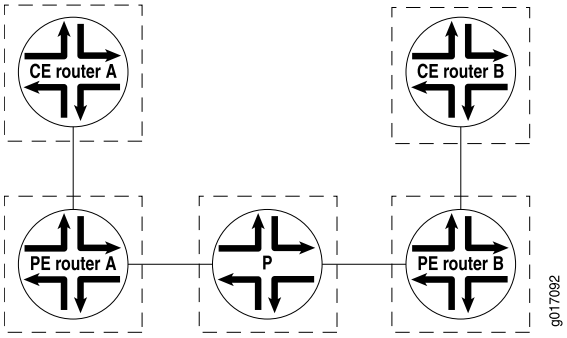
RSVP graceful restart must be enabled on the PE routers and P routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

Figure 95 on page 1101 illustrates how graceful restart might work on a CCC connection between two CE routers.

Figure 95: Remote Interface Switch Connecting Two CE Routers Using CCC



PE Router A is the ingress for the transmit LSP from PE Router A to PE Router B and the egress for the receive LSP from PE Router B to PE Router A. With RSVP graceful restart enabled on all the PE and P routers, the following occurs when PE router A restarts:

- PE Router A preserves the forwarding state associated with the CCC routes (those from CCC to MPLS and from MPLS to CCC).
- Traffic flows without disruption from CE router to CE router.
- After the restart, PE Router A preserves the label for the LSP for which PE Router A is the egress (the receive LSP, for example). The transmit LSP from PE Router A to PE Router B can derive new label mappings, but should not cause any traffic disruption.

Configuring CCC and TCC Graceful Restart

To enable CCC and TCC graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems *logical-system-name* routing-options]**

The **graceful-restart** statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

CCC and TCC graceful restart depend on RSVP graceful restart. If you disable RSVP graceful restart, CCC and TCC graceful restart will not work. For more information about RSVP graceful restart, see *RSVP Graceful Restart* and *Configuring RSVP Graceful Restart*.

Configuring an MPLS-Based VLAN CCC Using the Connection Method (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based connection using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based connections:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with **cspf** disabled:

   NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

   ```
   [edit protocols]
   user@switch# set mpls no-cspf
   ```

5. Enable VLAN tagging on the customer edge interface of the local PE switch:

   ```
   [edit]
   user@switch# set interfaces interface-name vlan-tagging
   ```

6. Configure the customer edge interface to use encapsulation **vlan-ccc**:

   ```
   [edit]
   user@switch# set interfaces interface-name encapsulation vlan-ccc
   ```

7. Configure the logical unit of the customer edge interface with a VLAN ID:

   NOTE: The VLAN ID cannot be configured on logical interface unit 0.

   The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

   ```
   [edit ]
   user@switch# set interfaces interface-name logical-unit-numberrbhadran vlan-id
   ```

8. Define the label switched path (LSP):

   ```
   [edit protocols]
   user@switch# set mpls label-switched-path lsp-name from address
   user@switch# set mpls label-switched-path lsp-name to address
   ```

   TIP: You will need to use the specified LSP name again when configuring the CCC.

9. Configure the connection between the two circuits in the CCC connection

   ```
   [edit protocols]
   user@switch# set connections remote-interface-switch interface-switch interface
   local-interface
   user@switch# set connections remote-interface-switch interface-switch transmit-lsp
   destination-lsp
   user@switch# set connections remote-interface-switch interface-switch receive-lsp source-lsp
   ```

Configuring CCC Switching for Point-to-Multipoint LSPs

You can configure circuit cross-connect (CCC) between two circuits to switch traffic from interfaces to point-to-multipoint LSPs. This feature is useful for handling multicast or broadcast traffic (for example, a digital video stream).

To configure CCC switching for point-to-multipoint LSPs, you do the following:

- On the ingress provider edge (PE) router, you configure CCC to switch traffic from an incoming interface to a point-to-multipoint LSP.
- On the egress PE, you configure CCC to switch traffic from an incoming point-to-multipoint LSP to an outgoing interface.

The CCC connection for point-to-multipoint LSPs is unidirectional.

For more information about point-to-multipoint LSPs, see "Point-to-Multipoint LSPs Overview" on page 527.

To configure a CCC connection for a point-to-multipoint LSP, complete the steps in the following sections:

- Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers on page 1104
- Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers on page 1105
- Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers on page 1105

Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers

To configure the ingress PE router with a CCC switch for a point-to-multipoint LSP, include the **p2mp-transmit-switch** statement:

```
p2mp-transmit-switch switch-name {
   input-interface input-interface-name.unit-number;
   transmit-p2mp-lsp transmitting-lsp;
}
```

You can include the **p2mp-transmit-switch** statement at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems *logical-system-name* protocols connections]**

switch-name specifies the name of the ingress CCC switch.

input-interface *input-interface-name.unit-number* specifies the name of the ingress interface.

transmit-p2mp-lsp *transmitting-lsp* specifies the name of the transmitting point-to-multipoint LSP.

Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers

In addition to configuring an incoming CCC interface to a point-to-multipoint LSP on an ingress PE router, you can also configure CCC to switch traffic on an incoming CCC interface to one or more outgoing CCC interfaces by configuring output interfaces as local receivers.

To configure output interfaces, include the **output-interface** statement at the **[edit protocols connections p2mp-transmit-switch** *p2mp-transmit-switch-name***]** hierarchy level.

```
[edit protocols connections]
p2mp-transmit-switch pc-ccc {
   input-interface fe-1/3/1.0;
   transmit-p2mp-lsp myp2mp;
   output-interface [fe-1/3/2.0 fe-1/3/3.0];
}
```

You can configure one or more output interfaces as local receivers on the ingress PE router using this statement.

Use the **show connections p2mp-transmit-switch (extensive | history | status)**, **show route ccc** *<interface-name>* **(detail | extensive)**, and **show route forwarding-table ccc** *<interface-name>* **(detail | extensive)** commands to view details of the local receiving interfaces on the ingress PE router.

Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers

To configure the CCC switch for a point-to-multipoint LSP on the egress PE router, include the **p2mp-receive-switch** statement.

```
p2mp-receive-switch switch-name {
   output-interface [ output-interface-name.unit-number ];
   receive-p2mp-lsp receptive-lsp;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems** *logical-system-name* **protocols connections]**

switch-name specifies the name of the egress CCC switch.

output-interface [*output-interface-name.unit-number* **]** specifies the name of one or more egress interfaces.

receive-p2mp-lsp *receptive-lsp* specifies the name of the receptive point-to-multipoint LSP.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 virtual private network (VPN) using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)" on page 81.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 VPN:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

```
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with **cspf** disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Define the label switched path (LSP):

```
[edit protocols]
user@switch# set mpls label-switched-path lsp_name to address
```

TIP: You will need to use the specified LSP name again when configuring the CCC.

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
```

7. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit 0. The logical unit number must be 1 or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-numbervlan-id vlan-id
```

12. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```
[edit protocols bgp]
user@switchPE1# set local-address address family l2vpn signaling
```

13. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@switchPE1# set group ibgp type internal
```

14. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE1# set neighbor address
```

15. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name instance-type l2vpn
```

16. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name interface interface-name
```

17. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name route-distinguisher address
```

18. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name vrf-target community
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Configuration Guide*.

19. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn encapsulation-type ethernet-vlan
```

20. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols interface interface-name description
description
```

21. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn site site-name site-identifier
identifier remote-site-id identifier
```

NOTE: The remote site ID (configured with the remote-site-id statement) corresponds to the site ID (configured with the site-identifier statement) configured on the other PE switch.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: You must use the same type of switch for the other PE switch. You cannot use an EX8200 as one PE switch and use an EX3200 or EX4200 as the other PE switch.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 circuit on the switch to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see "Configuring MPLS on Provider Switches" on page 71.

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 circuit:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

4. Enable the MPLS protocol with CSPF disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Configure the customer edge interface as a Layer 2 circuit from the local PE switch to the other PE switch:

```
[edit protocols]
user@switch# set l2circuit neighbor address interface interface-name virtual-circuit-id identifier
```

TIP: Use the switch address of the other switch as the neighbor address.

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
```

7. Configure LDP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set ldp interface lo0.0
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
```

```
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use VLAN CCC encapsulation:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit 0. The logical unit number must be 1 or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-idvlan-id
```

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: For EX Series switches, you must use the same type of switch for the other PE switch. h.

PART 8

MPLS for Software Defined Network (SDN)

CHAPTER 30

Introduction to Path Computation Element Protocol (PCEP)

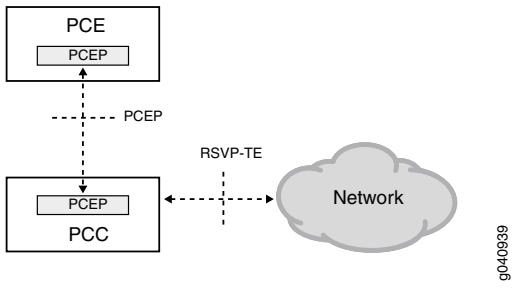
PCEP Overview

A Path Computation Element (PCE) is an entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE. The Path Computation Element Protocol (PCEP) enables communications between a PCC and a PCE, or between two PCEs (defined in RFC 5440).

PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain traffic engineered LSPs (TE LSPs). It provides a mechanism for a PCE to perform path computation for a PCC's external LSPs. The PCEP interactions include LSP status reports sent by the PCC to the PCE, and PCE updates for the external LSPs.

Figure 96 on page 1115 illustrates the role of PCEP in the client-side implementation of a stateful PCE architecture in an MPLS RSVP-TE enabled network.

Figure 96: PCEP Session



A TCP-based PCEP session connects a PCC to an external PCE. The PCC initiates the PCEP session and stays connected to the PCE for the duration of the PCEP session. During the PCEP session, the PCC requests LSP parameters from the stateful PCE. On receiving one or more LSP parameters from the PCE, the PCC re-signals the TE LSP. When the PCEP session is terminated, the underlying TCP connection is closed immediately, and the PCC attempts to re-establish the PCEP session.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between a PCC and a stateful PCE—When an active stateful PCE connection is detected, a PCC tries to delegate all LSPs to this PCE in a procedure called LSP state synchronization. PCEP enables synchronization of the PCC LSP state to the PCE.
- Delegation of control over LSP tunnels to a stateful PCE—An active stateful PCE controls one or more LSP attributes for computing paths, such as bandwidth, path (ERO), and priority (setup and hold). PCEP enables such delegation of LSPs for path computation.
- Stateful PCE control of timing and sequence of path computations within and across PCEP sessions–An active stateful PCE modifies one or more LSP attributes, such as bandwidth, path (ERO), and priority (setup and hold). PCEP communicates these new LSP attributes from the PCE to the PCC, after which the PCC re-signals the LSP in the specified path.

CHAPTER 31

Configuring PCEP for MPLS RSVP-TE

Support of the Path Computation Element Protocol for RSVP-TE Overview

This section contains the following topics:

Understanding MPLS RSVP-TE

Traffic engineering (TE) deals with performance optimization of operational networks, mainly mapping traffic flows onto an existing physical topology. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

For traffic engineering in large, dense networks, MPLS capabilities can be implemented because they potentially provide most of the functionality available from an overlay model, in an integrated manner, and at a lower cost than the currently competing alternatives. The primary reason for implementing MPLS traffic engineering is to control paths along which traffic flows through a network. The main advantage of implementing MPLS traffic engineering is that it provides a combination of the traffic engineering capabilities of ATM, along with the class-of-service (CoS) differentiation of IP.

In an MPLS network, data plane information is forwarded using label switching. A packet arriving on a provider edge (PE) router from the customer edge (CE) router has labels applied to it, and it is then forwarded to the egress PE router. The labels are removed at the egress router and it is then forwarded out to the appropriate destination as an IP packet. The label-switching routers (LSRs) in the MPLS domain use label distribution protocols to communicate the meaning of labels used to forward traffic between and through the LSRs. RSVP-TE is one such label distribution protocol that enables an LSR peer to learn about the label mappings of other peers.

When both MPLS and RSVP are enabled on a router, MPLS becomes a client of RSVP. The primary purpose of the Junos OS RSVP software is to support dynamic signaling within label-switched paths (LSPs). RSVP reserves resources, such as for IP unicast and multicast flows, and requests quality-of-service (QoS) parameters for applications. The protocol is extended in MPLS traffic engineering to enable RSVP to set up LSPs that can be used for traffic engineering in MPLS networks.

When MPLS and RSVP are combined, labels are associated with RSVP flows. Once an LSP is established, the traffic through the path is defined by the label applied at the ingress node of the LSP. The mapping of label to traffic is accomplished using different criteria. The set of packets that are assigned the same label value by a specific node belong to the same forwarding equivalence class (FEC), and effectively define the RSVP flow. When traffic is mapped onto an LSP in this way, the LSP is called an LSP tunnel.

LSP tunnels are a way to establish unidirectional label-switched paths. RSVP-TE builds on the RSVP core protocol by defining new objects and modifying existing objects used in the PATH and RESV objects for LSP establishment. The new objects—LABEL-REQUEST object (LRO), RECORD-ROUTE object (RRO), LABEL object, and EXPLICIT-ROUTE object (ERO)—are optional with respect to the RSVP protocol, except for the LRO and LABEL objects, which are both mandatory for establishing LSP tunnels.

In general, RSVP-TE establishes a label-switched path that ensures frame delivery from ingress to egress router. However, with the new traffic engineering capabilities, the following functions are supported in an MPLS domain:

- Possibility to establish a label-switched path using either a full or partial explicit route (RFC 3209).
- Constraint-based LSP establishment over links that fulfill requirements, such as bandwidth and link properties.
- Endpoint control, which is associated with establishing and managing LSP tunnels at the ingress and egress routers.
- Link management, which manages link resources to do resource-aware routing of traffic engineering LSPs and to program MPLS labels.
- MPLS fast reroute (FRR), which manages the LSPs that need protection and assigns backup tunnel information to these LSPs.

Current MPLS RSVP-TE Limitations

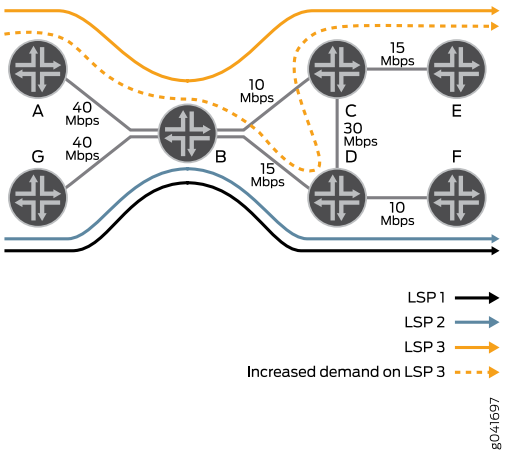
Although the RSVP extensions for traffic engineering enable better network utilization and meet requirements of classes of traffic, today's MPLS RSVP-TE protocol suite has several issues inherent to its distributed nature. This causes a number of issues during contention for bisection capacity, especially within an LSP priority class where a subset of LSPs share common setup and hold priority values. The limitations of RSVP-TE include:

- Lack of visibility of individual per-LSP, per-device bandwidth demands—The ingress routers in an MPLS RSVP-TE network establish LSPs without having a global view of the bandwidth demand on the network. Information about network resource utilization is only available as total reserved capacity by traffic class on a per interface basis. Individual LSP state is available locally on each label edge router (LER) for its own LSPs only. As a result, a number of issues related to demand pattern arise, particularly within a common setup and hold priority.
- Asynchronous and independent nature of RSVP signaling—In RSVP-TE, the constraints for path establishment are controlled by an administrator. As such, bandwidth reserved for an LSP tunnel is set by the administrator and does not automatically imply any limit on the traffic sent over the tunnel. Therefore, bandwidth available on a traffic engineering link is the bandwidth configured for the link, excluding the sum of all reservations made on the link. Thus, the unsignaled demands on an LSP tunnel lead to service degradation of the LSP requiring excess bandwidth, as well as the other LSPs that comply with the bandwidth requirements of the traffic engineering link.
- LSPs established based on dynamic or explicit path options in the order of preference—The ingress routers in an MPLS RSVP-TE network establish LSPs for demands based on the order of arrival. Because the ingress routers do not have a global view of the bandwidth demand on the network, using the order of preference to establish LSPs can cause traffic to be dropped or LSPs not being established at all when there is an excess of bandwidth demand.

As an example, Figure 97 on page 1120 is configured with MPLS RSVP-TE, in which A and G are the label edge routers (LERs). These ingress routers establish LSPs independently

based on the order of demands and have no knowledge or control over each other's LSPs. Routers B, C, and D are intermediate or transit routers that connect to the egress routers E and F.

Figure 97: Example MPLS Traffic Engineering



The ingress routers establish LSPs based on the order in which the demands arrive. If Router G receives two demands of capacity 5 each for G-F, then G signals two LSPs – LSP1 and LSP2 – through G-B-D-F. In the same way, when Router A receives the third demand of capacity 10 for A-E, then it signals an LSP, LSP3, through A-B-C-E. However, if the demand on the A-E LSP increases from 10 to 15, Router A cannot signal LSP3 using the same (A-B-C-E) path, because the B-C link has a lower capacity.

Router A should have signaled the increased demand on LSP3 using the A-B-D-C-E path. Since LSP1 and LSP2 have utilized the B-D link based on the order of demands received, LSP3 is not signaled.

Thus, although adequate max-flow bandwidth is available for all the LSPs, LSP3 is subject to potentially prolonged service degradation. This is due to Router A's lack of global demand visibility and the lack of systemic coordination in demand placement by the ingress routers A and G.

Use of an External Path Computing Entity

As a solution to the current limitations found in the MPLS RSVP-TE path computation, an external path computing entity with a global view of per-LSP, per-device demand in the network independent of available capacity is required.

Currently, only online and real-time constraint-based routing path computation is provided in an MPLS RSVP-TE network. Each router performs constraint-based routing calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status. The MPLS RSVP-TE tunnels are set up using the CLI. An operator configures the TE LSP, which is then signaled by the ingress router.

In addition to the existing traffic engineering capabilities, the MPLS RSVP-TE functionality is extended to include an external path computing entity, called the Path Computation Element (PCE). The PCE computes the path for the TE LSPs of ingress routers that have been configured for external control. The ingress router that connects to a PCE is called a Path Computation Client (PCC). The PCC is configured with the Path Computation Client Protocol (PCEP) to facilitate external path computing by a PCE.

For more information, see "Components of External Path Computing" on page 1121.

To enable external path computing for a PCC's TE LSPs, include the **lsp-external-controller** ***pccd*** statement at the **[edit mpls]** and **[edit mpls lsp** ***lsp-name*****]** hierarchy levels.

Components of External Path Computing

The components that make up an external path computing system are:

Path Computation Element

A Path Computation Element (PCE) can be any entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. However, a PCE can compute the path for only those TE LSPs of a PCC that have been configured for external control.

A PCE can either be stateful or stateless.

- Stateful PCE—A stateful PCE maintains strict synchronization between the PCE and network states (in terms of topology and resource information), along with the set of computed paths and reserved resources in use in the network. In other words, a stateful PCE utilizes information from the traffic engineering database as well as information about existing paths (for example, TE LSPs) in the network when processing new requests from the PCC.

  A stateful PCE is of two types:

  - Passive stateful PCE—Maintains synchronization with the PCC and learns the PCC LSP states to better optimize path calculations, but does not have control over them.
  - Active stateful PCE—Actively modifies the PCC LSPs, in addition to learning about the PCC LSP states.

NOTE: In a redundant configuration with main and backup active stateful PCEs, the backup active stateful PCE cannot modify the attributes of delegated LSPs until it becomes the main PCE at the time of a failover. There is no preempting of PCEs in the case of a switchover. The main PCE is backed by a backup PCE, and when the main PCE goes down, the backup PCE assumes the role of the main PCE and remains the main PCE even after the PCE that was previously the main PCE is operational again.

A stateful PCE provides the following functions:

- Offers offline LSP path computation.
- Triggers LSP re-route when there is a need to re-optimize the network.
- Changes LSP bandwidth when there is an increase in bandwidth demand from an application.
- Modifies other LSP attributes on the router, such as ERO, setup priority, and hold priority.

A PCE has a global view of the bandwidth demand in the network and maintains a traffic-engineered database to perform path computations. It performs statistics collection from all the routers in the MPLS domain using SNMP and NETCONF. This provides a mechanism for offline control of the PCC's TE LSPs. Although an offline LSP path computation system can be embedded in a network controller, the PCE acts like a full-fledged network controller that provides control over the PCC's TE LSPs, in addition to computing paths.

Although a stateful PCE allows for optimal path computation and increased path computation success, it requires reliable state synchronization mechanisms, with potentially significant control plane overhead and the maintenance of a large amount of data in terms of states, as in the case of a full mesh of TE LSPs.

- Stateless PCE—A stateless PCE does not remember any computed path, and each set of requests is processed independently of each other (RFC 5440).

Path Computation Client

A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE.

A PCC can connect to a maximum of 10 PCEs at one time. The PCC to PCE connection can be a configured static route or a TCP connection that establishes reachability. The PCC assigns each connected PCE a priority number. It sends a message to all the connected PCEs with information about its current LSPs, in a process called LSP state synchronization. For the TE LSPs that have external control enabled, the PCC delegates those LSPs to the main PCE. The PCC elects, as the main PCE, a PCE with the lowest priority number, or the PCE that it connects to first in the absence of a priority number.

The PCC re-signals an LSP based on the computed path it receives from a PCE. When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

Path Computation Element Protocol

The Path Computation Element Protocol (PCEP) is used for communication between PCC and PCE (as well as between two PCEs) (RFC 5440). PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain TE LSPs. The PCEP interactions include PCC messages, as well as notifications of specific states related to the use of a PCE in the context of MPLS RSVP-TE. When PCEP is used for PCE-to-PCE communication, the requesting PCE assumes the role of a PCC.

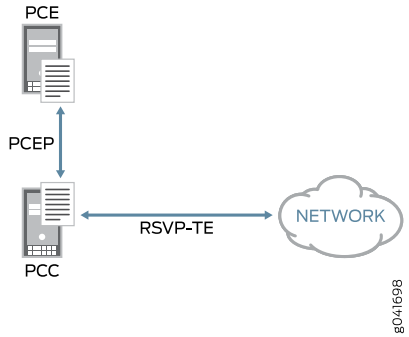
Thus, the PCEP functions include:

- LSP tunnel state synchronization between PCC and a stateful PCE.
- Delegation of control over LSP tunnels to a stateful PCE.

Interaction Between a PCE and a PCC Using PCEP

Figure 98 on page 1123 illustrates the relationship between a PCE, PCC, and the role of PCEP in the context of MPLS RSVP-TE.

Figure 98: PCC and RSVP-TE



The PCE to PCC communication is enabled by the TCP-based PCEP. The PCC initiates the PCEP session and stays connected to a PCE for the duration of the PCEP session.

NOTE: Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440. To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce *pce-id*]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains *key-chain*]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce *pce-id*]** hierarchy level.

The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session, thereby securing the PCEP communication between the devices, which might be subject to attacks and can disrupt services on the network.

For more information on securing PCEP sessions using MD5 authentication, see "TCP-MD5 Authentication for PCEP Sessions" on page 1130.

Once the PCEP session is established, the PCC performs the following tasks:

1. LSP state synchronization—The PCC sends information about all the LSPs (local and external) to all connected PCEs. For external LSPs, the PCC sends information about any configuration change, RRO change, state change, and so on, to the PCE.

   For PCE-initiated LSPs, there is no LSP configuration present on the PCC. The PCE initiating the LSP sends the LSP parameters to the PCC that has indicated its capability of supporting PCE-initiated LSPs.

   NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

2. LSP delegation—After the LSP state information is synchronized, the PCC then delegates the external LSPs to one PCE, which is the main active stateful PCE. Only the main PCE can set parameters for the external LSP. The parameters that the main PCE modifies include bandwidth, path (ERO), and priority (setup and hold). The parameters specified in the local configuration are overridden by the parameters that are set by the main PCE.

   NOTE: When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

   In the case of PCE-initiated LSPs, the PCC creates the LSP using the parameters received from the PCE. The PCC assigns the PCE-initiated LSP a unique LSP-ID, and automatically delegates the LSP to the PCE. A PCC cannot revoke the delegation for the PCE-initiated LSPs for an active PCEP session.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs – **delegation cleanup timeout** and **lsp cleanup timer** – to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE, by sending a create request for the LSP.

Control over PCE-initiated LSPs reverts to the PCC at the expiration of the **delegation cleanup timeout**. When the **delegation cleanup timeout** expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated LSPs, the PCC delegates these LSPs to the PCE and the **lsp cleanup timer** timer is stopped.

A PCE may return the delegation of the PCE-initiated LSP to the PCC to allow LSP transfer between PCEs. This triggers the **lsp cleanup timer** for the PCE-initiated LSP. The PCC waits for the LSP cleanup timer to expire before removing the non-delegated PCE-initiated LSPs from the failed PCE.

When the **lsp cleanup timer** expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the lsp-cleanup-timer must be greater than or equal to the delegation-cleanup-timeout for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

3. LSP signaling—On receiving one or more LSP parameters from the main active stateful PCE, the PCC re-signals the TE LSP based on the PCE provided path. If the PCC fails to set up the LSP, it notifies the PCE of the setup failure and waits for the main PCE to provide new parameters for that LSP, and then re-signals it.

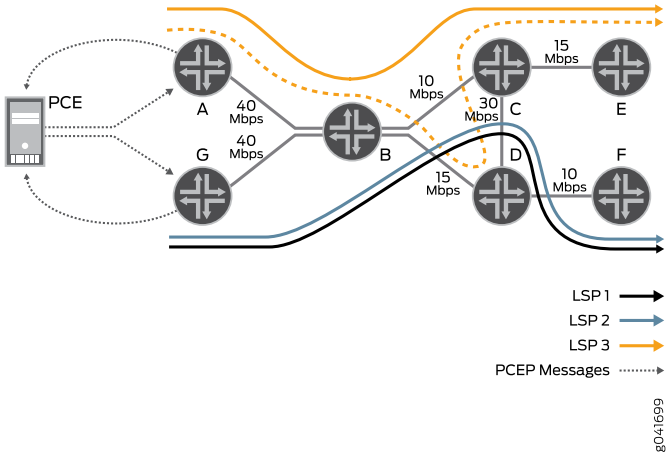
   When the PCE specifies a path that is incomplete or has loose hops where only the path endpoints are specified, the PCC does not perform local constraint-based routing to find out the complete set of hops. Instead, the PCC provides RSVP with the PCE provided path, as it is, for signaling, and the path gets set up using IGP hop-by-hop routing.

Considering the topology used in Figure 97 on page 1120, Figure 99 on page 1126 illustrates the partial client-side PCE implementation in the MPLS RSVP-TE enabled network. The ingress routers A and G are the PCCs that are configured to connect to the external stateful PCE through a TCP connection.

The PCE has a global view of the bandwidth demand in the network and performs external path computations after looking up the traffic engineering database. The active stateful

PCE then modifies one or more LSP attributes and sends an update to the PCC. The PCC uses the parameters it receives from the PCE to re-signal the LSP.

Figure 99: Example PCE for MPLS RSVP-TE



This way, the stateful PCE provides a cooperative operation of distributed functionality used to address specific challenges of a shortest interdomain constrained path computation. It eliminates congestion scenarios in which traffic streams are inefficiently mapped onto available resources, causing overutilization of some subsets of network resources, while other resources remain underutilized.

LSP Behavior with External Computing

LSP Types

In a client-side PCE implementation, there are three types of TE LSPs:

- CLI-controlled LSPs—The LSPs that do not have the **lsp-external-controller *pccd*** statement configured are called CLI-controlled LSPs. Although these LSPs are under local control, the PCC updates the connected PCEs with information about the CLI-controlled LSPs during the initial LSP synchronization process. After the initial LSP synchronization, the PCC informs the PCE of any new and deleted LSPs as well.
- PCE-controlled LSPs—The LSPs that have the **lsp-external-controller *pccd*** statement configured are called PCE-controlled LSPs. The PCC delegates the PCC-initiated LSPs to the main PCE for external path computation.

  The PCC informs the PCE about the configured parameters of a PCE-controlled LSP, such as bandwidth, ERO, and priorities. It also informs the PCE about the actual values used for these parameters to set up the LSP including the RRO, when available.

  The PCC sends such LSP status reports to the PCE only when a reconfiguration has occurred or when there is a change in the ERO, RRO, or status of the PCE-controlled LSPs under external control.

There are two types of parameters that come from the CLI configuration of an LSP for a PCE:

- Parameters that are not overridden by a PCE, and that are applied immediately.
- Parameters that are overridden by a PCE. These parameters include bandwidth, path, and priority (setup and hold values). When the control mode switches from external to local, the CLI-configured values for these parameters are applied at the next opportunity to re-signal the LSP. The values are not applied immediately.

- Externally-provisioned LSPs (or PCE-initiated LSPs)—The LSPs that have the **lsp-provisioning** statement configured are called PCE-initiated LSPs. A PCE-initiated LSP is dynamically created by an external PCE; as a result, there is no LSP configuration present on the PCC. The PCC creates the PCE-initiated LSP using the parameters provided by the PCE, and automatically delegates the LSP to the PCE.

NOTE: **Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.**

The CLI-controlled LSPs, PCE-controlled LSPs, and PCE-initiated LSPs can coexist on a PCC.

The CLI-controlled LSPs and PCE-controlled LSPs can coexist on a PCC.

LSP Control Mode

In a client-side PCE implementation, there are two types of control modes for a PCC-controlled LSP:

- External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP.
- Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control.

A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

For more information about CLI-controlled LSPs and PCE-controlled LSPs, see "LSP Types" on page 1126.

Configuration Statements Supported for External Computing

Table 46 on page 1128 lists the MPLS and existing LSP configuration statements that apply to a PCE-controlled LSP.

Table 46: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements can be configured along with the PCE configuration. However, they take effect only when the local configuration is in use. During PCE control, these configuration statements remain inactive.	• admin-group • auto-bandwidth • hop-limit • least-fill • most-fill • random	• admin-group • admin-groups • admin-group-extended • hop-limit • no-cspf • smart-optimize-timer
These configuration statements can be configured along with the PCE configuration, but are overridden by the PCE-controlled LSP attributes. However, when the local configuration is in use, the configured values for these configuration statements are applied. NOTE: Changes to the local configuration using the CLI while the LSP is under the control of a stateful PCE do not have any effect on the LSP. These changes come into effect only when the local configuration is applied.	• bandwidth • primary • priority	• priority
These configuration statements cannot be configured along with the PCE configuration.	• p2mp • template	• p2mp-lsp-next-hop

The rest of the LSP configuration statements are applicable in the same way as for existing LSPs. On configuring any of the above configuration statements for a PCE-controlled LSP, an MPLS log message is generated to indicate when the configured parameters take effect.

PCE-Controlled LSP Protection

The protection paths, including fast reroute and bypass LSPs, are locally computed by the PCC using constraint-based routing. A stateful PCE specifies the primary path (ERO) only. A PCE can also trigger a non-standby secondary path, even if the local configuration does not have a non-standby secondary path for LSP protection.

PCE-Controlled LSP ERO

For PCE-controlled LSPs (PCC-delegated LSPs and PCE-initated LSPs), only a full-blown Explicit Route Object (ERO) object has to be sent from the PCE to the PCC; otherwise the PCC rejects the PCUpdate or PCCreate message for that PCEP session.

Starting in Junos OS Release 17.2, in addition to **external cspf**, two new path computation types are introduced for the PCE-controlled LSPs: **local cspf** and **no cspf**.

- **local cspf**—A PCC uses the **local cspf** computation type only when the PCE sends in a Juniper Vendor TLV (enterprise number: 0x0a4c) of type 5.

- **no cspf**—Neither the PCE nor the PCC performs a constrained path calculation. The endpoints and constraints are given to the RSVP module for setting up the LSP with the IGP path.

  A PCC uses **no cspf** computation type in the following cases:

  - When the PCE sends **local cspf** TLV, and when the Junos OS configuration or matching template for this LSP included **no-cspf** in the PCC-delegated LSP.
  - When the PCE sends **local cspf** TLV, and when the Junos OS configuration template for this LSP included **no-cspf** in the PCE-initiated LSP.
  - When the PCE does not send **local cspf** TLV with an empty ERO or loose ERO (with loose bit set in the ERO object).

With these new computation types, a PCC can accept an ERO object either as a loose ERO, or as an empty ERO. An external path computing entity that is not capable of computing a path can modify parameters such as bandwidth and color, based on the analytics. In such cases, an empty ERO object or loose ERO is used and the path to be taken is decided by the PCC.

PCE Controlled Point-to-Multipoint RSVP-TE LSPs

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well. For a PCE, the point-to-multipoint LSP is similar to that of RSVP point-to-multipoint LSP, where the point-to-multipoint LSP is treated as collection of point-to-point LSPs grouped under a point-to-multipoint identifier.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce *pce-name*]** or **[edit protocols pcep pce-group *group-id*]** hierarchy levels. After the point-to-multipoint report capability is configured on a PCC, the PCC advertises this capability to the PCE. If the PCE advertises the same point-to-multipoint report capability in return, then the PCC reports the complete point-to-multipoint LSP tree to the PCE for LSP state synchronization.

A PCC with the point-to-multipoint TE LSP capability supports reporting of point-to-multipoint TE LSPs for stateful PCEs, point-to-multipoint update, and LSP database supporting point-to-multipoint LSP name as key. However, the following features and functions are not supported for Junos OS Release 15.1F6 and 16.1:

- Static point-to-multipoint LSPs
- PCE-delegated and PCE-initiated point-to-multipoint LSPs
- Auto-bandwidth
- TE++
- PCE request and reply message
- Creation of point-to-multipoint LSPs using templates

- Configuring forward entry on the PCE-initiated point-to-multipoint LSPs
- Configuring forward entry on the router pointing to a provisioned LSP.

Auto-Bandwidth and PCE-Controlled LSP

Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs. In earlier releases, the auto-bandwidth option did not apply to PCE-controlled LSPs, although LSPs under the control of auto-bandwdith and constraint-based routing could coexist with PCE-controlled LSPs. The statistics collection for auto-bandwidth was taking effect only when the control mode of a PCE-controlled LSP changes from external to local. This was happening in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

TCP-MD5 Authentication for PCEP Sessions

A stateful PCE server automates the creation of traffic engineering paths across the network, increasing network utilization and enabling a customized programmable networking experience with the use of PCEP communication with a PCC. A PCC sends LSP reports to a PCE server, and the PCE updates or provisions LSPs back to the PCC. The data sent over a PCEP session is crucial for a PCE server to perform external path computing. As a result, an attack on the PCEP communication can disrupt network services. If altered PCEP messages are sent to a PCC, inappropriate LSPs can be set up. Similarly, if altered PCEP messages are sent to a PCE, an incorrect view of the network is learned by the PCE.

Considering the significance of the PCEP communication between a PCE and PCC in executing the PCE functionalities effectively, Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440. This feature protects the communication between a PCE and PCC over a PCEP session, which might be subject to an attack, and can disrupt network services.

To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce *pce-id*]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains *key-chain*]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce *pce-id*]** hierarchy level.

The following configuration is executed on the PCC to establish a secure PCEP session with a PCE:

- Using MD5 authentication key:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key key
```

