, you must configure ES-IS on the device.

For more information about ES-IS, see the ISO 9542 standard.

Example: Configuring ES-IS for CLNS

This example shows how to create a routing instance and enable ES-IS for CLNS on all interfaces.

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

The configuration instructions in this topic describe how to create a routing-instance called aaaa, set the end system configuration timer for the interfaces to 180, and set a preference value to 30 for ES-IS.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa protocols esis interface all end-system-configuration-timer
  180
set routing-instances aaaa protocols esis preference 30
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure ES-IS for CLNS:

1. Configure the routing instance.

   ```
   [edit]
   user@host# edit routing-instances aaaa
   ```

2. Enable ES-IS on all interfaces.

```
[edit routing-instances aaaa]
user@host# set protocols esis interface all
```

3. Configure the end system configuration timer.

```
[edit routing-instances aaaa]
user@host# set protocols esis interface all end-system-configuration-timer 180
```

4. Configure the preference value.

```
[edit routing-instances aaaa]
user@host# set protocols esis preference 30
```

Results From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances
aaaa {
   protocols {
      esis {
         preference 30;
         interface all {
            end-system-configuration-timer 180;
         }
      }
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying Routing-Instance for CLNS on page 977
- Verifying ES-IS for CLNS on page 978

Verifying Routing-Instance for CLNS

Purpose Verify that the policy options are enabled for the routing instance.

Action From operational mode, enter the **show routing-instances** command.

Verifying ES-IS for CLNS

Purpose Verify that ES-IS is enabled.

Action From operational mode, enter the **show protocols** command.

Related Documentation

- CLNS Configuration Overview on page 974
- Understanding ES-IS for CLNS on page 975
- Verifying a CLNS VPN Configuration on page 988

Understanding IS-IS for CLNS

IS-IS extensions provide the basic interior gateway protocol (IGP) support for collecting intradomain routing information for Connectionless Network Service (CLNS) destinations within a CLNS network. Routers that learn host addresses through End System-to-Intermediate System (ES-IS) can advertise the addresses to other routers (intermediate systems) by using IS-IS.

For more information about IS-IS, see the ISO 10589 standard.

Example: Configuring IS-IS for CLNS

This example shows how to create a routing instance and enable IS-IS protocol on all interfaces.

- Requirements on page 978
- Overview on page 978
- Configuration on page 979
- Verification on page 980

Requirements

Before you begin, configure the network interfaces. See Interfaces Feature Guide for Security Devices.

Overview

The configuration instructions in this topic describe how to create a routing-instance called aaaa, enable IS-IS on all interfaces, and define BGP export policy name (dist-bgp), family (ISO), and protocol (BP), and apply the export policy to IS-IS.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa protocols isis clns-routing
set routing-instances aaaa protocols isis interface all
set routing-instances aaaa protocols isis no-ipv4-routing no-ipv6-routing
set policy-options policy-statement dist-bgp from family iso protocol bgp
set policy-options policy-statement dist-bgp then accept
set routing-instances aaaa protocols isis export dist-bgp
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure IS-IS for CLNS:

1. Configure the routing instance.

   ```
   [edit]
   user@host# edit routing-instances aaaa
   ```

2. Enable CLNS routing.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis clns-routing
   ```

3. Enable IS-IS on all interfaces.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis interface all
   ```

4. (Optional) Disable IPv4 and IPv6 routing to configure a pure CLNS network .

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis no-ipv4-routing no-ipv6-routing
   ```

5. Define the BGP export policy name, family, and protocol.

   ```
   [edit policy-options]
   user@host# set policy-statement dist-bgp from family iso protocol bgp
   ```

6. Define the action for the export policy.

```
[edit policy-options]
user@host# set policy-statement dist-bgp then accept
```

7. Apply the export policy to IS-IS.

```
[edit routing-instances aaaa]
user@host# set protocols isis export dist-bgp
```

Results From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances
aaaa {
   protocols {
      isis {
         export dist-bgp;
         no-ipv4-routing;
         no-ipv6-routing;
         clns-routing;
         interface all;
      }
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying Routing-Instance for CLNS on page 980
- Verifying IS-IS for CLNS on page 980

Verifying Routing-Instance for CLNS

Purpose Verify that the policy options are enabled for the routing instance.

Action From operational mode, enter the **show routing-instances** command.

Verifying IS-IS for CLNS

Purpose Verify that IS-IS is enabled.

Action From operational mode, enter the **show protocols** command.

Related Documentation

Understanding Static Routes for CLNS

The Connectionless Network Service (CLNS) is an ISO Layer 3 protocol that uses network service access point (NSAP) reachability information instead of IPv4 or IPv6 prefixes.

You can configure static routes to exchange CLNS routes within a CLNS island. A *CLNS island* is typically an IS-IS level 1 area that is part of a single IGP routing domain. An island can contain more than one area. CLNS islands can be connected by VPNs.

Example: Configuring Static Routes for CLNS When No IGP is Present

This example shows how to configure static routes for CLNS.

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

In this example, you configure static routes for CLNS. In the absence of an interior gateway protocol (IGP) on a certain link, a routing device might need to be configured with static routes for CLNS prefixes to be reachable by way of that link. This might be useful, for example, at an autonomous system (AS) boundary.

When you configure static routes for CLNS, consider the following tasks:

- Specify the **iso.0** routing table option to configure a primary instance CLNS static route.
- Specify the **instance-name.iso.0** routing table option to configure a CLNS static route for a particular routing instance.
- Specify the **route *nsap-prefix*** statement to configure the destination for the CLNS static route.

- Specify the **next-hop (*interface-name* | *iso-net*)** statement to configure the next hop, specified as an ISO network entity title (NET) or interface name.
- Include the **qualified-next-hop (*interface-name* | *iso-net*)** statement to configure a secondary backup next hop, specified as an ISO network entity title or interface name.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212
set routing-options rib iso.0 static iso-route
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop t1-0/2/2.0
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.eee0/152
  qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 preference
  20
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.eee0/152
  qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 metric 10
```

Step-by-Step Procedure

To configure static routes for CLNS:

1. Configure the routes.

```
[edit routing-options rib iso.0 static]
user@host# set iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212
user@host# set iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152
  next-hop t1-0/2/2.0
user@host# set iso-route 47.0005.80ff.f800.0000.eee0/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 preference 20
user@host# set iso-route 47.0005.80ff.f800.0000.eee0/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 metric 10
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show routing-options
rib iso.0 {
  static {
```

```
    iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
      47.0005.80ff.f800.0000.0108.0001.1921.6800.4212;
    iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop t1-0/2/2.0;
    iso-route 47.0005.80ff.f800.0000.eee0/152 {
      qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 {
        preference 20;
        metric 10;
      }
    }
  }
}
```

Verification

Checking the Routing Table

Purpose Make sure that the expected routes appear in the routing table.

Action `user@host>` **show route table iso.0**

```
iso.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152
                   *[Static/5] 00:00:25
                    > via t1-0/2/2.0
47.0005.80ff.f800.0000.eee0/84
                   *[Static/20] 00:04:01, metric 10, metric2 10
                    > to #75 0.12.0.34.0.56 via fe-0/0/1.0
47.0005.80ff.f800.0000.ffff.ffff/104
                   *[Static/5] 00:04:01, metric2 0
                    > via t1-0/2/2.0
```

Meaning The static routes appear in the routing table.

Understanding BGP for CLNS VPNs

BGP extensions allow BGP to carry Connectionless Network Service (CLNS) virtual private network (VPN) network layer reachability information (NLRI) between provider edge (PE) routers. Each CLNS route is encapsulated into a CLNS VPN NLRI and propagated between remote sites in a VPN.

CLNS is a Layer 3 protocol similar to IP version 4 (IPv4). CLNS uses network service access points (NSAPs) to address end systems. This allows for a seamless autonomous system (AS) based on International Organization for Standardization (ISO) NSAPs.

A single routing domain consisting of ISO NSAP devices are considered to be CLNS islands. CLNS islands are connected together by VPNs.

You can configure BGP to exchange ISO CLNS routes between PE routers connecting various CLNS islands in a VPN using multiprotocol BGP extensions. These extensions are the ISO VPN NLRIs.

Each CLNS network island is treated as a separate VPN routing and forwarding instance (VRF) instance on the PE router.

You can configure CLNS on the global level, group level, and neighbor level.

Example: Configuring BGP for CLNS VPNs

This example shows how to create a BGP group for CLNS VPNs, define the BGP peer neighbor address for the group, and define the family.

Requirements

Before you begin, configure the network interfaces. See the *Interfaces Feature Guide for Security Devices*.

Overview

In this example, you create the BGP group called pedge-pedge, define the BGP peer neighbor address for the group as 10.255.245.215, and define the BGP family.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols bgp group pedge-pedge neighbor 10.255.245.213
set protocols bgp family iso-vpn unicast
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure BGP for CLNS VPNs:

1. Configure the BGP group and define the BGP peer neighbor address.

```
[edit protocols bgp]
user@host# set group pedge-pedge neighbor 10.255.245.213
```

2. Define the family.

```
[edit protocols bgp]
user@host# set family iso-vpn unicast
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

Verifying the Neighbor Status

Purpose Display information about the BGP peer.

Action From operational mode, run the **show bgp neighbor 10.255.245.213** command. Look for **iso-vpn-unicast** in the output.

```
user@host> show bgp neighbor 10.255.245.213

Example: Configuring a VPN Routing Instance for CLNS

This example shows how to create a CLNS routing instance and set the instance type for Layer 3 VPNs.

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

The following example shows how to create a CLNS routing instance called aaaa and set the instance type to VRF for Layer 3 VPNs. Within the example, you specify that the lo0.1 interface, e1–2/0/0.0 interface, and t1–3/0/0.0 interface all belong to the routing instance. The route distinguisher is set as 10.255.245.1:1 and the policy for the Layer 3 VRF table is set as target:11111:1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa instance-type vrf
set routing-instances aaaa interface lo0.1
set routing-instances aaaa interface ge-0/0/3
set routing-instances aaaa interface ge-0/0/2
set routing-instances aaaa route-distinguisher 10.255.245.1:1
set routing-instances aaaa vrf-target target:11111:1
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a VPN routing instance:

1. Create the routing instance.

```
[edit]
user@host# edit routing-instances aaaa
```

2. Specify the routing instance type.

```
[edit routing-instances aaaa]
user@host# set instance-type vrf
```

3. Specify the interfaces that belong to the routing instance.

```
[edit routing-instances aaaa]
user@host# set interface lo0.1
user@host# set interface ge-0/0/3
user@host# set interface ge-0/0/2
```

4. Specify the route distinguisher.

```
[edit routing-instances aaaa]
user@host# set route-distinguisher 10.255.245.1:1
```

5. Specify the policy for the Layer 3 VRF table.

```
[edit routing-instances aaaa]
user@host# set vrf-target target:11111:1
```

6. Enable family ISO on the interfaces edit interfaces interface-name unit-id.

```
[edit routing-instances aaaa]
user@host# set family ISO
```

Results From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit ]
user@host# show routing-instances
instance-type vrf;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
interface lo0.1;
route-distinguisher 10.255.245.1:1;
vrf-target target:11111:1;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying the Configured CLNS Routing Instance

Purpose Confirm that the configuration is working properly.

Verify that the CLNS routing instance is configured.

Action From operational mode, enter the **show routing-instances** command.

CHAPTER 28

Configuring VPLS

VPLS Overview

Virtual private LAN service (VPLS) is an Ethernet-based point-to-multipoint Layer 2 VPN. It allows you to connect geographically dispersed Ethernet LAN sites to each other across an MPLS backbone. For customers who implement VPLS, all sites appear to be in the same Ethernet LAN even though traffic travels across the service provider's network.

VPLS, in its implementation and configuration, has much in common with an MPLS Layer 2 VPN. In a VPLS topology, a packet originating within a customer's network is sent first to a customer edge (CE) device (for example, a router or Ethernet switch). It is then sent to a provider edge (PE) router within the service provider's network. The packet traverses the service provider's network over an MPLS label-switched path (LSP). It arrives at the egress PE router, which then forwards the traffic to the CE device at the destination customer site.

The difference is that for VPLS, packets can traverse the service provider's network in point-to-multipoint fashion, meaning that a packet originating from a CE device can be broadcast to all the PE routers participating in a VPLS routing instance. In contrast, a Layer 2 VPN forwards packets in point-to-point fashion only. The paths carrying VPLS traffic between each PE router participating in a routing instance are signaled using BGP.

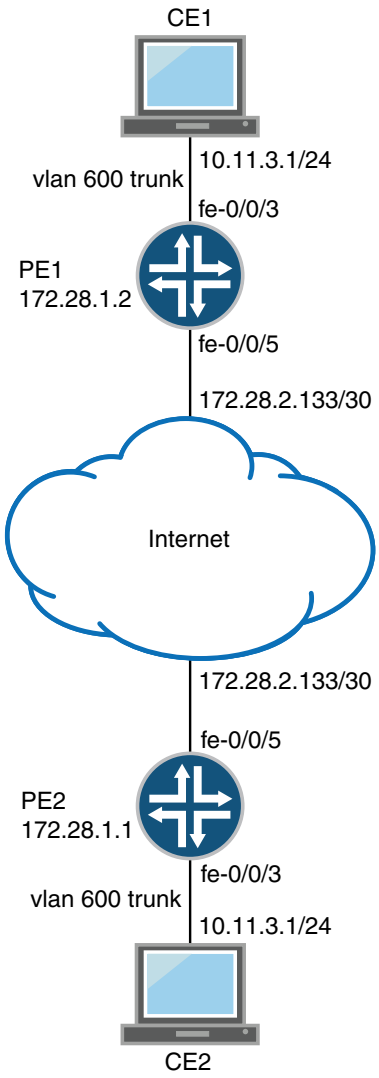
NOTE: **The RSVP automatic mesh feature with multiple RSVP neighbors on a single LAN is not supported on SRX Series devices because RSVP runs on WAN links in a service provider network. Most of these WAN interfaces are point-to-point and are rarely seen in LAN networks.**

This topic contains the following sections:

Sample VPLS Topology

Figure 79 on page 993 shows a basic VPLS topology.

Figure 79: Basic VPLS Topology



In this sample, the PE routers use the same autonomous system (AS). Within the AS, routing information is communicated through an interior gateway protocol (IGP). Outside the AS, routing information is shared with other ASs through BGP. The PE routers must use the same signaling protocols to communicate.

VPLS on PE Routers

Within a VPLS configuration, a device running Junos OS can act as a PE router. Junos OS passes the VPLS traffic through the following ports and PIMs on the Juniper Networks device to CE routers in the VPLS network:

- Built-in Ethernet ports on front panel
- Gigabit Ethernet uPIMs
- Gigabit Ethernet ePIMs

- Fast Ethernet PIMs
- Fast Ethernet ePIMs

NOTE: Ports on uPIMs and ePIMs must be in routing mode before you can configure the corresponding interfaces for VPLS.

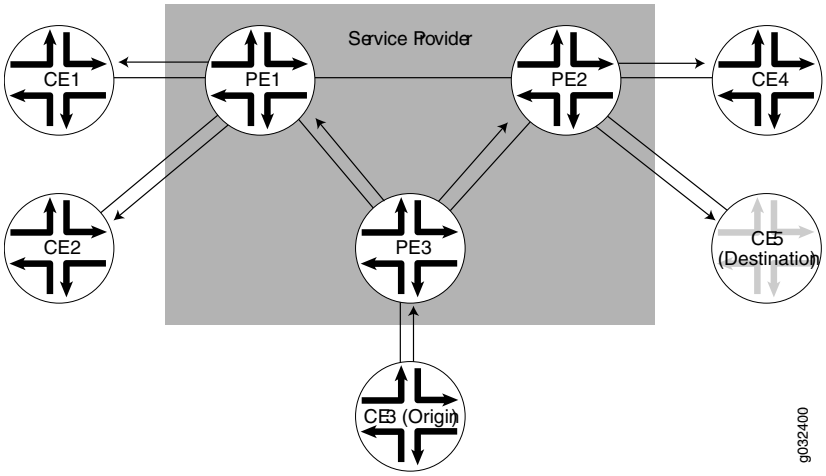
Because a VPLS carries Ethernet traffic across a service provider network, it must mimic an Ethernet network in some ways. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, it forwards the packet to the appropriate PE router or CE device. If it does not, it broadcasts the packet to all other PE routers and CE devices that are members of that VPLS routing instance. In both cases, the CE device receiving the packet must be different from the one sending the packet.

When a PE router receives a packet from another PE router, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, the PE router either forwards the packet or drops it depending on whether the destination is a local or remote CE device:

- If the destination is a local CE device, the PE router forwards the packet to it.
- If the destination is a remote CE device (connected to another PE router), the PE router discards the packet.

If the PE router cannot determine the destination of the VPLS packet, it floods the packet to all attached CE devices. Figure 80 on page 994 illustrates this process.

Figure 80: Flooding a Packet with an Unknown Destination



A VPLS interface can be directly connected to an Ethernet switch. Layer 2 information gathered by an Ethernet switch, for example, MAC addresses and interface ports, is included in the VPLS routing instance table.

An MPLS label-switched interface (LSI) label is used as the inner label for VPLS. This label maps to a VPLS routing instance on the ingress PE router. On the egress PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

One restriction on flooding behavior in VPLS is that traffic received from remote PE routers is never forwarded to other PE routers. This restriction helps prevent loops in the core network. However, if a CE Ethernet switch has two or more connections to the same PE router, you must enable the Spanning Tree Protocol (STP) on the CE switch to prevent loops.

NOTE: Under certain circumstances, VPLS PE routers might duplicate an Internet Control Message Protocol (ICMP) reply from a CE device when a PE router has to flood an ICMP request because the destination MAC address has not yet been learned. The duplicate ICMP reply can be triggered when a CE device with promiscuous mode enabled is connected to a PE router. The PE router automatically floods the promiscuous mode enabled CE device, which then returns the ICMP request to the VPLS PE routers. The VPLS PE routers consider the ICMP request to be new and flood the request again, creating a duplicate ping reply.