- Using predefined authentication keychain:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key-chain key-chain
user@PCC# set authentication-algorithm md5
```

For secure PCEP sessions to be established successfully, the MD5 authentication should be configured with the pre-shared authentication key on both the PCE server and the PCC. The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session.

NOTE:

- Junos OS Release 16.1 supports only TCP-MD5 authentication for PCEP sessions, without extending support for TLS and TCP-AO, such as protection against eavesdropping, tampering, and message forgery.
- Initial application of security mechanism to a PCEP session causes the session to reset.
- If MD5 is misconfigured or not configured on one side of the PCEP session, the session does not get established. Verify that the configurations on the PCC and PCE are matching.
- This feature does not provide support for any session authentication mechanism.
- To view the authentication keychain used by the PCEP session, use the **show path-computation-client status** and **show protocols pcep** command outputs.
- Use the **show system statistics tcp | match auth** command to view the number of packets that get dropped by TCP because of authentication errors.
- Operation of the keychain can be verified by using the **show security keychain detail** command output.

Impact of Client-Side PCE Implementation on Network Performance

The maintenance of a stateful database can be non-trivial. In a single centralized PCE environment, a stateful PCE simply needs to remember all the TE LSPs that the PCE has computed, the TE LSPs that were actually set up (if this can be known), and when the TE LSPs were torn down. However, these requirements cause substantial control protocol overhead in terms of state, network usage and processing, and optimizing links globally across the network. Thus, the concerns of a stateful PCE implementation include:

- Any reliable synchronization mechanism results in significant control plane overhead. PCEs might synchronize state by communicating with each other, but when TE LSPs are set up using distributed computation performed among several PCEs, the problems of synchronization and race condition avoidance become larger and more complex.
- Out-of-band traffic engineering database synchronization can be complex with multiple PCEs set up in a distributed PCE computation model, and can be prone to race conditions, scalability concerns, and so on.
- Path calculations incorporating total network state is highly complex, even if the PCE has detailed information on all paths, priorities, and layers.

In spite of the above concerns, the partial client-side implementation of the stateful PCE is extremely effective in large traffic engineering systems. It provides rapid convergence and significant benefits in terms of optimal resource usage, by providing the requirement for global visibility of a TE LSP state and for ordered control of path reservations across devices within the system being controlled.

Release History Table

Release	Description
17.2R1	Starting in Junos OS Release 17.2, in addition to **external cspf**, two new path computation types are introduced for the PCE-controlled LSPs: **local cspf** and **no cspf**.
16.1	Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440.
16.1	Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440.
14.2R4	Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs.

Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE

This example shows how to enable external path computing by a Path Computation Element (PCE) for traffic engineered label-switched paths (TE LSPs) on a Path Computation Client (PCC). It also shows how to configure the Path Computation Element Protocol (PCEP) on the PCC to enable PCE to PCC communication.

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series routers, M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Transport Router, one of which is configured as a PCC.

- A TCP connection to an external stateful PCE from the PCC.
- Junos OS Release 12.3 or later running on the PCC along with the JSDN add-on package.

NOTE: The JSDN add-on package is required to be installed along with the core Junos OS installation package.

Before you begin:

1. Configure the device interfaces.
2. Configure MPLS and RSVP-TE.
3. Configure IS-IS or any other IGP protocol.

Overview

Starting with Junos OS Release 12.3, the MPLS RSVP-TE functionality is extended to provide a partial client-side implementation of the stateful PCE architecture (draft-ietf-pce-stateful-pce) on a PCC.

NOTE: The partial client-side implementation of the stateful PCE architecture is based on version 2 of Internet draft draft-ietf-pce-stateful-pce. Starting with Junos OS Release 16.1, this implementation is upgraded to support version 7, as defined in Internet draft draft-ietf-pce-stateful-pce-07. Releases prior to 16.1 support the older version of the PCE draft, causing interoperability issues between a PCC running a previous release and a stateful PCE server that adheres to Internet draft draft-ietf-pce-stateful-pce-07.

To enable external path computing by a PCE, include the **lsp-external-controller** statement on the PCC at the **[edit mpls]** and **[edit mpls lsp *lsp-name*]** hierarchy levels.

```
lsp-external-controller pccd;
```

An LSP configured with the **lsp-external-controller** statement is referred to as a PCE-controlled LSP and is under the external control of a PCE by default. An active stateful PCE can override the parameters set from the CLI, such as bandwidth, path (ERO), and priority, for such PCE-controlled LSPs of the PCC.

To enable PCE to PCC communication, configure PCEP on the PCC at the **[edit protocols]** hierarchy level.

```
pcep { ... }
```

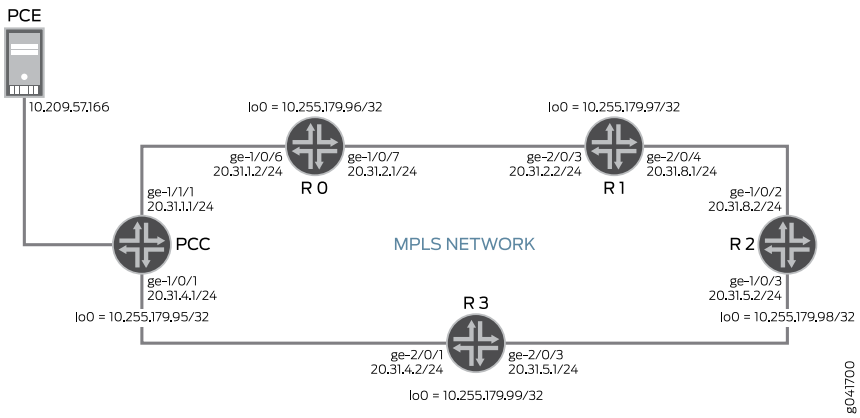
When configuring PCEP on a PCC, be aware of the following considerations:

- The JSDN add-on package is required to be installed along with the core Junos OS installation package.

- Junos OS Release 12.3 supports only stateful PCEs.
- A PCC can connect to a maximum of 10 stateful PCEs. At any given point in time, there can be only one main PCE (the PCE with the lowest priority value, or the PCE that connects to the PCC first in the absence of a PCE priority) to which the PCC delegates LSPs for path computation.
- For Junos OS Release 12.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-controlled LSPs.
- The auto-bandwidth option is turned off for PCE-controlled LSPs, although LSPs under the control of auto-bandwdith and constraint-based routing can coexist with PCE-controlled LSPs.
- PCE-controlled LSPs can be referred to by other CLI configurations, such as lsp-nexthop to routes, forwarding adjacencies, CCC connections, and logical tunnels.
- PCE-controlled LSPs do not support GRES.
- PCE-controlled LSPs under logical-systems are not supported.
- PCE-controlled LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- PCE-controlled LSPs cannot have secondary paths without a primary path.
- PCE-controlled LSPs depend on external path computation, which impacts overall setup time, reroutes, and make-before-break features.
- Setup time and convergence time (reroute, MBB) for exisiting LSPs is the same as in previous releases, in the absence of PCE-controlled LSPs. However, a small impact is seen in the presence of PCE-controlled LSPs.
- ERO computation time is expected to be significantly higher than local-CSPF.

Topology

Figure 100: Configuring PCEP for MPLS RSVP-TE



In this example, PCC is the ingress router that connects to the external active stateful PCE.

The external LSPs of Router PCC are computed as follows:

1. Router PCC receives the LSP tunnel configuration that was set up using the CLI. Assuming that the received configuration is enabled with external path computing, Router PCC becomes aware that some of the LSP attributes – bandwidth, path, and priority – are under the control of the stateful PCE and delegates the LSP to the PCE.

   In this example, the external LSP is called **PCC-to-R2** and it is being set up from Router PCC to Router R2 . The CLI-configured ERO for **PCC-to-R2** is PCC-R0-R1-R2. The bandwidth for **PCC-to-R2** is 10m, and both the setup and hold priority values are 4.

2. Router PCC tries to retrieve the PCE-controlled LSP attributes. To do this, Router PCC sends out a PCRpt message to the stateful PCE stating that the LSP has been configured. The PCRpt message communicates the status of the LSP and contains the local configuration parameters of the LSP.

3. The stateful PCE modifies one or more of the delegated LSP attributes and sends the new LSP parameters to Router PCC through the PCUpd message.

4. On receiving the new LSP parameters, Router PCC sets up a new LSP and re-signals it using the PCE-provided path.

   In this example, the PCE-provided ERO for **PCC-to-R2** is PCC-R3-R2. The bandwidth for **PCC-to-R2** is 8m, and both the setup and hold priority values are 3.

5. Router PCC sends a PCRpt with the new RRO to the stateful PCE.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

```
set interfaces ge-1/0/1 unit 0 family inet address 20.31.4.1/24

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PCC:

NOTE: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

   To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

   ```
   [edit interfaces]
   user@PCC# set ge-1/0/1 unit 0 family inet address 20.31.4.1/24
   user@PCC# set ge-1/0/1 unit 0 family iso
   user@PCC# set ge-1/0/1 unit 0 family mpls
   ```

```
user@PCC# set ge-1/1/1 unit 0 family inet address 20.31.1.1/24
user@PCC# set ge-1/1/1 unit 0 family iso
user@PCC# set ge-1/1/1 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 10.255.179.95/32
```

2. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

3. Configure the label-switched path (LSP) from Router PCC to Router R2 and enable external control of LSPs by the PCE.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
user@PCC# set mpls label-switched-path PCC-to-R2 to 10.255.179.98/32
user@PCC# set mpls label-switched-path PCC-to-R2 bandwidth 10m
user@PCC# set protocols mpls label-switched-path PCC-to-R2 priority 4 4
user@PCC# set protocols mpls label-switched-path PCC-to-R2 primary to-R2-path
user@PCC# set protocols mpls label-switched-path PCC-to-R2
   lsp-external-controller pccd
```

4. Configure the LSP from Router PCC to Router R2, which has local control and is overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path to-R2-path 20.31.1.2/30 strict
user@PCC# set mpls path to-R2-path 20.31.2.2/30 strict
```

5. Enable MPLS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Configure IS-IS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis interface all
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0
```

7. Define the PCE that Router PCC connects to, and configure the IP address of the PCE.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-ipv4-address 10.209.57.166
```

8. Configure the destination port for Router PCC that connects to a PCE using the TCP-based PCEP.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-port 4189
```

9. Configure the PCE type.

```
[edit protocols]
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-1/0/1 {
    unit 0 {
        family inet {
            address 20.31.4.1/24;
        }
        family iso;
        family mpls;
    }
}
ge-1/1/1 {
    unit 0 {
        family inet {
            address 20.31.1.1/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.179.95/32;
        }
    }
}
```

```
user@PCC# show protocols
```

```
rsvp {
   interface all;
   interface fxp0.0 {
      disable;
   }
}
mpls {
   lsp-external-controller pccd;
   label-switched-path PCC-to-R2 {
      to 10.255.179.98;
      bandwidth 10m;
      priority 4 4;
      primary to-R2-path;
      lsp-external-controller pccd;
   }
   path to-R2-path {
      20.31.1.2 strict;
      20.31.2.2 strict;
   }
   interface all;
   interface fxp0.0 {
      disable;
   }
}
isis {
   level 1 disable;
   interface all;
   interface fxp0.0 {
      disable;
   }
   interface lo0.0;
}
pcep {
   pce pce1 {
      destination-ipv4-address 10.209.57.166;
      destination-port 4189;
      pce-type active stateful;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying the PCEP Session Status on page 1141
- Verifying the PCE-Controlled LSP Status When LSP Control Is External on page 1142
- Verifying the PCE-Controlled LSP Status When LSP Control Is Local on page 1143

Verifying the PCEP Session Status

Purpose Verify the PCEP session status between the PCE and Router PCC when the PCE status is up.

Action From operational mode, run the **show path-computation-client active-pce** command.

```
user@PCC> show path-computation-client active-pce
PCE pce1
General
    IP address              : 10.209.57.166
    Priority                : 0
    PCE status              : PCE_STATE_UP
    Session type            : PCE_TYPE_STATEFULACTIVE
    PCE-mastership          : main

Counters
    PCReqs              Total: 0            last 5min: 0            last hour: 0

    PCReps              Total: 0            last 5min: 0            last hour: 0

    PCRpts              Total: 5            last 5min: 5            last hour: 5

    PCErr-sent
    PCE-PCC-NTFS
    PCC-PCE-NTFS
```

Meaning The output displays information about the current active stateful PCE that Router PCC is connected to. The **PCE status** output field indicates the current status of the PCEP session between the PCE and Router PCC.

For **pce1**, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established between the PCEP peers.

The statistics of **PCRpts** indicate the number of messages sent by Router PCC to the PCE to report the current status of LSPs. The **PCUpdates** statistics indicate the number of messages received by Router PCC from the PCE. The **PCUpdates** messages include the PCE modified parameters for the PCE-controlled LSPs.

Verifying the PCE-Controlled LSP Status When LSP Control Is External

Purpose Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP is under external control.

Action From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

```
user@PCC> show mpls lsp name PCC-to-R2 extensive
Ingress LSP: 1 sessions

Meaning In the output, the **LSP Control Status** output field shows that the LSP is under local control. Although the PCE-controlled LSP is under local control, Router PCC continues to use the PCE-provided parameters, until the next opportunity to re-signal the LSP.

The output now displays the LSP parameters that were configured using the CLI along with the PCE-provided parameters used to establish the LSP as the actual values in use.

- Bandwidth—10Mbps (ActualBandwidth: 8Mbps)
- Priorities—4 4 (ActualPriorities 3 3)

On the trigger to re-signal the LSP, Router PCC uses the local configuration parameters to establish the PCE-controlled LSP.

- Support of the Path Computation Element Protocol for RSVP-TE Overview on page 1117

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

This example shows how to configure the Path Computation Client (PCC) with the capability of supporting Path Computation Element (PCE)-initiated traffic-engineered point-to-point label-switched paths (LSPs).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- A TCP connection to two external stateful PCEs from the ingress router (PCC).
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE (RSVP-Traffic Engineering).
- Configure OSPF or any other IGP protocol.

Overview

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

By default, a PCC rejects the request for provisioning PCE-initiated point-to-point LSPs from a PCE. To enable support of PCE-initated LSPs on the PCC, include the *lsp-provisioning* statement at the **[edit protocols pcep pce *pce-id*]** or **[edit protocols pcep pce-group *group-id*]** hierarchy levels.

A PCC indicates its capability of supporting PCE-initiated point-to-point LSPs while establishing the Path Computation Element Protocol (PCEP) session with the PCE. A PCE selects a PCC with this capability to initiate an LSP. The PCE provides the PCC with the PCE-initiated LSP parameters. On receiving the PCE-initiated point-to-point LSP parameters, the PCC sets up the LSP, assigns an LSP ID, and automatically delegates the LSP to the PCE.

When the PCE initiating the LSP does not provide the PCE-initiated point-to-point LSP parameters, the PCC uses the default parameters. An optional LSP template may also be configured to specify values for the PCE-initiated point-to-point LSP when the LSP parameters are not provided by the PCE. To configure an LSP template for PCE-initiated point-to-point LSPs on the PCC, include the label-switched-path-template statement at the **[edit protocols mpls lsp-external-controller *lsp-external-controller*]** hierarchy level.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiatedLSPs—**delegation cleanup timeout** and **lsp cleanup timer**—to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE.

A PCE may return the delegation of the PCE-initiated point-to-point LSP to the PCC to allow LSP transfer between PCEs. Control over PCE-initiated LSPs reverts to the PCC at the expiration of the delegation cleanup timeout. When the delegation cleanup timeout expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated point-to-point LSPs, the PCC delegates these LSPs to the PCE and the LSP cleanup timer is stopped.

The PCC waits for the LSP cleanup timer to expire before deleting the non-delegated PCE-initiated point-to-point LSPs from the failed PCE. When the LSP cleanup timer expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

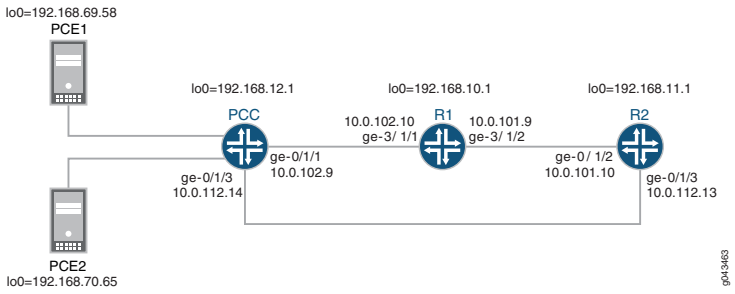
When configuring the support of PCE-initiated point-to-point LSPs for a PCC, be aware of the following considerations:

- Junos OS Release 13.3 supports only stateful PCEs.
- For Junos OS Release 13.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-initiated LSPs.
- PCE-initiated LSPs do not support graceful Routing Engine switchover (GRES).
- PCE-initiated LSPs under logical systems are not supported.
- PCE-initiated LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- RSVP-TE for unnumbered links is not supported. PCE-initiated LSPs support only numbered links.
- The PCE initiating a segment routing LSP can use the binding segment ID (SID) labels associated with non-colored segment routing LSPs to provision the PCE-initiated segment routing LSP paths.

  Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to a PCE through a PCEP session. These non-colored segment routing LSPs may have binding SID labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

Topology

Figure 101: Example PCE-Initated Point-to-Point LSP for MPLS RSVP-TE



In this example, PCC is the ingress router that connects to two external stateful PCEs: PCE1 and PCE2.

When there is a new demand, the active stateful PCE dynamically initiates an LSP to meet the requirement. Since PCC is configured with the capability of supporting the PCE-initiated LSP, path computation on PCC is performed as follows:

1. A PCE sends a PCCreate message to the PCC to initiate and provision an LSP. The PCC sets up the PCE-initiated LSP using the parameters received from the PCE, and automatically delegates the PCE-initiated LSP to the PCE that initiated it.

   In this example, PCE1 is the active stateful PCE that initiates and provisions the PCE-initiated LSP on PCC. On receiving the PCE-initiated LSP parameters, PCC sets up the LSP and automatically delegates the PCE-initiated LSP to PCE1.

2. When the PCEP session between PCC and PCE1 is terminated, PCC starts two timers for the PCE1-initiated LSP: delgation cleanup timeout and the LSP cleanup timer. During this time, PCE1 or PCE2 can acquire control of the PCE-initiated LSP.

3. If PCE2 acquires control over the PCE-initiated LSP before the expiration of the LSP cleanup timer, PCC delegates the PCE-initiated LSP to PCE2, and the LSP cleanup timer and the delegation cleanup timeout are stopped.

4. If the delegation cleanup timeout expired, and neither PCE1 nor PCE2 acquired control over the PCE-initiated LSP, PCC takes local control of the non-delegated PCE-initiated LSP until the expiration of the LSP cleanup timer.

5. After the expiration of the LSP cleanup timer, PCC deletes the PCE-initiated LSP provisioned by PCE1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

NOTE: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

   To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

   ```
   [edit interfaces]
   user@PCC# set ge-0/1/1 unit 0 family inet address 10.0.102.9/24
   user@PCC# set ge-0/1/1 unit 0 family iso
   user@PCC# set ge-0/1/1 unit 0 family mpls
   user@PCC# set ge-0/1/3 unit 0 family inet address 10.0.112.14/24
   user@PCC# set ge-0/1/3 unit 0 family iso
   user@PCC# set ge-0/1/3 unit 0 family mpls
   user@PCC# set lo0 unit 0 family inet address 192.168.12.1/32
   ```

2. Enable RSVP on all interfaces of the PCC, excluding the management interface.

   ```
   [edit protocols]
   user@PCC# set rsvp interface all
   user@PCC# set rsvp interface fxp0.0 disable
   ```

3. Enable external control of LSPs by the PCEs.

   ```
   [edit protocols]
   user@PCC# set mpls lsp-external-controller pccd
   ```

4. Enable MPLS on all interfaces of the PCC, excluding the management interface.

   ```
   [edit protocols]
   user@PCC# set mpls interface all
   user@PCC# set mpls interface fxp0.0 disable
   ```

5. Configure OSPF on all interfaces of the PCC, excluding the management interface.

   ```
   [edit protocols]
   user@PCC# set ospf traffic-engineering
   user@PCC# set ospf area 0.0.0.0 interface all
   user@PCC# set ospf area 0.0.0.0 interface fxp0.0 disable
   ```

```
user@PCC# set ospf interface lo0.0
```

6. Define the PCE group and enable support of PCE-initiated LSPs for the PCE group.

```
[edit protocols]
user@PCC# set protocols pcep pce-group PCEGROUP pce-type active
user@PCC# set protocols pcep pce-group PCEGROUP pce-type stateful
user@PCC# set protocols pcep pce-group PCEGROUP lsp-provisioning
user@PCC# set protocols pcep pce-group PCEGROUP lsp-cleanup-timer 30
```

7. Define the PCEs that connect to the PCC.

```
[edit protocols]
user@PCC# set pcep pce PCE1 destination-ipv4-address 192.168.69.58
user@PCC# set pcep pce PCE1 destination-port 4189
user@PCC# set pcep pce PCE1 pce-group PCEGROUP
user@PCC# set pcep pce PCE2 destination-ipv4-address 192.168.70.65
user@PCC# set pcep pce PCE2 destination-port 4189
user@PCC# set pcep pce PCE2 pce-group PCEGROUP
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/1/1 {
   unit 0 {
      family inet {
         address 10.0.102.9/24;
      }
      family iso;
      family mpls;
   }
}
ge-0/1/3 {
   unit 0 {
      family inet {
         address 10.0.112.14/24;
      }
      family iso;
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 192.168.12.1/32;
      }
```

```
    }
}
```

```
user@PCC# show protocols
rsvp {
    interface all;
    }
    interface fxp0.0 {
        disable;
    }
}
mpls {
    lsp-external-controller pccd;
    interface all;
    interface fxp0.0 {
        disable;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface all;
        interface fxp0.0 {
            disable;
        }
    }
}
pce-group PCEGROUP {
    pce-type active stateful;
    lsp-provisioning;
    lsp-cleanup-timer 30;
}
pce PCE1 {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    pce-group PCEGROUP;
}
pce PCE2 {
    destination-ipv4-address 192.168.70.65;
    destination-port 4189;
    pce-group PCEGROUP;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying PCC Status on page 1154
- Verifying PCE1 Status on page 1154
- Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned on page 1156

Verifying PCC Status

Purpose Verify the PCEP session status and LSP summary between the PCC and the connected PCEs.