Using an Ethernet Switch as the VPLS CE Device

For VPLS configurations, the CE device does not necessarily need to be a router. You can link the PE routers directly to Ethernet switches. However, be aware of the following configuration issues:

- When you configure VPLS routing instances and establish two or more connections between a CE Ethernet switch and a PE router, you must enable the Spanning Tree Protocol (STP) on the switch to prevent loops.
- Junos OS allows standard bridge protocol data unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

VPLS Exceptions on SRX Series Devices

The VPLS implementation on SRX Series device is similar to VPLS implementations on M Series, T Series, and MX Series routers, with the following exceptions:

- SRX Series devices do not support aggregated Ethernet interfaces. Therefore, aggregated Ethernet interfaces between CE devices and PE routers, and aggregated Ethernet interfaces between PE devices and PE routers are not supported for VPLS routing instances on SRX Series devices.
- VPLS multihoming, which allows connecting a CE device to multiple PE routers to provide redundant connectivity, is not supported on SRX Series devices.

- SRX Series devices do not support BGP mesh groups.
- SRX Series devices support only the following encapsulation types on VPLS interfaces that face CE devices: extended VLAN VPLS, Ethernet VPLS, and VLAN VPLS. Ethernet VPLS over ATM LLC encapsulation is not supported.
- Virtual ports are generated dynamically on a Tunnel Services PIC on some Juniper Networks routing platforms. SRX Series devices do not support Tunnel Services modules or virtual ports.
- The VPLS implementation on SRX Series devices does not support dual-tagged frames. Therefore, VLAN rewrite operations are not supported on dual-tagged frames. VLAN rewrite operations such as pop-pop, pop-swap, push-push, swap-push, and swap-swap, which are supported on M Series and T Series routing platforms, are not supported on SRX Series devices.

- VPLS Configuration Overview on page 996

VPLS Configuration Overview

To configure VPLS functionality, you must enable VPLS support on the provider edge (PE) routers. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the customer edge (CE) devices, as explained in the steps that follow.

NOTE: **Many configuration procedures for VPLS are identical to the procedures for Layer 2 and Layer 3 VPNs.**

To configure VPLS:

1. Determine which uPIM and ePIM ports correspond to the interfaces that will carry the VPLS traffic and enable routing mode on those ports.

2. Configure the interfaces that will carry the VPLS traffic between the PE router and CE devices. On the PE router interfaces that are facing the CE devices, specify a VPLS encapsulation type. The type of encapsulation depends on the interface type. See"Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.

3. Create a VPLS routing instance on each PE router that is participating in the VPLS. For each VPLS routing instance, specify which interfaces will carry the VPLS traffic between the PE and CE devices. On the CE device interface that faces the PE router, you must specify inet (for IPv4), and include the IP address. Additionally, each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP identify overlapping network layer reachability information (NLRI) messages from different VPNs.) See "Example: Configuring the VPLS Routing Instance" on page 1017.

4. Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 1061.

5. Configure MPLS LSPs between the PE routers. See "Example: Configuring MPLS on the VPLS PE Router" on page 1023.

6. Configure RSVP on the PE routers. Enable RSVP for all connections that participate in the MPLS LSP. See "Example: Configuring RSVP on the VPLS PE Router" on page 1022.

7. Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See "Example: Configuring BGP on the VPLS PE Router" on page 1059.

8. Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 1021.

9. Configure VLAN encapsulation. See "Example: Configuring VPLS VLAN Encapsulation on Gigabit Ethernet Interfaces" on page 1066,"Example: Configuring VPLS VLAN Encapsulation" on page 1063, and "Example: Configuring Extended VLAN VPLS Encapsulation" on page 1068.

Migrating from FEC128 LDP-VPLS to EVPN Overview

For service providers with virtual private LAN service (VPLS) networks and Ethernet VPN (EVPN) networks, there is a need to interconnect these networks. Prior to Junos OS Release 17.3, a logical tunnel interface on the interconnection point of the VPLS and EVPN routing instances was used for this purpose. In this case, the provider edge (PE)

devices in each network were unaware of the PE devices in the other technology network. Starting in Junos OS Release 17.3, a solution is introduced for enabling staged migration from FEC128 LDP-VPLS toward EVPN on a site-by-site basis for every VPN routing instance. In this solution, the PE devices running EVPN and VPLS for the same VPN routing instance and single-homed segments can coexist. During migration, there is minimal impact to the customer edge (CE) device-to-CE device traffic forwarding for affected customers.

The following sections describe the migration from LDP-VPLS to EVPN:

Technology Overview and Benefits

Virtual private LAN service (VPLS) is an Ethernet-based point-to-multipoint Layer 2 VPN. This technology allows you to connect geographically dispersed data center LANs to each other across an MPLS backbone while maintaining Layer 2 connectivity. The high availability features defined in VPLS standards (such as LER dual homing) and topology autodiscovery features using BGP signaling make VPLS scalable and easy to deploy. Because VPLS uses MPLS as its core, it provides low latency variation and statistically bound low convergence times within the MPLS network.

Ethernet VPN (EVPN), on the other hand, is a combined Layer 2 and Layer 3 VPN solution that is more scalable, resilient, and efficient than current technologies. It provides several benefits including greater network efficiency, reliability, scalability, virtual machine (VM) mobility, and policy control for service providers and enterprises.

Although VPLS is a widely deployed Layer 2 VPN technology, service provider networks migrate to EVPN because of the scaling benefits and ease of deployment. Some of the benefits of EVPN include:

- Control plane traffic is distributed with BGP and the broadcast and multicast traffic is sent using a shared multicast tree or with ingress replication.
- Control plane learning is used for MAC and IP addresses instead of data plane learning. MAC address learning requires the flooding of unknown unicast and ARP frames, whereas IP address learning does not require any flooding.
- Route reflector is used to reduce a full mesh of BGP sessions among PE devices to a single BGP session between a PE device and the route reflector.
- Autodiscovery with BGP is used to discover PE devices participating in a given VPN, PE devices participating in a given redundancy group, tunnel encapsulation types, multicast tunnel type, and multicast members.

- All-active multihoming is used. This allows a given CE device to have multiple links to multiple PE devices, and traffic traversing to-and-from that CE device fully utilizes all of these links (Ethernet segment).
- When a link between a CE device and a PE device fails, the PE devices for that EVPN instance (EVI) are notified of the failure with the withdrawal of a single EVPN route. This allows those PE devies to remove the withdrawing PE device as a next hop for every MAC address associated with the failed link (mass withdrawal).

FEC128 LDP-VPLS to EVPN Migration

Some service providers want to preserve their investments in VPLS. This leads to the need to connect the old VPLS networks to new networks that run EVPN. For this purpose, logical tunnel interfaces on the interconnection point of the VPLS and EVPN routing instances were used. However, all the other PE devices belonged either to the VPLS network or to the EVPN network and were unaware of the other technology.

Starting in Junos OS Release 17.3, EVPN can be introduced into an existing VPLS network in a staged manner, with minimal impact to VPLS services. On a VPLS PE device, some customers can be moved to EVPN, while other customers continue to use VPLS pseudowires. Other PE devices can be entirely VPLS and switching customers on other PE devices to EVPN. This solution provides support for the seamless migration Internet draft (expires January ,2018), *(PBB-)EVPN Seamless Integration with (PBB-)VPLS*.

The seamless migration from FEC128 LDP-VPLS to EVPN solution supports the following functionality:

- Allow for staged migration toward EVPN on a site-by-site basis per VPN instance. For instance, new EVPN sites to be provisioned on EVPN PE devices.
- Allow for the coexistence of PE devices running both EVPN and VPLS for the same VPN instance and single-homed segments.

In the LDP-VPLS to EVPN migration, the PE device where some customers have been migrated to EVPN while other customers are being served using VPLS is called a super PE device. As super PE devices discover other super PE devices within a routing instance, they use EVPN forwarding to communicate with other super PE devices and VPLS pseudowires to PE devices running VPLS. The PE device with no EVPN awareness, and running only VPLS for all the customers, is called a VPLS PE device.

The CE device connected to a super PE can reach CE devices connected to EVPN-only PE devices or VPLS-only PE devices, but CE devices connected to EVPN-only PE devices cannot reach CE devices connected to VPLS-only PE devices.

Because the migration from LDP-VPLS to EVPN is supported on a per-routing instance basis, and if the routing instance is serving multiple customers on a PE device, all are migrated together. EVPN is responsible for setting up data forwarding between the PE devices upgraded to EVPN, while VPLS continues to set up data forwarding to PE devices that run VPLS. There should be zero impact for customers that still use VPLS pseudowire on all the PE devices.

NOTE:

The following features are not supported with the LDP-VPLS to EVPN migration:

- Migration from FEC129 VPLS to EVPN.
- Migration from BGP-VPLS to EVPN.
- Migration of VPLS virtual switch to EVPN virtual switch.
- Migration of VPLS routing instance to EVPN virtual switch.
- Migration of VPLS routing instance or PBB-VPLS to PBB-EVPN.
- Seamless migration from EVPN back to VPLS.
- Enhancing EVPN to support the set of tools or statements and commands that VPLS supports.
- Active-active and active-standby multihoming. The migration to EVPN is supported only on single-homed deployments.
- Spanning all-active across EVPN and VPLS PE devices does not work, because the all-active multihoming feature is not supported on VPLS.
- Connecting EVPN-only PE devices with VPLS-only PE devices through super PE devices.
- IPv6, logical systems, multichassis support, and SNMP, because they are currently not supported on EVPN.

Sample Configuration for LDP-VPLS to EVPN Migration

The following sections provide the sample configuration required for performing the LDP-VPLS to EVPN migration.

- LDP-VPLS Configuration on page 1000
- EVPN Migration Configuration on page 1002

LDP-VPLS Configuration

A typical static LDP-VPLS routing instance configuration is as follows:

```
user@host# show routing-instance foo
instance-type vpls;
vlan-id 100; (not needed for VLAN bundle service)
interface ge-2/0/0.590;
interface ae500.590;
routing-interface irb.0;
forwarding-options {
   family vpls {
      filter {
         input UNKNOWN-UNICAST;
      }
```

```
    }
}
protocols {
    vpls {
        control-word;
        encapsulation-type ethernet-vlan;
        enable-mac-move-action;
        mac-table-size {
            100000;
            packet-action drop;
        }
        mac-table-aging-time ;
        interface-mac-limit {
            100000;
            packet-action drop;
        }
        no-tunnel-services; (use label-switched interfaces)
        vpls-id 245015;
        mtu 1552;
        ignore-mtu-mismatch;
        mac-flush {
            any-spoke;
        }
        no-vlan-id-validate;
        neighbor 192.168.252.64 {
            psn-tunnel-endpoint 10.0.0.31;
            pseudowire-status-tlv;
            revert-time 60;
            backup-neighbor 192.168.252.65 {
                psn-tunnel-endpoint 10.0.0.32;
                hot-standby;
            }
        }
        mesh-group Spoke { (access label-switched interface toward spoke)
        local-switching;
        neighbor 192.168.252.66 {
            psn-tunnel-endpoint 10.0.0.41;
            pseudowire-status-tlv;
        }
        neighbor 192.168.252.67 {
            psn-tunnel-endpoint 10.0.0.42;
            pseudowire-status-tlv;
        }
    }
    connectivity-type permanent;
}
```

```
user@host# show interfaces ge-2/0/0.590
encapsulation vlan-vpls;
vlan-id 590;
output-vlan-map {
    swap;
    tag-protocol-id 0x8100;
    inner-vlan-id 590;
```

```
}
family vpls {
   filter {
      input-list [ listA ];
      output-list listB;
   }
}
```

EVPN Migration Configuration

To perform the FEC128 LDP-VPLS to EVPN migration, do the following:

1. On the backup Routing Engine, load Junos OS Release 17.3R1.

2. Perform in-service software upgrade (ISSU) to acquire mastership. Ensure that the VPLS unified ISSU does not have any impact on the VPLS forwarding.

3. Identify routing instances (customers) that need to be migrated to EVPN.

4. Enable EVPN in a single routing instance.

   - Change routing instance type to **evpn**, and include the **evpn** statement at the **[edit routing-instances *routing-intance-name* protocols]** hierarchy level, and also include the **vpls** statement at the same hierarchy to support VPLS commands.

     For example:

     ```
     [edit routing-instances routing-instance-name]
     instance-type evpn;
     interface ge-2/0/0.590;
     interface ae500.590;
     routing-interface irb.0;
     route-distinguisher 1.1.1.1:50; (add for LDP-VPLS)
     vrf-target target:100:100; (add for LDP-VPLS)
     forwarding-options {
        family vpls {
           filter {
              input UNKNOWN-UNICAST;
           }
        }
     }
     protocols {
        vpls { (supports all existing VPLS commands)
     }
     ```

5. Enable family EVPN signaling in BGP.

   For example:

   ```
   protocols {
      bgp {
         local-as 102;
         group 2mx {
   ```

```
        type internal;
        local-address 81.1.1.1;
        family evpn {
        signaling;
      }
      neighbor 81.2.2.2;
      neighbor 81.9.9.9;
    }
}
```

After the configuration for the EVPN migration is committed, the routing protocol process and the Layer 2 address learning process start building the EVPN state to reflect interfaces, bridge domains, peers and routes. The locally learnt MAC addresses are synchronized by the Layer 2 address learning process in the instance.vpls.0 to the routing protocol process. When a local MAC ages out in the instance.vpls.0, the routing protocol process is informed by the Layer 2 address learning process.

When an EVPN peer is learnt, the routing protocol process sends a new message to the Layer 2 address learning process to remove the peer's label-switched interface or virtual tunnel logical interface from the VE mesh group and disables MAC-learning on it. The EVPN IM next-hop is then added to the VE mesh group. The EVPN behavior in the routing protocol process of learning MAC addresses over BGP and informing Layer 2 address learning process of the MPLS next hop is maintained.

The VPLS statements and commands continue to apply to the VPLS pseudowires between the PE devices and the MAC addresses learnt over them. The EVPN statements and commands apply to PE devices running EVPN.

Reverting to VPLS

If the EVPN migration runs into issues, you can revert back to VPLS until the issue is understood. The routing instance is reverted from a super PE to a VPLS PE in a non-catastrophic manner by enabling the following configuration:

```
[edit routing-instances routing-instance-name]
user@host# set instance-type vpls
user@host# delete protocols evpn
user@host# delete route-distinguisher (if running LDP-VPLS)
user@host# delete vrf-target (if running LDP-VPLS)
```

On reverting the EVPN migration to VPLS, the following happens:

1. The EVPN state information is deleted.

2. There is a trigger for withdrawal of EVPN control plane routes.

3. The routing protocol process sends a new message to the Layer 2 address learning process with the label-switched interface or the virtual tunnel logical interface for the routing instance and peer.

4. The label-switched or virtual tunnel interface adds the new message to the flood group and MAC learning is enabled.

5. The egress IM next hop is deleted by the routing protocols process, prompting the Layer 2 address learning process to remove it from the flood group.

6. Remote MAC addresses are learned again over the label-switched interface or virtual tunnel logical interface.

LDP-VPLS to EVPN Migration and Other Features

Table 43 on page 1004 describes the functionality of some of the related features, such as multihoming and integrated routing and bridging (IRB) with the LDP-VPLS to EVPN migration.

Table 43: EVPN Migration and Other Features Support

Feature	Supported Functionality in EVPN Migration
MAC move	MAC moves are supported between VPLS-only PE device and super PE devices. When a MAC address moves from a VPLS-only PE device to a super PE device, it is learned over BGP, and the routing protocol process informs the Layer 2 address learning process of the EVPN next hop to be updated in the foo.vpls.0 routing table. When a MAC address moves from a super PE device to a VPLS-only PE device, it is learned in the Packet Forwarding Engine on the label-switched interface or virtual tunnel interface. The Layer 3 address learning process updates it to VPLS or the label-switched interface next hop. When the type 2 route is withdrawn by EVPN BGP, the MAC address is not deleted from the forwarding table, so there is no loss of data. The forwarding MAC table is shared by VPLS and EVPN. Some attributes, such as **mac-table-size** and **mac-table-aging-time** could be configured under both EVPN and VPLS. When there is a conflict, the values under EVPN take precedence.
IRB	No changes needed in IRB. On a super PE device, EVPN populates the /32 host routes learned over MAC+IP type 2 routes from EVPN peers in a Layer 3 virtual routing and forwarding, while VPLS IRB forwarding using subnet routes works on sites still running VPLS.

Table 43: EVPN Migration and Other Features Support (continued)

Feature	Supported Functionality in EVPN Migration
Hierarchical VPLS	In an H-VPLS network with hub-and-spoke PE devices, when the hub PE device is migrated to EVPN, local MAC addresses learned over the access label-switched or virtual tunnel interface need to be advertised to BGP, so that the other EVPN-only PE devices or super PE devices can reach them. Take the following into consideration when migrating an H-VPLS network to EVPN: • Hubs typically have local switching enabled as interspoke traffic is forwarded through the hub. If spokes alone are migrated to EVPN and spokes have Layer 3 or MPLS reachability to each other, the label-switched or virtual tunnel interface to the hub and EVPN next hop (remote spoke) is present in the VPLS edge (VE) floodgroup. This results in two copies of broadcast, unknown unicast, and multicast (BUM) traffic received by the remote spoke. One option to avoid this behavior is to migrate the hubs to EVPN too. • EVPN is not aware of hierarchy. All peers are considered core-facing. Once hubs and spokes are migrated to EVPN, split horizon prevents the BUM traffic from being forwarded to other core-facing PE devices.
ESI configuration	Ethernet segment identifier (ESI) is configured at the physical interface or port level.

- *EVPN Overview*

Understanding VPLS Interfaces

For each VPLS routing instance on a PE router, you specify which interfaces are to be used to carry VPLS traffic between the PE and CE devices.

This topic contains the following sections:

Interface Name

Specify both the physical and logical portions of the interface name, in the following format:

physical.logical

For example, in ge-1/2/1.2, ge-1/0/1 is the physical portion of the interface name and 2 is the logical portion. If you do not specify the logical portion of the interface name, 0 is set by default. A logical interface can be associated with only one routing instance.

Encapsulation Type

The physical link-layer encapsulation type for a VPLS interface can be one of the following:

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol Identifier (TPID) values.
- **extended-vlan-vpls**—Use extended virtual LAN (VLAN) VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. All VLAN IDs from 1 through 1023 are valid for VPLS VLANs on Fast Ethernet interfaces, and all VLAN IDs from 1 through 4094 are valid for VPLS VLANs on Gigabit Ethernet interfaces.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. You must configure this encapsulation type on both the physical interface and the logical interface. VLAN IDs 1 through 511 are reserved for normal Ethernet VLANs, IDs 512 through 1023 are reserved for VPLS VLANs on Fast Ethernet interfaces, and IDs 512 through 4094 are reserved for VPLS VLANs on Gigabit Ethernet interfaces.
- **flexible-ethernet-services**—Use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. This encapsulation type allows you to configure any combination of route, TCC, CCC, and VPLS encapsulations on a single physical port. Aggregated Ethernet bundles cannot use this encapsulation type.

  For flexible Ethernet services encapsulation, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

Flexible VLAN Tagging

For untagged packets to be accepted on an 802.1Q VLAN-tagged port, specify the native VLAN ID with the flexible VLAN tagging option. (No other flexible VLAN tagging features are supported.)

VLAN Rewrite

You can rewrite VLAN tags on VPLS interfaces. Rewriting VLAN tags allows you to use an additional (outer) VLAN tag to differentiate between CE devices that share a VLAN ID.

You can configure rewrite operations to stack (push), remove (pop), or rewrite (swap) tags on single-tagged frames. If a port is not configured for VLAN tagging, rewrite operations are not supported on any logical interface on that port.

You can configure the following VLAN rewrite operations:

- pop—Remove a VLAN tag from the top of the VLAN tag stack. The outer VLAN tag of the frame is removed.
- push—Add a new VLAN tag to the top of the VLAN stack. An outer VLAN tag is pushed in front of the existing VLAN tag.
- swap—Replace the VLAN tag at the top of the VLAN tag stack with a user-specified VLAN tag value.

You perform VLAN rewrite operations by applying input and output VLAN maps at the ingress and egress, respectively, of the interface. For incoming frames, use the input-vlan-map; for outgoing frames, use the output-vlan-map.

The VPLS implementation on SRX Series devices does not support dual-tagged frames. Therefore, VLAN rewrite operations are not supported on dual-tagged frames. VLAN rewrite operations such as pop-pop, pop-swap, push-push, swap-push, and swap-swap, which are supported on M Series and T Series routing platforms, are not supported on SRX Series devices.

Example: Configuring Routing Interfaces on the VPLS PE Router

This example shows how to configure routing interfaces on the VPLS PE router.

Requirements

Before you begin, see *Understanding Selective Stateless Packet-Based Services* .

Overview

In this example, you configure the PE1 router loopback interface and the interface to the PE2 router ge-2/0/1.

Configuration

Step-by-Step Procedure

To configure the routing interface on the VPLS PE router:

1. Configure the loopback interface.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet address 10.255.7.168/32 primary
```

2. Configure the IP address on the MPLS core interface.

```
[edit]
user@host# set interfaces ge-3/0/2 unit 0 family inet address 100.1.1.1/30
```

3. Configure the MPLS family.

```
[edit]
user@host# set interfaces ge-3/0/2 unit 0 family mpls
```

4. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces** command.

- Understanding VPLS Interfaces on page 1005

Example: Configuring the Interface to the VPLS CE Device

This example shows how to configure the router interface that is connected to the CE device to include VPLS encapsulation.

- Requirements on page 1008
- Overview on page 1008
- Configuration on page 1008
- Verification on page 1009

Requirements

Before you begin, see *Understanding Selective Stateless Packet-Based Services* .

Overview

In this example, you configure the router interface ge-1/2/1 that is connected to the CE device to include VPLS encapsulation.

Configuration

Step-by-Step Procedure

To configure the interface to the VPLS CE device:

1. Configure VPLS encapsulation for the interface facing the CE router.

```
[edit]
user@host# set interfaces ge-1/2/1 encapsulation ethernet-vpls
```

2. Configure the interface for the VPLS family group.

```
[edit]
user@host# set interfaces ge-1/2/1 unit 0 family vpls
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces ge-1/2/1** command.

VPLS Filters and Policers Overview

This feature permits users to configure both firewall filters and policers for virtual private LAN service (VPLS). Firewall filters enable you to filter packets based on their components and perform an action on packets that match the filter. Policers enable you to limit the amount of traffic that passes into or out of an interface.

This feature can be enabled by configuring VPLS filters, policers, and accounting through various CLI commands. VPLS filters and policers act on a Layer 2 frame that includes the media access control (MAC) header (after any VLAN rewrite or other rules are applied), but that does not include the cyclical redundancy check (CRC) field.

NOTE: You can apply VPLS filters and policers on the PE routers only to customer-facing (PE-CE) interfaces.

Related Documentation

- Example: Configuring VPLS Policers on page 1012
- Example: Configuring VPLS Filters on page 1009

Example: Configuring VPLS Filters

This example shows how to configure VPLS filters.

- Requirements on page 1010
- Overview on page 1010

Requirements

Before you begin:

- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 1017.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 1021.
- Configure RSVP-TE on the PE routers. See "Example: Configuring RSVP on the VPLS PE Router" on page 1022.

Overview

This example describes how to configure filtering and accounting for VPLS.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your device to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device.

Configuration

CLI Quick Configuration

To quickly configure VPLS filters, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall family vpls filter blue term term1 from interface ge-3/0/0.512
set firewall family vpls filter blue term term1 from interface fe-5/0/0.512
set firewall family vpls filter blue term term1 then count count1
set firewall family vpls filter blue accounting-profile fw_profile
set accounting-options file fw_acc size 500k
set accounting-options file fw_acc transfer-interval 5
set accounting-options filter-profile fw_profile file fw_acc
set accounting-options filter-profile fw_profile interval 1
set accounting-options filter-profile fw_profile counters count1
set interfaces ge-0/0/1 unit 512 family vpls filter input blue
```

Step-by-Step Procedure

To configure filters for VPLS:

1. Configure a filter with a GE interface as the match condition and count as the action.

```
[edit ]
user@host# set firewall family vpls filter blue term term1 from interface ge-3/0/0.512
```

2. Configure a filter with an FE interface as the match condition and count as the action.

```
[edit ]
user@host# set firewall family vpls filter blue term term1 from interface fe-5/0/0.512
```

3. Configure the count.

```
[edit ]
user@host# set firewall family vpls filter blue term term1 then count count1
```

4. Configure the accounting profile to refer it to the counter.

```
[edit ]
user@host# set firewall family vpls filter blue accounting-profile fw_profile
```

5. Configure the account file size.

```
[edit ]
user@host# set accounting-options file fw_acc size 500k
```

6. Configure the account transfer interval.

```
[edit ]
user@host# set accounting-options file fw_acc transfer-interval 5
```

7. Configure the filter for the accounting profile.

```
[edit ]
user@host# set accounting-options filter-profile fw_profile file fw_acc
```

8. Configure the filter for the interval.

```
[edit ]
user@host# set accounting-options filter-profile fw_profile interval 1
```

9. Configure the counter.

```
[edit ]
```

```
user@host# set accounting-options filter-profile fw_profile counters count1
```

10. Apply the filter to the interface.

```
[edit ]
user@host# set interfaces ge-0/0/1 unit 512 family vpls filter input blue
```

11. If you are done configuring the device, commit the configuration.

```
[edit ]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show firewall** and **show accounting records** commands.

Example: Configuring VPLS Policers

This example shows how to configure VPLS policers.

Requirements

Before you begin:

- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 1017.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 1021.
- Configure RSVP-TE on the PE routers. See "Example: Configuring RSVP on the VPLS PE Router" on page 1022.

Overview

This example describes how to configure policing and apply it on the interface for VPLS.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your device to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device.

Configuration

CLI Quick Configuration

To quickly configure VPLS policers, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall policer police2 if-exceeding bandwidth-percent 10
set firewall policer police2 if-exceeding burst-size-limit 1500
set firewall policer police2 then discard
set interfaces ge-0/0/1 unit 512 family vpls policer input police2
```

Step-by-Step Procedure

To configure filters for VPLS:

1. Configure bandwidth percentage.

   ```
   [edit ]
   user@host# set firewall policer police2 if-exceeding bandwidth-percent 10
   ```

2. Configure the burst size limit.

   ```
   [edit ]
   user@host# set firewall policer police2 if-exceeding burst-size-limit 1500
   ```

3. Configure the terminal action on the packet.

   ```
   [edit ]
   user@host# set firewall policer police2 then discard
   ```

4. Apply the policer to the interface.

   ```
   [edit ]
   user@host# set interfaces ge-0/0/1 unit 512 family vpls policer input police2
   ```

5. If you are done configuring the device, commit the configuration.

```
[edit ]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show firewall** command.

Understanding VPLS Routing Instances

To configure VPLS functionality, you must enable VPLS support on the PE router. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the CE devices.

You create a VPLS routing instance on each PE router that is participating in the VPLS. The routing instance has the same name on each PE router. To configure the VPLS routing instance, you specify the following:

- Route distinguisher—Helps BGP distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPLS instances. Each routing instance that you configure on a PE router must have a unique route distinguisher.
- Route target—Defines which route is part of a VPLS. A unique route target helps distinguish between different VPLS services on the same router.
- Site name—Provides unique name for the VPLS site.
- Site identifier—Provides unique numerical identifier for the VPLS site.
- Site range—Specifies total number of sites in the VPLS. The site range must be greater than the site identifier.
- Interface to the CE router—Specifies the physical interface to the CE router that carries VPLS traffic. The interface must be configured for a VPLS encapsulation type.

NOTE: In addition to the VPLS routing instance, you must configure MPLS label-switched paths (LSPs) between the PE routers, internal BGP (IBGP) sessions between the PE routers, and an interior gateway protocol (IGP) on the PE routers.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your router to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the router performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the router.

This topic contains the following sections:

BGP Signaling

BGP is used to signal the paths between each of the PE routers participating in the VPLS routing instance. These paths carry VPLS traffic across the service provider's network between the VPLS sites.

NOTE: LDP signaling is not supported for the VPLS routing instance.

To configure BGP signaling, you specify the following:

- VPLS site name and site identifier—When you configure BGP signaling for the VPLS routing instance, you must specify each VPLS site that has a connection to the router. For each VPLS site, you must configure a site name and site identifier (a numerical identifier between 1 to 65,534 that uniquely identifies the VPLS site).
- Site range—When you enable BGP signaling for the VPLS routing instance, you need to configure a site range. The site range specifies the total number of sites in the VPLS.

  NOTE: The site range value must be greater than the largest site identifier.

- Site preference—You can specify the preference value advertised for a particular VPLS site. The site preference value is encoded in the BGP local preference attribute. When a PE router receives multiple advertisements with the same VPLS edge (VE) device identifier, the advertisement with the highest local preference value is preferred.

VPLS Routing Table

The VPLS routing table contains MAC addresses and interface information for both physical and virtual ports. You can configure the following characteristics for the table:

- Table size—You can modify the size of the VPLS MAC address table. The default table size is 512 MAC addresses; the minimum is 16 addresses, and the maximum is 65,536 addresses.

If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

The interfaces affected include all of the interfaces within the VPLS routing instance, including the local interfaces and the LSI interfaces.

- Timeout interval—You can modify the timeout interval for the VPLS table. The default timeout interval is 300 seconds; the minimum is 10 seconds, and the maximum is 1,000,000 seconds. We recommend you configure longer values for small, stable VPLS networks and shorter values for large, dynamic VPLS networks. If the VPLS table does not receive any updates during the timeout interval, the router waits one additional interval before automatically clearing the MAC address entries from the VPLS table.
- Number of addresses learned from an interface—You can configure a limit on the number of MAC addresses learned by a VPLS routing instance by setting the MAC table size. The default is 512 addresses; the minimum is 16, and the maximum is 65,536 addresses. If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

  Because this limit applies to each VPLS routing instance, the MAC addresses of a single interface can consume all the available space in the table, preventing the routing instance from acquiring addresses from other interfaces. You can limit the number of MAC addresses learned from all interfaces configured for a VPLS routing instance, as well as limit the number of MAC addresses learned from a specific interface.

  The MAC limit configured for an individual interface overrides the limit configured for all interfaces for the VPLS routing instance. Also, the table limit can override the limits configured for the interfaces.

  The MAC address limit applies only to interfaces to CE devices.

Trace Options

The following trace flags display operations associated with VPLS:

- **all**—All VPLS tracing options
- **connections**—VPLS connections (events and state changes)
- **error**—Error conditions
- **nlri**—VPLS advertisements received or sent using BGP
- **route**—Trace-routing information
- **topology**—VPLS topology changes caused by reconsideration or advertisements received from other PE routers using BGP

Example: Configuring the VPLS Routing Instance

This example shows how to create a VPLS routing instance on each PE router that is participating in the VPLS.

- Requirements on page 1017
- Overview on page 1017
- Configuration on page 1017
- Verification on page 1019

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services* .
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.

Overview

This example describes how to create a VPLS routing instance; configure VPLS site identifier, site range, no tunnel services option, route distinguisher, and route target for the VPLS routing instance; and specify the VPLS interface to the CE router.

NOTE: **You must specify no tunnel services in the VPLS routing instance configuration, because SRX Series devices do not support tunnel serial PICs.**

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances green instance-type vpls
set routing-instances green protocols vpls site-range 10 site R3 site-identifier 2
set routing-instances green protocols vpls no-tunnel-services
set routing-instances green route-distinguisher 10.255.7.1:1
set routing-instances green vrf-target target:11111:1
set routing-instances green instance-type vpls interface ge-1/2/1.0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a VPLS routing instance:

1. Configure the routing instance of type VPLS.

```
[edit]
user@host# edit routing-instances green
```

2. Enable the VPLS instance type.

```
[edit routing-instances green]
user@host# set instance-type vpls
```

3. Configure the VPLS site identifier and range for the VPLS routing instance.

```
[edit routing-instances green protocols vpls]
user@host# set site-range 10 site R3 site-identifier 2
```

4. Configure the no-tunnel-services option for the VPLS routing instance.

```
[edit routing-instances green protocols vpls]
user@host# set no-tunnel-services
```

5. Configure the route distinguisher.

```
[edit routing-instances green]
user@host# set route-distinguisher 10.255.7.1:1
```

6. Configure the route target.

```
[edit routing-instances green]
user@host# set vrf-target target:11111:1
```

7. Specify the VPLS interface to the CE router.

```
[edit routing-instances green]
user@host# set instance-type vpls interface ge-1/2/1.0
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances green** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances green
instance-type vpls;
interface ge-1/2/1.0;
route-distinguisher 10.255.7.1:1;
vrf-target target:11111:1;
protocols {
   vpls {
      site-range 10;
      no-tunnel-services;
      site R3 {
         site-identifier 2;
      }
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Example: Configuring Automatic Site Identifiers for VPLS

This example shows how to configure automatic site identifiers for VPLS sites.

Requirements

Before you begin, see information on selective stateless packet-based services in *Interfaces Feature Guide for Security Devices*.

Overview

When you enable automatic site identifiers, the Junos OS automatically assigns site identifiers to VPLS sites. In this example, you configure a routing instance called vpls instance and enable automatic site identifiers for VPLS.

NOTE: Site identifiers for VPLS sites can be different for different routing instances.

Configuration

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure automatic site identifiers:

1. Configure the routing instance of type VPLS.

```
[edit]
user@host#set routing-instances vpls-instance
```

2. Enable automatic site identifiers.

```
[edit routing-instances vpls-instance]
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
  collision-detect-time 10
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
  new-site-wait-time 20
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
  reclaim-wait-time minimum 5 maximum 20
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
  startup-wait-time 5
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show vpls connections** command.

Example: Configuring OSPF on the VPLS PE Router

This example shows how to configure OSPF on the VPLS PE router.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services* .
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 1017.

Overview

The PE routers exchange routing information using an IGP such as OSPF. In this example, you configure OSPF area 0.0.0.0 on the VPLS PE router and traffic engineering for OSPF.

Configuration

Step-by-Step Procedure

To configure OSPF on the VPLS PE router:

1. Configure the OSPF area on the VPLS PE router.

```
[edit]
user@host# set protocols ospf area 0.0.0.0 interface t1-1/0/1.0
user@host# set protocols ospf area 0.0.0.0 interface lo0.0
```

2. Configure traffic engineering for OSPF.

```
[edit]
user@host# set protocols ospf traffic-engineering
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

Example: Configuring RSVP on the VPLS PE Router

This example shows how to configure RSVP on the VPLS PE router.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services* .
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See"Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 1017.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 1021.

Overview

This example describes how to enable RSVP for all connections that participate in the LSP on the PE1 router.

Configuration

Step-by-Step Procedure

To configure RSVP on the VPLS PE router:

1. Configure the interface to the PE2 router for RSVP.

```
[edit ]
user@host# set protocols rsvp interface t1-1/0/1.0
```

2. Configure the loopback interface for RSVP.

```
[edit ]
```

```
user@host# set protocols rsvp interface lo0.0
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

Example: Configuring VPLS over GRE with IPsec VPNs

This example demonstrates a network scenario consisting of a central office and one branch office that will use VPLS, MPLS, GRE, and IPsec to create secure Ethernet connectivity over a Layer 3 network. This configuration can be expanded to add many other branch sites.

Requirements

Before you begin:

- Ensure that a layer 3 network is in place for all branch offices and that there is an ingress (head-end) device at the central office configured to terminate the VPNs from each branch office.
- Obtain IDP licenses for each SRX Series device. IDP is used to reassemble GRE packets that might become fragmented.

Overview

Junos OS can selectively choose whether traffic is processed by the flow engine or packet engine using the selective stateless packet-based feature. This feature allows you to combine flow and packet-based services in a single device. In this example, we describe a deployment scenario that uses this feature to deploy large-scale VPLS over GRE. This enables SRX devices to securely transport Ethernet traffic over Layer 3 networks when used in conjunction with IPsec.

In this scenario you configure a central office ingress (head-end) using an SRX650 device and one branch office using an SRX240 device. This setup is accomplished by carrying MPLS pseudowires over GRE, which in turn, is encapsulated in IPsec in order to guarantee data integrity and confidentiality. By default, SRX Series devices use secure flow forwarding. Because VPLS services are provided in packet-mode only, the configuration requires the GRE tunnel to be terminated in a packet-mode routing instance (the default routing instance).