Action From operational mode, run the **show path-computation-client status** command.

```
user@PCC# show path-computation-client status
Session              Type                        Provisioning   Status
  PCE1               Stateful Active             On             Up
  PCE2               Stateful Active             On             Up

LSP Summary
  Total number of LSPs        : 1
  Static LSPs                 : 0
  Externally controlled LSPs  : 0
  Externally provisioned LSPs : 1/16000 (current/limit)
  Orphaned LSPs               : 0

PCE1 (main)
  Delegated              : 1
  Externally provisioned : 1
PCE2
  Delegated              : 0
  Externally provisioned : 0
```

Meaning The output displays the status of the PCEP session between the active stateful PCEs and the PCC. It also displays information about the different types of LSPs on the PCC, and the number of LSPs provisioned by the connected PCEs and delegated to them.

PCE1 is the main active PCE and has one PCE-initiated LSP that has been automatically delegated to it by the PCC.

Verifying PCE1 Status

Purpose Verify the status of the main active stateful PCE.

Action From operational mode, run the **show path-computation-client active-pce detail** command.

```
user@PCC# show path-computation-client active-pce
PCE PCE1

Errors
    PCErr-recv
    PCErr-sent
    PCE-PCC-NTFS
    PCC-PCE-NTFS
```

Meaning The output displays information about the current active stateful PCE to which the PCC is connected. The **PCE status** output field indicates the current status of the PCEP session between a PCE and PCC.

For PCE1, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established with the PCC.

Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned

Purpose Verify the status of the PCE-initiated LSP.

Action From operational mode, run the **show mpls lsp externally-provisioned detail** command.

```
user@PCC# show mpls lsp externally-provisioned detail
Ingress LSP: 1 sessions

10.0.101.10
  From: 10.0.102.9, State: Up, ActiveRoute: 0, LSPname: lsp15
  ActivePath: path1 (primary)
  Link protection desired
  LSPtype: Externally Provisioned, Penultimate hop popping
  LSP Control Status: Externally controlled
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   path1            State: Up
    Priorities: 7 0
    Bandwidth: 8Mbps
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 3)
 10.0.102.10 S 10.0.101.9 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node
10=SoftPreempt 20=Node-ID):
 10.0.102.10 S 10.0.101.9 S
```

Meaning In the output, the **LSPtype** output field shows that the LSP is externally provisioned.

The PCEP session between PCC and PCE1 is up, and the PCC receives the following PCE-initiated LSP parameters:

- ERO (path)—10.0.102.10 and 10.0.101.9
- Bandwidth—8 Mbps
- Priority—7 0 (setup and hold values)

Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

You can configure a Path Computation Client (PCC) with the capability of supporting dynamically created label switched paths (LSPs) from a centralized external path computing entity. A stateful Path Computaiton Element (PCE) can be used to perform external path computation and generate dynamic LSPs when there is an increase in demand.

A PCC creates the PCE-initiated point-to-point LSP using the PCE-provided LSP parameters, or parameters from a pre-configured LSP template when the PCE does not provision the LSP, and automatically delegates the PCE-initiated point-to-point LSP to the respective PCE. As a result, for PCE-initiated LSPs, there is no need for a locally configured LSP on the PCC.

A CLI-controlled LSP, PCE-controlled LSP, and PCE-initiated LSP can coexist with each other on a PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

To configure PCC to support PCE-initiated point-to-point LSPs, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@PCC# edit protocols pcep
```

2. Specify the number of messages per minute that the PCC can receive at maximum.

```
[edit protocols pcep]
user@PCC# set message-rate-limit messages-per-minute
```

3. Specify the number of externally provisioned label switched paths (LSPs) over all connected PCEs that the PCC can accept at maximum.

```
[edit protocols pcep]
user@PCC# set max-provisioned-lsps max-count
```

4. Specify the unique user defined ID for the connected PCE to configure the PCE parameters.

```
[edit protocols pcep]
```

```
user@PCC# edit pce pce-id
```

5. Specify the amount of time (in seconds) that the PCC must wait before returning control of LSPs to the routing protocol process after a PCEP session is disconnected.

```
[edit protocols pcep pce pce-id]
user@PCC# set delegation-cleanup-timeout seconds
```

6. Specify the IPv4 address of the PCE to connect with.

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-ipv4-address ipv4-address
```

7. Specify the TCP port number that the PCE is using

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-port port-number
```

The value can range from 1 through 65535 and the default value is 4189.

8. Specify the amount of time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-cleanup-timer seconds
```

9. Configure the PCC to accept SPs that are externally provisioned by connected PCEs. By default, the PCC rejects PCE-initiated LSPs.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-provisioning
```

10. Specify the number of unknown messages per minute that the PCC can receive at maximum after which the PCEP session is closed.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-messages messages-per-minute
```

The value can range from 1 through 16384, and the default value is 0 (disabled or no limit).

11. Specify the number of unknown requests per minute that the PCC can receive at maximum after which the PCEP session is terminated.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-requests requests-per-minute
```

The value can range from 0 through 16384, and the default value is 5. A value of 0 disables this statement.

12. Configure the PCE type.

```
[edit protocols pcep pce pce-id]
user@PCC# set pce-type active stateful
```

13. Specify the amount of time (in seconds) that the PCC must wait for a reply before resending a request.

```
[edit protocols pcep pce pce-id]
user@PCC# set request-timer seconds
```

The value can range from 0 through 65535 seconds.

14. Verify and commit the configuration.

```
user@PCC# show
user@PCC# commit
```

Sample Output

```
[edit]
user@PCC# edit protocols pcep

[edit protocols pcep]
user@PCC# set message-rate-limit 50

[edit protocols pcep]
user@PCC# set max-provisioned-lsps 16000

[edit protocols pcep]
user@PCC# edit pce PCE

[edit protocols pcep pce PCE]
user@PCC# set delegation-cleanup-timeout 20

[edit protocols pcep pce PCE]
user@PCC# set destination-ipv4-address 192.168.69.58

[edit protocols pcep pce PCE]
user@PCC# set destination-port 4189

[edit protocols pcep pce PCE]
user@PCC# set lsp-cleanup-timer 50

[edit protocols pcep pce PCE]
user@PCC# set lsp-provisioning

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-messages 5

[edit protocols pcep pce PCE]
```

```
user@PCC# set max-unknown-requests 5

[edit protocols pcep pce PCE]
user@PCC# set request-timer 50

[edit protocols pcep pce PCE]
user@PCC# up

[edit protocols pcep]
user@PCC# show
message-rate-limit 50;
max-provisioned-lsps 16000;
pce PCE {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    lsp-provisioning;
    lsp-cleanup-timer 50;
    request-timer 50;
    max-unknown-requests 5;
    max-unknown-messages 5;
    delegation-cleanup-timeout 20;
}

[edit protocols pcep]
user@PCC# commit
commit complete

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Controlled Point-to-Multipoint LSPs

This example shows how to configure the Path Computation Client (PCC) with the capability of reporting point-to-multipoint traffic engineered label-switched paths (TE LSPs) to a Path Computation Element (PCE).

- Requirements on page 1161
- Overview on page 1161
- Configuration on page 1162
- Verification on page 1173

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- One virtual machine configured with Virtual Route Reflector (VRR) feature.
- A TCP connection to an external stateful PCE from the VRR.
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

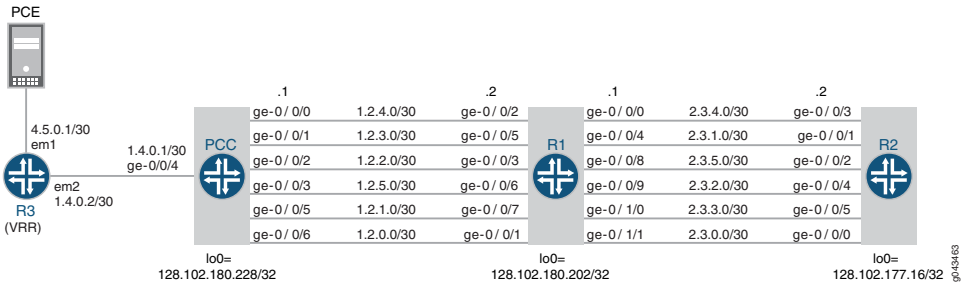
Overview

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce *pce-name*]** or **[edit protocols pcep pce-group *group-id*]** hierarchy levels.

Topology

Figure 102: Example PCE-Controlled Point-to-Multipoint LSPs



In this example, PCC is the ingress router, Router R1 is the transit router, and Router R2 is the egress router. PCC is connected to a Virtual Route Reflector (VRR) that is connected to a PCE. There are many point-to-multipoint interfaces between PCC, Router R1, and Router R2.

The reporting of point-to-multipoint LSPs is executed as follows:

1. If Router PCC is configured with point-to-point and point-to-multipoint LSPs without the support for point-to-multipoint reporting capability, only the point-to-point LSPs are reported to the connected PCE. By default, a PCC does not support point-to-multipoint LSP reporting capability.

2. When Router PCC is configured with point-to-multipoint LSP reporting capability, PCC first advertises this capability to PCE through a report message.

3. By default, a PCE provides support for point-to-multipoint LSP capability. On receiving the PCC's advertisement for point-to-multipoint LSP capability, the PCE in return advertises its capability to the PCC.

4. On receiving the PCE's advertisement of the point-to-multipoint capability, PCC reports all branches of point-to-multipoint LSPs to the PCE using the update message.

5. Once all the LSPs are reported to the PCE, LSP state is synchronized between the PCE and PCC.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

1. Configure the interfaces of Router PCC. To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```
[edit interfaces]
user@PCC# set ge-0/0/0 unit 0 family inet address 1.2.4.1/30
user@PCC# set ge-0/0/0 unit 0 family mpls
user@PCC# set ge-0/0/1 unit 0 family inet address 1.2.3.1/30
user@PCC# set ge-0/0/1 unit 0 family mpls
user@PCC# set ge-0/0/2 unit 0 family inet address 1.2.2.1/30
user@PCC# set ge-0/0/2 unit 0 family mpls
user@PCC# set ge-0/0/3 unit 0 family inet address 1.2.5.1/30
user@PCC# set ge-0/0/3 unit 0 family mpls
user@PCC# set ge-0/0/4 unit 0 family inet address 1.4.0.1/30
user@PCC# set ge-0/0/4 unit 0 family mpls
user@PCC# set ge-0/0/5 unit 0 family inet address 1.2.1.1/30
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set ge-0/0/6 unit 0 family inet address 1.2.0.1/30
user@PCC# set ge-0/0/6 unit 0 family mpls
```

2. Configure the autonomous system number for Router PCC.

```
[edit routing-options]
user@PCC# set autonomous-system 100
```

3. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure a dynamic LSP and disable automatic path computation for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp_template_no_cspf template
user@PCC# set mpls label-switched-path lsp_template_no_cspf no-cspf
```

6. Configure point-to-multipoint LSPs and define external path computing entity for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp1-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc lsp-external-controller pccd
```

7. Enable external path computing for the MPLS LSPs and assign a template for externally provisioned LSPs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
  pcc_delegated_no_cspf_* label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
  pce_initiated_no_ero_no_cspf_* label-switched-path-template
  lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
  pce_initiated_loose_ero_no_cspf_* label-switched-path-template
  lsp_template_no_cspf
```

8. Configure the LSPs that have local control and are overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path loose-path 1.2.3.2 loose
user@PCC# set mpls path strict-path 1.2.3.2 strict
user@PCC# set mpls path strict-path 2.3.3.2 strict
user@PCC# set mpls path path-B
user@PCC# set mpls path path-C
```

9. Configure MPLS administrative group policies for constrained-path LSP computation.

```
[edit protocols]
user@PCC# set mpls admin-groups violet 1
user@PCC# set mpls admin-groups indigo 2
user@PCC# set mpls admin-groups blue 3
user@PCC# set mpls admin-groups green 4
user@PCC# set mpls admin-groups yellow 5
user@PCC# set mpls admin-groups orange 6
```

10. Assign the configured administrative group policies to Router PCC interfaces.

```
[edit protocols]
user@PCC# set mpls interface ge-0/0/6.0 admin-group violet
```

```
user@PCC# set mpls interface ge-0/0/5.0 admin-group indigo
user@PCC# set mpls interface ge-0/0/2.0 admin-group blue
user@PCC# set mpls interface ge-0/0/1.0 admin-group green
user@PCC# set mpls interface ge-0/0/0.0 admin-group yellow
user@PCC# set mpls interface ge-0/0/3.0 admin-group orange
```

11. Configure a traffic engineering database (TED) import policy.

```
[edit protocols]
user@PCC# set mpls traffic-engineering database import policy TE
```

12. Configure a BGP internal group.

```
[edit protocols]
user@PCC# set bgp group northstar type internal
user@PCC# set bgp group northstar local-address 128.102.180.228
user@PCC# set bgp group northstar neighbor 128.102.180.215
```

13. Configure traffic engineering for BGP and assign the export policy.

```
[edit protocols]
user@PCC# set bgp group northstar family traffic-engineering unicast
user@PCC# set bgp group northstar export TE
```

14. Configure OSPF area 0 on all the point-to-multipoint interfaces of Router PCC.

```
[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface lo0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/3.0
```

15. Configure OSPF area 0 on the point-to-point interface of Router PCC.

```
[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/4.0 interface-type p2p
```

16. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
```

17. Define the PCE that Router PCC connects to, and configure the the PCE parameters.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 10.102.180.228
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.246
user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 lsp-cleanup-timer 0
user@PCC# set pcep pce pce1 delegation-cleanup-timeout 60
```

18. Configure Router PCC to enable point-to-multipoint LSP capability for external path computing.

```
[edit protocols]
set pcep pce pce1 p2mp-lsp-report-capability
```

19. Configure the traffic engineering policy.

```
[edit policy-options]
user@PCC# set policy-statement TE term 1 from family traffic-engineering
user@PCC# set policy-statement TE term 1 then accept
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/0/0 {
   unit 0 {

Related Documentation

- Support of the Path Computation Element Protocol for RSVP-TE Overview on page 1117

Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

Benefits of PCE-Initiated Point-to-Multipoint LSPs

Meets the requirements of point-to-multipoint traffic engineering LSP placement in response to application demands through dynamic creation and tear down of point-to-multipoint LSPs, thereby creating a dynamic network that is centrally controlled and deployed.

Signaling of PCE-Initiated Point-to-Multipoint LSPs

The signaling of PCE-initiated point-to-multipoint LSPs is as follows:

- **When a new branch is added (Grafting)**—Only the new branch sub-LSP is signaled and does not result in re-signaling of the entire point-to-multipoint tree.

  If any topology changes occurred before provisioning of the new sub-LSP, then the Path Computation Server (PCS) re-computes the entire point-to-multipoint tree and updates the point-to-multipoint LSP using a PC update message.

- **When a branch is deleted (Pruning)**—The deleted branch sub-LSP is torn down and does not result in re-signaling of the entire point-to-multipoint tree.

- **When a branch sub-LSP parameter is changed**—Change in sub-LSP parameters, such as Explicit Route Object (ERO), bandwidth, or priority, can happen either because of optimization, or on user request. If there is a re-signaling request for a sub-LSP, the entire point-to-multipoint tree is re-signaled, and then the switchover to the new instance happens once the new instances of all the branches are up.

- **When a branch sub-LSP path fails**—An error is reported to the PCS for the failed branch sub-LSP. On receiving the new ERO from the PCS, the entire point-to-multipoint tree is re-signaled along with the failed branch sub-LSP, and the switchover to the new instance happens in a make-before-break (MBB) fashion.

Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure

When a PCEP session fails, the PCE-initiated point-to-multipoint LSPs are orphaned until the expiration of the **state timeout** timer. After the **state timeout** timer expires, the PCE-initiated LSPs are cleaned up.

To obtain control of a PCE-initiated point-to-multipoint LSP after a PCEP session failure, the primary or secondary PCE sends a **PCInitiate** message before the **state timeout** timer expires.

Configuring PCE-Initiated Point-to-Multipoint LSP Capability

By default, the creation and provisioning of point-to-multipoint LSPs by a PCE is not supported on a PCC. To enable this capability, include the **p2mp-lsp-init-capability** and **p2mp-lsp-update-capability** statements at the **[edit protocols pcep pce *pce-name*]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

The **p2mp-lsp-init-capability** statement provides the capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. The **p2mp-lsp-update-capability** statement provides the capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE.

Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs

The following features are supported with PCE-initiated point-to-multipoint LSPs:

- Partial compliance with the Internet draft draft-ietf-pce-stateful-pce-p2mp (expires October 2018), *Path Computation Element (PCE) Protocol Extensions for Stateful PCE usage for Point-to-Multipoint Traffic Engineering Label Switched Paths*.

The following features are not supported with PCE-initiated point-to-multipoint LSPs:

- Delegation of point-to-multipoint locally controlled LSP.
- LSP control delegation.
- Interior gateway protocol (IGP) extension for PCE discovery within an IGP routing domain.
- Request/response messaging.
- Direct movement of branch sub-LSP from one point-to-multipoint tree to another.

  The same can be achieved by deleting a branch sub-LSP from the first point-to-multipoint tree and re-adding it to another after the **PCReport** message indicates LSP removal from the device.
- IPv6 is not supported.
- SERO based signalling is not supported.
- Empty-ERO feature is not supported.
- Link protection is not supported.

CHAPTER 32

Configuring PCEP for MPLS SPRING-TE

Support of SPRING-TE for the Path Computation Element Protocol Overview

The traffic engineering (TE) capabilities of Source Packet Routing in Networking (SPRING) are supported in the Path Computation Element Protocol (PCEP) implementation of Junos OS. With this support, the advantages of SPRING are extended to the label-switched paths (LSPs) initiated by a Path Computation Element (PCE), augmenting the benefits of external path computing in an MPLS network. This topic describes the PCEP implementation for SPRING-TE LSPs.

SPRING for Traffic Engineering

Traditionally, RSVP has been used to address traffic engineering problems. RSVP-TE is an extension to RSVP that allows MPLS labels to be generated for prefixes, and at the same time uses the resource reservation capabilities to reserve specific LSPs through the network. Currently, the Junos OS implementation of PCEP uses RSVP-TE. Starting in Junos OS Release 17.2, the PCEP implementation is extended to support SPRING-TE as well.

SPRING can operate over an IPv4 or IPv6 data plane, and supports equal-cost multipath (ECMP). With the IGP extensions built into it, SPRING integrates with the rich multiservice capabilities of MPLS, including Layer 3 VPN (L3VPN), Virtual Private Wire Service (VPWS), Virtual Private LAN Service (VPLS), and Ethernet VPN (EVPN).

Some of the high-level components of the SPRING-TE solution are:

- Use of an IGP for advertising link characteristics. This is similar to RSVP-TE.

- Use of CSPF on the ingress device or the PCE.
- Use of an IGP for advertising labels for links.

  With SPRING, the ingress device constructs an LSP by stacking the labels of the links that it wants to traverse. The per-link IGP advertisement is combined with label stacking to create source routed LSPs on the ingress, so the transit devices are not aware of the end-to-end LSPs. As a result, there is no per-LSP signaling in SPRING-TE, and the ability to stack per-neighbor labels contributes to the control plane scaling property. This enables creation of LSPs between edge nodes without placing any per-LSP memory requirements on the transit devices. However, the label stacking feature of SPRING-TE results in the management of a large number of labels, which might be difficult for some platforms to support.

Junos OS Implementation of PCEP for SPRING-TE LSPs

The Junos OS implementation of SPRING-TE LSPs for PCEP allows creation of tunnel routes for SPRING-TE LSPs, and using the tunnel routes for placing IP traffic or services. The SPRING-TE LSPs are created by the PCE using the adjacency and node segments.

Junos OS SPRING-TE LSPs cannot be longer than six hops. The PCE computes the path of the SPRING-TE LSP, and provisions the LSP on the Path Computation Client (PCC) using PCEP segment routing (SR) extensions. The PCEP SR extensions are parsed and a tunnel is created on the PCC. Like any other tunnel route, IP traffic and services can be resolved over the tunnel.

The Junos OS implementation of PCEP for SPRING-TE LSPs includes the following components:

- SPRING-TE Module on page 1182
- Traffic Engineering Database on page 1183
- PCEP Interaction on page 1183

SPRING-TE Module

SPRING-TE LSPs are created on the PCC, making the tunnel routes available in the inet.3 routing table. The PCC selects the outgoing interface based on the first network access identifier (NAI) in the source Explicit Route Object (S-ERO). If the PCC receives an S-ERO that does not have labels in it, it rejects the S-ERO. SPRING-TE creates tunnel routes that have their own preference value.

If the path has more than five labels, then the path is unviable. So, any S-ERO that carries more than six hops is rejected. When there are multiple LSPs to the same destination with the same metric, the PCC creates an equal-cost multipath (ECMP) route.

Junos OS supports S-EROs that contain the first hop as a strict hop; there is no support on the PCC to select the outgoing interface based on a loose hop node segment ID. However, the remaining hops can be loose. No specific processing is done for the S-EROs that are beyond the first hop, other than to simply use the label for next-hop creation.

Traffic Engineering Database

After a PCE has provisioned a SPRING-TE LSP for the PCC, a few things can change, such as:

- The label used by a path can change.
- The label used by a path can be withdrawn.
- One of the interfaces traversed by the LSP can go down, which is detected by monitoring IGP advertisements.

The PCC does not react to any of the above changes. The PCC waits for the PCE to process the event, and either re-program the LSP or bring down the LSP, as appropriate. However, when the directly attached interface of a SPRING-TE LSP goes down, that SPRING-TE LSP is not used for tunnel route creation.

PCEP Interaction

The Junos OS implementation of PCEP provides support to process received provisioning type S-ERO objects on the PCC. If the PCC looses connection with the PCE, the SPRING-TE LSPs remain up for 300 seconds, and then get purged out. If the PCE supplies parameters, such as setup priority, that do not apply to SR, the PCC ignores them.

The PCEP interaction with SPRING-TE LSPs is based on the Internet drafts—*draft-ietf-pce-lsp-setup-type-03.txt* and *draft-ietf-pce-segment-routing-06.txt*. The PCEP draft compliance is as follows:

- Support the PCE capability type, length, and value TLV. The maximum service identifier (SID) is set to 5 by default. The **max-sid-depth** statement can be used to control the maximum SID depth advertised.
- Path setup TLV is supported.
- ERO is supported, but loose hop expansion is not supported.
- Only IPv4 node IDs and adjacencies are supported. IPv6 or unnumbered adjacencies are not supported.
- Because the maximum SID depth is always set to five, the metric object is also set to five.

NOTE: The S-ERO objects that do not carry labels are rejected.

Configuration of PCEP for SPRING-TE

Enabling SPRING for PCEP

To enable SPRING for PCEP, you need to configure MPLS and SPRING-TE.

NOTE: PCEP for RSVP-TE cannot be disabled when PCEP for SPRING-TE is enabled.

To enable PCEP for SPRING-TE LSPs, the following configuration must be executed:

1. Enable external path computing capabilities for MPLS. This configuration is required for PCEP for RSVP-TE as well.

```
[edit protocols]
user@host# set mpls lsp-external-controller
```

2. Configure SPRING-TE with external path computing capabilities.

```
[edit protocols]
user@host# set spring-traffic-engineering lsp-external-controller pccd
```

3. Enable SPRING on a PCE.

```
[edit protocols]
user@host# set pcep pce pce1 spring-capability
```

Configuring Maximum SID Depth

The maximum SID depth value for SPRING-TE is set to five by default. The following configuration can be used to control the maximum SID depth that is advertised:

```
[edit protocols]
user@host# set pcep pce pce1 max-sid-depth 5
```

Configuring Preference Value for SPRING-TE

The default preference value of SPRING-TE is eight.

```
[edit protocols]
user@host# set spring-te preference preference-value
```

Configuring SPRING-TE Logging

The following configuration is used to control logging for SPRING-TE LSPs:

```
[edit protocols]
user@host# set spring-te traceoptions file file-name size file-size
user@host# set spring-te traceoptions flag [controller | state | route | general | interface
   | all]
```

Viewing SPRING-TE LSPs

The **show spring-te lsp** command displays the SPRING-TE LSPs on the device.

```
show spring-te lsp name lsp-name
show spring-te lsp extensive
```

Limitations and Unsupported Features for PCEP SPRING-TE

The support of SPRING for PCEP does not add any additional performance burden on the system; however, the PCEP SPRING-TE implementation has the following limitations:

- A SPRING-TE LSP is not locally protected on the PCC. When the LSP is over six hops, no other service is provided on the LSP other than to carry plain IP.
- Graceful Routing Engine switchover (GRES) and unified ISSU in-service software upgrade are not supported.
- Nonstop active routing (NSR) is not supported.
- IPv6 is not supported.
- Logical systems are not supported.

Related Documentation

- Example: Configuring Path Computation Element Protocol for SPRING-TE LSPs on page 1185

Example: Configuring Path Computation Element Protocol for SPRING-TE LSPs

This example shows how to configure Path Computation Element Protocol (PCEP) for traffic engineered label-switched paths (LSPs) of Source Packet Routing in Networking (SPRING). The advantages of SPRING are leveraged with the benefits of external path computing for efficient traffic engineering.

Requirements

This example uses the following hardware and software components:

- Four MX Series 5G Universal Routing Platforms, where the ingress router is the Path Computation Client (PCC).
- A TCP connection to an external stateful Path Computation Element (PCE) from the PCC.
- Junos OS Release 17.2 or later running on the PCC.

Before you begin:

- Configure the device interfaces.

- Configure MPLS.
- Configure IS-IS.

Overview

Starting in Junos OS Release 17.2, the traffic engineering capabilities of Source Packet Routing in Networking (SPRING) are supported in PCEP sessions for the LSPs initiated by a PCE. Tunnel routes are created in the inet.3 routing table of the PCC corresponding to the SPRING-TE LSPs. Similar to any other tunnel route, the SPRING-TE tunnel routes can be used for resolving indirect next hops for plain IP and service traffic. The SPRING-TE LSPs are created by the PCE for the adjacency and node segments.

The SPRING-TE LSPs can be a maximum of six hops long. The PCE computes the path of the SPRING-TE LSP, and provisions the LSP on the Path Computation Client (PCC) using PCEP segment routing (SR) extensions. Tunnel routes are created in the inet.3 routing table of the PCC corresponding to the SPRING-TE LSPs. Similar to any other tunnel route, the SPRING-TE tunnel routes can be used for resolving indirect next hops for plain IP and service traffic.

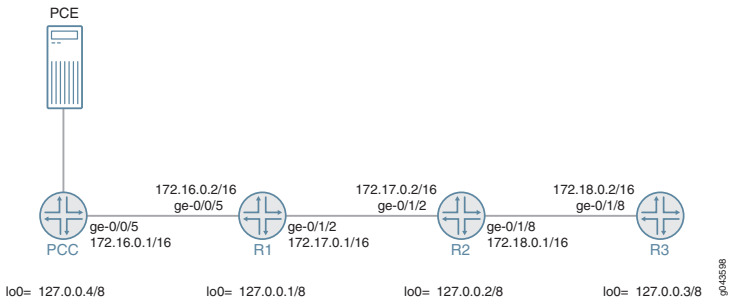
To configure SPRING-TE for PCEP:

- Enable external path computing for MPLS and SPRING-TE at the **[edit protocols]** hierarchy level.
- Enable spring capability for the PCE at the **[edit protocols pcep pce *pce*]** hierarchy level.

Topology

Figure 103 on page 1186 illustrates a sample network topology that has PCE as the external path computing entity, and the PCC as the ingress router that connects to the PCE. Routers R1, R2, and R3 are the other routers in the network. The PCC is enabled with SPRING-TE capability for the PCEP sessions. A static route is configured on the PCC to Router R3 to verify the use of SPRING-TE tunnel routes when routing traffic for the static route.

Figure 103: PCEP for SPRING-TE LSPs



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

PCC

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure PCC:

1. Configure the interfaces of the PCC.

```
[edit interfaces]
user@PCC# set ge-0/0/5 unit 0 family inet address 172.16.0.1/16
user@PCC# set ge-0/0/5 unit 0 family iso
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 127.0.0.4/8 primary
user@PCC# set lo0 unit 0 family iso address 49.0011.0110.0000.0101.00
user@PCC# set lo0 unit 0 family mpls
```

2. Configure the router ID and assign an autonomous system number for the PCC.

```
[edit routing-options]
user@PCC# set router-id 127.0.0.4
user@PCC# set autonomous-system 11
```

3. Configure a static route from the PCC to Router R3.

   The static route is created for verification purpose only and does not affect the feature functionality.

```
[edit routing-options]
user@PCC# set static route 100.1.1.1/32 next-hop 127.0.0.3
```

4. Configure RSVP on all the interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface fxp0.0 disable
user@PCC# set rsvp interface all
```

5. Configure MPLS on all the interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Enable external path computing capability for the PCC.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
```

7. Configure IS-IS level 2 on all the interfaces of the PCC, excluding the management and loopback interfaces.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis level 2 wide-metrics-only
user@PCC# set isis interface all point-to-point
user@PCC# set isis interface all level 2 metric 10
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0 passive
```

8. Configure Segment routing global block (SRGB) attributes for SPRING.