NOTE: You can also use an MX Series device as the ingress (head-end) device, which is mentioned later in this topic.

To better understand this configuration, we will discuss two scenarios. The first scenario uses pseudowires to allow the creation of point-to-point circuits between two endpoints carried over the MPLS network. If we leave the signaling protocols aside (that is, there are a few ways to provision the pseudowires), these connections are just point-to-point connections. Using this approach provides an end-to-end wire between sites. This is

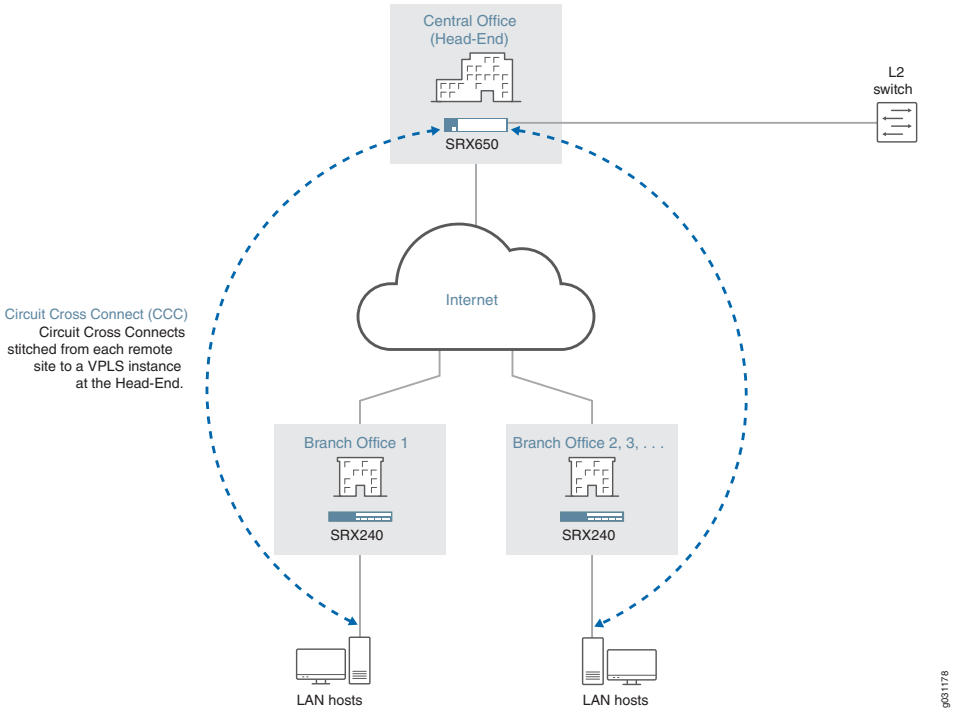
beneficial from a traffic processing point of view because the gateways do not need to do MAC address learning, they simply forward anything they receive to the pseudowire. Because of this, it may be difficult to deploy this setup when trying to provide connectivity to multiple branch offices.

The second scenario could use VPLS to provide a Layer 2 network abstraction. With VPLS, endpoints are expected to negotiate LSPs and pseudowires with every other endpoint (that is, they are fully meshed). When a node receives an Ethernet frame from one of its LAN interfaces the source MAC address is learned, if it's not already known, and flooded using every pseudowire connecting to all other branch nodes. However, if the destination has been previously learned, then the frame is sent to the appropriate destination. When an Ethernet frame is received through one of the pseudowires (that is, from the MPLS network), source MAC address learning is performed. The next time a frame is sent to that MAC it does not need to be flooded and the frame is flooded to every single LAN interface in the node, but not over the pseudowires. In other words, the network acts as a distributed Layer 2 switch providing any-to-any Ethernet connectivity between the devices connected to the different nodes in the network.

While the advantages of this second scenario is evident (any-to-any connectivity, automated provisioning, and simple abstraction), it comes at the cost of complexity. Every PE node has to perform Layer 2 learning and flooding of traffic, which can cause problems when either multiple broadcast/multicast or frames to unknown MAC addresses are used. As an example, if you had a topology with a thousand branch offices, each office that receives a broadcast packet must replicate it 999 times, encapsulate each copy in GRE and IPsec and forward the resulting traffic. Additionally, because each node performs Layer 2 learning, there are limitations in the maximum number of MAC addresses that each node can learn, limiting the total number of nodes in the domain.

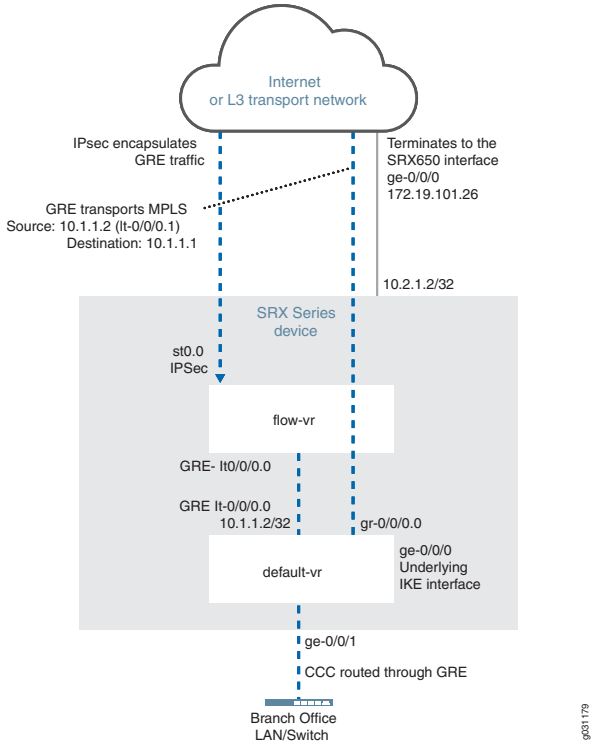
In this example, we use a hybrid approach to these two scenarios. We use a circuit cross connect (CCC) at each branch office stitched to a VPLS instance at central office (ingress). This solution makes sense if most of the traffic flows from the branch offices to central office, and the branch-to-branch office traffic is always forwarded through the hub. The use of CCCs at branch offices combined with VPLS stitching at the central office provides a scalable way to deploy large hub-and-spoke topologies where Ethernet must be transported over an IP network (with or without encryption). At the expense of configuration complexity, it is possible to use SRX Series devices to terminate such connections, providing a scalable and cost-effective way to deploy small-to-large networks where Ethernet traffic is carried transparently using lower cost IP connections. Figure 81 on page 1028 shows this topology.

Figure 81: VPLS Deployment Scenario



In this deployment, VPLS services are provided only in packet mode and must be configured in the default routing instance. Unfortunately, IPsec is only provided in flow mode. Hence, a flow-mode routing-instance is used that provides both GRE reassembly and IPsec termination. While the GRE termination is done in the default routing instance, a flow-mode routing instance is connected between the default routing instance and the Internet (or whatever Layer 3 network is used as a transport), and it terminates the IPsec tunnel towards the ingress device. Because it is likely that a single public IP address is available, the Internet-facing Interface is connected to the default routing instance and is used to terminate IKE; however, the tunnel interface (st0) is bound to the flow-mode routing instance. See Figure 82 on page 1029.

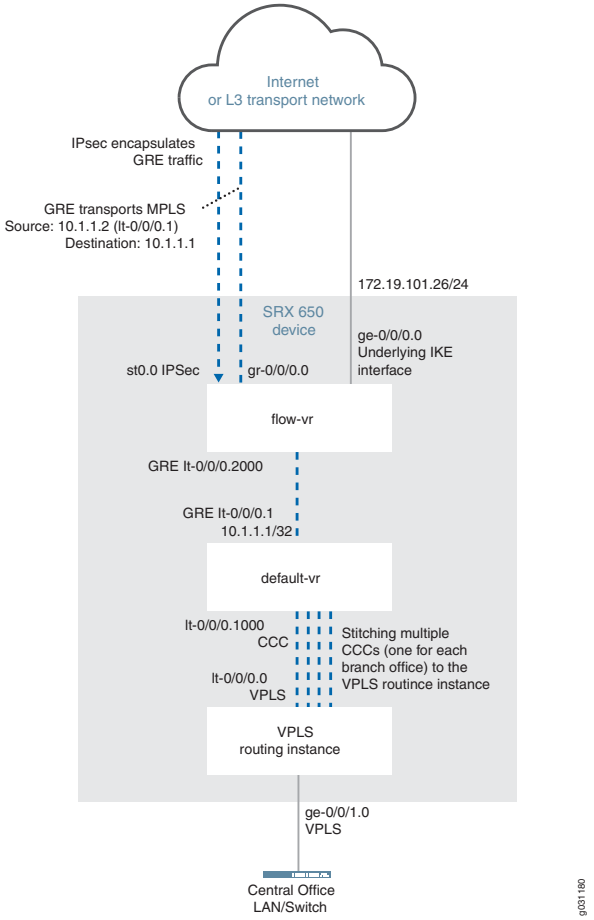
Figure 82: Branch Office Circuit Cross Connect Termination



When configuring the central office SRX650, the first thing you do is terminate the IPsec tunnels, GRE, and CCC connections. Because a SRX Series device is used as the ingress (head-end), the configuration to terminate the CCC circuits is identical to the one used at each branch office, with the exception that instead of one tunnel, multiple tunnels (and pseudowires) are terminated.

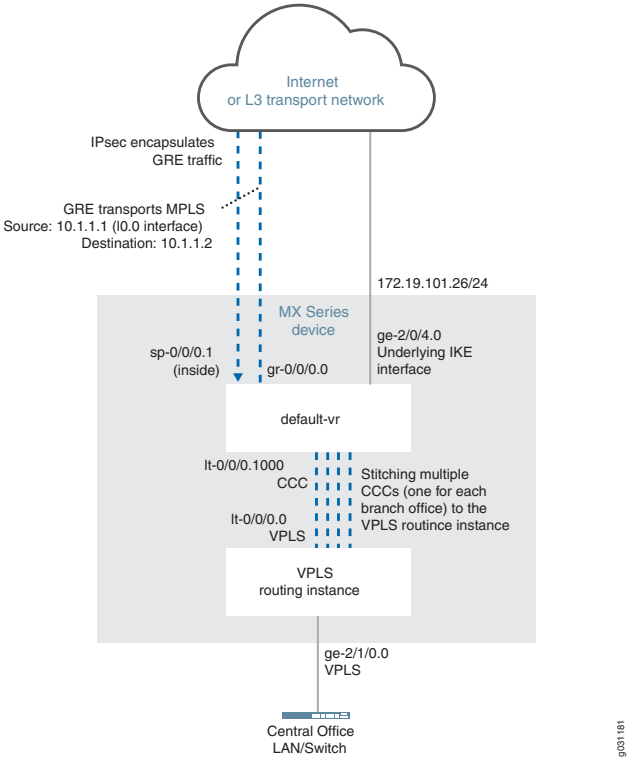
The pseudowires are stitched to a VPLS routing instance using logical tunnel (lt) interfaces. It is possible to use an lt interface unit to terminate a CCC connection and connect this unit to a different unit that is part of a VPLS routing instance. The overall result is as if the pseudowires were terminated directly in the VPLS routing instance. Figure 83 on page 1030 illustrates this configuration.

Figure 83: Central Office Ingress (Head-End) Configuration with an SRX Series Device



You can also use an MX Series device as the central office ingress (head-end) to terminate all branch office connections. The differences in the configuration are due to the way IPsec is configured and the fact that on MX Series devices IDP is not required to reassemble the GRE packets; MX Series devices natively support GRE reassembly. With this configuration, you still use lt interfaces to stitch the CCCs between the remote branch offices and the VPLS routing instance as shown in Figure 84 on page 1031.

Figure 84: Central Office Ingress (Head-End) Configuration with an MX Series Device



Configuration

In this example, we use SRX Series devices and the branch and ingress (head-end) sites will typically be connected to the Internet by Frame-Relay/T1-E1/xDSL/T3/E3 or even Ethernet. A provider MPLS network is not required.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the SRX240 at the branch office:

1. Configure a GRE tunnel to the central office.

```
[edit interfaces]
user@host# set gr-0/0/0 description "GRE tunnel to SRX650”
user@host# set gr-0/0/0 unit 0 clear-dont-fragment-bit
user@host# set gr-0/0/0 unit 0 tunnel source 10.1.1.2
user@host# set gr-0/0/0 unit 0 tunnel destination 10.1.1.1
user@host# set gr-0/0/0 unit 0 tunnel allow-fragmentation
user@host# set gr-0/0/0 unit 0 family inet mtu 2000
user@host# set gr-0/0/0 unit 0 family inet filter input inet-packet-mode
user@host# set gr-0/0/0 unit 0 family mpls mtu 1900
user@host# set gr-0/0/0 unit 0 family mpls filter input mpls-packet-mode
```

2. Create a logical interface that connects to the default routing instance.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 0 encapsulation frame-relay
user@host# set lt-0/0/0 unit 0 dlci 16
user@host# set lt-0/0/0 unit 0 peer-unit 1
user@host# set lt-0/0/0 unit 0 family inet
user@host# set lt-0/0/0 unit 0 description "Flow-vr Instance"
```

3. Connect the logical tunnel interface to the flow mode virtual router.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 1 encapsulation frame-relay
user@host# set lt-0/0/0 unit 1 dlci 16
user@host# set lt-0/0/0 unit 1 peer-unit 0
user@host# set lt-0/0/0 unit 1 family inet filter input inet-packet-mode
user@host# set lt-0/0/0 unit 1 family inet address 10.1.1.2/32
```

4. Connect the CCC interface to the branch LAN.

```
[edit interfaces]
user@host# set ge-0/0/1 encapsulation ethernet-ccc
user@host# set ge-0/0/1 unit 0 description "CCC Interface to customer LAN"
user@host# set ge-0/0/1 unit 0 family ccc filter input ccc-packet-mode
```

5. Configure the interface bound to the default virtual router.

```
[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 172.19.101.45/24
```

6. Set the loopback interface to terminate the CCC connection.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.2.1.2/32
```

7. Bind the IPsec tunnel interface to the flow-mode virtual router.

```
[edit interfaces]
user@host# set st0 unit 0 family inet
```

8. Set a static route address, which will be the default gateway to the Internet.

```
[edit routing-options]
user@host# set static route 0.0.0.0/0 next-hop 172.19.101.1
```

9. Set a static route for the remote GRE tunnel endpoint.

```
[edit routing-options]
user@host# set static route 10.1.1.1/32 next-hop lt-0/0/0.1
```

10. Set a static route for the loopback interface of the SRX650 ingress (head-end) device.

```
[edit routing-options]
user@host# set static route 10.2.1.1/32 next-hop gr-0/0/0.0
```

11. Configure MPLS and the CCC using LDP as the label protocol.

```
[edit]
user@host# set routing-options router-id 10.2.1.2
user@host# set protocols mpls interface gr-0/0/0.0
user@host# set protocols ldp interface gr-0/0/0.0
user@host# set protocols ldp interface lo0.0
user@host# set protocols l2circuit neighbor 10.2.1.1 interface ge-0/0/1.0
  virtual-circuit-id 1
```

12. Configure the IPsec tunnel.

NOTE: The underlying IKE interface is not in the same routing instance as the tunnel interface.

```
[edit security]
user@host# set ike policy SRX650 mode main
user@host# set ike policy SRX650 proposal-set standard
user@host# set ike policy SRX650 pre-shared-key ascii-text "$ABC123"
user@host# set ike gateway SRX650 ike-policy SRX650
user@host# set ike gateway SRX650 address 172.19.101.26
user@host# set ike gateway SRX650 external-interface ge-0/0/0.0
user@host# set ipsec policy SRX650 proposal-set standard
user@host# set ipsec vpn SRX650 bind-interface st0.0
user@host# set ipsec vpn SRX650 ike gateway SRX650
user@host# set ipsec vpn SRX650 ike ipsec-policy SRX650
user@host# set ipsec vpn SRX650 establish-tunnels immediately
```

13. Configure security zones.

NOTE: In a production environment, host-inbound traffic should be restricted to only allow the necessary protocols and services.

```
[edit security]
user@host# set zones security-zone untrust host-inbound-traffic system-services
  all
user@host# set zones security-zone untrust host-inbound-traffic protocols all
user@host# set zones security-zone untrust interfaces gr-0/0/0.0
user@host# set zones security-zone untrust interfaces lo0.0
```

```
user@host# set zones security-zone untrust interfaces lt-0/0/0.1
user@host# set zones security-zone untrust interfaces ge-0/0/0.0
user@host# set zones security-zone vpn host-inbound-traffic system-services all
user@host# set zones security-zone vpn host-inbound-traffic protocols all
user@host# set zones security-zone vpn interfaces st0.0
user@host# set zones security-zone trust-flow host-inbound-traffic system-services
  all
user@host# set zones security-zone trust-flow host-inbound-traffic protocols all
user@host# set zones security-zone trust-flow interfaces lt-0/0/0.0
```

14. Configure IDP.

```
[edit security]
user@host# set policies from-zone trust-flow to-zone vpn policy gre match
  source-address any
user@host# set policies from-zone trust-flow to-zone vpn policy gre match
  destination-address any
user@host# set policies from-zone trust-flow to-zone vpn policy gre match
  application junos-gre
user@host# set policies from-zone trust-flow to-zone vpn policy gre then permit
  application-services idp
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-all match
  application junos-gre
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-all then
  action ignore-connection
user@host# set idp active-policy gre-reassembly
```

15. Configure packet-mode filters.

```
[edit firewall]
user@host# set family inet filter inet-packet-mode term control-traffic from protocol
  tcp
user@host# set family inet filter inet-packet-mode term control-traffic from port
  22
user@host# set family inet filter inet-packet-mode term control-traffic from port
  80
user@host# set family inet filter inet-packet-mode term control-traffic from port
  8080
user@host# set family inet filter inet-packet-mode term control-traffic then accept
user@host# set family inet filter inet-packet-mode term packet-mode then
  packet-mode
user@host# set family inet filter inet-packet-mode term packet-mode then accept
user@host# set family mpls filter mpls-packet-mode term packet-mode then
  packet-mode
user@host# set family mpls filter mpls-packet-mode term packet-mode then accept
user@host# set family ccc filter ccc-packet-mode term all then packet-mode
user@host# set family ccc filter ccc-packet-mode term all then accept
```

16. Configure the flow-mode virtual router.