```
[edit protocols]
user@PCC# set isis source-packet-routing srgb start-label 800000
user@PCC# set isis source-packet-routing srgb index-range 4000
user@PCC# set isis source-packet-routing node-segment ipv4-index 101
user@PCC# set isis source-packet-routing node-segment ipv6-index 11
```

9. Configure SPRING with external path computing capability.

```
[edit protocols]
user@PCC# set spring-traffic-engineering lsp-external-controller pccd
```

10. Configure the PCE parameters and enable provisioning of LSP by the PCE and SPRING capability.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 127.0.0.4
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.232
user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 spring-capability
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/0/5 {
   unit 0 {
      family inet {
         address 172.16.0.1/16;
      }
      family iso;
      family mpls;
   }
}
lo0 {
   unit 0 {
      family inet {
         address 127.0.0.4/8 {
            primary;
         }
      }
      family iso {
         address 49.0011.0110.0000.0101.00;
      }
      family mpls;
   }
}
```

```
user@PCC# show routing-options
static {
   route 100.1.1.1/32 next-hop 127.0.0.3;
}
router-id 127.0.0.4;
autonomous-system 11;
```

```
user@PCC# show protocols
rsvp {
   interface fxp0.0 {
      disable;
   }
   interface all;
}
mpls {
   lsp-external-controller pccd;
   interface all;
   interface fxp0.0 {
      disable;
   }
}
isis {
```

```
    source-packet-routing {
        srgb start-label 800000 index-range 4000;
        node-segment {
            ipv4-index 101;
            ipv6-index 11;
        }
    }
    level 1 disable;
    level 2 wide-metrics-only;
    interface all {
        point-to-point;
        level 2 metric 10;
    }
    interface fxp0.0 {
        disable;
    }
    interface lo0.0 {
        passive;
    }
}
spring-traffic-engineering {
    lsp-external-controller pccd;
}
pcep {
    pce pce1 {
        local-address 127.0.0.4;
        destination-ipv4-address 10.102.180.232;
        destination-port 4189;
        pce-type active stateful;
        lsp-provisioning;
        spring-capability;
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying IS-IS Adjacency and Labels on page 1192
- Verifying the Traffic Engineering Database on page 1199
- Verifying SPRING-TE LSPs on page 1202
- Verifying Tunnel Route Creation on page 1204
- Verifying Forwarding Table Entries on page 1206
- Verifying Use of Tunnel Routes for Static Route Forwarding on page 1208

Verifying IS-IS Adjacency and Labels

Purpose Verify the IS-IS adjacency and label assignments for interfaces and nodes on the PCC.

Action From operational mode, run the **show isis adjacency extensive**, **show isis database extensive**, and **show isis overview** commands.

```
user@PCC> show isis adjacency extensive
R1

user@PCC> **show isis overview**

```
Instance: master
  Router ID: 127.0.0.4
  Hostname: PCC
  Sysid: 0110.0000.0101
  Areaid: 49.0011
  Adjacency holddown: enabled
  Maximum Areas: 3
  LSP life time: 1200
  Attached bit evaluation: enabled
  SPF delay: 200 msec, SPF holddown: 5000 msec, SPF rapid runs: 3
  IPv4 is enabled, IPv6 is enabled, SPRING based MPLS is enabled
  Traffic engineering: enabled
  Restart: Disabled
    Helper mode: Enabled
  Layer2-map: Disabled
  Source Packet Routing (SPRING): Enabled
```

```
  SRGB Config Range:
    SRGB Start-Label : 800000, SRGB Index-Range : 4000
  SRGB Block Allocation: Success
    SRGB Start Index : 800000, SRGB Size : 4000, Label-Range: [ 800000, 803999 ]
  Node Segments: Enabled
    Ipv4 Index : 101, Ipv6 Index : 11
Level 1
  Internal route preference: 15
  External route preference: 160
  Prefix export count: 0
  Wide metrics are enabled, Narrow metrics are enabled
  Source Packet Routing is enabled
Level 2
  Internal route preference: 18
  External route preference: 165
  Prefix export count: 0
  Wide metrics are enabled
  Source Packet Routing is enabled
```

Meaning The IS-IS adjacency between the PCC and PCE and the PCC and Router R1 is up and operational. The output also displays the label assignments for the adjacent and node segments.

Verifying the Traffic Engineering Database

Purpose Verify the traffic engineering database entries on the PCC.

Action From operational mode, run the **show ted database extensive** command.

```
user@PCC# show ted database extensive
```

```

```

Meaning The traffic engineering database includes entries advertised from Routers R1, R2, and R3, which the PCE uses for external path computing for the PCC.

Verifying SPRING-TE LSPs

Purpose Verify the creation of SPRING-TE LSP on the PCC.

Action From operational mode, run the **show path-computation-client lsp** and **show spring-traffic-engineering lsp detail** commands.

```
user@PCC> show path-computation-client lsp

  Name                                Status            PLSP-Id  LSP-Type
Controller       Path-Setup-Type       Template
  adj_sid_lsp                         (Up)              3        ext-provised
pce1              spring-te
  node_sid_lsp                        (Up)              5        ext-provised
pce1              spring-te
```

```
user@PCC> show spring-traffic-engineering lsp detail

Name: adj_sid_lsp
To: 127.0.0.3
State: Up, Outgoing interface: ge-0/0/5.0
SR-ERO hop count: 3
  Hop 1 (Strict):
    NAI: IPv4 Adjacency ID, 172.16.0.1 -> 172.16.0.2
    SID type: 20-bit label, Value: 16
  Hop 2 (Strict):
    NAI: IPv4 Adjacency ID, 172.17.0.1 -> 172.17.0.2
    SID type: 20-bit label, Value: 17
  Hop 3 (Strict):
    NAI: IPv4 Adjacency ID, 172.18.0.1 -> 172.18.0.2
    SID type: 20-bit label, Value: 16

Name: node_sid_lsp
To: 127.0.0.3
State: Up, Outgoing interface: ge-0/0/5.0
SR-ERO hop count: 3
  Hop 1 (Strict):
    NAI: IPv4 Adjacency ID, 172.16.0.1 -> 172.16.0.2
    SID type: 20-bit label, Value: 16
  Hop 2 (Strict):
    NAI: IPv4 Node ID, Node address: 127.0.0.1
    SID type: 20-bit label, Value: 800105
  Hop 3 (Strict):
    NAI: IPv4 Node ID, Node address: 127.0.0.2
    SID type: 20-bit label, Value: 800103

Total displayed LSPs: 2 (Up: 2, Down: 0)
```

```
user@PCC> show route protocol spring-te

inet.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)

inet.3: 3 destinations, 4 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.3/8      *[SPRING-TE/8] 00:23:32, metric 0
                      to 172.16.0.2 via ge-0/0/5.0, Push 16, Push 17(top)
                    > to 172.16.0.2 via ge-0/0/5.0, Push 800103, Push 800105(top)

iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
```

```
mpls.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)

inet6.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
```

Meaning The outputs show that two SPRING-TE LSPs—**adj_sid_lsp** and **node_sid_lsp**—have been created by the PCE for the adjacency and node segments, respectively.

Verifying Tunnel Route Creation

Purpose Verify the tunnel routes created for the SPRING-TE LSPs that are included in the inet.3 routing table on the PCC.

Action From operation mode, run the **show route table inet.3 extensive** command.

```
user@PCC> show route table inet.3 extensive

inet.3: 3 destinations, 4 routes (3 active, 0 holddown, 0 hidden)

```

Meaning Tunnel routes have been created for the PCE-controlled LSP destination with SPRING-TE as the protocol label.

Verifying Forwarding Table Entries

Purpose Verify that the SPRING-TE LSP destination to Device R3 is installed in the forwarding table of the PCC.

Action From operation mode, run the **show route forwarding-table destination *ip-address* extensive**

```
user@PCC> show route forwarding-table destination 127.0.0.3 extensive
Routing table: default.inet [Index 0]
Internet:
Enabled protocols: Bridging,

Destination: 127.0.0.3/8
  Route type: user
  Route reference: 0                   Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE, rt nh decoupled
  Nexthop: 172.16.0.2
  Next-hop type: unicast               Index: 581      Reference: 14
  Next-hop interface: ge-0/0/5.0

Routing table: __pfe_private__.inet [Index 3]
Internet:
Enabled protocols: Bridging,

Destination:  default
  Route type: permanent
  Route reference: 0                   Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE
  Next-hop type: discard               Index: 517      Reference: 2

Routing table: __juniper_services__.inet [Index 5]
Internet:
Enabled protocols: Bridging,

Destination:  default
  Route type: permanent
  Route reference: 0                   Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE
  Next-hop type: discard               Index: 530      Reference: 2

Routing table: __master.anon__.inet [Index 6]
Internet:
Enabled protocols: Bridging, Dual VLAN,

Destination:  default
  Route type: permanent
  Route reference: 0                   Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE
  Next-hop type: reject                Index: 545      Reference: 1
```

Meaning The SPRING-TE LSP destination IP address to Router R3 is installed as a forwarding entry.

Verifying Use of Tunnel Routes for Static Route Forwarding

Purpose Verify that the static route is taking the tunnel route created for the SPRING-TE LSPs.

Action From operational mode, run the **show route *ip-address*** and **show route forwarding-table destination *ip-address*** commands.

```
user@PCC>show route 100.1.1.1
```

```
inet.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Static Segment Routing Label Switched Path

You can create static segment routing label switched paths (LSPs) for MPLS networks. For more information, see the following topics:

Understanding Static Segment Routing LSP in MPLS Networks

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Essentially, segments are provisioned on transit routers using the following two methods:

- First, by configuring static segment MPLS label switched paths (LSPs) at **[edit protocols mpls static-label-switched-path]** hierarchy level.
- Second, by using IGPs like ISIS and OSPF to manage segments and advertise segment labels.

The non-colored static segment routing LSPs are then configured on ingress routers at the **[edit protocols source-packet-routing sourc-routing-path]** hierarchy level. These non-colored static segment routing LSPs refer to segment-lists which consists of the labels of the segments provisioned on the transit routers.

Segment routing leverages the source routing paradigm. A node steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress node to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack. Segment routing can be applied to the IPv6 architecture, with a new type of routing extension header. A segment is encoded as an IPv6 address. An ordered list of segments is encoded as an ordered list of IPv6 addresses in the routing extension header. The segment to process is indicated by a pointer in the routing extension header. Upon completion of a segment, the pointer is incremented. Static segment routing provisioning in MPLS networks supports static adjacency segments, prefix segment, and non-colored segment routing label switched paths. Static segment routing provisioning in an MPLS network involves segment provisioning, segment information distribution, and segment routing LSP provisioning.

Static Segment Routing Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique segment identifier(SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. A route for the SID label is then installed in the mpls.0 table. The next-hop of the route is obtained either through pops-and-forwards for an adjacency SID label, or through swaps-and-forwards for a prefix SID label or node SID label.

Junos OS allows static segment routing LSPs by configuring the **segment** statement at the **[edit protocols mpls static-label-switched-path *static-label-switched-path*]** hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the **static-label-range *static-label-range*** statement at the **[edit protocols mpls label-range]** hierarchy level. The default range of static label pool is 100000 through 1048575. The static segment LSP performs pop-and-forward label operation for adjacency segment or swap-and-forward label operation for prefix or node segment. For both the types of label operation, the static segment LSP has a next hop operation that specifies the remote IP address or the name of an outgoing interface. The interface name is only acceptable for point-to-point interface. For each static segment LSP, the SID label route is installed in the mpls.0 table with the next hop as per the label operation and the outgoing interface. For an adjacency segment that uses pop-and-forward label operation, a clone route is installed in the mpls.0 table as well. The adjacency segment, prefix segment, and node segment are locally unprotected static segments.

Benefits of using Static Segment Routing of Label Switched Path

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

Non-Colored Static Segment Routing LSP

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

Segment List

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. For a segment routing LSP to be considered as non-colored static LSP, the first hop of the segment list has to be an IP address of an outgoing interface and the second to Nth hops can be SID labels. The number of SID labels in the segment list should not exceed the maximum segment list limit. By default, the maximum segment list limit is

5. You can configure the maximum segment list limit at the **[edit protocols source-packet-routing]** hierarchy level with a range of 2 through 5 SID labels.

Non-colored Segment Routing LSP

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the inet.3 routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1. A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may specify a metric and a preference at **[edit protocols source-packet-routing source-routing-path *lsp-name*]** for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

Static Segment Routing LSP Provisioning

Junos OS currently has a limitation that the next hop cannot be built to push more than 5 labels. So, a segment list with more than 5 SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than 5, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed 5. You can configure the maximum segment list limit at **[edit protocols source-packet-routing]** hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to 5 SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label. The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring **no-ingress** statement at **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session. These non-colored segment routing LSPs may have binding segment ID (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

Limitations

- A segment-list is usable for non-colored static segment routing LSPs only if the first hop specifies an IP address. If the first hop specifies only as SID label, it cannot be used to resolve an outgoing interface, and a log message is displayed. If the first hop specifies both an IP address and a SID label, the SID label is simply ignored.
- A maximum of 8 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- The maximum depth of label stack that a next hop can push is 5. If any segment-list is configured with more labels then the configuration commit check fails with an error.

Example: Configuring Static Segment Routing Label Switched Path

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

Overview

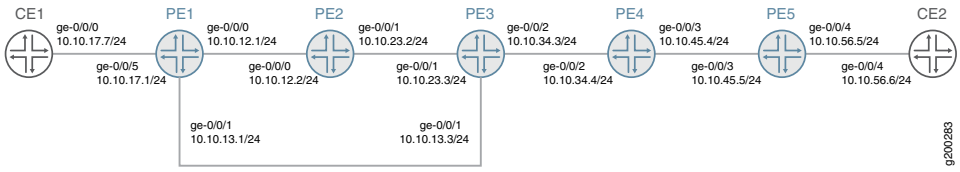
Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the **segment-list** statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure segment routing tunnel by configuring the **source-routing-path** statement at **[edit protocols source-packet-routing]** hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels

corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5 . Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

Figure 104: Static Segment Routing Label Switched Path



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring Device PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5

set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5

set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
```

```
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRIs in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
  ge-0/0/0 {
    unit 0 {
      family inet {
        address 55.1.12.1/24;
      }
      family mpls {
        maximum-labels 5;
      }
```

```
    }
  }
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 55.1.13.1/24;
      }
      family mpls {
        maximum-labels 5;
      }
    }
  }
  ge-0/0/5 {
    unit 0 {
      family inet {
        address 55.1.17.1/24;
      }
    }
  }
```

```

}
```

Configuring Device PE2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls

set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
```

```
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-0/0/0 {
   unit 0 {
      family inet {
         address 55.1.12.2/24;
      }
      family mpls;
   }
}
ge-0/0/1 {
   unit 0 {
      family inet {
         address 55.1.23.2/24;
      }
      family mpls;
   }
}
```

```
user@PE2# show protocols
mpls {
   static-label-switched-path adj-23 {
      segment {
         1000123;
         next-hop 55.1.23.3;
         pop;
      }
```

```
    }
    static-label-switched-path adj-21 {
      segment {
        1000221;
        next-hop 55.1.12.1;
        pop;
      }
    }
    interface ge-0/0/0.0;
    interface ge-0/0/1.0;
    label-range {
      static-label-range 1000000 1000999;
    }
}
ospf {
    area 0.0.0.0 {
      interface ge-0/0/0.0;
      interface ge-0/0/1.0;
    }
}
```

Verification

Confirm that the configuration is working properly.

Verifying Route Entry of Routing Table inet.3 of Router PE1

Purpose Verify the route entry of routing table inet.3 of router PE1.

Action From operational mode, enter the **show route table inet.3** command.

```
user@PE1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32   *[SPRING-TE/8] 03:09:26, metric 1
                   > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)

                        to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134,
Push 1000123(top)
```

Meaning The output displays the ingress routes of segment routing tunnels.

Verifying Route Table Entries of Routing Table mpls.0 of Router PE1

Purpose Verify the route entries of routing table mpls.0

Action From operational mode, enter the **show route table mpls.0** command.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 03:25:52, metric 1
                      Receive
1                  *[MPLS/0] 03:25:52, metric 1
                      Receive
2                  *[MPLS/0] 03:25:52, metric 1
                      Receive
13                 *[MPLS/0] 03:25:52, metric 1
                      Receive
16                 *[VPN/0] 03:25:52
                    > via lsi.0 (VRF1), Pop
1000999            *[SPRING-TE/8] 03:04:03, metric 1
                   > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)

                      to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134,
Push 1000123(top)
```

Meaning The output displays the SID labels of segment routing tunnels.

Verifying SPRING Traffic Engineered LSP of Router PE1

Purpose Verify SPRING traffic engineered LSPs on the ingress routers.

Action From operational mode, enter the **show spring-traffic-engineering overview** command.

```
user@PE1> show spring-traffic-engineering overview
```

```
Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
   < Not configured >
```

Meaning The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1

Purpose Verify SPRING traffic engineered LSPs on the ingress router.

Action From operational mode, enter the **show spring-traffic-engineering lsp detail** command.

```
user@PE1# show spring-traffic-engineering lsp detail
Name: lsp-15
To: 192.168.146.181
State: Up
  Path: sl-15-primary
  Outgoing interface: ge-0/0/1.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 3
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.13.3
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145
  Path: sl-15-backup
  Outgoing interface: ge-0/0/0.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 4
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.12.2
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000123
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 4 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145

Total displayed LSPs: 1 (Up: 1, Down: 0)
```

Meaning The output displays details of SPRING traffic engineered LSPs on the ingress router

Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2

Purpose Verify the routing table entries of routing table mpls.0 of router PE2.

Action From operational mode, enter the **show route table mpls.0** command.

```
user@PE2> show route table mpls.0
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 03:22:29, metric 1
                      Receive
1                  *[MPLS/0] 03:22:29, metric 1
                      Receive
2                  *[MPLS/0] 03:22:29, metric 1
                      Receive
13                 *[MPLS/0] 03:22:29, metric 1
                      Receive
1000123            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000123(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.23.3 via ge-0/0/1.0, Pop
1000221            *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
1000221(S=0)       *[MPLS/6] 03:22:29, metric 1
                       > to 10.10.12.1 via ge-0/0/0.0, Pop
```

Verifying the Status of Static MPLS LSP Segments of Router PE2

Purpose Verify the status of MPLS LSP segments of router PE2.

Action From operational mode, enter the **show mpls static-lsp** command.

```
user@PE2> show mpls static-lsp
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname                              SID-label       State
adj-21                               1000221         Up
adj-23                               1000123         Up
Total 2, displayed 2, Up 2, Down 0
```

Meaning The output displays the status of static MPLS LSP segments of router PE2.

Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.

PART 9

Troubleshooting MPLS

CHAPTER 33

Troubleshooting MPLS

Verify MPLS Interfaces

Purpose If the MPLS protocol is not configured correctly on the routers in your network, the interfaces are not able to perform MPLS switching.

Action To verify MPLS interfaces, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls interface
```

Sample Output 1

The following sample output is for all routers in the network shown in *MPLS Network Topology*.

```
user@R1> show mpls interface
Interface           State       Administrative groups
so-0/0/0.0          Up          <none>
so-0/0/1.0          Up          <none>
so-0/0/2.0          Up          <none>

user@R2> show mpls interface
Interface           State       Administrative groups
so-0/0/0.0          Up          <none>
so-0/0/1.0          Up          <none>
so-0/0/2.0          Up          <none>
so-0/0/3.0          Up          <none>
```

```
user@R3> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>

user@R4> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>

user@R5> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>

user@R6> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>
```

Sample Output 2

```
user@R6>  show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/3.0        Up          <none>        # so-0/0/2.0 is missing
```

Sample Output 3

```
user@host> show mpls interface
MPLS not configured
```

Meaning Sample Output 1 shows that all MPLS interfaces on all routers in the network are enabled (**Up**) and can perform MPLS switching. If you fail to configure the correct interface at the [**edit protocols mpls**] hierarchy level or include the **family mpls** statement at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level, the interface cannot perform MPLS switching, and does not appear in the output for the **show mpls interface** command.

Administrative groups are not configured on any of the interfaces shown in the example network in *MPLS Network Topology*. However, if they were, the output would indicate which affinity class bits are enabled on the router.

Sample Output 2 shows that interface **so-0/0/2.0** is missing and therefore might be incorrectly configured. For example, the interface might not be included at the [**edit protocols mpls**] hierarchy level, or the **family mpls** statement might not be included at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level. If the interface is configured correctly, RSVP might not have signaled over this interface yet. For more information on determining which interface is incorrectly configured, see "Verify Protocol Families" on page 1521.

Sample Output 3 shows that the MPLS protocol is not configured at the [**edit protocols mpls**] hierarchy level.

Verify the MPLS Configuration

Purpose After you have checked the transit and ingress routers, use the **traceroute** command to verify the BGP next hop, and used the **ping** command to verify the active path, you can check for problems with the MPLS configuration at the [**edit protocols mpls**] and [**edit interfaces**] hierarchy levels.

Action To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show configuration protocols mpls
user@host> show configuration interfaces
```

Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
```

```
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured
```

Sample Output 2

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/1 {
    unit 0 {
        family inet {
            address 10.1.46.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.26.2/30;
        }

        }
```

```
    }
}
```

Meaning Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the [**edit protocols mpls**] hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

Checklist for Checking the MPLS Layer

Problem **Description:** This checklist provides the steps and commands for checking the Multiprotocol Label Switching (MPLS) layer of the layered MPLS model. The checklist provides links to an overview of the MPLS layer and more detailed information about the commands used to investigate the problem.

Table 47 on page 1241 provides commands for checking the MPLS layer.

Table 47: Checklist for Checking the MPLS Layer

Solution

Tasks	Command or Action
"Checking the MPLS Layer" on page 1242	
1. Verify the LSP on page 1244	**show mpls lsp** **show mpls lsp extensive** **show mpls lsp name *name*** **show mpls lsp name *name* extensive**
2. Verify the LSP Route on the Transit Router on page 1247	**show route table mpls.0**
3. Verify the LSP Route on the Ingress Router on page 1248	**show route *destination***
4. Verify MPLS Labels with the traceroute Command on page 1250	**traceroute *hostname***
5. Verify MPLS Labels with the ping Command on page 1251	On the ingress router: **ping mpls rsvp *lsp-name* detail**
6. Verify the MPLS Configuration on page 1239	**show configuration protocols mpls** **show configuration interfaces**

Table 47: Checklist for Checking the MPLS Layer (continued)

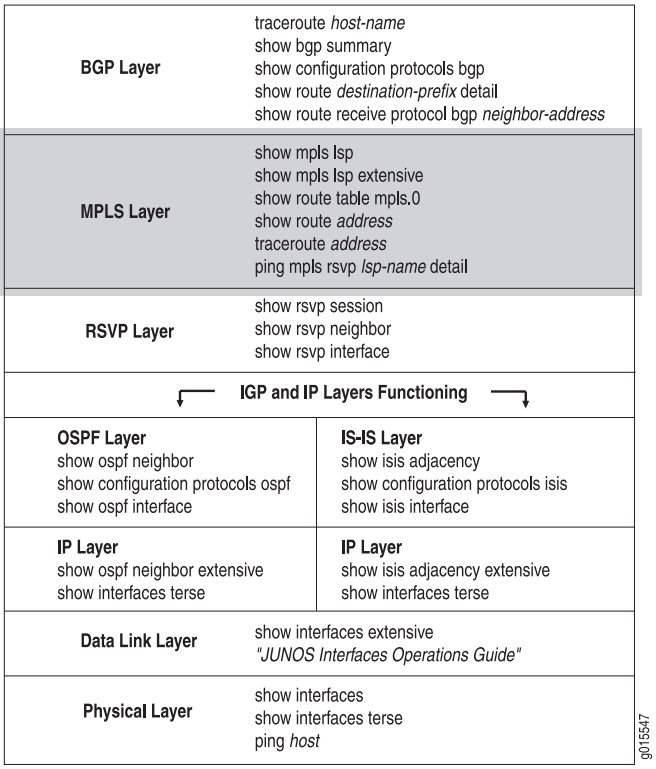
Tasks	Command or Action
7. Take Appropriate Action on page 1254	The following sequence of commands addresses the specific problem described in this topic: **edit** **edit protocols mpls** **[edit protocols mpls]** **show** **activate interface so-0/0/3.0** **show** **commit**
8. Verify the LSP Again on page 1255	**show mpls lsp extensive**

Checking the MPLS Layer

Purpose After you have configured the label-switched path (LSP), issued the **show mpls lsp** command, and determined that there is an error, you might find that the error is not in the physical, data link, Internet Protocol (IP), interior gateway protocol (IGP), or Resource Reservation Protocol (RSVP) layers. Continue investigating the problem at the MPLS layer of the network.

Figure 105 on page 1243 illustrates the MPLS layer of the layered MPLS model.

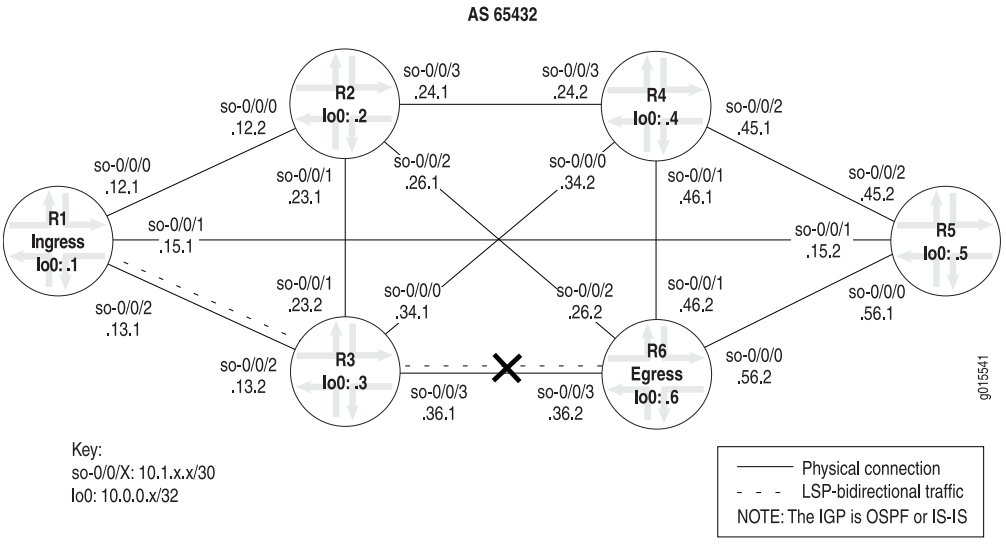
Figure 105: Checking the MPLS Layer



With the MPLS layer, you check whether the LSP is up and functioning correctly. If the network is not functioning at this layer, the LSP does not work as configured.

Figure 106 on page 1243 illustrates the MPLS network used in this topic.

Figure 106: MPLS Network Broken at the MPLS Layer



The network shown in Figure 106 on page 1243 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface.

The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the reverse LSP is down without a path from **R6** to **R1**.

The cross shown in Figure 106 on page 1243 indicates where the LSP is broken. Some possible reasons the LSP is broken might include an incorrectly configured MPLS protocol, or interfaces that are incorrectly configured for MPLS.

In the network shown in Figure 106 on page 1243, a configuration error on egress router **R6** prevents the LSP from traversing the network as expected.

To check the MPLS layer, follow these steps:

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive)** as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive).**

Action To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-toR1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only one LSP is configured in the example network in Figure 106 on page 1243. However, in a large network with many LSPs configured, the results would be quite different between the two commands.