```
[edit routing-instances]]
```

```
user@host# set flow-vr instance-type virtual-router
user@host# set flow-vr interface lt-0/0/0.0
user@host# set flow-vr interface st0.0
user@host# set flow-vr routing-options static route 10.1.1.1/32 next-hop st0.0
user@host# set flow-vr routing-options static route 10.1.1.2/32 next-hop lt-0/0/0.0
```

17. Disable syn check and sequence check to bypass LDP session from syn check and sequence check.

```
[edit ]
user@host# set security flow tcp-session no-syn-check
user@host# set security flow tcp-session no-sequence-check
```

18. Enable syn check and sequence check at the policy level.

```
[edit ]
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy
  all then permit tcp-options syn-check-required
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy
  all then permit tcp-options sequence-check-required
user@host# set security policies apply-groups test
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the SRX650 Device at the Central Office

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the ingress (head-end) SRX650 device at the central office:

1. Configure the interface bound to the default virtual router.

```
[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 172.19.101.26/24
```

2. Create the GRE tunnel from the SRX650 to the SRX240 device.

NOTE: As the network expands to include multiple branch offices, you will need to add a similar GRE tunnel configuration on the SRX650 device (head-end) along with a corresponding IPsec configuration to connect to each additional SRX device (SRX240).

```
[edit interfaces]
user@host# set gr-0/0/0 unit 0 clear-dont-fragment-bit
user@host# set gr-0/0/0 unit 0 tunnel source 10.1.1.1
user@host# set gr-0/0/0 unit 0 tunnel destination 10.1.1.2
user@host# set gr-0/0/0 unit 0 tunnel allow-fragmentation
user@host# set gr-0/0/0 unit 0 family inet mtu 1500
user@host# set gr-0/0/0 unit 0 family inet filter input inet-packet-mode
user@host# set gr-0/0/0 unit 0 family mpls filter input mpls-packet-mode
```

3. Configure a logical tunnel interface to stitch the CCC connection to the VPLS instance.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 0 description "VPLS hub port - Interconnect for CCC
   to SRX240"
user@host# set lt-0/0/0 unit 0 encapsulation ethernet-vpls
user@host# set lt-0/0/0 unit 0 peer-unit 1000
```

4. Set unit 1000 to terminate the CCC connection.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 1000 description "Stitch to VPLS for CCC to SRX240"
user@host# set lt-0/0/0 unit 1000 encapsulation ethernet-ccc
user@host# set lt-0/0/0 unit 1000 peer-unit 0
user@host# set lt-0/0/0 unit 1000 family ccc filter input ccc-packet-mode
```

5. Configure the logical tunnel interface.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 2000 encapsulation frame-relay
user@host# set lt-0/0/0 unit 2000 dlci 1
user@host# set lt-0/0/0 unit 2000 peer-unit 2001
user@host# set lt-0/0/0 unit 2000 family inet
```

6. Bind the logical tunnel interface to the default virtual router.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 2001 encapsulation frame-relay
user@host# set lt-0/0/0 unit 2001 dlci 1
user@host# set lt-0/0/0 unit 2001 peer-unit 2000
user@host# set lt-0/0/0 unit 2001 family inet filter input inet-packet-mode
user@host# set lt-0/0/0 unit 2001 family inet address 10.1.1.1/32
```

7. Set the interface to the central office LAN network.

```
[edit interfaces]
user@host# set ge-0/0/1 unit 0
user@host# set ge-0/0/1 encapsulation ethernet-vpls
```

8. Set the loopback interface to terminate the CCC connections to each SRX device.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.2.1.1/32
```

9. Bind the IPsec interface to the flow-mode virtual router.

```
[edit interfaces]
user@host# set st0 unit 0 family inet
```

10. Set a static route for the remote GRE tunnel endpoint.

```
[edit routing-options]
user@host# set static route 10.1.1.2/32 next-hop lt-0/0/0.2001
```

11. Set a static route for the loopback interface of the SRX device.

```
[edit]
user@host# set routing-options static route 10.2.1.2/32 next-hop gr-0/0/0.0
```

12. Configure MPLS and CCC using LDP as the label protocol.

```
[edit protocols]
user@host# set mpls interface gr-0/0/0.0
user@host# set ldp interface gr-0/0/0.0
user@host# set ldp interface lo0.0
user@host# set l2circuit neighbor 10.2.1.2 interface lt-0/0/0.1000 virtual-circuit-id
  1
```

13. Configure the IPsec tunnel.

NOTE: The underlying IKE interface is not in the same routing instance as the tunnel interface.

```
[edit security]
user@host# set ike policy SRX mode main
user@host# set ike policy SRX proposal-set standard
user@host# set ike policy SRX pre-shared-key ascii-text "$ABC123"
user@host# set ike gateway SRX240-1 ike-policy SRX
```

```
user@host# set ike gateway SRX240-1 address 172.19.101.45
user@host# set ike gateway SRX240-1 external-interface ge-0/0/0.0
user@host# set ipsec policy SRX proposal-set standard
user@host# set ipsec vpn SRX240-1 bind-interface st0.0
user@host# set ipsec vpn SRX240-1 ike gateway SRX240-1
user@host# set ipsec vpn SRX240-1 ike ipsec-policy SRX
user@host# set ipsec vpn SRX240-1 establish-tunnels immediately
```

14. Configure security zones.

NOTE: In a production environment, restrict host-inbound traffic to only the necessary protocols and services.

```
[edit security]

  application junos-gre
user@host# set policies from-zone vpn to-zone trust-flow policy GRE then permit
  application-services idp
```

```
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-gre match
  application junos-gre
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-gre then
  action ignore-connection
user@host# set idp active-policy gre-reassembly
```

16. Configure packet-mode filters.

```
[edit firewall]
user@host# set family inet filter inet-packet-mode term control-traffic from protocol
  tcp
user@host# set family inet filter inet-packet-mode term control-traffic from port
  22
user@host# set family inet filter inet-packet-mode term control-traffic from port
  80
user@host# set family inet filter inet-packet-mode term control-traffic from port
  8080
user@host# set family inet filter inet-packet-mode term control-traffic then accept
user@host# set family inet filter inet-packet-mode term packet-mode then
  packet-mode
user@host# set family inet filter inet-packet-mode term packet-mode then accept
user@host# set family mpls filter mpls-packet-mode term packet-mode then
  packet-mode
user@host# set family mpls filter mpls-packet-mode term packet-mode then accept
user@host# set family ccc filter ccc-packet-mode term all then packet-mode
user@host#set family ccc filter ccc-packet-mode term all then accept
```

17. Configure the flow-mode virtual router.

```
[edit routing-instances]
user@host# set flow-vr instance-type virtual-router
user@host# set flow-vr interface lt-0/0/0.2000
user@host# set flow-vr interface st0.0
user@host# set flow-vr routing-options static route 10.1.1.1/32 next-hop
  lt-0/0/0.2000
user@host# set flow-vr routing-options static route 10.1.1.2/32 next-hop st0.0
```

18. Configure the VPLS instance.

```
[edit routing-instances]
user@host# set vpls-hub instance-type vpls
user@host# set vpls-hub interface lt-0/0/0.0
user@host# set vpls-hub interface ge-0/0/1.0
```

19. Disable syn check and sequence check to bypass LDP session from syn check and sequence check.

```
[edit ]
user@host# set security flow tcp-session no-syn-check
user@host# set security flow tcp-session no-sequence-check
```

20. Enable syn check and sequence check at the policy level.

```
[edit ]
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy
   all then permit tcp-options syn-check-required
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy
   all then permit tcp-options sequence-check-required
user@host# set security policies apply-groups test
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying Interfaces

Purpose Verify that the interfaces are configured properly on each device in the VPLS network.

Action From configuration mode, enter **show interfaces** and verify that the IP addressing is correct for each interface, including logical tunnel (lt), loopback (lo), GRE (gr), IPsec tunnel st0, and GE interfaces.

Verifying an IPsec tunnel

Purpose Verify that an IPsec tunnel is working.

Action From operational mode, enter the **show security ipsec security associations** and the **show security ipsec statistics** command.

Verifying GRE

Purpose Verify that GRE is working.

Action From operational mode, enter the **show security flow session protocol gre** command. You can also do a ping between loopback addresses.

Verifying the CCC/L2 circuit.

Purpose Verify that the CCC/L2 circuit is working.

Action From operational mode, enter the **show connections** command.

Verifying that LDP sessions are working.

Purpose Verify that LDP sessions are being created between devices.

Action From operational mode, enter the **show interfaces gr-0/0/0 detail** command.

Example: Configuring VPLS with BGP Signaling

This example shows how to configure VPLS with BGP signaling between two devices.

Requirements

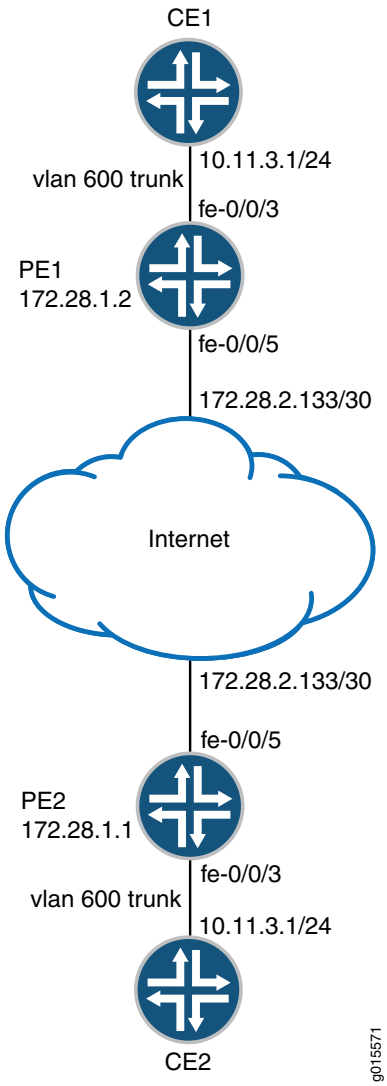
Before you begin, see *Understanding Selective Stateless Packet-Based Services* .

Overview

This example shows a minimum configuration for PE devices and CE devices to create a VPLS network with BGP signaling. The topology consists of two PE devices and two CE devices. In this example, you configure a VPLS routing instance vpls-instance between two PE devices, PE1 and PE2. You also configure the CE1 and CE2 devices that use Ethernet-based interfaces to connect VLAN 600 to their local PE devices. On the CE1 device, configure the Fast Ethernet interface that connects to the PE1 device. The VLAN identifier and IP address must match those of the CE2 device.

Figure 85 on page 1046 shows the topology used in this example.

Figure 85: Configuring VPLS with BGP Signaling



Configuration

Configuring the CE1 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family inet address 10.11.3.1/24
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Enable VLAN tagging on the VPLS interface.

```
[edit interfaces fe-0/0/3]
user@host# set vlan-tagging
```

2. Configure the VLAN ID on the logical interface.

```
[edit interfaces fe-0/0/3 unit 0]
user@host# set vlan-id 600
```

3. Configure the VPLS family on the logical interface.

```
[edit interfaces fe-0/0/3 unit 0]
user@host# set family inet address 10.11.3.1/24
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
fe-0/0/3 {
    vlan-tagging;
    unit 0 {
        vlan-id 600;
        family inet {
            address 10.11.3.1/24;
        }
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the PE1 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system host-name PE1
set interfaces fe-0/0/3 description "CE1 on PE1"
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family vpls
set interfaces fe-0/0/5 vlan-tagging

set protocols ospf area 0.0.0.0 interface fe-0/0/5.37
set routing-instances vpls-instance description "Routing instance from VPLS routing"
set routing-instances vpls-instance instance-type vpls
set routing-instances vpls-instance interface fe-0/0/3.0
set routing-instances vpls-instance route-distinguisher 172.28.1.2:1
set routing-instances vpls-instance vrf-target target:65512:1
set routing-instances vpls-instance protocols vpls site-range 10
set routing-instances vpls-instance protocols vpls no-tunnel-services site site10
  automatic-site-id
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure PE1:

1. Configure the hostname for the PE1 device.

```
[edit ]
user@host# set system host-name PE1
```

2. Configure VPLS VLAN encapsulation on the VPLS PE1 device.

```
[edit interfaces]
user@host# set fe-0/0/3 description "CE1 on PE1"
user@host# set fe-0/0/3 vlan-tagging
user@host# set fe-0/0/3 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 vlan-id 600
```

```
user@host# set fe-0/0/3 unit 0 family vpls
```

3. Configure the routing interface on the VPLS PE1 device.

```
[edit interfaces]
user@host# set fe-0/0/5 vlan-tagging
user@host# set fe-0/0/5 unit 37 vlan-id 37
user@host# set fe-0/0/5 unit 37 family inet address 172.28.2.133/30
user@host# set fe-0/0/5 unit 37 family mpls
user@host# set lo0 unit 0 family inet address 172.28.1.2/32
```

NOTE: For this example, it is optional to configure VLAN tagging. Remove the VLAN tagging configuration on the physical interfaces if you do not plan to configure VLAN tagging.

4. Configure the routing options on the VPLS PE1 device.

```
[edit routing-options]
user@host# set router-id 172.28.1.2
user@host# set autonomous-system 65512
```

5. Configure RSVP on the VPLS PE1 device.

```
[edit protocols]
user@host# set rsvp interface fe-0/0/5.37
```

6. Configure MPLS on the VPLS PE1 device.

```
[edit protocols]
user@host# set mpls label-switched-path pe1-to-pe2 to 172.28.1.1
user@host# set mpls interface fe-0/0/5.37
user@host# set mpls interface lo0.0
```

7. Configure BGP on the VPLS PE1 device.

```
[edit protocols]
user@host# set bgp group vpls-peering type internal
user@host# set bgp group vpls-peering local-address 172.28.1.2
user@host# set bgp group vpls-peering family l2vpn signaling
user@host# set bgp group vpls-peering neighbor 172.28.1.1
```

8. (Optional) Configure OSPF on the VPLS PE1 device.

NOTE: For this example, it is optional to configure OFPF. You must configure OSPF only in cases where two PE devices are not connected directly.

```
[edit protocols]
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
user@host# set ospf area 0.0.0.0 interface fe-0/0/5.37
```

9. Create a VPLS routing instance.

```
[edit ]
user@host# set routing-instances vpls-instance
```

10. Configure a VPLS routing instance.

```
[edit routing-instances vpls-instance]
user@host# set description "Routing instance from VPLS routing"
user@host# set instance-type vpls
user@host# set interface fe-0/0/3.0
user@host# set route-distinguisher 172.28.1.2:1
user@host# set vrf-target target:65512:1
user@host# set protocols vpls site-range 10
user@host# set protocols vpls no-tunnel-services site site10 automatic-site-id
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system
host-name PE1;
```

```
[edit]
user@host# show interfaces
fe-0/0/5 {
   vlan-tagging;
   unit 37 {
      vlan-id 37;
      family inet {
         address 172.28.2.133/30;
      }
      family mpls;
   }
}
fe-0/0/3 {
   description "CE1 on PE1";
```

```
    vlan-tagging;
    encapsulation vlan-vpls;
    unit 0 {
      encapsulation vlan-vpls;
      vlan-id 600;
      family vpls;
    }
}
lo0 {
    unit 0 {
      family inet {
        address 172.28.1.2/32;
      }
    }
}
```

```
[edit]
user@host# show routing-options
router-id 172.28.1.2;
autonomous-system 65512;
```

```
[edit]
user@host# show protocols
rsvp {

    }
    interface fe-0/0/5.37;
    interface lo0.0;
}
bgp {
    group vpls-peering {
      type internal;
      local-address 172.28.1.2;
      family l2vpn {
        signaling;
      }
      neighbor 172.28.1.1;
    }
}
ospf {
    area 0.0.0.0 {
      interface lo0.0 {
        passive;
      }
      interface fe-0/0/5.37;
    }
}
```

```
[edit]
```

```
user@host# show routing-instances
vpls-instance {
   description "Routing instance from VPLS routing";
   instance-type vpls;
   interface fe-0/0/3.0;
   route-distinguisher 172.28.1.2:1;
   vrf-target target:65512:1;
   protocols {
      vpls {
         site-range 10;
         no-tunnel-services;
         site site10 {
            automatic-site-id;
         }
      }
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the PE2 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system host-name PE2
set interfaces fe-0/0/3 description "CE2 on PE2"
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family vpls
set interfaces fe-0/0/5 vlan-tagging
set interfaces fe-0/0/5 unit 37 vlan-id 37
set interfaces fe-0/0/5 unit 37 family inet address 172.28.2.133/30
set interfaces fe-0/0/5 unit 37 family mpls
set interfaces lo0 unit 0 family inet address 172.28.1.1/32
set routing-options router-id 172.28.1.1
set routing-options autonomous-system 65512
set protocols rsvp interface fe-0/0/5.37
set protocols mpls label-switched-path pe2-to-pe1 to 172.28.1.2
set protocols mpls interface fe-0/0/5.37
set protocols mpls interface lo0.0
set protocols bgp group vpls-peering type internal
set protocols bgp group vpls-peering local-address 172.28.1.1
set protocols bgp group vpls-peering family l2vpn signaling
set protocols bgp group vpls-peering neighbor 172.28.1.2
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-0/0/5.37
set routing-instances vpls-instance description "Routing instance for VPLS routing"
set routing-instances vpls-instance instance-type vpls
```

```
set routing-instances vpls-instance interface fe-0/0/3.0
set routing-instances vpls-instance route-distinguisher 172.28.1.1:1
set routing-instances vpls-instance vrf-target target:65512:1
set routing-instances vpls-instance protocols vpls site-range 10
set routing-instances vpls-instance protocols vpls no-tunnel-services site site11
  automatic-site-id
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure PE2:

1. Configure the hostname for the device.

```
[edit ]
user@host# set system host-name PE2
```

2. Configure VPLS VLAN encapsulation on the VPLS PE2 device.

```
[edit interfaces]
user@host# set fe-0/0/3 description "CE2 on PE2"
user@host# set fe-0/0/3 vlan-tagging
user@host# set fe-0/0/3 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 vlan-id 600
user@host# set fe-0/0/3 unit 0 family vpls
```

3. Configure the routing interface on the VPLS PE2 device.

```
[edit interfaces]
user@host# set fe-0/0/5 vlan-tagging
user@host# set fe-0/0/5 unit 37 vlan-id 37
user@host# set fe-0/0/5 unit 37 family inet address 172.28.2.133/30
user@host# set fe-0/0/5 unit 37 family mpls
user@host# set lo0 unit 0 family inet address 172.28.1.1/32
```

NOTE: For this example, it is optional to configure VLAN tagging. Remove the VLAN tagging configuration on the physical interfaces if you do not plan to configure VLAN tagging.