Verify the LSP Route on the Transit Router

Purpose If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

Action To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

Sample Output 1

```
user@R3> show route table mpls.0
mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
1                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
2                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
```

Sample Output 2

```
user@R3> show route table mpls.0
```

```
mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
1                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
2                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
100864             *[RSVP/7] 00:07:23, metric 1
                    > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0)        *[RSVP/7] 00:07:23, metric 1
                    > via so-0/0/2.0, label-switched-path R6-to-R1
100880             *[RSVP/7] 00:07:01, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0)        *[RSVP/7] 00:07:01, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see "Checklist for Verifying LSP Use" on page 1411.

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries represent two routes. There are two entries per route because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding.*

Verify the LSP Route on the Ingress Router

Purpose Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

Action To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

Sample Output 1

```
user@R1> show route 10.0.0.6

inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.6/32        *[IS-IS/18] 6d 01:41:37, metric 20
                      to 10.1.12.2 via so-0/0/0.0
                    > to 10.1.15.2 via so-0/0/1.0
                      to 10.1.13.2 via so-0/0/2.0

user@R6> show route 10.0.0.1

inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32        *[IS-IS/18] 5d 01:01:38, metric 20
                      to 10.1.56.1 via so-0/0/0.0
                    > to 10.1.26.1 via so-0/0/2.0
                      to 10.1.36.1 via so-0/0/3.0
```

Sample Output 2

```
user@R1> show route 10.0.0.6
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[IS-IS/18] 6d 02:13:42, metric 20
                      to 10.1.12.2 via so-0/0/0.0
                    > to 10.1.15.2 via so-0/0/1.0
                      to 10.1.13.2 via so-0/0/2.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[RSVP/7] 00:08:07, metric 20
                    > via so-0/0/2.0,  label-switched-path R1-to-R6

user@R6> show route 10.0.0.1

inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32        *[IS-IS/18] 5d 01:34:03, metric 20
                      to 10.1.56.1 via so-0/0/0.0
                    > to 10.1.26.1 via so-0/0/2.0
                      to 10.1.36.1 via so-0/0/3.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32        *[RSVP/7] 00:10:39, metric 20
                    >  via so-0/0/3.0, label-switched-path R6-to-R1
```

Meaning Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in Figure 106 on page 1243.

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

Verify MPLS Labels with the traceroute Command

Purpose Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the **traceroute** command as a debugging tool to determine whether the LSP is being used to forward traffic.

Action To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6>  traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

Sample Output 2

```
user@R1>  traceroute 100.100.6.1
 to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
      MPLS Label=100912 CoS=0 TTL=1 S=1
 2  10.1.36.2 (10.1.36.2)  0.577 ms !N  0.597 ms !N  0.546 ms !N

user@R6>  traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.36.1 (10.1.36.1)  0.802 ms  0.716 ms  0.688 ms
      MPLS Label=100896 CoS=0 TTL=1 S=1
 2  10.1.13.1 (10.1.13.1)  0.570 ms !N  0.568 ms !N  0.546 ms !N
```

Meaning Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in Figure 106 on page 1243) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

Verify MPLS Labels with the ping Command

Purpose When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

Action To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

Sample Output 1

```
user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.
```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.15.2 (10.1.15.2)  0.708 ms  0.613 ms  0.576 ms
 2  10.0.0.6 (10.0.0.6)  0.763 ms  0.708 ms  0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok

5 packets transmitted, 5 packets received, 0% packet loss
```

Meaning Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

Verify the MPLS Configuration

Purpose After you have checked the transit and ingress routers, use the **traceroute** command to verify the BGP next hop, and used the **ping** command to verify the active path, you can check for problems with the MPLS configuration at the [**edit protocols mpls**] and [**edit interfaces**] hierarchy levels.

Action To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show configuration protocols mpls
user@host> show configuration interfaces
```

Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
```

```
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured
```

Sample Output 2

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/1 {
    unit 0 {
        family inet {
            address 10.1.46.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.26.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/3 {
    unit 0 {
        family inet {
            address 10.1.36.2/30;
        }
        family iso;
        family mpls;
    }
}
fxp0 {
    unit 0 {
```

```
        family inet {
            address 192.168.70.148/21;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.6/32;
            address 127.0.0.1/32;
        }
        family iso {
            address 49.0003.1000.0000.0006.00;
        }
    }
}
```

Meaning Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the [**edit protocols mpls**] hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the [**edit protocols mpls**] hierarchy level on egress router **R6.**

Solution To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
user@R6#  activate interface so-0/0/3

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete
```

Meaning The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the [**edit protocols mpls**] hierarchy level. The LSP can now come up.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

Action To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions
```

```

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify That Node-Link Protection Is Up

Purpose After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in Figure 6 on page 112, two bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

Action To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

show mpls lsp (See Sample Output on page ?)
show mpls lsp extensive (See Sample Output on page 1260)
show rsvp interface (See Sample Output on page 1261)
show rsvp interface extensive (See Sample Output on page 1262)
show rsvp session detail (See Sample Output on page 1263)

Sample Output

```
user@R1> show mpls lsp

Meaning Sample output from **R1** for the **show mpls lsp extensive** command shows detailed information about all LSPs for which **R1** is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass **LSP Bypass->10.0.12.14->10.0.24.2.**

Sample Output

```
user@R1> show rsvp interface

```

Meaning Sample output from **R1** for the **show rsvp interface** command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5.** Interface **fe-0/1/0.0** is the connecting interface between R1 and R2, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the **show rsvp interface extensive** command.

Sample Output

```
user@R1> show rsvp interface extensive
RSVP interface: 3 active
fe-0/1/0.0 Index 67, State Ena/Up
  NoAuthentication, NoAggregate, NoReliable, LinkProtection
  HelloInterval 9(second)

```

Meaning

Sample output from **R1** for the **show rsvp interface extensive** command shows more detailed information about the activity on all RSVP interfaces (**3**). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14**is a link protection bypass path (**Type: LP**), protecting the link between **R1** and **R2 fe-0/1/0.0.** The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding **R2** in case of node failure.

Sample Output

```

Meaning Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5)** originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

Conclusion Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection

provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment. Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

Related Information For additional information about MPLS fast reroute and MPLS protection methods, see the following:

- *Junos Feature Guide*

- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*

Verify That Link Protection Is Up

Purpose When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in Figure 107 on page 1270, a bypass path should be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

Action To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface
```

Sample Output

```
user@R1> show mpls lsp extensive | no-more

Meaning The sample output from ingress router **R1** shows that **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have link protection up, and both LSPs are using the bypass path, **10.0.12.14**. However, the **show mpls lsp** command does not list the bypass path. For information about the bypass path, use the **show rsvp session** command.

Sample Output

Meaning The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the **show mpls lsp** command. However, because link protection is an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass >** ***interface-address***, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1** (**lsp2-r1-to-r5)** is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0.** Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

Sample Output

```

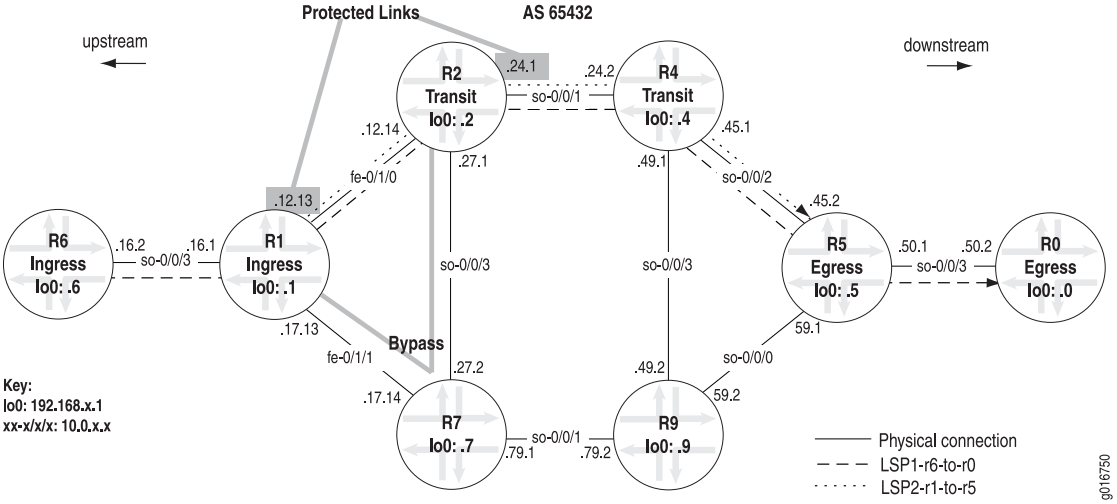
Meaning The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

Many-to-One Link Protection (Facility Backup) Overview

Many-to-one (facility backup) is based on interface rather than on LSP. While fast reroute protects interfaces or nodes along the entire path of a LSP, many-to-one protection can be applied on interfaces as needed, as shown in Figure 107 on page 1270. In Figure 107 on page 1270, a bypass path is set up around the link to be protected (**10.0.12.14**) using an alternate interface to forward traffic. The bypass path is shared by all protected LSPs traversing the failed link (many LSPs protected by one bypass path).

Figure 107: Many-to-One or Link Protection



In Figure 107 on page 1270, two LSPs (**lsp1-r6-to-r0** and **lsp2-r1-to-r5**) are protected by one preestablished bypass path from **R1** to **R2** through **R7**. Both LSPs have strict paths configured that go through interface **fe-0/1/0**. On **R1**, the interface **10.0.12.13** has link protection configured that protects the next hop **10.0.12.14**.

Link protection (many-to-one or facility backup) allows a router immediately upstream from a link failure to use an alternate interface to forward traffic to its downstream neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link. A single bypass path can safeguard a set of protected LSPs. When an outage occurs, the router immediately upstream from the link outage switches protected traffic to the bypass link, then signals the link failure to the ingress router.

Like fast reroute, link protection provides local repair and restores connectivity faster than the ingress router switching traffic to a standby secondary path. However, unlike fast reroute, link protection does not provide protection against the failure of the downstream neighbor.

Link protection is appropriate in the following situations:

- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

Verify One-to-One Backup

Purpose You can verify that one-to-one backup is established by examining the ingress router and the other routers in the network.

Action To verify one-to-one backup, enter the following Junos OS CLI operational mode commands:

```
user@host> show mpls lsp ingress extensive
user@host> show rsvp session
```

Sample Output

The following sample output is from the ingress router **R1** :

```
user@R1> show mpls lsp ingress extensive
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
  ActivePath: via-r2 (primary)
   FastReroute desired
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary   via-r2           State: Up
    SmartOptimizeTimer: 180
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 3)
 10.0.12.14 S 10.0.24.2 S 10.0.45.2 S
     Received RRO  (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node
10=SoftPreempt):
           10.0.12.14(flag=9) 10.0.24.2(flag=1) 10.0.45.2
     8 May 11 14:51:46 Fast-reroute Detour Up
     7 May 11 14:50:55 Record Route: 10.0.12.14(flag=9) 10.0.24.2(flag=1) 10.0.45.2
    6 May 11 14:50:55 Record Route:  10.0.12.14(flag=9) 10.0.24.2 10.0.45.2
    5 May 11 14:50:52 Selected as active path

    3 May 11 14:50:52 Up
    2 May 11 14:50:52 Originate Call
    1 May 11 14:50:52 CSPF: computation result accepted
  Created: Thu May 11 14:50:52 2006
Total 1 displayed, Up 1, Down 0
```

Meaning The sample output from **R1** shows that the **FastReroute desired** object was included in the Path messages for the LSP, allowing **R1** to select the active path for the LSP and establish a detour path to avoid **R2**.

In line 8, **Fast-reroute Detour Up** shows that the detour is operational. Lines 6 and 7 indicate that transit routers **R2** and **R4** have established their detour paths.

R2, **10.0.12.14**, includes **(flag=9)**, indicating that node protection is available for the downstream node and link. **R4**, **10.0.24.2**, includes **(flag=1)**, indicating that link protection is available for the next downstream link. In this case, **R4** can protect only the downstream link because the node is the egress router **R5**, which cannot be protected. For more information about flags, see the *Junos Feature Guide*.

The output for the **show mpls lsp extensive** command does not show the actual path of the detour. To see the actual links used by the detour paths, you must use the **show rsvp session ingress detail** command.

Sample Output The following sample output is from the ingress router **R1** in the network shown in Figure 123 on page 1470.

```
user@R1> show rsvp session ingress detail
Ingress RSVP: 1 sessions

192.168.5.1
  From: 192.168.1.1,  LSPstate: Up,  ActiveRoute: 0

```

Meaning The sample output from **R1** shows the RSVP session of the main LSP. The detour path is established, **Detour is Up**. The physical path of the detour is displayed in **Detour Explct route**. The detour path uses **R7** and **R9** as transit routers to reach **R5**, the egress router.

Sample Output The following sample output is from the first transit router R2 in the network shown in Figure 123 on page 1470:

```
user@R2> show rsvp session transit detail
Transit RSVP: 1 sessions

192.168.5.1
  From: 192.168.1.1, LSPstate: Up, ActiveRoute: 1

    Detour Label out: 100736
Total 1 displayed, Up 1, Down 0
```

Meaning The sample output from **R2** shows the detour is established (**Detour is Up**) and avoids **R4**, and the link connecting **R4** and **R5** (**10.0.45.2**). The detour path is through **R7** (**10.0.27.2**) and **R9** (**10.0.79.2**) to **R5** (**10.0.59.1**), which is different from the explicit route for the detour from **R1**. **R1** has the detour passing through the **10.0.17.14** link on **R7**, while **R1** is using the **10.0.27.2** link. Both detours merge at **R9** through the **10.0.79.2** link to **R5** (**10.0.59.1**).

Sample Output The following sample output is from the second transit router R4 in the network shown in Figure 123 on page 1470:

```
user@R4> show rsvp session transit detail
Transit RSVP: 1 sessions

192.168.5.1
  From: 192.168.1.1,  LSPstate: Up, ActiveRoute: 1
   LSPname: r1-to-r5, LSPpath: Primary
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent: 3
  Resv style: 1 FF, Label in: 100448, Label out: 3
  Time left:  155, Since: Wed May 10 16:15:38 2006
  Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
  Port number: sender 5 receiver 9216 protocol 0
   FastReroute desired
  PATH rcvfrom: 10.0.24.1 (so-0/0/1.0) 178 pkts

    Detour Label out: 100352
Total 1 displayed, Up 1, Down 0
```

Meaning The sample output from **R4** shows the detour is established (**Detour is Up**) and avoids the link connecting **R4** and **R5** (**10.0.45.2**). The detour path is through R9 (**10.0.49.2**) to **R5** (**10.0.59.1**). Some of the information is similar to that found in the output for **R1** and **R2**. However, the explicit route for the detour is different, going through the link connecting **R4** and **R9** (**so-0/0/3** or **10.0.49.2.**

Sample Output The following sample output is from **R7**, which is used in the detour path in the network shown in Figure 123 on page 1470:

```
user@R7> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

192.168.5.1
  From: 192.168.1.1, LSPstate: Up, ActiveRoute: 1
   LSPname: r1-to-r5, LSPpath: Primary

    RESV rcvfrom: 10.0.79.2 (so-0/0/1.0) 179 pkts
    Explct route: 10.0.79.2 10.0.59.1
     Record route: 10.0.12.13 10.0.27.1 <self> 10.0.79.2 10.0.59.1
     Label in: 100736, Label out: 100368
   Detour branch from 10.0.17.13, to skip 192.168.2.1, Up
    Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
    Adspec: received MTU 1500
    Path MTU: received 0
    PATH rcvfrom: 10.0.17.13 (fe-0/1/1.0) 179 pkts
    Adspec: received MTU 1500
    PATH sentto: 10.0.79.2 (so-0/0/1.0) 0 pkts
    RESV rcvfrom: 10.0.79.2 (so-0/0/1.0) 0 pkts
    Explct route: 10.0.79.2 10.0.59.1
     Record route: 10.0.17.13 <self> 10.0.79.2 10.0.59.1
     Label in: 100752, Label out: 100368
Total 1 displayed, Up 1, Down 0
```

Meaning The sample output from **R7** shows the same information as for a regular transit router used in the primary path of the LSP: the ingress address (**192.168.1.1**), the egress address (**192.168.5.1**), and the name of the LSP (**r1-to-r5**). Two detour paths are displayed; the first to avoid **R4** (**192.168.4.1**) and the second to avoid **R2** (**192.168.2.1**). Because **R7** is used as a transit router by **R2** and **R4**, **R7** can merge the detour paths together as indicated by the identical **Label out** value (**100368**) for both detour paths. Whether **R7** receives traffic from **R4** with a label value of **100736** or from **R2** with a label value of **100752**, **R7** forwards the packet to **R5** with a label value of **100368**.

Sample Output The following sample output is from R9, which is a router used in the detour path in the network shown in Figure 123 on page 1470:

```
user@R9> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

192.168.5.1
  From: 192.168.1.1, LSPstate: Up, ActiveRoute: 1
  LSPname: r1-to-r5, LSPpath: Primary
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent: 3
  Resv style: 1 FF, Label in: 100352, Label out: 3
  Time left:  141, Since: Wed May 10 16:16:40 2006
  Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
  Port number: sender 5 receiver 9216 protocol 0
   Detour branch from 10.0.49.1, to skip 192.168.5.1, Up
    Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
    Adspec: received MTU 1500
    Path MTU: received 0
    PATH rcvfrom: 10.0.49.1 (so-0/0/3.0) 183 pkts
    Adspec: received MTU 1500 sent MTU 1500
    PATH sentto: 10.0.59.1 (so-0/0/0.0) 182 pkts
    RESV rcvfrom: 10.0.59.1 (so-0/0/0.0) 183 pkts
    Explct route: 10.0.59.1
     Record route: 10.0.12.13 10.0.24.1 10.0.49.1 <self> 10.0.59.1
    Label in: 100352, Label out: 3
   Detour branch from 10.0.27.1, to skip 192.168.4.1, Up
    Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
    Adspec: received MTU 1500
    Path MTU: received 0
   Detour branch from 10.0.17.13, to skip 192.168.2.1, Up
    Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
    Adspec: received MTU 1500
    Path MTU: received 0
    PATH rcvfrom: 10.0.79.1 (so-0/0/1.0) 181 pkts
    Adspec: received MTU 1500
    PATH sentto: 10.0.59.1 (so-0/0/0.0) 0 pkts
    RESV rcvfrom: 10.0.59.1 (so-0/0/0.0) 0 pkts
     Explct route: 10.0.59.1
    Record route: 10.0.12.13 10.0.27.1 10.0.79.1 <self> 10.0.59.1
     Label in: 100368, Label out: 3
Total 1 displayed, Up 1, Down 0
```

Meaning The sample output from **R9** shows that **R9** is the penultimate router for the detour path, the explicit route includes only the egress link address (**10.0.59.1**), and the **Label out** value (**3**) indicates that **R9** has performed penultimate-hop label popping. Also, the detour branch from **10.0.27.1** does not include path information because **R7** has merged the detour paths from **R2** and **R4**. Notice that the **Label out** value in the detour branch from **10.0.17.13** is **100368**, the same value as the **Label out** value on **R7**.

Sample Output The following sample output is from the egress router R5 in the network shown in Figure 123 on page 1470:

```
user@R5> show rsvp session egress detail
Egress RSVP: 1 sessions, 1 detours

Total 1 displayed, Up 1, Down 0
```

Meaning The sample output from **R5** shows the main LSP in the **Record route** field and the detours through the network.

Verify That the Primary Path Is Operational

Purpose Primary paths must always be used in the network if they are available, therefore an LSP always moves back to the primary path after a failure, unless the configuration is adjusted. For more information on adjusting the configuration to prevent a failed primary path from reestablishing, see "Preventing Use of a Path That Previously Failed" on page 117.

Action To verify that the primary path is operational, enter the following Junos OS command-line interface (CLI) operational mode commands:

```
user@host> show mpls lsp extensive ingress
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show mpls lsp extensive ingress
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
   ActivePath: via-r2 (primary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
 *Primary  via-r2            State: Up

```

Meaning Sample output 1 shows that the LSP is operational and is using the primary path (**via-r2**) with **R2** (**10.0.12.14**) and **R4** (**10.0.24.2**) as transit routers. The priority values are the same for setup and hold, **6 6**. Priority 0 is the highest (best) priority and 7 is the lowest (worst) priority. The Junos OS default for setup and hold priority is 7:0. Unless some LSPs are more important than others, preserving the default is a good practice. Configuring a setup priority that is better than the hold priority is not allowed, resulting in a failed commit in order to avoid preemption loops.

Verify That the Secondary Path Is Established

Purpose When the secondary path is configured with the **standby** statement, the secondary path should be *up* but *not active*; it will become active if the primary path fails. A secondary path configured without the **standby** statement will not come up unless the primary path fails. To test that the secondary path is correctly configured and would come up if the primary path were to fail, you must deactivate a link or node critical to the primary path, then issue the **show mpls lsp *lsp-path-name* extensive** command.

Action To verify that the secondary path is established, enter the following Junos OS CLI operational mode command:

Sample Output

```
user@R1> show mpls lsp extensive
```

Sample Output

The following sample output shows a correctly configured secondary path before and after it comes up. In the example, interface **fe-0/1/0** on **R2** is deactivated, which brings down the primary path **via-r2**. The ingress router **R1** switches traffic to the secondary path **via-r7**.

Meaning The sample output from egress router **R1** shows a correctly configured standby secondary path in a down state because the primary path is still up. Upon deactivation of an interface (**interface fe-0/1/0** on **R2**) critical to the primary path, the primary path **via-r2** goes down and the standby secondary path **via-r7** comes up, allowing **R1** to switch traffic to the standby secondary path.

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name** *name* or **show mpls lsp name** *name* **extensive**).

Action To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```

Meaning Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-toR1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only one LSP is configured in the example network in Figure 106 on page 1243. However, in a large network with many LSPs configured, the results would be quite different between the two commands.

Verify the LSP Route on the Transit Router

Purpose If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched

router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

Action To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

Sample Output 1

```
user@R3> show route table mpls.0
mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
1                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
2                  *[MPLS/0] 16w2d 21:52:40, metric 1
                      Receive
```

Sample Output 2

```
user@R3> show route table mpls.0
mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
1                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
2                  *[MPLS/0] 16w2d 22:26:08, metric 1
                      Receive
100864             *[RSVP/7] 00:07:23, metric 1
                    > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0)        *[RSVP/7] 00:07:23, metric 1
                    > via so-0/0/2.0, label-switched-path R6-to-R1
100880             *[RSVP/7] 00:07:01, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0)        *[RSVP/7] 00:07:01, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see "Checklist for Verifying LSP Use" on page 1411.

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries

represent two routes. There are two entries per route because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

Verify the LSP Route on the Ingress Router

Purpose Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

Action To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

Sample Output 1

```
user@R1> show route 10.0.0.6

inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.6/32        *[IS-IS/18] 6d 01:41:37, metric 20
                      to 10.1.12.2 via so-0/0/0.0
                    > to 10.1.15.2 via so-0/0/1.0
                      to 10.1.13.2 via so-0/0/2.0

user@R6> show route 10.0.0.1

inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32        *[IS-IS/18] 5d 01:01:38, metric 20
                      to 10.1.56.1 via so-0/0/0.0
                    > to 10.1.26.1 via so-0/0/2.0
                      to 10.1.36.1 via so-0/0/3.0
```

Sample Output 2

```
user@R1> show route 10.0.0.6

inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[IS-IS/18] 6d 02:13:42, metric 20
                      to 10.1.12.2 via so-0/0/0.0
                    > to 10.1.15.2 via so-0/0/1.0
                      to 10.1.13.2 via so-0/0/2.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[RSVP/7] 00:08:07, metric 20
                    > via so-0/0/2.0,  label-switched-path R1-to-R6
```

```
user@R6> show route 10.0.0.1

inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32        *[IS-IS/18] 5d 01:34:03, metric 20
                      to 10.1.56.1 via so-0/0/0.0
                    > to 10.1.26.1 via so-0/0/2.0
                      to 10.1.36.1 via so-0/0/3.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32        *[RSVP/7] 00:10:39, metric 20
                     >  via so-0/0/3.0, label-switched-path R6-to-R1
```

Meaning Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in Figure 106 on page 1243.

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

Verify MPLS Labels with the traceroute Command

Purpose Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the **traceroute** command as a debugging tool to determine whether the LSP is being used to forward traffic.

Action To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

Sample Output 2

```
user@R1> traceroute 100.100.6.1
 to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
      MPLS Label=100912 CoS=0 TTL=1 S=1
 2  10.1.36.2 (10.1.36.2)  0.577 ms !N  0.597 ms !N  0.546 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.36.1 (10.1.36.1)  0.802 ms  0.716 ms  0.688 ms
      MPLS Label=100896 CoS=0 TTL=1 S=1
 2  10.1.13.1 (10.1.13.1)  0.570 ms !N  0.568 ms !N  0.546 ms !N
```

Meaning Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in Figure 106 on page 1243) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

Verify MPLS Labels with the ping Command

Purpose When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

Action To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

Sample Output 1

```
user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.
```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.15.2 (10.1.15.2)  0.708 ms  0.613 ms  0.576 ms
 2  10.0.0.6 (10.0.0.6)  0.763 ms  0.708 ms  0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 69, label 100880
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 69, label 100880
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 69, label 100880
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

user@R6> ping mpls rsvp R6-to-R1 detail
Request for seq 1, to interface 70, label 100864
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 70, label 100864
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 70, label 100864
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 70, label 100864
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 70, label 100864
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Meaning Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the [**edit protocols mpls**] hierarchy level on egress router **R6.**

Solution To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
user@R6#  activate interface so-0/0/3

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete
```

Meaning The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the [**edit protocols mpls**] hierarchy level. The LSP can now come up.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

Action To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions
```

```

```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Checklist for Working with the Layered MPLS Troubleshooting Model

Problem **Description:** This checklist provides a link to more detailed information about the layered Multiprotocol Label Switching network.

Solution Table 48 on page 1293 provides commands for working with the layered MPLS troubleshooting model.

Table 48: Checklist for Working with the Layered MPLS Troubleshooting Model

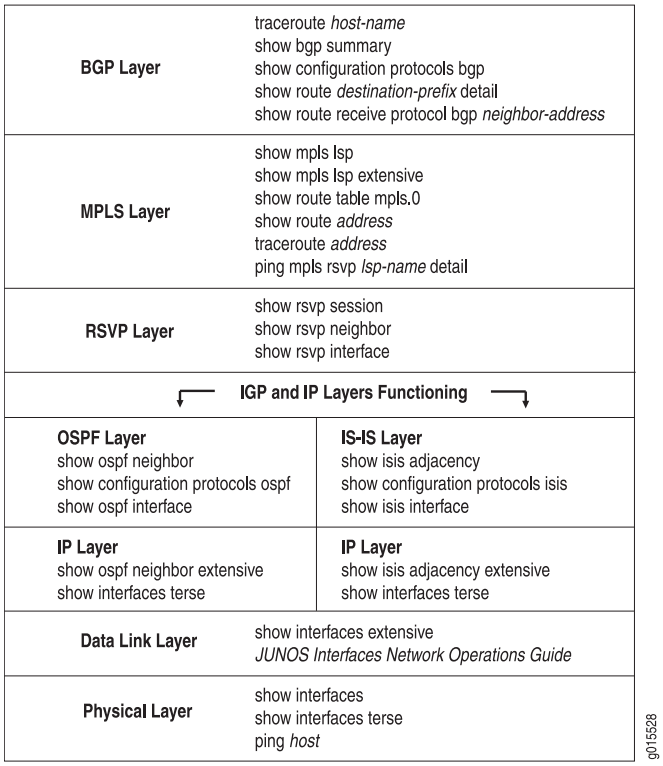
Tasks	Command or Action
"Understanding the Layered MPLS Troubleshooting Model" on page 1293	**show mpls lsp** **show mpls lsp extensive** **show mpls lsp name *name*** **show mpls lsp name *name* extensive**

Understanding the Layered MPLS Troubleshooting Model

Problem **Description:** The layered MPLS troubleshooting model is a disciplined approach to investigating problems with an MPLS network. Figure 108 on page 1294 illustrates the layers in the model, and the commands you can use to structure your investigation. Because of the complexity of the MPLS network, you can obtain much better results from your investigations if you progress through the layers and verify the functioning of each layer on the ingress, egress, and transit routers before moving on to the next layer.

Solution Figure 108 on page 1294 shows the layered MPLS troubleshooting model that you can use to troubleshoot problems with your MPLS network.

Figure 108: Layered MPLS Network Troubleshooting Model



As you move from one layer of the model to the next, you verify the correct functioning of a different component of the MPLS network and eliminate that layer as the source of the problem.

Physical Layer When you investigate the physical layer, you check that the routers are connected, and the interfaces are up and configured correctly. To check the physical layer, enter the **show interfaces**, **show interfaces terse**, and **ping** commands. If there is a problem in the physical layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information on checking the physical layer, see "Checklist for Verifying the Physical Layer" on page 1300.

Data Link Layer When you investigate the data link layer, you check the encapsulation mode, for example, Point-to-Point Protocol (PPP) or Cisco High-Level Data Link Control (HDLC); PPP options, for example, header encapsulation; frame check sequence (FCS) size; and whether keepalive frames are enabled or disabled.To check the data link layer, enter the **show interfaces extensive** command. If there is a problem in the data link layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information on checking the data link layer, see "Checking the Data Link Layer" on page 1314 and the *Junos Interfaces Operations Guide*.

IP Layer When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that the interior gateway protocol (IGP) neighbor adjacencies are established. To check the IP layer, enter the **show interfaces terse**, **show ospf neighbor extensive**, and

show isis adjacency extensive commands. If there is a problem in the IP layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command.

IGP Layer

When you investigate the IGP layer, you verify that the the Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) protocols are configured and running correctly.