4. Configure the routing options on the VPLS PE2 device.

```
[edit routing-options]
user@host# set router-id 172.28.1.1
user@host# set autonomous-system 65512
```

5. Configure RSVP on the VPLS PE2 device.

```
[edit protocols]
user@host# set rsvp interface fe-0/0/5.37
```

6. Configure MPLS on the VPLS PE2 device.

```
[edit protocols]
user@host# set mpls label-switched-path pe2-to-pe1 to 172.28.1.2
user@host# set mpls interface fe-0/0/5.37
user@host# set mpls interface lo0.0
```

7. Configure BGP on the VPLS PE2 device.

```
[edit protocols]
user@host# set bgp group vpls-peering type internal
user@host# set bgp group vpls-peering local-address 172.28.1.1
user@host# set bgp group vpls-peering family l2vpn signaling
user@host# set bgp group vpls-peering neighbor 172.28.1.2
```

8. (Optional) Configure OSPF on the VPLS PE2 device.

NOTE: For this example, it is optional to configure OFPF. You must configure OSPF only in cases where two PE devices are not connected directly.

```
[edit protocols]
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
user@host# set ospf area 0.0.0.0 interface fe-0/0/5.37
```

9. Create a VPLS routing instance.

```
[edit ]
user@host# set routing-instances vpls-instance
```

10. Configure a VPLS routing instance.

```
[edit routing-instances vpls-instance]
user@host# set description "Routing instance for VPLS routing"
user@host# set instance-type vpls
user@host# set interface fe-0/0/3.0
user@host# set route-distinguisher 172.28.1.1:1
user@host# set vrf-target target:65512:1
user@host# set protocols vpls site-range 10
user@host# set protocols vpls no-tunnel-services site site11 automatic-site-id
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Enable VLAN tagging on the VPLS interface.

```
[edit interfaces fe-0/0/3]
user@host# set vlan-tagging
```

2. Configure the VLAN ID on the logical interface.

```
[edit interfaces fe-0/0/3 unit 0]
user@host# set vlan-id 600
```

3. Configure the VPLS family on the logical interface.

```
[edit interfaces fe-0/0/3 unit 0]
user@host# set family inet address 10.11.3.2/24
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
fe-0/0/3 {
   vlan-tagging;
   unit 0 {
      vlan-id 600;
      family inet {
         address 10.11.3.2/24;
      }
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: If VLAN trunking is not needed between the CE devices, remove the configuration on VLAN tagging on the interfaces connecting the CE and PE devices. Also, use ethernet-VPLS-encapsulation instead of vlan-vpls on the CE facing interfaces of the PE devices.

Verification

Confirm that the configuration is working properly.

- Verifying Interfaces on page 1058
- Verifying Routing Information on page 1058

- Verifying VPLS Information on page 1058
- Verifying Automatic Site Identifier Generation on page 1058

Verifying Interfaces

Purpose Verify that the interfaces are configured correctly.

Action From operational mode, enter the **show interfaces terse** command.

Verifying Routing Information

Purpose Verify that the routing information is configured correctly.

Action From operational mode, enter the following commands:

- **show route forwarding-table family mpls**
- **show route forwarding-table family vpls (destination | extensive | matching | table)**
- **show route instance (detail)**

Verifying VPLS Information

Purpose Verify that the VPLS is configured correctly.

Action From operational mode, enter the following commands:

- **show system statistics vpls**
- **show vpls connections**
- **show vpls statistics**

Verifying Automatic Site Identifier Generation

Purpose Verify that the automatic site identifier has been generated.

Action From operational mode, enter the **show vpls connections** command.

```
[edit]
user@host# show vpls connections

Example: Configuring BGP on the VPLS PE Router

This example shows how to configure BGP on the VPLS PE router.

Requirements

Before you begin:

- See *Understanding Selective Stateless Packet-Based Services* .
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 1017.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 1021.
- Configure RSVP-TE. See "Example: Configuring RSVP on the VPLS PE Router" on page 1022. Then configure MPLS LSPs on the PE routers. See "Example: Configuring MPLS on the VPLS PE Router" on page 1023. Alternatively, configure LDP on the PE routers. See "Example: Configuring LDP on the VPLS PE Router" on page 1024.
- Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 1061.

Overview

In this example, you configure an internal BGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. The PE routers use this information to determine which labels to use for traffic destined for remote sites.

NOTE: On all SRX Series devices, BGP-based virtual private LAN service (VPLS) works on child ports and physical interfaces, but not over aggregated Ethernet (ae) interfaces.

Configuration

Step-by-Step Procedure

To configure BGP on the VPLS PE router:

1. Configure the BGP internal group on the VPLS PE router.

```
[edit ]
user@host# set protocols bgp group ibgp type internal local-address 10.255.7.168
   neighbor 10.255.7.164
```

2. Configure the BGP family L2vpn and specify NLRI signaling.

```
[edit ]
user@host# set protocols bgp family L2 VPN signaling
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

Related Documentation

- VPLS Configuration Overview on page 996
- VPLS Overview on page 992

Example: Configuring Routing Options on the VPLS PE Router

This example shows how to configure the routing options on the VPLS PE router.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services* .
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See"Example: Configuring Routing Interfaces on the VPLS PE Router" on page 1007 and "Example: Configuring the Interface to the VPLS CE Device" on page 1008.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 1017.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 1021
- Configure RSVP-TE, see "Example: Configuring RSVP on the VPLS PE Router" on page 1022 and then MPLS LSPs on the PE routers, see "Example: Configuring MPLS on the VPLS PE Router" on page 1023. Alternatively configure LDP on the PE routers, see "Example: Configuring LDP on the VPLS PE Router" on page 1024.

Overview

This example describes how to specify the router ID and the AS number for each router involved in the VPLS . In this example, the routers PE1 and PE2 use the same AS number (100).

Configuration

Step-by-Step Procedure

To configure the routing options on the VPLS PE router:

1. Configure the router ID on the VPLS PE router.

```
[edit]
user@host# set routing-options router-id 10.255.7.168
```

2. Configure the AS number on the VPLS PE router.

```
[edit]
user@host# set routing-options autonomous-system 100
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show routing-options** command.

Understanding VPLS VLAN Encapsulation

Gigabit Ethernet IQ, Gigabit Ethernet PIMs with small form-factor pluggable optics (SFPs), SRX Series devices with Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces with VLAN tagging enabled can use flexible Ethernet services, VLAN virtual private LAN service (VPLS) encapsulation.

NOTE: **VLAN encapsulation is not supported on SRX100 devices because there is no Gigabit Ethernet port.**

Aggregated Ethernet interfaces configured for VPLS can use Ethernet VPLS or VLAN VPLS.

To configure the encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface, include the **encapsulation** statement at the **[edit interfaces interface-name]** hierarchy level, specifying **vlan-ccc** or **vlan-vpls**:

[edit interfaces *interface-name*] encapsulation (vlan-ccc | vlan-vpls);

To configure the encapsulation on an aggregated Ethernet interface, include the encapsulation statement at the **[edit interfaces *interface-name*]** hierarchy level, specifying **ethernet-vpls** or **vlan-vpls**:

[edit interfaces interface-name] encapsulation (ethernet-vpls | vlan-vpls);

Ethernet interfaces in VLAN mode can have multiple logical interfaces. In CCC and VPLS modes, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for CCC or VPLS VLANs. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for CCC or VPLS VLANs.

- VPLS Overview on page 992

Understanding VPLS VLAN Encapsulation on a Logical Interface

You can configure a logical interface with VLAN VPLS encapsulation by using the following methods:

- Configure the physical interface with the same encapsulation and set VLAN ID of 512 or higher.
- Configure the physical interface with flexible Ethernet services encapsulation. If you configure flexible Ethernet services encapsulation, the VLAN ID restriction is removed.

Ethernet interfaces in VLAN mode can have multiple logical interfaces. In VPLS mode, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for VPLS VLAN. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for VPLS VLAN.

For encapsulation type **flexible-ethernet-services**, all VLAN IDs are valid.

- Configure RSVP-TE, see "Example: Configuring RSVP on the VPLS PE Router" on page 1022 and then MPLS LSPs on the PE routers, see "Example: Configuring MPLS on the VPLS PE Router" on page 1023. Alternatively configure LDP on the PE routers, see "Example: Configuring LDP on the VPLS PE Router" on page 1024.
- Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 1061.
- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See "Example: Configuring BGP on the VPLS PE Router" on page 1059.

Overview

This example describes how to enable VLAN tagging on VPLS interface ge-3/0/6, configure the encapsulation type on the physical and logical interfaces, and configure the VPLS family on the logical interface.

NOTE: **Perform the following CLI quick configuration and procedures on all of the PE interfaces (CE facing).**

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-3/0/6 vlan-tagging
set interfaces ge-3/0/6 encapsulation vlan-vpls
set interfaces ge-3/0/6 unit 0 encapsulation vlan-vpls
set interfaces ge-3/0/6 unit 0 vlan-id 512
```

```
set interfaces ge-3/0/6 unit 0 family vpls
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*

To configure VPLS VLAN encapsulation:

1. Enable VLAN tagging on the VPLS interface.

```
[edit interfaces ge-3/0/6]
user@host# set vlan-tagging
```

2. Configure the encapsulation type on the physical interface.

```
[edit interfaces ge-3/0/6]
user@host# set interfaces ge-3/0/6 encapsulation vlan-vpls
```

3. Configure the encapsulation type on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]
user@host# set encapsulation vlan-vpls
```

4. Configure the VLAN ID on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]
user@host# set vlan-id 512
```

5. Configure the family VPLS on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]
user@host# set family vpls
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces ge-3/0/6** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces ge-3/0/6
vlan-tagging;
encapsulation vlan-vpls;
unit 0 {
   encapsulation vlan-vpls;
   vlan-id 512;
   family vpls;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying VPLS VLAN Encapsulation

Purpose Verify that the VPLS VLAN encapsulation is enabled at the interfaces.

Action From operational mode, enter the **show interfaces** command.

Verifying VPLS VLAN Encapsulation for Logical Interfaces

Purpose Verify that the VPLS VLAN encapsulation is enabled at the logical interface.

Action From operational mode, enter the **show interfaces ge-3/0/6 unit 0** command.

- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See "Example: Configuring BGP on the VPLS PE Router" on page 1059

Overview

This example describes how to configure Ethernet VPLS encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface and enable the VPLS family on the interface.

Configuration

Step-by-Step Procedure

To configure VPLS VLAN encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface:

1. Configure the ethernet-vpls encapsulation on the interface.

```
[edit ]
user@host# set interfaces ge-3/0/6 encapsulation ethernet-vpls
```

2. Enable the VPLS family on the interface.

```
[edit ]
user@host# set interfaces ge-3/0/6 unit 0 family vpls
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces** command.

Alternatively configure LDP on the PE routers, see "Example: Configuring LDP on the VPLS PE Router" on page 1024.
- Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 1061.
- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See "Example: Configuring BGP on the VPLS PE Router" on page 1059.

Overview

This example describes how to enable VLAN tagging on the VPLS interface ge-3/0/6, configure the extended-vlan-vpls type on the physical and logical interfaces, and configure the VPLS family on the logical interface.

NOTE: **Perform the following CLI quick configurations and procedures on all PE interfaces (CE facing).**

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-3/0/6 vlan-tagging
set interfaces ge-3/0/6 encapsulation extended-vlan-vpls
set interfaces ge-3/0/6 unit 0 vlan-id 100
set interfaces ge-3/0/6 unit 0 family vpls
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure extended VPLS VLAN encapsulation:

1. Enable VLAN tagging on the VPLS interface as it will receive tagged packets from CE.

   ```
   [edit interfaces ge-3/0/6]
   user@host# set vlan-tagging
   ```

2. Configure the encapsulation type on the physical interface.

   ```
   [edit interfaces ge-3/0/6]
   user@host# set interfaces ge-3/0/6 encapsulation vlan-vpls
   ```

3. Configure the VLAN ID on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set encapsulation vlan-vpls vlan-id 100
   ```

4. Configure the VPLS family on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set family vpls
   ```

Results

From configuration mode, confirm your configuration by entering the **show interfaces ge-3/0/6** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces ge-3/0/6
vlan-tagging;
```

```
encapsulation extended-vlan-vpls;
unit 0 {
   encapsulation vlan-vpls;
   vlan-id 100;
   family vpls;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

CHAPTER 29

Configuring Circuit Cross-Connect (CCC) and Translational Cross-Connect (TCC)

CCC Overview

Circuit cross-connect (CCC) allows you to configure transparent connections between two circuits, where a circuit can be a Frame Relay data-link connection identifier (DLCI), an Asynchronous Transfer Mode (ATM) virtual circuit (VC), a Point-to-Point Protocol (PPP) interface, a Cisco High-Level Data Link Control (HDLC) interface, or an MPLS label-switched path (LSP). Using CCC, packets from the source circuit are delivered to the destination circuit with, at most, the Layer 2 address being changed. No other

processing—such as header checksums, time-to-live (TTL) decrementing, or protocol processing—is done.

NOTE: The QFX10000 Series switches do not support ATM virtual circuits.

CCC circuits fall into two categories: logical interfaces, which include DLCIs, VCs, virtual local area network (VLAN) IDs, PPP and Cisco HDLC interfaces, and LSPs. The two circuit categories provide three types of cross-connect:

- Layer 2 switching—Cross-connects between logical interfaces provide what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.
- MPLS tunneling—Cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit.
- LSP stitching—Cross-connects between LSPs provide a way to "stitch" together two label-switched paths, including paths that fall in two different traffic engineering database areas.

For Layer 2 switching and MPLS tunneling, the cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first. For LSP stitching, the cross-connect is unidirectional.

You can police (control) the amount of traffic flowing over CCC circuits. For more information, see the *Junos OS VPNs Library for Routing Devices*.

It is also possible to use the **ping** command to check the integrity of CCC LSPs. See "Pinging CCC LSPs" on page 421 for more information.

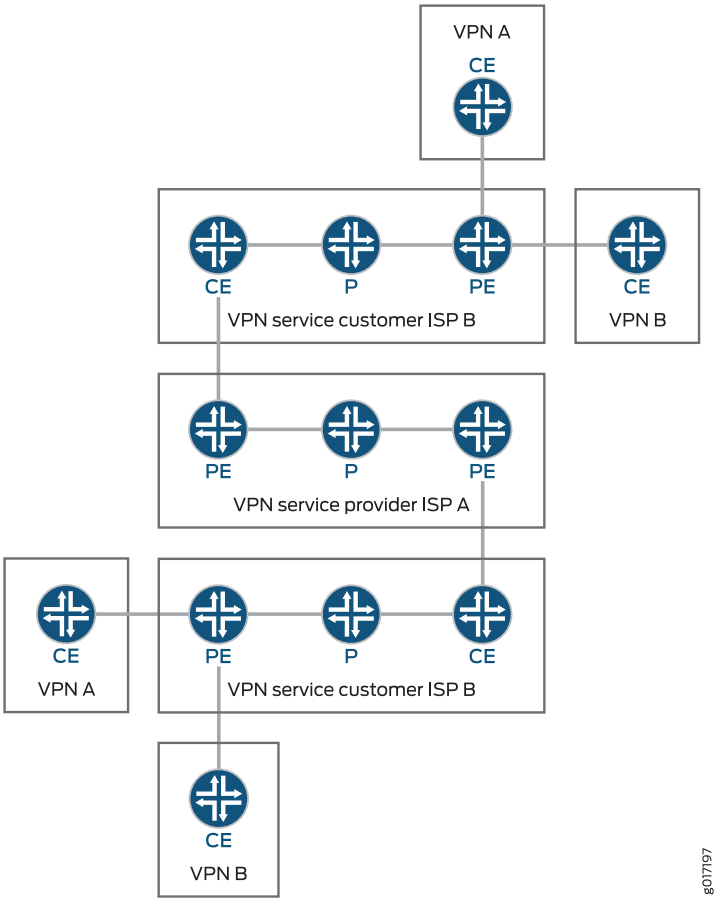
Understanding Carrier-of-Carriers VPNs

The customer of a VPN service provider might be a service provider for the end customer. The following are the two main types of carrier-of-carriers VPNs (as described in RFC 4364:

- "Internet Service Provider as the Customer" on page 1074—The VPN customer is an ISP that uses the VPN service provider's network to connect its geographically disparate regional networks. The customer does not have to configure MPLS within its regional networks.
- "VPN Service Provider as the Customer" on page 1074—The VPN customer is itself a VPN service provider offering VPN service to its customers. The carrier-of-carriers VPN service customer relies on the backbone VPN service provider for inter-site connectivity. The customer VPN service provider is required to run MPLS within its regional networks.

Figure 86 on page 1073 illustrates the network architecture used for a carrier-of-carriers VPN service.

Figure 86: Carrier-of-Carriers VPN Architecture



This topic covers the following:

Internet Service Provider as the Customer

In this type of carrier-of-carriers VPN configuration, ISP A configures its network to provide Internet service to ISP B. ISP B provides the connection to the customer wanting Internet service, but the actual Internet service is provided by ISP A.

This type of carrier-of-carriers VPN configuration has the following characteristics:

- The carrier-of-carriers VPN service customer (ISP B) does not need to configure MPLS on its network.
- The carrier-of-carriers VPN service provider (ISP A) must configure MPLS on its network.
- MPLS must also be configured on the CE routers and PE routers connected together in the carrier-of-carriers VPN service customer's and carrier-of-carriers VPN service provider's networks.