- If you have the OSPF protocol configured, you must check the IP layer first, and then the OSPF configuration. When you investigate the OSPF layer, you check that the protocol, interfaces, and traffic engineering are configured correctly. To check the OSPF layer, enter the **show configuration protocols ospf** and **show ospf interface** commands. If the problem exists in the OSFP layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information about checking the OSPF layer, see "Verifying the OSPF Protocol" on page 1359.
- If you have the IS-IS protocol configured, because IS-IS and IP are independent of each other, it doesn't matter which one you check first. When you check the IS-IS configuration, you verify that IS-IS adjacencies are up, and the interfaces and IS-IS protocol are configured correctly. To check the IS-IS layer, enter the **show isis adjacency**, **show configuration protocols isis**, and **show isis interfaces** commands. If the problem exists in the IS-IS layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information about checking the IS-IS layer, see *Verifying the IS-IS Protocol*.

NOTE: The IS-IS protocol has traffic engineering enabled by default.

RSVP and MPLS Layers

After you have both the IP and IGP layers functioning and the problem is still not solved, you can begin to check the Resource Reservation Protocol (RSVP) and MPLS layers to determine if the problem is in one of these layers.

- When you investigate the RSVP layer, you are checking that dynamic RSVP signaling is occurring as expected, neighbors are connected, and interfaces are configured correctly for RSVP. To check the RSVP layer, enter the **show rsvp session**, **show rsvp neighbor**, and **show rsvp interface** commands. If there is a problem in the RSVP layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command.
- When you investigate the MPLS layer, you are checking whether the LSP is up and functioning correctly. To check the MPLS layer, enter the **show mpls lsp**, **show mpls lsp extensive**, **show route table mpls.0**,**show route *address***, **traceroute *address***, and **ping mpls rsvp *lsp-name* detail** commands. If there is a problem in the MPLS layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command.

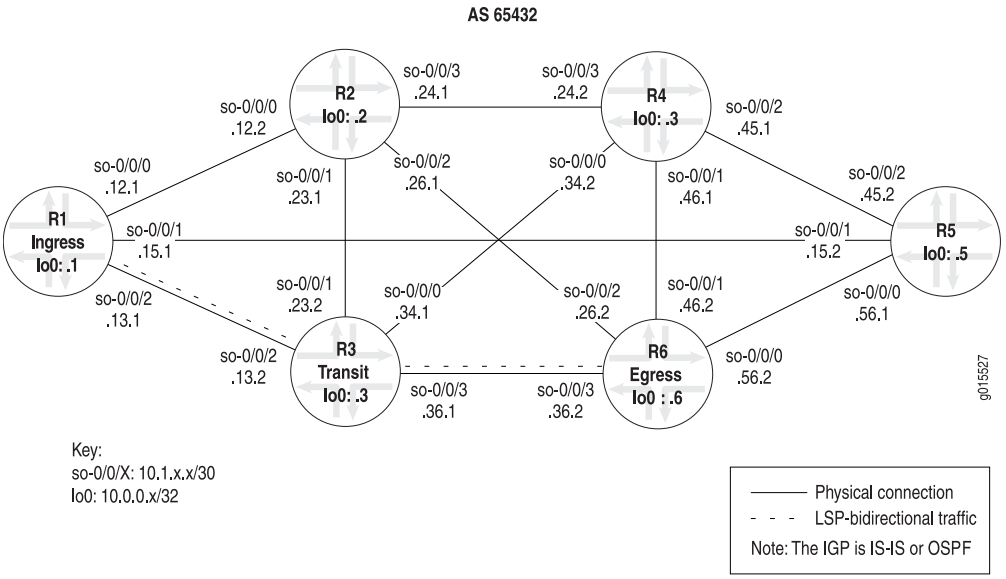
BGP Layer If the problem persists after you have checked the RSVP and MPLS layers, you must verify that the Border Gateway Protocol (BGP) is working correctly. There is no point in checking the BGP layer unless the LSP is established because BGP uses the MPLS LSP to forward traffic. When you check the BGP layer, you verify that the route is present and active, and more importantly, you ensure that the next hop is the LSP. To check the BGP layer, enter the **traceroute** ***host-name***, **show bgp summary**, **show configuration protocols bgp**, **show route** ***destination-prefix*** **detail**, and **show route receive protocol bgp** ***neighbor-address*** commands. For more information on checking the BGP layer, see *Checking the BGP Layer*.

In reality, you could start at any level of the MPLS model to investigate a problem with your MPLS network. However, a disciplined approach, as the one described here, produces more consistent and reliable results.

Figure 109 on page 1296 illustrates the basic network topology used in the following topics that demonstrate how to troubleshoot an MPLS network:

- Checklist for Verifying the Physical Layer on page 1300
- Checklist for Checking the Data Link Layer on page 1314
- Checklist for Verifying the IP and IGP Layers on page 1334
- Checklist for Checking the RSVP Layer on page 1385
- Checklist for Checking the MPLS Layer on page 1241
- *Checklist for Checking the BGP Layer*

Figure 109: MPLS Basic Network Topology Example



The MPLS network consists of the following components:

- Router-only network with SONET interfaces
- MPLS protocol enabled on all routers, with interfaces selectively deactivated to illustrate a particular problem scenario
- All interfaces configured with MPLS
- A full-mesh IBGP topology, using AS 65432
- IS-IS or OSPF as the underlying IGP, using one level (IS-IS Level 2) or one area (OSPF area 0.0.0.0)
- A **send-statics** policy on routers R1 and R6, allowing a new route to be advertised into the network
- Two LSPs between routers R1 and R6, allowing for bidirectional traffic.

After you have configured an LSP, it is considered best practice to issue the **show mpls lsp** command to verify that the LSP is up, and to investigate further if you find an error message in the output. The error message can indicate a problem at any layer of the MPLS network.

The LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive)** as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive)**.

Action To begin the investigation of an error in your MPLS network, from the ingress router, enter some or all of the following Junos OS command-line interface (CLI) operational mode commands:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```

Meaning The sample output from the ingress router **R1** shows that the label-switched path is traversing the network as intended, from **R1** through **R3** to **R6,** and another LSP in the reverse direction, from **R6** through **R3** to **R1**.

If your network has numerous LSPs, you might consider using the **show mpls lsp** command for quick verification of the LSP state. and the **show mpls lsp name** *name* **extensive** command to continue your investigation if you find that the LSP is down.

For more information about the status and statistics of the **show mpls lsp** command, see "Checklist for Determining LSP Status" on page 1409. For more information on the availability and valid use of an LSP, see "Checklist for Verifying LSP Use" on page 1411.

In all the following topics, the network topology is broken at different layers of the network so that you can investigate various MPLS network problems. The problems presented are not inclusive. Instead, the problems serve to illustrate one possible process of investigation into the different layers of the troubleshooting model.

Checklist for Verifying the Physical Layer

Problem **Description:** This checklist provides the steps and commands for investigating a problem at the physical layer of a Multiprotocol Label Switching (MPLS) network. The checklist provides links to an overview of verifying the physical layer and more detailed information about the commands used to investigate the problem.

Solution Table 49 on page 1301 provides commands for verifying the physical layer.

Table 49: Checklist for Verifying the Physical Layer

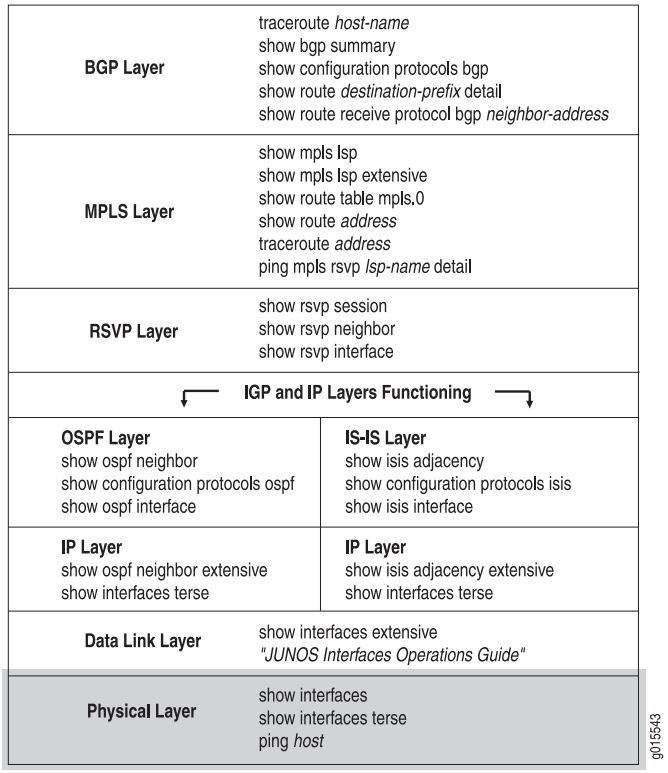
Tasks	Command or Action
"Verifying the Physical Layer" on page 1301	
1. Verify the LSP on page 1303	**show mpls lsp extensive**
2. Verify Router Connection on page 1305	**ping** *host*
3. Verify Interfaces on page 1306	**show interfaces terse** **show configuration interfaces** *type-fpc/pic/port*
4. Take Appropriate Action on page 1306	The following sequence of commands addresses the specific problem described in this topic: [**edit interfaces** *type-fpc/pic/port*] **set family mpls** **show** **commit**
5. Verify the LSP Again on page 1307	**show mpls lsp extensive**

Verifying the Physical Layer

Purpose After you have configured the LSP, issued the **show mpls lsp extensive** command, and determined that there is an error, you can start investigating the problem at the physical layer of the network.

Figure 110 on page 1302 illustrates the physical layer of the layered MPLS model.

Figure 110: Verifying the Physical Layer

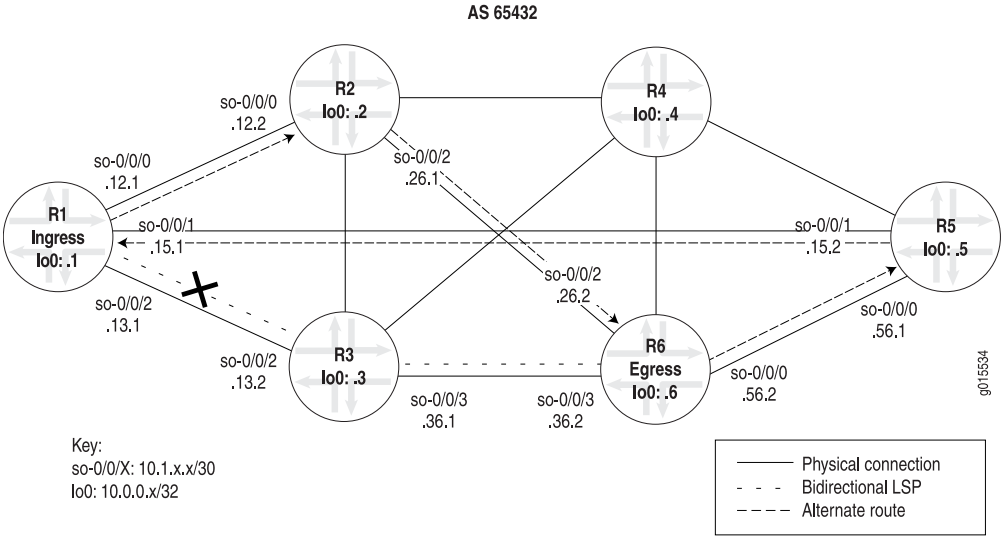


With this layer, you must ensure that the routers are connected, and that the interfaces are up and configured correctly on the ingress, egress, and transit routers.

If the network is not functioning at this layer, the label-switched path (LSP) does not work as configured.

Figure 111 on page 1303 illustrates the MPLS network and the problem described in this topic.

Figure 111: MPLS Network Broken at the Physical Layer



The network shown in Figure 111 on page 1303 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, traffic does not use the configured LSP. Instead traffic uses the alternate route from **R1** through **R2** to **R6**, and in the reverse direction, from **R6** through **R5 to R1**.

When you become aware of a situation where an alternate route is used rather than the configured LSP, verify that the physical layer is functioning correctly. You might find that routers are not connected, or that interfaces are not up and configured correctly on the ingress, egress, or transit routers.

The cross shown in Figure 111 on page 1303 indicates where the LSP is broken because of a configuration error on ingress router **R1**.

To check the physical layer, follow these steps:

1. Verify the LSP on page 1303
2. Verify Router Connection on page 1305
3. Verify Interfaces on page 1306
4. Take Appropriate Action on page 1306
5. Verify the LSP Again on page 1307

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However, for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has

numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name** *name* or **show mpls lsp name** *name* **extensive**).

Action To determine whether the LSP is up, enter the following command from the ingress router:

```
user@ingress-router> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6

  Record route:  10.1.56.2 10.1.15.2 <self>
Total 1 displayed, Up 1, Down 0
```

```
Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output from ingress router **R1** shows that the LSP is using an alternate path rather than the configured path. The configured path for the LSP is **R1** through **R3** to **R6,** and for the reverse LSP, **R6** through **R3** to **R1**. The alternate path used by the LSP is **R1** through **R2** to **R6,** and for the reverse LSP, **R6 t**hrough **R5** to **R1**.

Verify Router Connection

Purpose Confirm that the appropriate ingress, transit, and egress routers are functioning by examining whether the packets have been received and transmitted with 0% packet loss.

Action To determine that the routers are connected, enter the following command from the ingress and transit routers:

```
user@host> ping host
```

Sample Output

```
user@R1> ping 10.0.0.3 count 3
PING 10.0.0.3 (10.0.0.3): 56 data bytes
64 bytes from 10.0.0.3: icmp_seq=0 ttl=254 time=0.859 ms
64 bytes from 10.0.0.3: icmp_seq=1 ttl=254 time=0.746 ms
64 bytes from 10.0.0.3: icmp_seq=2 ttl=254 time=0.776 ms

--- 10.0.0.3 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.746/0.794/0.859/0.048 ms

user@R3>  ping 10.0.0.6 count 3
PING 10.0.0.6 (10.0.0.6): 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=0 ttl=255 time=0.968 ms
64 bytes from 10.0.0.6: icmp_seq=1 ttl=255 time=3.221 ms
64 bytes from 10.0.0.6: icmp_seq=2 ttl=255 time=0.749 ms

--- 10.0.0.6 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.749/1.646/3.221/1.117 ms
```

Meaning The sample output shows that ingress router **R1** is receiving packets from transit router **R3**, and that the transit router is receiving packets from the egress router. Therefore, the routers in the LSP are connected.

Verify Interfaces

Purpose Confirm that the interfaces are configured correctly with the **family mpls** statement.

Action To determine that the relevant interfaces are up and configured correctly, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
user@host> show configuration interfaces type-fpc/pic/port
```

Sample Output

```
user@R1> show interfaces so* terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up
so-0/0/0.0              up    up   inet  10.1.12.1/30
                                  iso
                                  mpls
so-0/0/1                up    up
so-0/0/1.0              up    up   inet  10.1.15.1/30
                                  iso
                                  mpls
so-0/0/2                up    up
so-0/0/2.0              up    up   inet  10.1.13.1/30
                                  iso   <<< family mpls is missing
so-0/0/3                up    down

user@R1>  show configuration interfaces so-0/0/2
unit 0 {
    family inet {
        address 10.1.13.1/30;
    }
    family iso; <<<  family mpls is missing
}
```

Meaning The sample output shows that interface **so-0/0/2.0** on the ingress router does not have the **family mpls** statement configured at the [**edit interfaces** *type-fpc/pic/port*] hierarchy level, indicating that the interface is incorrectly configured to support the LSP. The LSP is configured correctly at the [**edit protocols mpls**] hierarchy level.

The output from the transit and egress routers (not shown) shows that the interfaces on those routers are configured correctly.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the **family mpls** statement, which was missing, is included in the configuration of ingress router **R1**.

Solution To correct the error in this example, enter the following commands:

```
[edit interfaces type-fpc/pic/port]
user@R1# set family mpls
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2 unit 0]
user@R1# set family mpls

[edit interfaces so-0/0/2 unit 0]
user@R1# show
family inet {
    address 10.1.13.1/30;
}
family iso;
family mpls;

[edit interfaces so-0/0/2 unit 0]
user@R1# commit
commit complete
```

Meaning The sample output from ingress router **R1** shows that the **family mpls** statement is configured correctly for interface **so-0/0/2.0**, and that the LSP is now functioning as originally configured.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the physical layer has been resolved.

Action To verify that the LSP is up and traversing the network as expected, enter the following command:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Up, ActiveRoute: 1, LSPname: R1-to-R6

    to 10.0.0.6;
}
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
```

Meaning Sample Output 1 from ingress router **R1** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 2 from ingress router **R1** shows that the LSP is forced to take the intended path because MPLS is deactivated on **R1** interfaces **so-0/0/0.0** and **so-0/0/1.0**. If these

interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However, for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive)** as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive).**

Action To determine whether the LSP is up, enter the following command from the ingress router:

```
user@ingress-router> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Total 0 displayed, Up 0, Down 0
```

Meaning The sample output from ingress router **R1** shows that the LSP is using an alternate path rather than the configured path. The configured path for the LSP is **R1** through **R3** to **R6,** and for the reverse LSP, **R6** through **R3** to **R1**. The alternate path used by the LSP is **R1** through **R2** to **R6,** and for the reverse LSP, **R6 t**hrough **R5** to **R1**.

Verify Router Connection

Purpose Confirm that the appropriate ingress, transit, and egress routers are functioning by examining whether the packets have been received and transmitted with 0% packet loss.

Action To determine that the routers are connected, enter the following command from the ingress and transit routers:

```
user@host> ping host
```

Sample Output

```
user@R1> ping 10.0.0.3 count 3
PING 10.0.0.3 (10.0.0.3): 56 data bytes
64 bytes from 10.0.0.3: icmp_seq=0 ttl=254 time=0.859 ms
64 bytes from 10.0.0.3: icmp_seq=1 ttl=254 time=0.746 ms
64 bytes from 10.0.0.3: icmp_seq=2 ttl=254 time=0.776 ms

--- 10.0.0.3 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.746/0.794/0.859/0.048 ms

user@R3>  ping 10.0.0.6 count 3
PING 10.0.0.6 (10.0.0.6): 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=0 ttl=255 time=0.968 ms
64 bytes from 10.0.0.6: icmp_seq=1 ttl=255 time=3.221 ms
64 bytes from 10.0.0.6: icmp_seq=2 ttl=255 time=0.749 ms

--- 10.0.0.6 ping statistics ---
```

```
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.749/1.646/3.221/1.117 ms
```

Meaning The sample output shows that ingress router **R1** is receiving packets from transit router **R3**, and that the transit router is receiving packets from the egress router. Therefore, the routers in the LSP are connected.

Verify Interfaces

Purpose Confirm that the interfaces are configured correctly with the **family mpls** statement.

Action To determine that the relevant interfaces are up and configured correctly, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
user@host> show configuration interfaces type-fpc/pic/port
```

Sample Output

```
user@R1> show interfaces so* terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up
so-0/0/0.0              up    up   inet  10.1.12.1/30
                                  iso
                                  mpls
so-0/0/1                up    up
so-0/0/1.0              up    up   inet  10.1.15.1/30
                                  iso
                                  mpls
so-0/0/2                up    up
so-0/0/2.0              up    up   inet  10.1.13.1/30
                                  iso   <<< family mpls is missing
so-0/0/3                up    down

user@R1>   show configuration interfaces so-0/0/2
unit 0 {
    family inet {
        address 10.1.13.1/30;
    }
    family iso; <<<  family mpls is missing
}
```

Meaning The sample output shows that interface **so-0/0/2.0** on the ingress router does not have the **family mpls** statement configured at the [**edit interfaces *type-fpc/pic/port***] hierarchy level, indicating that the interface is incorrectly configured to support the LSP. The LSP is configured correctly at the [**edit protocols mpls**] hierarchy level.

The output from the transit and egress routers (not shown) shows that the interfaces on those routers are configured correctly.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the **family mpls** statement, which was missing, is included in the configuration of ingress router **R1**.

Solution To correct the error in this example, enter the following commands:

```
[edit interfaces type-fpc/pic/port]
user@R1# set family mpls
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2 unit 0]
user@R1# set family mpls

[edit interfaces so-0/0/2 unit 0]
user@R1# show
family inet {
    address 10.1.13.1/30;
}
family iso;
family mpls;

[edit interfaces so-0/0/2 unit 0]
user@R1# commit
commit complete
```

Meaning The sample output from ingress router **R1** shows that the **family mpls** statement is configured correctly for interface **so-0/0/2.0**, and that the LSP is now functioning as originally configured.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the physical layer has been resolved.

Action To verify that the LSP is up and traversing the network as expected, enter the following command:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions
```

```
10.0.0.6

Total 0 displayed, Up 0, Down 0
```

Sample Output 2

```
[edit protocols mpls]
user@R1# show
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
```

Meaning Sample Output 1 from ingress router **R1** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 2 from ingress router **R1** shows that the LSP is forced to take the intended path because MPLS is deactivated on **R1** interfaces **so-0/0/0.0** and **so-0/0/1.0**. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Checklist for Checking the Data Link Layer

Problem **Description:** This checklist provides the steps and commands for investigating a problem at the data link layer of the Multiprotocol Label Switching (MPLS) network. The checklist provides links to an overview of the data link layer and more detailed information about the commands used to investigate the problem.

Solution Table 50 on page 1314 provides commands for checking the data link layer.

Table 50: Checklist for Checking the Data Link Layer

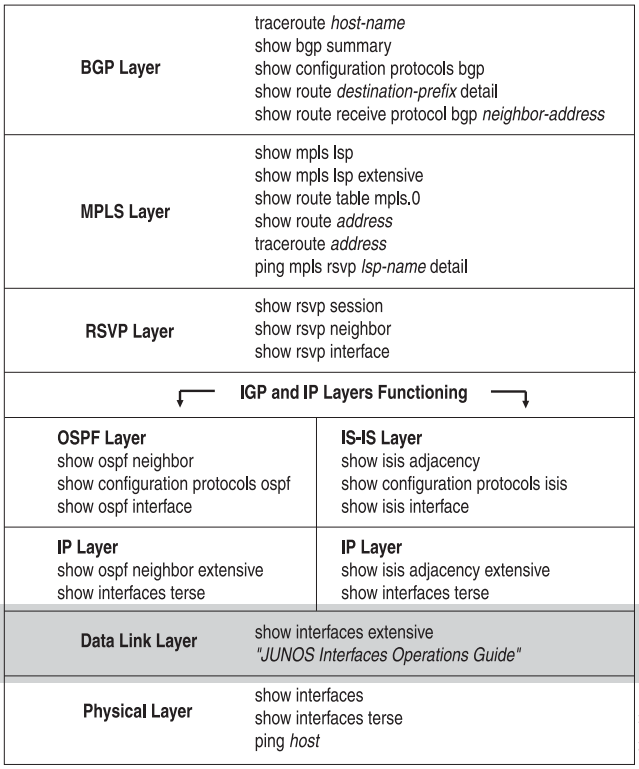
Tasks	Command or Action
"Checking the Data Link Layer" on page 1314	
1. Verify the LSP on page 1316	**show mpls lsp extensive**
2. Verify Interfaces on page 1317	**show interfaces *type-fpc/pic/port* extensive** **show interfaces *type-fpc/pic/port***
3. Take Appropriate Action on page 1321	The following sequence of commands addresses the specific problem described in this topic: **[edit interfaces *type-fpc/pic/port*]** **show** **delete encapsulation** **show** **commit**
4. Verify the LSP Again on page 1322	**show mpls lsp extensive**

Checking the Data Link Layer

Purpose After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical layer. Continue investigating the problem at the data link layer of the network.

Figure 112 on page 1315 illustrates the data link layer of the layered MPLS model.

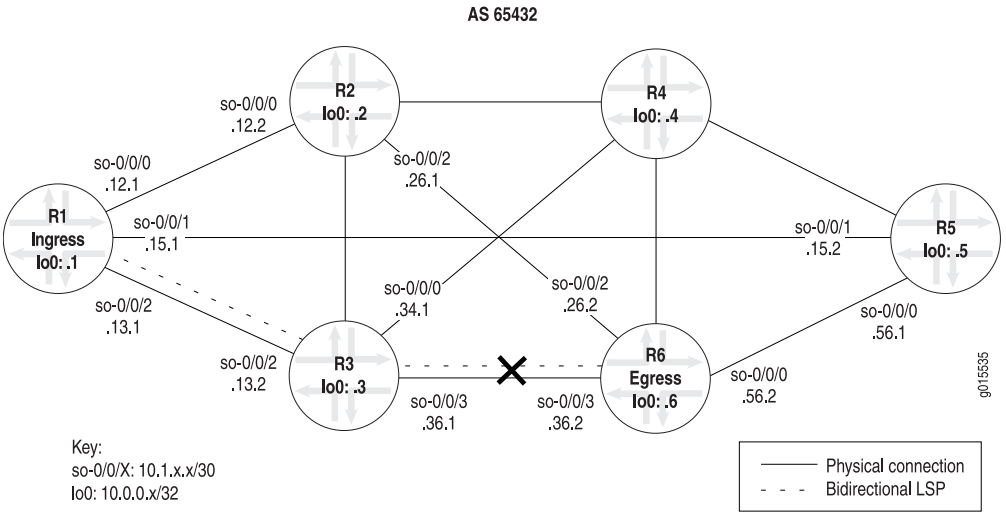
Figure 112: Checking the Data Link Layer



With this layer, you must check the encapsulation mode, for example, Point-to-Point Protocol (PPP) or Cisco High-Level Data Link Control (HDLC); PPP options, for example, header encapsulation; frame check sequence (FCS) size; and whether keepalive frames are enabled or disabled. Also, check the ingress, egress, and transit routers.

Figure 113 on page 1315 illustrates the MPLS network used in this topic.

Figure 113: MPLS Network Broken at the Data Link Layer



The network shown in Figure 113 on page 1315 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

When you verify that the data link layer is not functioning correctly, you might find a mismatch with PPP or Cisco HDLC encapsulation, PPP options, or keepalive frames.

The cross shown in Figure 113 on page 1315 indicates where the LSP is broken because of a configuration error on ingress router **R1** that prevents the LSP from traversing the network as expected.

To check the data link layer, follow these steps:

1. Verify the LSP on page 1316
2. Verify Interfaces on page 1317
3. Take Appropriate Action on page 1321
4. Verify the LSP Again on page 1322

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1 , State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
   ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn
    Will be enqueued for recomputation in 15 second(s).
    140 Sep 30 12:01:12 CSPF failed: no route toward 10.0.0.6[26 times]
   139 Sep 30 11:48:57 Deselected as active
   138 Sep 30 11:48:56 CSPF failed: no route toward 10.0.0.6
```

```
   137 Sep 30 11:48:56 Clear Call
   136 Sep 30 11:48:56 CSPF: link down/deleted
10.1.36.1(R3.00/10.0.0.3)->10.1.36.2(R6.00/10.0.0.6)
135 Sep 30 11:48:56 ResvTear received
   134 Sep 30 11:48:56 Down
   133 Sep 30 11:48:56 CSPF failed: no route toward 10.0.0.6
   132 Sep 30 11:48:56 10.1.13.2: No Route toward dest
   [...Output truncated...]
  Created: Sat Jul 10 18:18:44 2004
Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output from ingress router **R1** shows the LSPs within which it participates. The ingress LSP is down, without a path from **R1** to **R6.** Because a reverse LSP is configured in the network shown in Figure 113 on page 1315, we would expect an egress LSP session to be up. However, **R1** does not have any egress LSPs, indicating that the LSP from **R6** to **R1** is not functioning.

Verify Interfaces

Purpose From your network topology, determine the adjacent interfaces through which the LSP is meant to traverse, and examine the output for the encapsulation type, PPP options, FCS size, and whether keepalive frames are enabled or disabled

NOTE: **Before you proceed with this step, check the physical layer to ensure that the problem is not in the physical layer.**

Action To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show interfaces type-fpc/pic/port extensive
user@host> show interfaces type-fpc/pic/port
```

Sample Output 1

```
user@R6> show interfaces so-0/0/3 extensive
Physical interface: so-0/0/3, Enabled, Physical link is Up

     Flags: None
```

Sample Output 2

```
user@R3> show interfaces so-0/0/3
Physical interface: so-0/0/3, Enabled, Physical link is Up
  Interface index: 131, SNMP ifIndex: 24
   Link-level type: PPP , MTU: 4474, Clocking: Internal, SONET mode, Speed: OC3,
Loopback: None,  FCS: 16 ,
  Payload scrambler: Enabled
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
   Link flags   : Keepalives
  Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
  Keepalive: Input: 736827 (00:00:03 ago), Output: 736972 (00:00:05 ago)
  LCP state: Opened
  NCP state: inet: Opened, inet6: Not-configured, iso: Opened, mpls: Opened
  CHAP state: Not-configured
  CoS queues     : 4 supported
  Last flapped   : 2004-07-21 16:08:01 PDT (10w5d 19:57 ago)
  Input rate     : 40 bps (0 pps)
  Output rate    : 48 bps (0 pps)
  SONET alarms   : None
  SONET defects  : None

   Logical interface so-0/0/3.0 (Index 70) (SNMP ifIndex 51)
    Flags: Point-To-Point SNMP-Traps  Encapsulation: PPP
    Protocol inet, MTU: 4470
      Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.1.36.0/30, Local: 10.1.36.1, Broadcast: 10.1.36.3
    Protocol iso, MTU: 4470
      Flags: None
    Protocol mpls, MTU: 4458
      Flags: None
```

Meaning Sample Output 1 from egress router **R6** shows that there are no SONET alarms or defects (**none**), the states are all **OK**, and the path trace shows the distant end (**R3 so-0.0.0**), indicating that the physical link is up. However, the logical link is down, and the link-level type is Cisco HDLC.