VPN Service Provider as the Customer

A VPN service provider can have customers that are themselves VPN service providers. In this type of configuration, also called a hierarchical or recursive VPN, the customer VPN service provider's VPN-IPv4 routes are considered external routes, and the backbone VPN service provider does not import them into its VRF table. The backbone VPN service provider imports only the customer VPN service provider's internal routes into its VRF table.

The similarities and differences between interprovider and carrier-of-carriers VPNs are shown in Table 44 on page 1074.

Table 44: Comparison of Interprovider and Carrier-of-Carriers VPNs

Feature	ISP Customer	VPN Service Provider Customer
Customer edge device	AS border router	PE router
IBGP sessions	Carry IPv4 routes	Carry external VPN-IPv4 routes with associated labels
Forwarding within the customer network	MPLS is optional	MPLS is required

Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

Release History Table

Release	Description
17.1R1	Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

Related Documentation

- *Interprovider VPNs*

Understanding Interprovider and Carrier-of-Carriers VPNs

All interprovider and carrier-of-carriers VPNs share the following characteristics:

- Each interprovider or carrier-of-carriers VPN customer must distinguish between internal and external customer routes.
- Internal customer routes must be maintained by the VPN service provider in its PE routers.
- External customer routes are carried only by the customer's routing platforms, not by the VPN service provider's routing platforms.

The key difference between interprovider and carrier-of-carriers VPNs is whether the customer sites belong to the same AS or to separate ASs:

- *Interprovider VPNs*—The customer sites belong to different ASs. You need to configure EBGP to exchange the customer's external routes.
- "Understanding Carrier-of-Carriers VPNs" on page 1073—The customer sites belong to the same AS. You need to configure IBGP to exchange the customer's external routes.

In general, each service provider in a VPN hierarchy is required to maintain its own internal routes in its P routers, and the internal routes of its customers in its PE routers. By recursively applying this rule, it is possible to create a hierarchy of VPNs.

The following are definitions of the types of PE routers specific to interprovider and carrier-of-carriers VPNs:

- The AS border router is located at the AS border and handles traffic leaving and entering the AS.
- The end PE router is the PE router in the customer VPN; it is connected to the CE router at the end customer's site.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 circuit on the switch to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on Provider Switches" on page 71.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 circuit:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with CSPF disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Configure the customer edge interface as a Layer 2 circuit from the local PE switch to the other PE switch:

```
[edit protocols]
user@switch# set l2circuit neighbor address interface interface-name virtual-circuit-id identifier
```

TIP: Use the switch address of the other switch as the neighbor address.

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
```

7. Configure LDP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set ldp interface lo0.0
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
```

```
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use VLAN CCC encapsulation:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit 0. The logical unit number must be 1 or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-idvlan-id
```

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: For EX Series switches, you must use the same type of switch for the other PE switch. h.

VLAN CCC Encapsulation on Transport Side of Pseudowire Client Logical Interfaces Overview

Currently, Junos OS does not allow the same VLAN ID to be configured on more than one logical interface under the same pseudowire client physical interface. To support **vlan-ccc** encapsulation on transport pseudowire service (PS) interface on the provider edge (PE) device, this restriction is removed and you can configure the same VLAN ID on more than one logical interface.

The primary reason to configure **vlan-ccc** on the transport PS interface is interoperability with the existing access and aggregate devices in the network. Currently, Junos OS supports **ethernet-ccc** encapsulation on the transport PS interface. Typically, while establishing a pseudowire connection, the access device initiates a VLAN-based pseudowire (also known as VLAN-tagged mode), and a PE router signals the Ethernet mode VLAN back to the access device. For this type of pseudowire connection to be established, you can use the **ignore-encapsulation-mismatch** statement. However, the Junos OS device (access device) might not support the **ignore-encapsulation-mismatch** statement and, as a result, the pseudowire connection is not formed. When the

ignore-encapsulation-mismatch statement is not supported on the access device, you can configure **vlan-ccc** between the nodes to form a pseudowire connection.

The forwarding data path is not changed with the new **vlan-ccc** encapsulation on the transport PS interface and the behavior similar to that when the **ethernet-ccc** encapsulation is configured on the transport PS interface. The transport PS interface either encapsulates or de-encapsulate the outer Layer 2 header and MPLS headers on the transmitted or received packets on the WAN port. Inner Ethernet or VLAN headers of the packet are handled on pseudowire client service logical interfaces. You must configure pseudowire client service logical interfaces with appropriate VLAN IDs or VLAN tags.

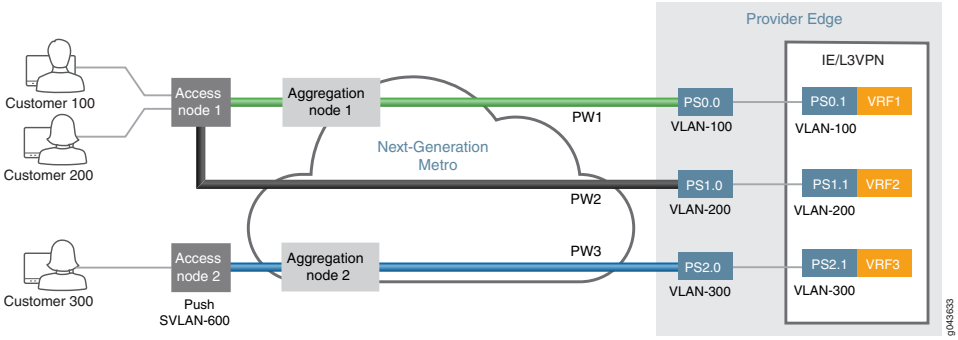
The following sections provides details, along with a sample configuration, about pseudowire configuration from both access and aggregation nodes.

Pseudowire Configuration from Access Node

These pseudowires are set up using VLANs from the access node for customer devices attached to the Layer 2 circuit configured on access and PE routers with customer VLANs (C-VLANs). The ingress traffic (from the access node side) on the PE router is single VLAN tagged (inner Ethernet header), and thus the service logical interfaces must be configured with the same VLAN IDs corresponding to the C-VLAN IDs attached to the access node.

Figure 87 on page 1079 provides the details of a transport PS interface from an access node (access node).

Figure 87: Pseudowire Client Transport Logical Interface from Access Node



The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an access node:

```
interfaces {
  ps0 {
    anchor-point lt-3;
    unit 0 {
      encapsulation VLAN-ccc;
      VLAN ID 100;
    }
    unit 1 {
```

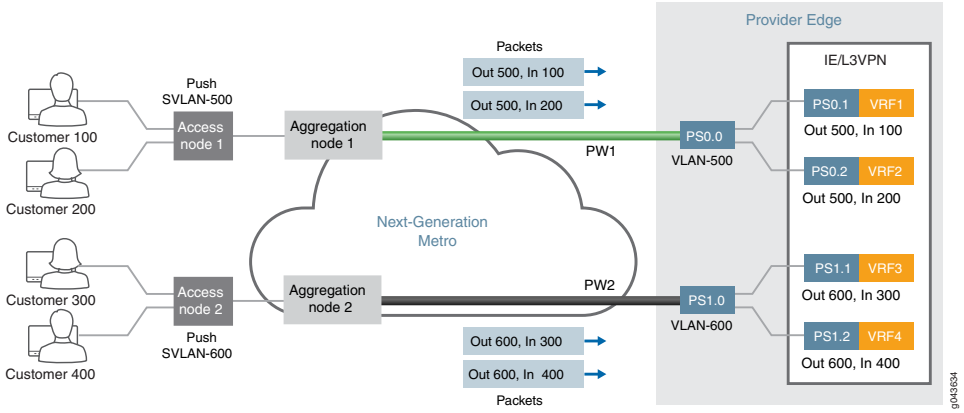
```
        VLAN ID 100;
        family inet;
      }
    }
}
```

Pseudowire Configuration from Aggregation Node

In this case, the aggregation node processes a stacked VLAN (also known as Q-in-Q). The pseudowire originates from aggregation node and terminates on a PE router. The aggregation node pushes the service VLAN (S-VLAN) tag, and the PE router is expected to operate on two VLAN tags—the outer VLAN tag corresponds to an S-VLAN and the inner VLAN tag corresponds to a C-VLAN. The VLAN ID configured on the transport PS interface at the PE router must match the VLAN tag of the S-VLAN. On the pseudowire client service logical interface, the outer VLAN tag must be configured to match the S-VLAN and the inner VLAN tag must be configured to match the C-VLAN.

Figure 88 on page 1080 provides the details of a transport PS interface from an aggregation node.

Figure 88: Pseudowire Client Transport Logical Interface from Aggregation Node



The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an aggregation node:

```
interfaces {
  ps0 {
    anchor-point lt-3;
    unit 0 {
      encapsulation VLAN-ccc;
      VLAN ID 500;
    }
    unit 1 {
      VLAN tags {
        outer 500;
        inner 100;
      }
    }
```

```
    unit 2 {
      VLAN tags {
        outer 500;
        inner 200;
      }
    }
  }
}
```

- *Pseudowire Subscriber Logical Interfaces Overview*

Transmitting Nonstandard BPDUs

CCC protocol (and Layer 2 Circuit and Layer 2 VPN) configurations can transmit nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment. This is the default behavior on all supported PICs and requires no additional configuration.

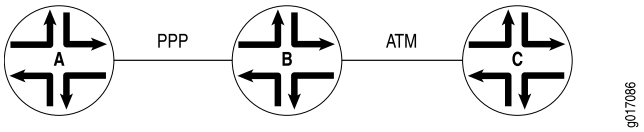
The following PICs are supported on M320 and T Series routers:

- 1-port Gigabit Ethernet PIC
- 2-port Gigabit Ethernet PIC
- 4-port Gigabit Ethernet PIC
- 10-port Gigabit Ethernet PIC

TCC Overview

Translational cross-connect (TCC) is a switching concept that enables you to establish interconnections between a variety of Layer 2 protocols or circuits. It is similar to CCC. However, whereas CCC requires the same Layer 2 encapsulations on each side of a Juniper Networks router (such as PPP-to-PPP or Frame Relay-to-Frame Relay), TCC enables you to connect different types of Layer 2 protocols interchangeably. When you use TCC, combinations such as PPP-to-ATM (see Figure 89 on page 1081) and Ethernet-to-Frame Relay connections are possible.

Figure 89: TCC Example



The Layer 2 circuits and encapsulation types that can be interconnected by TCC are:

- Ethernet
- Extended VLANs
- PPP

- HDLC
- ATM
- Frame Relay

TCC works by removing the Layer 2 header when frames enter the router and adding a different Layer 2 header on the frames before they leave the router. In Figure 89 on page 1081, the PPP encapsulation is stripped from the frames arriving at Router B, and the ATM encapsulation is added before the frames are sent to Router C.

Note that all control traffic is terminated at the interconnecting router (Router B). Examples of traffic controllers include the Link Control Protocol (LCP) and the Network Control Protocol (NCP) for PPP, keepalives for HDLC, and Local Management Interface (LMI) for Frame Relay.

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, TTL decrementing, or protocol handling is performed. TCC is supported for IPv4 only.

Address Resolution Protocol (ARP) packet policing on TCC Ethernet interfaces is effective for releases 10.4 and onwards.

You can configure TCC for interface switching and for Layer 2 VPNs. TCC encapsulation can be configured on **family (inet | iso | mpls)** on most platforms. However, Table 45 on page 1082 shows the platforms and Flexible PIC Concentrator (FPC) combinations that cannot forward ISO traffic when encapsulated with TCC.

Table 45: Platforms/FPCs that Cannot Forward TCC Encapsulated ISO Traffic

Hardware Platform	FPC
T320	T320 FPC
T640	FPC, E-FPC
T1600	T640 E-FPC Type 4, FPC, E-FPC
TX Matrix	T640 E-FPC Type 4, FPC, E-FPC
TX Matrix Plus	T640 E-FPC Type 4, FPC, E-FPC
M320	M320 FPC

For more information about using TCC for virtual private networks (VPNs), see the *Junos OS VPNs Library for Routing Devices*.

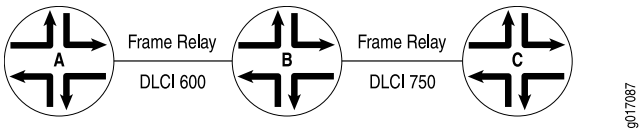
Configuring Layer 2 Switching Cross-Connects Using CCC

Layer 2 switching cross-connects join logical interfaces to form what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.

Figure 90 on page 1083 illustrates a Layer 2 switching cross-connect. In this topology, Router A and Router C have Frame Relay connections to Router B, which is a Juniper Networks router. Circuit cross-connect (CCC) allows you to configure Router B to act as a Frame Relay (Layer 2) switch.

To configure Router B to act as a Frame Relay switch, you configure a circuit from Router A to Router C that passes through Router B, effectively configuring Router B as a Frame Relay switch with respect to these routers. This configuration allows Router B to transparently switch packets (frames) between Router A and Router C without regard to the packets' contents or the Layer 3 protocols. The only processing that Router B performs is to translate DLCI 600 to 750.

Figure 90: Layer 2 Switching Cross-Connect



If the Router A–to–Router B and Router B–to–Router C circuits were PPP, for example, the Link Control Protocol and Network Control Protocol exchanges occur between Router A and Router C. These messages are handled transparently by Router B, allowing Router A and Router C to use various PPP options (such as header or address compression and authentication) that Router B might not support. Similarly, Router A and Router C exchange keepalives, providing circuit-to-circuit connectivity status.

You can configure Layer 2 switching cross-connects on PPP, Cisco HDLC, Frame Relay, Ethernet, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

To configure Layer 2 switching cross-connects, you must configure the following on the router that is acting as the switch (Router B in Figure 90 on page 1083):

- Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects on page 1083
- Configuring the CCC Connection for Layer 2 Switching Cross-Connects on page 1088
- Configuring MPLS for Layer 2 Switching Cross-Connects on page 1088
- Example: Configuring a Layer 2 Switching Cross-Connect on page 1089

Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, configure the CCC encapsulation on the router that is acting as the switch (Router B in Figure 90 on page 1083).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the family statement at the [edit interfaces *interface-name* unit *logical-unit-number*] hierarchy level.

For instructions for configuring the encapsulation for Layer 2 switching cross-connects, see the following sections:

Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects

For ATM circuits, specify the encapsulation when configuring the virtual circuit (VC). Configure each VC as a circuit or a regular logical interface by including the following statements:

```
at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    encapsulation encapsulation-type;
    point-to-point; # Default interface type
    vci vpi-identifier.vci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems** *logical-system-name* **interfaces]**

Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects

For Ethernet circuits, specify **ethernet-ccc** in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must also configure a logical interface (unit 0).

Ethernet interfaces with standard Tag Protocol Identifier (TPID) tagging can use Ethernet CCC encapsulation. On M Series Multiservice Edge Routers, except the M320, one-port Gigabit Ethernet, two-port Gigabit Ethernet, four-port Gigabit Ethernet, and four-port Fast Ethernet PICs can use Ethernet CCC encapsulation. On T Series Core Routers and M320 routers, one-port Gigabit Ethernet and two-port Gigabit Ethernet PICs installed in FPC2 can use Ethernet CCC encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.

```
fe-fpc/pic/port {
  encapsulation ethernet-ccc;
  unit 0;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects

An Ethernet virtual LAN (VLAN) circuit can be configured using either the **vlan-ccc** or **extended-vlan-ccc** encapsulation. If you configure the **extended-vlan-ccc** encapsulation on the physical interface, you cannot configure the **inet** family on the logical interfaces. Only the **ccc** family is allowed. If you configure the **vlan-ccc** encapsulation on the physical interface, both the **inet** and **ccc** families are supported on the logical interfaces. Ethernet interfaces in VLAN mode can have multiple logical interfaces.

For encapsulation type **vlan-ccc**, VLAN IDs from 512 through 4094 are reserved for CCC VLANs. For the **extended-vlan-ccc** encapsulation type, all VLAN IDs 1 and higher are valid. VLAN ID 0 is reserved for tagging the priority of frames.

NOTE: Some vendors use the proprietary TPIDs 0x9100 and 0x9901 to encapsulate a VLAN-tagged packet into a VLAN-CCC tunnel to interconnect a geographically separated metro Ethernet network. By configuring the extended-vlan-ccc encapsulation type, a Juniper Networks router can accept all three TPIDs (0x8100, 0x9100, and 0x9901).

Configure an Ethernet VLAN circuit with the **vlan-ccc** encapsulation as follows:

```
interfaces {
  type-fpc/pic/port {
    vlan-tagging;
    encapsulation vlan-ccc;
    unit logical-unit-number {
      encapsulation vlan-ccc;
      vlan-id vlan-id;
    }
  }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Configure an Ethernet VLAN circuit with the **extended-vlan-ccc** encapsulation statement as follows:

```
interfaces {
   type-fpc/pic/port {
      vlan-tagging;
      encapsulation extended-vlan-ccc;
      unit logical-unit-number {
         vlan-id vlan-id;
         family ccc;
      }
   }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems** *logical-system-name* **interfaces]**

Whether you configure the encapsulation as **vlan-ccc** or **extended-vlan-ccc**, you must enable VLAN tagging by including the **vlan-tagging** statement.

Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects

You can configure aggregated Ethernet interfaces for CCC connections and for Layer 2 virtual private networks (VPNs).

Aggregated Ethernet interfaces configured with VLAN tagging can be configured with multiple logical interfaces. The only encapsulation available for aggregated Ethernet logical interfaces is **vlan-ccc**. When you configure the **vlan-id** statement, you are limited to VLAN IDs 512 through 4094.

Aggregated Ethernet interfaces configured without VLAN tagging can be configured only with the **ethernet-ccc** encapsulation. All untagged Ethernet packets received are forwarded based on the CCC parameters.