Sample Output 2 from transit router **R3** shows that the link-level type is PPP, indicating that the encapsulation types are mismatched, resulting in the LSP going down.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the encapsulation types are mismatched.

Solution To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/3]
user@R1# show
user@R1# delete encapsulation
user@R1# show
user@R1# commit
```

Sampel Output

```
[edit interfaces so-0/0/3]
user@R6# show
encapsulation cisco-hdlc;
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# delete encapsulation

[edit interfaces so-0/0/3]
user@R6# show
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# commit
commit complete
```

Meaning The sample output from egress router **R6** shows that the Cisco HDLC was incorrectly configured on interface **so-0/0/3** which prevented the LSP from using the intended path. The problem was corrected when the **encapsulation** statement was deleted and the configuration committed.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the data link layer has been resolved.

Action From the ingress, egress, and transit routers, verify that the LSP is up and traversing the network as expected:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

Meaning Sample Outputs 1 and 2 from ingress router **R1** and egress router **R6,** respectively, show that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 3 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**.

Sample Output 4 shows the interfaces that were deactivated on the ingress, egress, and transit routers, forcing the LSP to take the intended path. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive)** as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name** *name* or **show mpls lsp name** *name* **extensive).**

Action To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1 , State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
   ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
```

```
  Primary                  State: Dn
    Will be enqueued for recomputation in 15 second(s).
    140 Sep 30 12:01:12 CSPF failed: no route toward 10.0.0.6[26 times]
   139 Sep 30 11:48:57 Deselected as active
   138 Sep 30 11:48:56 CSPF failed: no route toward 10.0.0.6

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output from ingress router **R1** shows the LSPs within which it participates. The ingress LSP is down, without a path from **R1** to **R6.** Because a reverse LSP is configured in the network shown in Figure 113 on page 1315, we would expect an egress LSP session to be up. However, **R1** does not have any egress LSPs, indicating that the LSP from **R6** to **R1** is not functioning.

Verify Interfaces

Purpose From your network topology, determine the adjacent interfaces through which the LSP is meant to traverse, and examine the output for the encapsulation type, PPP options, FCS size, and whether keepalive frames are enabled or disabled

NOTE: Before you proceed with this step, check the physical layer to ensure that the problem is not in the physical layer.

Action To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show interfaces type-fpc/pic/port extensive
user@host> show interfaces type-fpc/pic/port
```

Sample Output 1

```
user@R6> show interfaces so-0/0/3 extensive
Physical interface: so-0/0/3, Enabled, Physical link is Up
```

```

     Flags: None
   Protocol mpls, MTU: 4458, Generation: 48, Route table: 0
     Flags: None
```

Sample Output 2

```
user@R3> show interfaces so-0/0/3
Physical interface: so-0/0/3, Enabled, Physical link is Up
  Interface index: 131, SNMP ifIndex: 24
   Link-level type: PPP , MTU: 4474, Clocking: Internal, SONET mode, Speed: OC3,
Loopback: None,  FCS: 16 ,
  Payload scrambler: Enabled
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
   Link flags   : Keepalives
  Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
  Keepalive: Input: 736827 (00:00:03 ago), Output: 736972 (00:00:05 ago)
  LCP state: Opened
  NCP state: inet: Opened, inet6: Not-configured, iso: Opened, mpls: Opened
  CHAP state: Not-configured
  CoS queues     : 4 supported
  Last flapped   : 2004-07-21 16:08:01 PDT (10w5d 19:57 ago)
  Input rate     : 40 bps (0 pps)
  Output rate    : 48 bps (0 pps)
  SONET alarms   : None
  SONET defects  : None

   Logical interface so-0/0/3.0 (Index 70) (SNMP ifIndex 51)
    Flags: Point-To-Point SNMP-Traps  Encapsulation: PPP
    Protocol inet, MTU: 4470
      Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.1.36.0/30, Local: 10.1.36.1, Broadcast: 10.1.36.3
    Protocol iso, MTU: 4470
      Flags: None
    Protocol mpls, MTU: 4458
      Flags: None
```

Meaning Sample Output 1 from egress router **R6** shows that there are no SONET alarms or defects (**none**), the states are all **OK**, and the path trace shows the distant end (**R3 so-0.0.0**), indicating that the physical link is up. However, the logical link is down, and the link-level type is Cisco HDLC.

Sample Output 2 from transit router **R3** shows that the link-level type is PPP, indicating that the encapsulation types are mismatched, resulting in the LSP going down.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the encapsulation types are mismatched.

Solution To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/3]
user@R1# show
user@R1# delete encapsulation
user@R1# show
user@R1# commit
```

Sampel Output

```
[edit interfaces so-0/0/3]
user@R6# show
encapsulation cisco-hdlc;
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# delete encapsulation

[edit interfaces so-0/0/3]
user@R6# show
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# commit
commit complete
```

Meaning The sample output from egress router **R6** shows that the Cisco HDLC was incorrectly configured on interface **so-0/0/3** which prevented the LSP from using the intended path. The problem was corrected when the **encapsulation** statement was deleted and the configuration committed.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the data link layer has been resolved.

Action From the ingress, egress, and transit routers, verify that the LSP is up and traversing the network as expected:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

interface so-0/0/3.0;
```

Meaning Sample Outputs 1 and 2 from ingress router **R1** and egress router **R6,** respectively, show that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 3 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**.

Sample Output 4 shows the interfaces that were deactivated on the ingress, egress, and transit routers, forcing the LSP to take the intended path. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Checklist for Verifying the IP and IGP Layers

Problem **Description:** This checklist provides the steps and commands for investigating a problem at the Internet Protocol (IP) and interior gateway protocol (IGP) layers of the layered Multiprotocol Label Switching (MPLS) model. The checklist provides links to an overview of the IP and IGP layers and more detailed information about the commands used to investigate the problem.

Solution Table 51 on page 1334 provides commands for verifying the IP and IGP layers.

Table 51: Checklist for Verifying the IP and IGP Layers

Tasks	Command or Action
"Verifying the IP and IGP Layers" on page 1336	
"Verifying the IP Layer" on page 1338	
1. Verify the LSP on page 1339	**show mpls lsp extensive**
2. Verify IP Addressing on page 1340	**show interfaces terse**
3. Verify Neighbors or Adjacencies at the IP Layer on page 1342	**show ospf neighbor extensive** **show isis adjacency extensive**

Table 51: Checklist for Verifying the IP and IGP Layers (continued)

Tasks	Command or Action
4. Take Appropriate Action on page 1345	The following sequence of commands addresses the specific problem described in this topic: **[edit interfaces so-0/0/2]** **show** **rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30** **show** **commit**
5. Verify the LSP Again on page 1346	**show mpls lsp extensive**
"Verifying the OSPF Protocol" on page 1359	
1. Verify the LSP on page 1359	**show mpls lsp extensive**
2. Verify OSPF Interfaces on page 1363	**show ospf interface**
3. Verify OSPF Neighbors on page 1364	**show ospf neighbor**
4. *Verifying an OSPF Configuration*	**show configuration protocols ospf**
5. *Taking Appropriate Action for Resolving the Network Problem*	The following sequence of commands addresses the specific problem described in this topic: **[edit]** **edit protocols ospf area 0.0.0.0** **[edit protocols ospf area 0.0.0.0]** **set interface lo0** **set interface lo0 passive** **up** **[edit protocols ospf]** **set traffic-engineering** **show** **commit**
6. Verify the LSP Again on page 1367	**show mpls lsp extensive**
Verifying the IS-IS Protocol	
1. Verify the LSP on page 1378	**show mpls lsp extensive**
2. Verify IS-IS Adjacencies and Interfaces on page 1379	**show isis adjacency** **show isis interface**
3. Verify the IS-IS Configuration on page 1381	**show configuration protocols isis**

Table 51: Checklist for Verifying the IP and IGP Layers (continued)

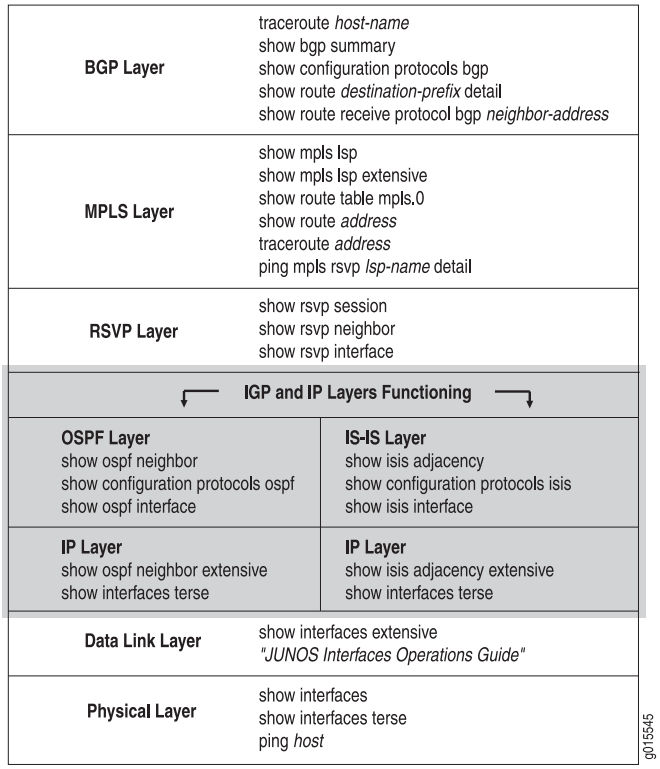
Tasks	Command or Action
4. *Taking Appropriate Action for Resolving the Network Problem*	The following sequence of commands addresses the specific problem described in this topic: **edit** **[edit]** **edit protocols isis** **[edit protocols isis]** **show** **delete level 2** **set level 1 disable** **show** **commit** **run show isis adjacency**
5. Verify the LSP Again on page 1382	**show mpls lsp extensive**

Verifying the IP and IGP Layers

Problem **Description:** After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical or data link layers. Continue investigating the problem at the IP and IGP layers of the network.

Figure 114 on page 1337 illustrates the IP and IGP layers of the layered MPLS model.

Figure 114: IP and IGP Layers



Solution At the IP and IGP layers, you must check the following:

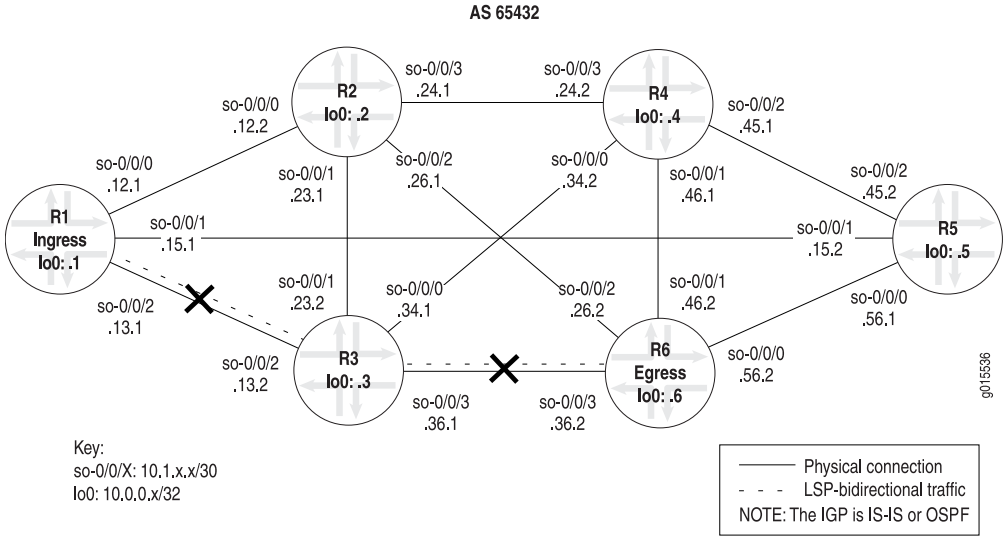
- Interfaces have correct IP addressing, and the IGP neighbors or adjacencies are established.
- Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) protocols are configured and running correctly.
  - If the OSPF protocol is configured, check the IP layer first, then the OSPF configuration, making sure that the protocol, interfaces, and traffic engineering are configured correctly.
  - If the IS-IS protocol is configured, it doesn't matter whether you check IS-IS or IP first because both protocols are independent of each other. Verify that IS-IS adjacencies are up, and that the interfaces and IS-IS protocol are configured correctly.

NOTE: The IS-IS protocol has traffic engineering enabled by default.

If the network is not functioning at the IP or IGP layers, the LSP does not work as configured.

Figure 115 on page 1338 illustrates the MPLS network used in this topic.

Figure 115: MPLS Network Broken at the IP and IGP Layers



The network shown in Figure 115 on page 1338 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6**, through **R3**, to **R1**, creating bidirectional traffic. The crosses in Figure 115 on page 1338 indicate where the LSP is not working because of the following problems at the IP and IGP layer:

- An IP address is configured incorrectly on the ingress router (**R1**).
- The OSPF protocol is configured with a router ID (RID) but without the loopback (**lo0**) interface, and traffic engineering is missing from the transit router (**R3**).
- Levels in the IS-IS network are mismatched.

Related Documentation

To check the IP and IGP layers, follow these steps:

- Verifying the IP Layer on page 1338
- Verifying the OSPF Protocol on page 1359
- *Verifying the IS-IS Protocol*

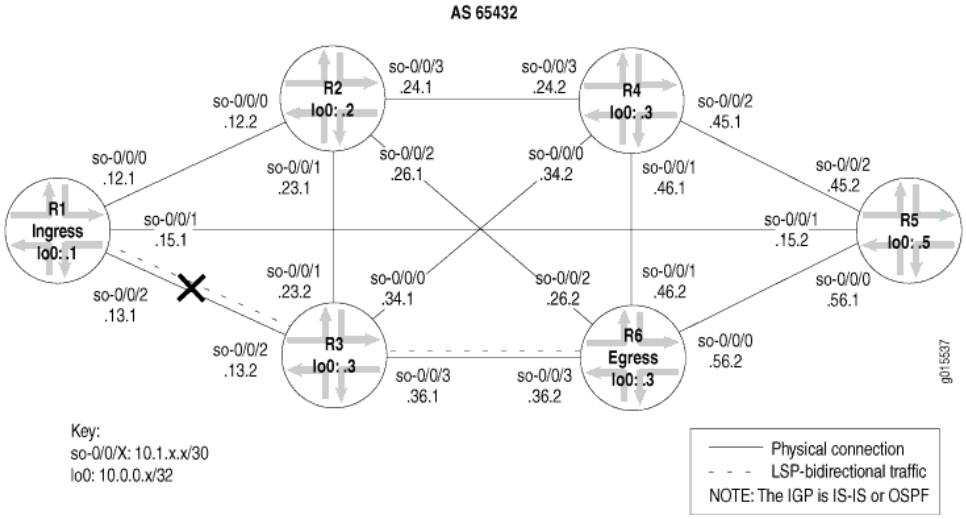
Verifying the IP Layer

Purpose

You can check the IP layer before or after you check the interior gateway protocol (IGP) layer, depending on whether you have OSPF or IS-IS configured as the IGP. If your MPLS network is configured with OSPF as the IGP, you must first verify the IP layer, checking that the interfaces have correct IP addressing and that the OSPF neighbors are established before you check the OSPF layer.

If you have IS-IS configured as the IGP in your MPLS network, you can verify either the IP layer or the IS-IS protocol layer first. The order in which you check the IP or IS-IS layer does not affect the results.

Figure 116: MPLS Network Broken at the IP Layer



The cross in Figure 116 on page 1339 indicates where the LSP is broken because of the incorrect configuration of an IP address on ingress router **R1**.

1. Verify the LSP on page 1339
2. Verify IP Addressing on page 1340
3. Verify Neighbors or Adjacencies at the IP Layer on page 1342
4. Take Appropriate Action on page 1345
5. Verify the LSP Again on page 1346

Verify the LSP

Purpose After configuring the LSP, you must verify that the LSP is up. LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive**) as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name** *name* or **show mpls lsp name** *name* **extensive**).

Action To verify that the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
```

```
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
   ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                  State: Dn
    Will be enqueued for recomputation in 25 second(s).
   44 Oct 15 16:56:11 CSPF failed:  no route toward 10.0.0.6 [2685 times]
   43 Oct 14 19:07:09 Clear Call
   42 Oct 14 19:06:56 Deselected as active
   41 Oct 14 19:06:56 10.1.12.1: MPLS label allocation failure
   40 Oct 14 19:06:56 Down
   39 Oct 14 18:43:43 Selected as active path
   38 Oct 14 18:43:43 Record Route:  10.1.13.2 10.1.36.2
   37 Oct 14 18:43:43 Up
   [...Output truncated...]
  Created: Thu Oct 14 16:04:33 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed , Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed , Up 0, Down 0
```

Meaning The sample output from ingress router **R1** shows that an MPLS label allocation failure occurred and the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.6** on **R6**.

Verify IP Addressing

Purpose When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that OSPF neighbors or IS-IS adjacencies are established. In this example, an IP address is configured incorrectly on the ingress router (**R1**).

Action To verify IP addressing, enter the following command from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
```

Sample Output

```
user@R1> show interfaces terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up

                                    iso
                                    mpls
so-0/0/2                up    up
so-0/0/2.0              up    up   inet  10.1.26.2/30
                                    iso
                                    mpls
so-0/0/3                up    up
so-0/0/3.0              up    up   inet  10.1.36.2/30
                                    iso
                                    mpls
lo0.0                   up    up   inet  10.0.0.6
                                    iso   49.0004.1000.0000.0006.00
```

Meaning The sample output shows that the IP addresses for interface **so-0/0/2.0** on **R1** and interface **so-0/0/2.0** on **R3** are identical. Interface IP addresses within a network must be unique for the interface to be identified correctly.

Verify Neighbors or Adjacencies at the IP Layer

Purpose If the IP addressing is configured incorrectly then the OSPF neighbors or IS-IS adjacencies both need to be checked to determine if one or both of them are established.

Action To verify neighbors (OSPF) or adjacencies (IS-IS), enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor extensive
user@host> show isis adjacency extensive
```

Sample Output 1

```
user@R1> show ospf neighbor extensive

```

Meaning Sample Output 1 from the ingress, transit, and egress routers shows that **R1** and **R3** are not established OSPF neighbors. Considering that the two interfaces **so-0/0/2.0** (**R1** and **R3**) are configured with identical IP addresses, you would expect this. The OSPF protocol routes IP packets based solely on the destination IP address contained in the IP packet header. Therefore, identical IP addresses in the autonomous system (AS) result in neighbors not establishing.

Sample Output 2 from the ingress, transit, and egress routers shows that **R1** and **R3** have established an IS-IS adjacency despite the identical IP addresses configured on interfaces **so-0/0/2.0** on **R1** and **R3**. The IS-IS protocol behaves differently from the OSPF protocol because it does not rely on IP to establish an adjacency. However, if the LSP is not up, it is still useful to check the IP subnet addressing in case there is a mistake in that layer. Correcting the addressing error might bring the LSP back up.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the IP address of an interface on transit router **R2** is incorrectly configured.

Solution To correct the error in this example, enter the following commands:

```
[edit interfaces  so-0/0/2]
user@R1# show
user@R1#  rename unit 0 family inet address 10.1.13.2/30 to address  10.1.13.1/30
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.2/30;  <<< Incorrect IP address
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30

[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {

[edit interfaces so-0/0/2]
user@R1# commit
commit complete
```

Meaning The sample output shows that interface **so-0/0/2** on ingress router **R1** is now configured with the correct IP address. This correction results in unique subnet IP addresses for all interfaces in the MPLS network in Figure 115 on page 1338, and the possibility that the LSP might come up.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the OSPF protocol has been resolved.

Action To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up. The output shows that the egress LSP session **R6-to-R1** received and sent a recovery label.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1.** Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify the LSP

Purpose After configuring the LSP, you must verify that the LSP is up. LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive)** as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive)**.

Action To verify that the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1>  show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6

```

Meaning The sample output from ingress router **R1** shows that an MPLS label allocation failure occurred and the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.6** on **R6**.

Verify IP Addressing

Purpose When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that OSPF neighbors or IS-IS adjacencies are established. In this example, an IP address is configured incorrectly on the ingress router (**R1**).

Action To verify IP addressing, enter the following command from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
```

Sample Output

```
user@R1> show interfaces terse
Interface               Admin Link Proto Local                 Remote

so-0/0/3                up    up
so-0/0/3.0              up    up   inet  10.1.36.2/30
                                  iso
                                  mpls
lo0.0                   up    up   inet  10.0.0.6
                                  iso   49.0004.1000.0000.0006.00
```

Meaning The sample output shows that the IP addresses for interface **so-0/0/2.0** on **R1** and interface **so-0/0/2.0** on **R3** are identical. Interface IP addresses within a network must be unique for the interface to be identified correctly.

Verify Neighbors or Adjacencies at the IP Layer

Purpose If the IP addressing is configured incorrectly then the OSPF neighbors or IS-IS adjacencies both need to be checked to determine if one or both of them are established.

Action To verify neighbors (OSPF) or adjacencies (IS-IS), enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor extensive
user@host> show isis adjacency extensive
```

Sample Output 1

```
user@R1> show ospf neighbor extensive

```

Meaning Sample Output 1 from the ingress, transit, and egress routers shows that **R1** and **R3** are not established OSPF neighbors. Considering that the two interfaces **so-0/0/2.0** (**R1** and **R3**) are configured with identical IP addresses, you would expect this. The OSPF protocol routes IP packets based solely on the destination IP address contained in the IP packet header. Therefore, identical IP addresses in the autonomous system (AS) result in neighbors not establishing.

Sample Output 2 from the ingress, transit, and egress routers shows that **R1** and **R3** have established an IS-IS adjacency despite the identical IP addresses configured on interfaces **so-0/0/2.0** on **R1** and **R3**. The IS-IS protocol behaves differently from the OSPF protocol because it does not rely on IP to establish an adjacency. However, if the LSP is not up, it is still useful to check the IP subnet addressing in case there is a mistake in that layer. Correcting the addressing error might bring the LSP back up.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the IP address of an interface on transit router **R2** is incorrectly configured.

Solution To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/2]
user@R1# show
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.2/30;  <<< Incorrect IP address
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30

[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.1/30;  <<< Correct IP address.
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# commit
commit complete
```

Meaning The sample output shows that interface **so-0/0/2** on ingress router **R1** is now configured with the correct IP address. This correction results in unique subnet IP addresses for all

interfaces in the MPLS network in Figure 115 on page 1338, and the possibility that the LSP might come up.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the OSPF protocol has been resolved.

Action To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up. The output shows that the egress LSP session **R6-to-R1** received and sent a recovery label.

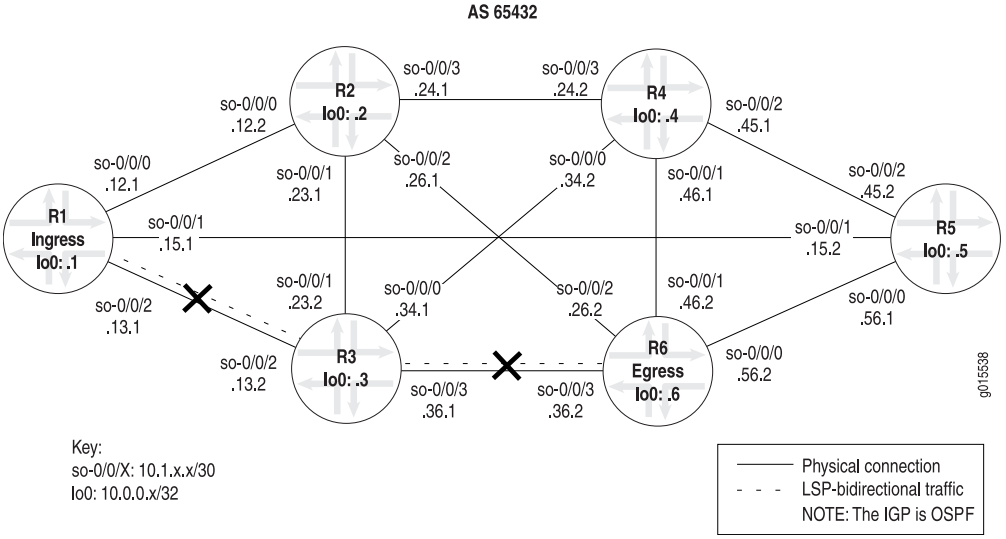
Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1.** Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verifying the OSPF Protocol

Purpose After you have verified that the LSP is down, and the cause is not in the physical, datalink, or IP layer, verify the OSPF configuration. Check the routers in your network to ensure that the interfaces and the OSPF protocol are configured correctly, and that the neighbors are established.

Figure 117: MPLS Network Broken at the OSPF Protocol Layer



1. Verify the LSP on page 1359
2. Verify OSPF Interfaces on page 1363
3. Verify OSPF Neighbors on page 1364
4. Verify the OSPF Protocol Configuration on page 1365
5. Take Appropriate Action on page 1366
6. Verify the LSP Again on page 1367

Verify the LSP

Purpose Confirm that interfaces are configured for OSPF, the OSPF protocol is configured correctly and that neighbors are established.

Action To verify the LSP, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

Meaning Sample Outputs 1, 2, and 3 show that the LSP and the reverse LSP are down:

- Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** does not have a route towards the destination (**R6**).
- Sample Output 2 from transit router **R3** shows that there are no LSP sessions.
- Sample Output 3 from egress router **R6** also shows that reverse LSP **R6-to-R1** is down.

Sample Outputs 4, 5, and 6 show that the LSP is up and the reverse LSP is down:

- Sample Output 4 from ingress router **R1** shows that LSP **R1-to-R6** is up and there are no egress LSP sessions.
- Sample Output 5 from transit router R3 shows that there is one ingress LSP session (**R1-to-R6)** and no egress LSP sessions.
- Sample Output 6 from egress router **R6** shows that LSP **R6-to-R1** is down due to an MPLS label allocation failure.

Verify OSPF Interfaces

Purpose After you have verified that the LSP is down, and the cause is not in the physical, data link, or IP layer, check the routers in your network to determine that all relevant OSPF interfaces are configured correctly.

Action To verify OSPF interfaces, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf interface
```

Sample Output 1

```
user@R1> show ospf interface
Interface       State     Area            DR ID           BDR ID       Nbrs

so-0/0/3.0      PtToPt   0.0.0.0         0.0.0.0         0.0.0.0         1
```

Meaning Sample Output 1 shows that all interfaces on all routers are in the correct area (**0.0.0.0**), and the loopback (**lo0**) interface is missing from the list of interfaces on all routers. The missing loopback (**lo0**) interface is a problem in this configuration.

In an MPLS network configured with OSPF as the IGP, when you manually configure the RID, it is important to explicitly configure the loopback interface at the [**edit protocols ospf**] hierarchy level. If the RID is not manually configured, OSPF automatically advertises the loopback (**lo0**) interface. In the configuration of all the routers in this network, the RID is configured manually, therefore, the loopback (**lo0**) interface must be explicitly configured at the [**edit protocols ospf**] hierarchy level. In addition, the loopback (**lo0**) interface is configured with the **passive** statement to ensure that the protocols are not run over the loopback (**lo0**) interface and it is correctly advertised throughout the network.

Sample Output 2 shows that all the relevant interfaces on the ingress, transit, and egress routers, including the loopback (**lo0**) interface, are in the correct area (**0.0.0.0**). Because the configuration of the interfaces is correct, further investigation is required to determine the reason for the LSP problem.

Verify OSPF Neighbors

Purpose After you have checked OSPF interfaces, check your network topology to determine that all relevant neighbors are established.