To configure aggregated Ethernet interfaces for CCC connections, include the **ae0** statement at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
ae0 {
   encapsulation (ethernet-ccc | extended-vlan-ccc | vlan-ccc);
   vlan-tagging;
   aggregated-ether-options {
      minimum-links links;
      link-speed speed;
   }
   unit logical-unit-number {
      encapsulation vlan-ccc;
      vlan-id identifier;
      family ccc;
   }
}
```

Be aware of the following limitations when configuring CCC connections over aggregated Ethernet interfaces:

- If you configured load balancing between child links, be aware that a different hash key is used to distribute packets among the child links. Standard aggregated interfaces have family inet configured. An IP version 4 (IPv4) hash key (based on the Layer 3 information) is used to distribute packets among the child links. A CCC connection over an aggregated Ethernet interface has family ccc configured instead. Instead of an IPv4 hash key, an MPLS hash key (based on the destination media access control [MAC] address) is used to distributed packets among the child links.
- The extended-vlan-ccc encapsulation is not supported on the 12-port Fast Ethernet PIC and the 48-port Fast Ethernet PIC.
- The Junos OS does not support the Link Aggregation Control Protocol (LACP) when an aggregated interface is configured as a VLAN (with vlan-ccc encapsulation). LACP can be configured only when the aggregated interface is configured with the ethernet-ccc encapsulation.

For more information about how to configure aggregated Ethernet interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects

For Frame Relay circuits, specify the encapsulation when configuring the DLCI. Configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be from 1 through 511. For CCC interfaces, it must be from 512 through 4094.

```
interfaces {
   type-fpc/pic/port {
      unit logical-unit-number {
         dlci dlci-identifier;
         encapsulation encapsulation-type;
         point-to-point; # Default interface type
      }
   }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems** *logical-system-name* **interfaces]**

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects

For PPP and Cisco HDLC circuits, specify the encapsulation in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must configure a logical interface (unit 0).

```
interfaces type-fpc/pic/port {
   encapsulation encapsulation-type;
```

```
    unit 0;
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces** *type-fpc/pic/port***]**
- **[edit logical-systems** *logical-system-name* **interfaces** *type-fpc/pic/port***]**

Configuring the CCC Connection for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, define the connection between the two circuits by including the **interface-switch** statement. You configure this connection on the router that is acting as the switch (Router B in Figure 90 on page 1083). The connection joins the interface that comes from the circuit's source to the interface that leads to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

```
interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems** *logical-system-name* **protocols connections]**

Configuring MPLS for Layer 2 Switching Cross-Connects

For Layer 2 switching cross-connects to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- **[edit interfaces** *interface-name* **unit** *logical-unit-number***]**
- **[edit logical-systems** *logical-system-name* **interfaces** *interface-name* **unit** *logical-unit-number***]**

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
    interface interface-name; # Required to enable MPLS on the interface
```

```
}
```

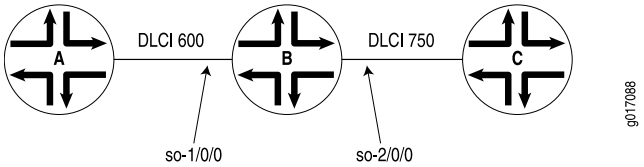
You can configure these statements at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

Example: Configuring a Layer 2 Switching Cross-Connect

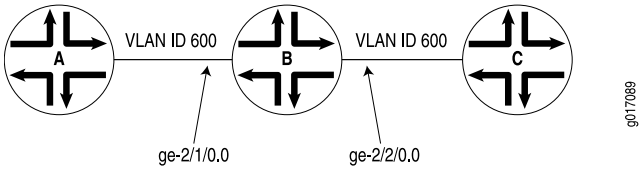
Configure a full-duplex Layer 2 switching cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the virtual switch. See the topology in Figure 91 on page 1089 and Figure 92 on page 1090.

Figure 91: Topology of a Frame Relay Layer 2 Switching Cross-Connect



```
[edit]
interfaces {
   so-1/0/0 {
      encapsulation frame-relay-ccc;
      unit 1 {
         point-to-point;
         encapsulation frame-relay-ccc;
         dlci 600;
      }
   }
   so-2/0/0 {
      encapsulation frame-relay-ccc;
      unit 2 {
         point-to-point;
         encapsulation frame-relay-ccc;
         dlci 750;
      }
   }
}
protocols {
   connections {
      interface-switch router-a-to-router-c {
         interface so-1/0/0.1;
         interface so-2/0/0.2;
      }
   }
   mpls {
      interface all;
   }
}
```

Figure 92: Sample Topology of a VLAN Layer 2 Switching Cross-Connect



```
[edit]
interfaces {
   ge-2/1/0 {
      vlan-tagging;
      encapsulation vlan-ccc;
      unit 0 {

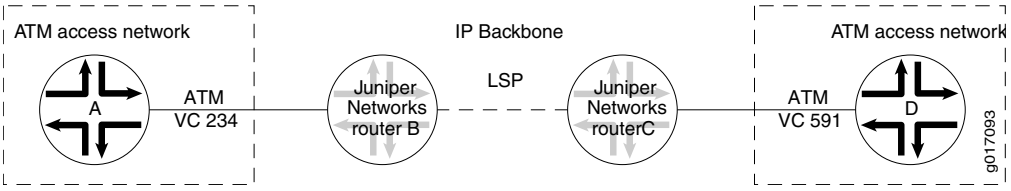
- *Understanding Encapsulation on an Interface*

Configuring MPLS LSP Tunnel Cross-Connects Using CCC

MPLS tunnel cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as

the conduit. The topology in Figure 93 on page 1091 illustrates an MPLS LSP tunnel cross-connect. In this topology, two separate networks, in this case ATM access networks, are connected through an IP backbone. CCC allows you to establish an LSP tunnel between the two domains. With LSP tunneling, you tunnel the ATM traffic from one network across a SONET backbone to the second network by using an MPLS LSP.

Figure 93: MPLS Tunnel Cross-Connect



When traffic from Router A (VC 234) reaches Router B, it is encapsulated and placed into an LSP, which is sent through the backbone to Router C. At Router C, the label is removed, and the packets are placed onto the ATM permanent virtual circuit (PVC) (VC 591) and sent to Router D. Similarly, traffic from Router D (VC 591) is sent over an LSP to Router B, then placed on VC 234 to Router A.

You can configure LSP tunnel cross-connect on PPP, Cisco HDLC, Frame Relay, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

When you use MPLS tunnel cross-connects to support IS-IS, you must ensure that the LSP's maximum transmission unit (MTU) can, at a minimum, accommodate a 1492-octet IS-IS protocol data unit (PDU) in addition to the link-level overhead associated with the technology being connected.

For the tunnel cross-connects to work, the IS-IS frame size on the edge routers (Routers A and D in Figure 94 on page 1094) must be smaller than the LSP's MTU.

NOTE: **Frame size values do not include the frame check sequence (FCS) or delimiting flags.**

To determine the LSP MTU required to support IS-IS, use the following calculation:

```
IS-IS MTU (minimum 1492, default 1497) + frame overhead + 4 (MPLS shim header) =
  Minimum LSP MTU
```

The framing overhead varies based on the encapsulation being used. The following lists the IS-IS encapsulation overhead values for various encapsulations:

- ATM
  - AAL5 multiplex—8 bytes (RFC 1483)
  - VC multiplex—0 bytes
- Frame Relay
  - Multiprotocol—2 bytes (RFCs 1490 and 2427)

    - VC multiplex—0 bytes
- HDLC—4 bytes
- PPP—4 bytes
- VLAN—21 bytes (802.3/LLC)

For IS-IS to work over VLAN-CCC, the LSP's MTU must be at least 1513 bytes (or 1518 for 1497-byte PDUs). If you increase the size of a Fast Ethernet MTU above the default of 1500 bytes, you might need to explicitly configure jumbo frames on intervening equipment.

To modify the MTU, include the **mtu** statement when configuring the logical interface family at the **[edit interfaces** *interface-name* **unit** *logical-unit-number* **encapsulation** *family***]** hierarchy level. For more information about setting the MTU, see the *Junos OS Network Interfaces Library for Routing Devices*.

To configure an LSP tunnel cross-connect, you must configure the following on the interdomain router (Router B in Figure 94 on page 1094):

- Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects on page 1092
- Configuring the CCC Connection for LSP Tunnel Cross-Connects on page 1093
- Example: Configuring an LSP Tunnel Cross-Connect on page 1094

Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, you must configure the CCC encapsulation on the ingress and egress routers (Router B and Router C, respectively, in Figure 94 on page 1094).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the family statement at the **[edit interfaces** *interface-name* **unit** *logical-unit-number***]** hierarchy level.

For PPP or Cisco HDLC circuits, include the **encapsulation** statement to configure the entire physical device. For these circuits to work, you must configure logical unit 0 on the interface.

```
type-fpc/pic/port {
    encapsulation (ppp-ccc | cisco-hdlc-ccc);
    unit 0;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems** *logical-system-name* **interfaces]**

For ATM circuits, specify the encapsulation when configuring the VC by including the following statements. For each VC, you configure whether it is a circuit or a regular logical interface.

```
at-fpc/pic/port {
   atm-options {
      vpi vpi-identifier maximum-vcs maximum-vcs;
   }
   unit logical-unit-number {
      point-to-point; # Default interface type
      encapsulation atm-ccc-vc-mux;
      vci vpi-identifier.vci-identifier;
   }
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

For Frame Relay circuits, include the following statements to specify the encapsulation when configuring the DLCI. For each DLCI, you configure whether it is a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range 1 through 511. For CCC interfaces, it must be in the range 512 through 1022.

```
type-fpc/pic/port {
   encapsulation frame-relay-ccc;
   unit logical-unit-number {
      point-to-point; # default interface type
      encapsulation frame-relay-ccc;
      dlci dlci-identifier;
   }
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

For more information about the **encapsulation** statement, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring the CCC Connection for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, include the **remote-interface-switch** statement to define the connection between the two circuits on the ingress and egress routers (Router B and Router C, respectively, in Figure 94 on page 1094). The connection joins the interface or LSP that comes from the circuit's source to the interface or LSP that leads to the circuit's destination. When you specify the interface name, include the logical portion of the name, which corresponds to the logical unit number. For the cross-connect to be bidirectional, you must configure cross-connects on two routers.

```
remote-interface-switch connection-name {
   interface interface-name.unit-number;
   transmit-lsp label-switched-path;
   receive-lsp label-switched-path;
}
```

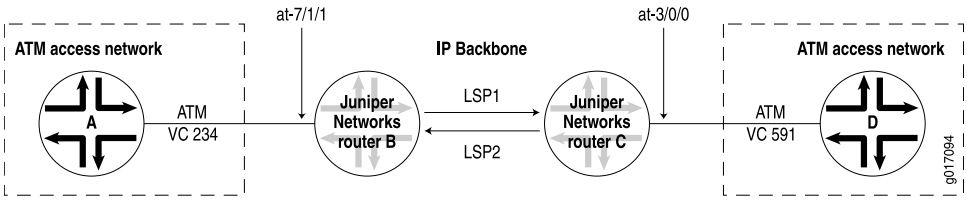
You can include these statements at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems *logical-system-name* protocols connections]**

Example: Configuring an LSP Tunnel Cross-Connect

Configure a full-duplex MPLS LSP tunnel cross-connect from Router A to Router D, passing through Router B and Router C. See the topology in Figure 94 on page 1094.

Figure 94: Example Topology of MPLS LSP Tunnel Cross-Connect



On Router B:

```
[edit]
interfaces {
   at-7/1/1 {
      atm-options {
         vpi 1 maximum-vcs 600;
      }
      unit 1 {
         point-to-point; # default interface type
         encapsulation atm-ccc-vc-mux;
         vci 1.234;
      }
   }
}
protocols {
   connections {
      remote-interface-switch router-b-to-router-c {
         interface at-7/1/1.1;
         transmit-lsp lsp1;
         receive-lsp lsp2;
      }
   }
}
```

On Router C:

```
[edit]
```

```
interfaces {
   at-3/0/0 {
      atm-options {
         vpi 2 maximum-vcs 600;
      }
      unit 2 {
         point-to-point; # default interface type
         encapsulation atm-ccc-vc-mux;
         vci 2.591;
      }
   }
}
protocols {
   connections {
      remote-interface-switch router-b-to-router-c {
         interface at-3/0/0.2;
         transmit-lsp lsp2;
         receive-lsp lsp1;
      }
   }
}
```

Configuring TCC

This section describes how to configure translational cross-connect (TCC).

To configure TCC, you must perform the following tasks on the router that is acting as the switch:

- Configuring the Encapsulation for Layer 2 Switching TCCs on page 1095
- Configuring the Connection for Layer 2 Switching TCCs on page 1099
- Configuring MPLS for Layer 2 Switching TCCs on page 1099

Configuring the Encapsulation for Layer 2 Switching TCCs

To configure a Layer 2 switching TCC, specify the TCC encapsulation on the desired interfaces of the router that is acting as the switch.

NOTE: You cannot configure standard protocol families on TCC or CCC interfaces. Only the CCC family is allowed on CCC interfaces, and only the TCC family is allowed on TCC interfaces.

For Ethernet circuits and Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See "Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations" on page 1098.

- Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs on page 1096
- Configuring ATM Encapsulation for Layer 2 Switching TCCs on page 1096
- Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs on page 1096

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs

For PPP and Cisco HDLC circuits, configure the encapsulation type for the entire physical device by specifying the appropriate value for the **encapsulation** statement. For these circuits to work, you must also configure the logical interface **unit 0**.

```
encapsulation (ppp-tcc | cisco-hdlc-tcc);
unit 0{...}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces *interface-name*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name*]**

Configuring ATM Encapsulation for Layer 2 Switching TCCs

For ATM circuits, configure the encapsulation type by specifying the appropriate value for the **encapsulation** statement in the virtual circuit (VC) configuration. Specify whether each VC is a circuit or a regular logical interface.

```
atm-options {
   vpi vpi-identifier maximum-vcs maximum-vcs;
}
unit logical-unit-number {
   encapsulation (atm-tcc-vc-mux | atm-tcc-snap);
   point-to-point;
   vci vpi-identifier.vci-identifier;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces at-*fpc/pic/port*]**
- **[edit logical-systems *logical-system-name* interfaces at-*fpc/pic/port*]**

Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs

For Frame Relay circuits, configure the encapsulation type by specifying the value **frame-relay-tcc** for the **encapsulation** statement when configuring the data-link connection identifier (DLCI). You configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range from 1 through 511, but for TCC and CCC interfaces it must be in the range from 512 through 1022.

```
encapsulation frame-relay-tcc;
unit logical-unit-number {
   dlci dlci-identifier;
   encapsulation frame-relay-tcc;
```

```
    point-to-point;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces** *interface-name***]**
- **[edit logical-systems** *logical-system-name* **interfaces** *interface-name***]**

Configuring Ethernet Encapsulation for Layer 2 Switching TCCs

For Ethernet TCC circuits, configuring the encapsulation type for the entire physical device by specifying the value **ethernet-tcc** for the **encapsulation** statement.

You must also specify static values for a remote address and a proxy address at the **[edit interfaces** *interface-name* **unit** *unit-number* **family tcc]** or **[edit logical-systems** *logical-system-name* **interfaces** *interface-name* **unit** *unit-number* **family tcc]** hierarchy level.

The remote address is associated with the TCC switching router's Ethernet neighbor; in the **remote** statement you must specify both the IP address and the media access control (MAC) address of the Ethernet neighbor. The proxy address is associated with the TCC router's other neighbor connected by the unlike link; in the **proxy** statement you must specify the IP address of the non-Ethernet neighbor.

You can configure Ethernet TCC encapsulation for the interfaces on 1-port Gigabit Ethernet, 2-port Gigabit Ethernet, 4-port Fast Ethernet, and 4-port Gigabit Ethernet PICs.

```
encapsulation ethernet-tcc;
unit logical-unit-number {
    family tcc {
        proxy {
            inet-address ip-address;
        }
        remote {
            inet-address ip-address;
            mac-address mac-address;
        }
    }
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces (fe | ge)-***fpc/pic/port***]**
- **[edit logical-systems** *logical-system-name* **interfaces (fe | ge)-***fpc/pic/port***]**

NOTE: For Ethernet circuits, you must also configure the Address Resolution Protocol (ARP). See "Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations" on page 1098.

Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs

For Ethernet extended VLAN circuits, configure the encapsulation type for the entire physical device by specifying the value **extended-vlan-tcc** for the **encapsulation** statement.

You must also enable VLAN tagging. Ethernet interfaces in VLAN mode can have multiple logical interfaces. With encapsulation type **extended-vlan-tcc**, all VLAN IDs from 0 through 4094 are valid, up to a maximum of 1024 VLANs. As with Ethernet circuits, you must also specify a proxy address and a remote address at the **[edit interfaces *interface-name* unit *logical-unit-number* family tcc]** or **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family tcc]** hierarchy level (see "Configuring Ethernet Encapsulation for Layer 2 Switching TCCs" on page 1097).

```
encapsulation extended-vlan-tcc;
vlan-tagging;
unit logical-unit-number {
  vlan-id identifier;
  family tcc;
  proxy {
    inet-address ip-address;
  }
  remote {
    inet-address ip-address;
    mac-address mac-address;
  }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces *interface-name*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name*]**

NOTE: For Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See "Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations" on page 1098.

Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations

For Ethernet and Ethernet extended VLAN circuits with TCC encapsulation, you must also configure ARP. Because TCC simply removes one Layer 2 header and adds another, the default form of dynamic ARP is not supported; you must configure static ARP.

Because remote and proxy addresses are specified on the router performing TCC switching, you must apply the static ARP statement to the Ethernet-type interfaces of the routers that connect to the TCC-switched router. The **arp** statement must specify the IP address and the MAC address of the remotely connected neighbor by use of the unlike Layer 2 protocol on the far side of the TCC switching router.

```
arp ip-address mac mac-address;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]**

Configuring the Connection for Layer 2 Switching TCCs

You must configure the connection between the two circuits of the Layer 2 switching TCC on the router acting as the switch. The connection joins the interface coming from the circuit's source to the interface leading to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted from the second interface, and those received on the second interface are transmitted from the first.

To configure a connection for a local interface switch, include the following statements:

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
lsp-switch connection-name {
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems *logical-system-name* protocols connections]**

To configure a connection for a remote interface switch, include the following statements:

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems *logical-system-name* protocols connections]**

Configuring MPLS for Layer 2 Switching TCCs

For a Layer 2 switching TCC to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
   interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

NOTE: MPLS LSP link protection does not support TCC.

CCC and TCC Graceful Restart

CCC and TCC graceful restart allows Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.