Action To verify OSPF neighbors, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor
```

Sample Output

```
user@R1> show ospf neighbor
  Address         Interface             State      ID              Pri  Dead
10.1.12.2         so-0/0/0.0            Full       10.0.0.2        128   39
10.1.15.2         so-0/0/1.0            Full       10.0.0.5        128   39
10.1.13.2         so-0/0/2.0            Full       10.0.0.3        128   33

user@R3> show ospf neighbor
Address         Interface             State      ID              Pri  Dead
10.1.34.2         so-0/0/0.0            Full       10.0.0.4        128   33
10.1.23.1         so-0/0/1.0            Full       10.0.0.2        128   33
10.1.13.1         so-0/0/2.0            Full       10.0.0.1        128   33
10.1.36.2         so-0/0/3.0            Full       10.0.0.6        128   33

user@R6> show ospf neighbor
```

```
Address         Interface             State      ID              Pri  Dead
10.1.56.1        so-0/0/0.0             Full      10.0.0.5          128   30
10.1.46.1        so-0/0/1.0             Full      10.0.0.4          128   38
10.1.26.1        so-0/0/2.0             Full      10.0.0.2          128   34
10.1.36.1        so-0/0/3.0             Full      10.0.0.3          128   35
```

Meaning The sample output shows that all neighbors are fully adjacent, indicating that each router has exchanged a full copy of its link-state database with the other routers, passed through several neighbor states, and become fully adjacent. These adjacencies are created by router link and network link advertisements.

Verify the OSPF Protocol Configuration

Purpose After you have checked interfaces and neighbors, verify the OSPF protocol configuration.

Action To verify the OSPF protocol configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols ospf
```

Sample Output 1

```
user@R1> show configuration protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;       <<< The loopback interface (lo0) is missing
}
```

Sample Output 2

```
user@R3>show configuration protocols ospf
area 0.0.0.0 { <<< traffic engineering is missing
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
    interface so-0/0/3.0;      <<< The loopback interface (lo0) is missing
}
```

Sample Output 3

```
user@R6> show configuration protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
```

```
    interface so-0/0/3.0;      <<< The loopback interface (lo0) is missing
}
```

Meaning All three sample outputs show that the loopback interface is not included on any of the routers. Including the loopback (**lo0**) interface is important when you have the RID manually configured.

In addition, Sample Output 2 from transit router **R3** shows that traffic engineering is not configured. Traffic engineering must be manually enabled when you configure OSPF for an MPLS network.

Because the loopback interface and traffic engineering are missing from the OSPF protocol configuration, the LSP does not work as expected.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the loopback (**lo0**) interface is missing from all routers, and traffic engineering is missing from the transit router (**R3**).

Solution To correct the errors in this example, follow these steps:

1. Include the loopback (**lo0**) interface on all routers that have the RID manually configured. Enter the following configuration mode commands:

   ```
   [edit]
   user@R3# edit protocols ospf area 0.0.0.0
   [edit protocols ospf area 0.0.0.0]
   user@R3# set interface lo0
   user@R3# set interface lo0 passive
   ```

2. Move up one level of the configuration hierarchy:

   ```
   [edit protocols ospf area 0.0.0.0]
   user@R3# up
   [edit protocols ospf]
   user @R3#
   ```

3. Include traffic engineering on the transit router (**R3**). Enter the following configuration mode command:

   ```
   [edit protocols ospf]
   user@R3#  set traffic-engineering
   ```

4. On all routers, verify and commit the configuration:

   ```
   user@R3# show
   user@R3# commit
   ```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols ospf area 0.0.0.0

[edit protocols ospf area 0.0.0.0]
user@R3#  set interface lo0

[edit protocols ospf area 0.0.0.0]
user@R3# set interface lo0 passive

[edit protocols ospf area 0.0.0.0]
user@R3# up

[edit protocols ospf]
user@R3# set traffic-engineering

[edit protocols ospf]
user@R3# show
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
     interface lo0.0; {
         passive
}
}

[edit protocols ospf]
user@R3# commit
commit complete
```

Meaning The sample output shows that the loopback (**lo0**) interface and traffic engineering are now correctly configured on transit router **R3**. When traffic engineering is configured, OSPF advertises the traffic engineering capabilities of the links.

In the OSPF configuration, you must manually include the loopback (**lo0**) interface and set it to passive when you manually configure an RID. Setting the loopback (**lo0**) interface to passive ensures that protocols are not run over the loopback (**lo0**) interface and the loopback (**lo0**) interface is advertised correctly throughout the network.. If you do not manually configure an RID, there is no need to explicitly include the loopback interface because the OSPF protocol automatically includes the loopback (**lo0**) interface.

For more information about configuring LSPs and MPLS, see the *Junos MPLS Applications Configuration Guide*.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the IS-IS protocol has been resolved.

Action To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive

Meaning Sample Outputs 1, 2, and 3 show that the LSP and the reverse LSP are down:

- Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** does not have a route towards the destination (**R6**).
- Sample Output 2 from transit router **R3** shows that there are no LSP sessions.
- Sample Output 3 from egress router **R6** also shows that reverse LSP **R6-to-R1** is down.

Sample Outputs 4, 5, and 6 show that the LSP is up and the reverse LSP is down:

- Sample Output 4 from ingress router **R1** shows that LSP **R1-to-R6** is up and there are no egress LSP sessions.
- Sample Output 5 from transit router R3 shows that there is one ingress LSP session (**R1-to-R6)** and no egress LSP sessions.
- Sample Output 6 from egress router **R6** shows that LSP **R6-to-R1** is down due to an MPLS label allocation failure.

Verify OSPF Interfaces

Purpose After you have verified that the LSP is down, and the cause is not in the physical, data link, or IP layer, check the routers in your network to determine that all relevant OSPF interfaces are configured correctly.

Action To verify OSPF interfaces, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf interface
```

Sample Output 1

```
user@R1> show ospf interface
Interface      State     Area           DR ID          BDR ID       Nbrs
so-0/0/0.0      PtToPt   0.0.0.0        0.0.0.0        0.0.0.0         1

```

Meaning Sample Output 1 shows that all interfaces on all routers are in the correct area (**0.0.0.0**), and the loopback (**lo0**) interface is missing from the list of interfaces on all routers. The missing loopback (**lo0**) interface is a problem in this configuration.

In an MPLS network configured with OSPF as the IGP, when you manually configure the RID, it is important to explicitly configure the loopback interface at the [**edit protocols ospf**] hierarchy level. If the RID is not manually configured, OSPF automatically advertises the loopback (**lo0**) interface. In the configuration of all the routers in this network, the RID is configured manually, therefore, the loopback (**lo0**) interface must be explicitly configured at the [**edit protocols ospf**] hierarchy level. In addition, the loopback (**lo0**) interface is configured with the **passive** statement to ensure that the protocols are not run over the loopback (**lo0**) interface and it is correctly advertised throughout the network.

Sample Output 2 shows that all the relevant interfaces on the ingress, transit, and egress routers, including the loopback (**lo0**) interface, are in the correct area (**0.0.0.0**). Because the configuration of the interfaces is correct, further investigation is required to determine the reason for the LSP problem.

Verify OSPF Neighbors

Purpose After you have checked OSPF interfaces, check your network topology to determine that all relevant neighbors are established.

Action To verify OSPF neighbors, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor
```

Sample Output

```
user@R1> show ospf neighbor
  Address          Interface              State      ID               Pri  Dead
10.1.12.2          so-0/0/0.0             Full       10.0.0.2         128   39
10.1.15.2          so-0/0/1.0             Full       10.0.0.5         128   39
10.1.13.2          so-0/0/2.0             Full       10.0.0.3         128   33

user@R3> show ospf neighbor
Address          Interface              State      ID               Pri  Dead
10.1.34.2          so-0/0/0.0               Full       10.0.0.4         128   33
10.1.23.1          so-0/0/1.0               Full       10.0.0.2         128   33
10.1.13.1          so-0/0/2.0               Full       10.0.0.1         128   33
10.1.36.2          so-0/0/3.0               Full       10.0.0.6         128   33

user@R6> show ospf neighbor
Address          Interface              State      ID               Pri  Dead
10.1.56.1          so-0/0/0.0               Full       10.0.0.5         128   30
10.1.46.1          so-0/0/1.0               Full       10.0.0.4         128   38
10.1.26.1          so-0/0/2.0               Full       10.0.0.2         128   34
10.1.36.1          so-0/0/3.0               Full       10.0.0.3         128   35
```

Meaning The sample output shows that all neighbors are fully adjacent, indicating that each router has exchanged a full copy of its link-state database with the other routers, passed through several neighbor states, and become fully adjacent. These adjacencies are created by router link and network link advertisements.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the IS-IS protocol has been resolved.

Action To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive

Total 0 displayed, Up 0, Down 0
```

Meaning The sample output from ingress router **R1** and egress router **R6** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**. In addition, the sample output from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6**, and the other from **R6** to **R1**.

Verify the LSP

Purpose Confirm that interfaces are configured for IS-IS, that the IS-IS protocol is configured correctly, and that adjacencies are established.

Action To verify the label-switched path (LSP), enter the following command on the ingress, transit, and egress routers:

```
user@host>  show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning The sample output shows that LSP **R1-to-R6** and the reverse LSP **R6-to-R1** are down, and there are no LSP sessions on transit router R3.

Verify IS-IS Adjacencies and Interfaces

Purpose When you check the IS-IS layer, you verify that IS-IS adjacencies are up and that the IS-IS interfaces are included at the protocol level.

Action To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show isis adjacency
user@host> show isis interface
```

Sample Output 1

```
user@R1> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R2             2 Up                   20
so-0/0/1.0            R5             2 Up                   23
so-0/0/2.0            R3             2 Up                   26

user@R3> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R4             2 Up                   23
so-0/0/1.0            R2             2 Up                   21
so-0/0/2.0            R1             2 Up                   19
so-0/0/3.0      R6      2 Down                    0

user@R6> show isis adjacency
IS-IS instance is not running
```

Sample Output 2

```
user@R1> show isis interface
IS-IS interface database:

so-0/0/3.0            1    0x1 Point to Point     Disabled             10/10
```

Meaning Sample Output 1 shows that ingress router R1 has established adjacencies with the relevant routers. Transit router R3 does not have an adjacency with egress router R6, and egress router R6 has no adjacencies established in the network shown in Figure 115 on page 1338, indicating that the problem might be at the IS-IS protocol level.

Sample Output 2 shows that R1 and R2 are Level 2 routers, in contrast to R6 which is a Level 1 router. When a router is configured explicitly as a Level 1 or Level 2 router, it does

not communicate with routers configured at a different level. Level 1 routers communicate with other Level 1 routers within their area, while Level 2 routers communicate with other Level 2 routers, and toward other autonomous systems. Because all the routers in this network are configured for Level 2, they cannot form an adjacency with R6, which is incorrectly configured as a Level 1 router.

Verify the IS-IS Configuration

Purpose When you have determined that the problem is probably at the IS-IS protocol level, check the IS-IS configuration of the routers in your network.

Action To verify the IS-IS configuration, enter the following command from the relevant routers:

```
user@host> show configuration protocols isis
```

Sample Output

```
user@R1> show configuration protocols isis
level 1 disable;
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface lo0.0; {
    passive

user@R3> show configuration protocols isis
level 1 disable;
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
    disable;
}
interface lo0.0; {
    passive

user@R6> show configuration protocols isis
level 2 disable; <<< Incorrect level disabled
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
    disable;
}
interface lo0.0; {
    passive
```

Meaning The sample output shows that R6 has Level 2 disabled, while R1 and R3 have Level 1 disabled. For IS-IS adjacencies to establish, routers need to be at the same level. Another common configuration error is to omit the loopback interface (lo0) from the configuration at the **[edit protocols isis]** hierarchy level. IS-IS does not function correctly if the loopback interface (lo0) is not configured at this level. In addition, including the **passive** statement ensures that protocols are not run over the loopback interface (lo0) and that the loopback interface (lo0) is advertised correctly throughout the network.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the label-switched path (LSP) needs to be checked again to confirm that the problem in the RSVP layer has been resolved.

Action To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

```

Meaning Sample Outputs 1 and 3 from ingress router R1 and egress router R6 show that the LSP is now traversing the network along the expected path, from R1 through R3 to R6, and the reverse LSP, from R6 through R3 to R1. In addition, Sample Output 2 from transit router R3 shows that there are two transit LSP sessions, one from R1 to R6, and the other from R6 to R1.

Checklist for Checking the RSVP Layer

Problem **Description:** This checklist provides the steps and commands for checking the Resource Reservation Protocol (RSVP) layer of the layered Multiprotocol Label Switching (MPLS) model. The checklist provides links to an overview of the RSVP layer and more detailed information about the commands used to investigate the problem.

Table 52 on page 1385 provides commands for checking the RSVP layer.

Table 52: Checklist for Checking the RSVP Layer

Solution

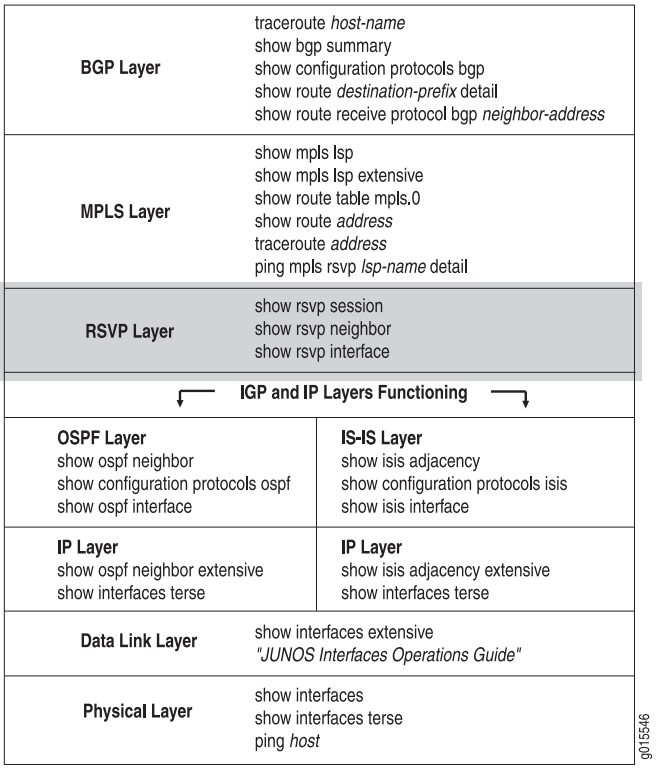
Tasks	Command or Action
"Checking the RSVP Layer" on page 1385	
1. Verify the LSP on page 1388	**show mpls lsp extensive**
2. Verify RSVP Sessions on page 1389	**show rsvp session**
3. Verify RSVP Neighbors on page 1391	**show rsvp neighbor**
4. Verify RSVP Interfaces on page 1392	**show rsvp interface**
5. Verify the RSVP Protocol Configuration on page 1393	**show configuration protocols rsvp**
6. Take Appropriate Action on page 1394	The following sequence of commands addresses the specific problem described in this topic: **[edit]** **edit protocols rsvp** **[edit protocols rsvp]** **show** **set interface *type-fpc/pic/port*** **show** **commit**
7. Verify the LSP Again on page 1395	**show mpls lsp extensive**

Checking the RSVP Layer

Purpose After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical, data link, or Internet Protocol (IP) and interior gateway protocol (IGP) layers. Continue investigating the problem at the RSVP layer of the network.

Figure 118 on page 1386 illustrates the RSVP layer of the layered MPLS model.

Figure 118: Checking the RSVP Layer

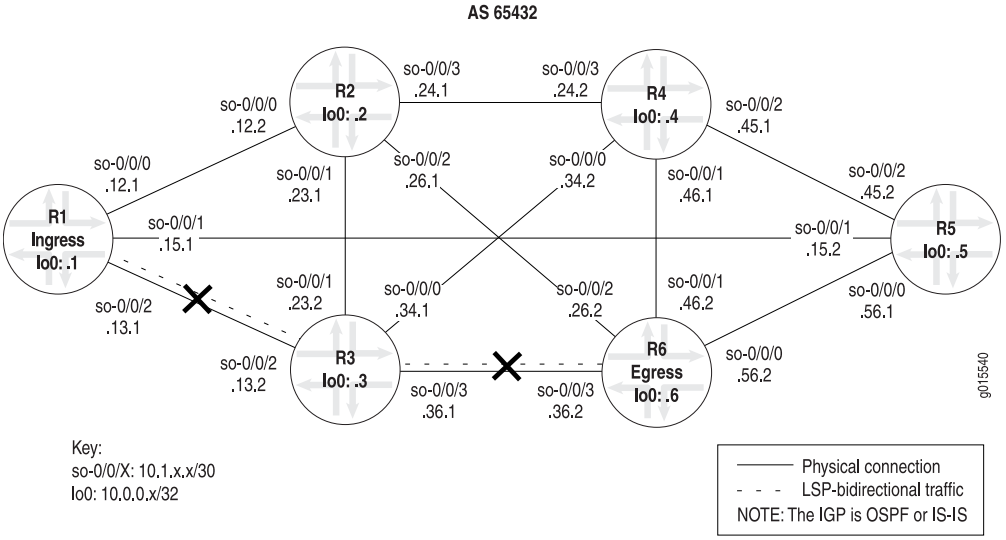


With this layer, you check that dynamic RSVP signaling is occurring as expected, neighbors are connected, and interfaces are configured correctly for RSVP. Check the ingress, egress, and transit routers.

If the network is not functioning at this layer, the LSP does not work as configured.

Figure 119 on page 1387 illustrates the MPLS network used in this topic.

Figure 119: MPLS Network Broken at the RSVP Layer



The network shown in Figure 119 on page 1387 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

The crosses shown in Figure 119 on page 1387 indicate where the LSP is broken. Some possible reasons the LSP is broken might include that dynamic RSVP signaling is not occurring as expected, neighbors are not connected, or interfaces are incorrectly configured for RSVP.

In the network in Figure 119 on page 1387, a configuration error on transit router **R3** prevents the LSP from traversing the network as expected.

To check the RSVP layer, follow these steps:

1. Verify the LSP on page 1388
2. Verify RSVP Sessions on page 1389
3. Verify RSVP Neighbors on page 1391
4. Verify RSVP Interfaces on page 1392
5. Verify the RSVP Protocol Configuration on page 1393
6. Take Appropriate Action on page 1394
7. Verify the LSP Again on page 1395

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive)** as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive).**

Action To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0,  LSPname: R1-to-R6

10.0.0.1
  From: 10.0.0.6, State: Dn, ActiveRoute: 0,  LSPname: R6-to-R1
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn
    Will be enqueued for recomputation in 22 second(s).
```

```
    1 Oct 27 14:59:12  CSPF failed: no route toward 10.0.0.1 [4 times]
  Created: Wed Oct 27 14:57:44 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output shows that the LSP is down in both directions, from **R1** to **R6**, and from **R6** to **R1**. The output from **R1** shows that **R1** is using a no-cspf LSP since it tried to originate the call without being able to reach the destination. The output from **R6** shows that the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.1**.

Verify RSVP Sessions

Purpose When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, the LSP does not work as configured.

Action To verify currently active RSVP sessions, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp session
```

Sample Output 1

```
user@R1> show rsvp session

10.0.0.1        10.0.0.6        Up     1 1 FF  100784        3  R6-to-R1
10.0.0.6        10.0.0.1        Up     1 1 FF  100768        3  R1-to-R6
Total 2 displayed,  Up 2 , Down 0

user@R6>  show rsvp session
Ingress RSVP: 1 sessions
To              From            State Rt Style Labelin Labelout LSPname
10.0.0.1        10.0.0.6        Up     1 1 FF       -   100784  R6-to-R1
Total 1 displayed,  Up 1 , Down 0

Egress RSVP: 1 sessions
To              From            State Rt Style Labelin Labelout LSPname
10.0.0.6        10.0.0.1        Up     0 1 FF       3        -  R1-to-R6
Total 1 displayed,  Up 1 , Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from all routers shows that no RSVP sessions were successfully created, even though the LSP **R6-to-R1** is configured. Continue investigating the problem in "Verify RSVP Neighbors" on page 1391.

In contrast to Sample Output 1and to illustrate correct output, Sample Output 2 shows the output from the ingress, transit, and egress routers when the RSVP configuration is correct, and the LSP is traversing the network as configured. **R1** and **R6** both show an ingress and egress RSVP session, with the LSP **R1-to-R6**, and the reverse LSP **R6-to-R1**. Transit router **R3** shows two transit RSVP sessions.

Verify RSVP Neighbors

Purpose Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors unless the RSVP configuration is removed from the router.

Action To verify RSVP neighbors, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp neighbor
```

Sample Output 1

```
user@R1> show rsvp neighbor
RSVP neighbor: 1 learned
Address           Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.2           10   1/0         9:22        9    64/64   32

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address           Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1            0  1/0       28:20        9   190/190  41
10.1.36.2         16:50   1/1        15:37        9   105/78   38

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address           Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1         17:30   1/1        16:15        9   104/78   39
```

Sample Output 2

```
user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address           Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1            5   1/0         9:14        9    63/63   33
10.1.36.2            5   1/0         9:05        9    62/62   32

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address           Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1            5   1/0        8:54        9    61/61   32
```

Meaning Sample Output 1 shows that **R1** and **R6** have one RSVP neighbor each, **R3**. However, the values in the **Up/Dn** field are different. **R1** has a value of **1/0** and **R6** has a value of **1/1**,

indicating that **R1** is an active neighbor with **R3**, but **R6** is not. When the up count is one more than the down count, the neighbor is active; if the values are equal, the neighbor is down. The values for **R6** are equal, **1/1**, indicating that the neighbor **R3** is down.

Transit router **R3** knows about two neighbors, **R1** and **R6**. The **Up/Dn** field indicates that **R1** is an active neighbor and **R6** is down. At this point it is not possible to determine if the problem resides with **R3** or **R6**, because both neighbors are not active. Continue investigating the problem in "Verify RSVP Interfaces" on page 1392.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the correct neighbor relationship between transit router **R3** and egress router **R6**. The **Up/Dn** field shows the up count to be one more than the down count, **1/0**, indicating that the neighbors are active.

Verify RSVP Interfaces

Purpose Display the status of each interface on which RSVP is enabled to determine where the configuration error occurred.

Action To verify the status of RSVP interfaces, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show rsvp interface
RSVP interface: 3 active
                    Active  Subscr- Static      Available   Reserved    Highwater
Interface   State   resv    iption  BW          BW          BW          mark

so-0/0/2.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/3.0  Up          1    100%  155.52Mbps  155.52Mbps  0bps        0bps
```

Meaning Sample Output 1 shows that even though each router has interfaces that are up and have RSVP active, there are no reservations (**Active resv**) on any of the routers. In this example, we would expect at least one reservation on the ingress and egress routers, and two reservations on the transit router.

In addition, interface **so-0/0/3** on transit router **R3** is not included in the configuration. The inclusion of this interface is critical to the success of the LSP.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the relevant interfaces with active reservations.

Verify the RSVP Protocol Configuration

Purpose After you have checked RSVP sessions, interfaces, neighbors, and determined that there might be a configuration error, verify the RSVP protocol configuration.

Action To verify the RSVP configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols rsvp
```

Sample Output

```
user@R1> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}

user@R6> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;
interface fxp0.0 {
    disable;
}
```

Meaning The sample output shows that **R3** has interface **so-0/0/3.0** missing from the RSVP protocol configuration. This interface is critical for the correct functioning of the LSP.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is missing from the configuration of router R3.

Solution To correct the error in this example, follow these steps:

1. Include the missing interface in the configuration of transit router R3:

```
user@R3> edit
user@R3#  edit protocols rsvp
[edit protocols rsvp]
user@R3# show
user@R3#  set interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols rsvp]
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols rsvp

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}
[edit protocols rsvp]
user@R3# set interface so-0/0/3.0

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
interface so-0/0/3.0; <<< Interface now included in the configuration

[edit protocols rsvp]
user@R3# commit
commit complete
```

Meaning The sample output shows that the missing interface **so-0/0/3.0** on transit router **R3** is now correctly included at the [**edit protocols rsvp**] hierarchy level. This results in the possibility that the LSP might come up.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the MPLS layer has been resolved.

Action To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
```

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify the LSP

Purpose Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive)** as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive).**

Action To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0,  LSPname: R1-to-R6

  Primary                  State: Dn
    Will be enqueued for recomputation in 22 second(s).
    1 Oct 27 14:59:12  CSPF failed: no route toward 10.0.0.1 [4 times]
  Created: Wed Oct 27 14:57:44 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output shows that the LSP is down in both directions, from **R1** to **R6**, and from **R6** to **R1**. The output from **R1** shows that **R1** is using a no-cspf LSP since it tried to originate the call without being able to reach the destination. The output from **R6** shows that the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.1**.

Verify RSVP Sessions

Purpose When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, the LSP does not work as configured.

Action To verify currently active RSVP sessions, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp session
```

Sample Output 1

```
user@R1> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R3> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R6> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Sample Output 2

```
user@R1> show rsvp session
Ingress RSVP: 1 sessions
To              From            State Rt Style Labelin Labelout LSPname

10.0.0.1        10.0.0.6        Up     1 1 FF       -   100784  R6-to-R1
Total 1 displayed,  Up 1 , Down 0

Egress RSVP: 1 sessions
To              From            State Rt Style Labelin Labelout LSPname
10.0.0.6        10.0.0.1        Up     0 1 FF       3        -  R1-to-R6
Total 1 displayed,  Up 1 , Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from all routers shows that no RSVP sessions were successfully created, even though the LSP **R6-to-R1** is configured. Continue investigating the problem in "Verify RSVP Neighbors" on page 1391.

In contrast to Sample Output 1and to illustrate correct output, Sample Output 2 shows the output from the ingress, transit, and egress routers when the RSVP configuration is correct, and the LSP is traversing the network as configured. **R1** and **R6** both show an ingress and egress RSVP session, with the LSP **R1-to-R6**, and the reverse LSP **R6-to-R1**. Transit router **R3** shows two transit RSVP sessions.

Verify RSVP Neighbors

Purpose Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors unless the RSVP configuration is removed from the router.

Action To verify RSVP neighbors, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp neighbor
```

Sample Output 1

```
user@R1> show rsvp neighbor
RSVP neighbor: 1 learned
Address           Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.2           10   1/0         9:22        9    64/64   32

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
```

```
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1             0  1/0       28:20        9   190/190  41
10.1.36.2          16:50   1/1        15:37        9   105/78   38

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1          17:30   1/1        16:15        9   104/78   39
```

Sample Output 2

```
user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1             5   1/0         9:14        9    63/63   33
10.1.36.2             5   1/0         9:05        9    62/62   32

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1             5   1/0        8:54        9    61/61   32
```

Meaning Sample Output 1 shows that **R1** and **R6** have one RSVP neighbor each, **R3**. However, the values in the **Up/Dn** field are different. **R1** has a value of **1/0** and **R6** has a value of **1/1**, indicating that **R1** is an active neighbor with **R3**, but **R6** is not. When the up count is one more than the down count, the neighbor is active; if the values are equal, the neighbor is down. The values for **R6** are equal, **1/1**, indicating that the neighbor **R3** is down.

Transit router **R3** knows about two neighbors, **R1** and **R6**. The **Up/Dn** field indicates that **R1** is an active neighbor and **R6** is down. At this point it is not possible to determine if the problem resides with **R3** or **R6**, because both neighbors are not active. Continue investigating the problem in "Verify RSVP Interfaces" on page 1392.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the correct neighbor relationship between transit router **R3** and egress router **R6**. The **Up/Dn** field shows the up count to be one more than the down count, **1/0**, indicating that the neighbors are active.

Verify RSVP Interfaces

Purpose Display the status of each interface on which RSVP is enabled to determine where the configuration error occurred.

Action To verify the status of RSVP interfaces, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show rsvp interface
RSVP interface: 3 active
                   Active  Subscr- Static      Available   Reserved    Highwater

so-0/0/2.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/3.0  Up          1    100%  155.52Mbps  155.52Mbps  0bps        0bps
```

Meaning Sample Output 1 shows that even though each router has interfaces that are up and have RSVP active, there are no reservations (**Active resv)** on any of the routers. In this example, we would expect at least one reservation on the ingress and egress routers, and two reservations on the transit router.

In addition, interface **so-0/0/3** on transit router **R3** is not included in the configuration. The inclusion of this interface is critical to the success of the LSP.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the relevant interfaces with active reservations.

Verify the RSVP Protocol Configuration

Purpose After you have checked RSVP sessions, interfaces, neighbors, and determined that there might be a configuration error, verify the RSVP protocol configuration.

Action To verify the RSVP configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols rsvp
```

Sample Output

```
user@R1> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}

user@R6> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;
interface fxp0.0 {
```

```
    disable;
}
```

Meaning The sample output shows that **R3** has interface **so-0/0/3.0** missing from the RSVP protocol configuration. This interface is critical for the correct functioning of the LSP.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is missing from the configuration of router R3.

Solution To correct the error in this example, follow these steps:

1. Include the missing interface in the configuration of transit router R3:

```
user@R3> edit
user@R3#   edit protocols rsvp
[edit protocols rsvp]
user@R3# show
user@R3#   set interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols rsvp]
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols rsvp

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}
[edit protocols rsvp]
user@R3# set interface so-0/0/3.0

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
interface so-0/0/3.0; <<< Interface now included in the configuration

[edit protocols rsvp]
user@R3# commit
commit complete
```

Meaning The sample output shows that the missing interface **so-0/0/3.0** on transit router **R3** is now correctly included at the [**edit protocols rsvp**] hierarchy level. This results in the possibility that the LSP might come up.

Verify the LSP Again

Purpose After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the MPLS layer has been resolved.

Action To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

  Time left:  119, Since: Wed Oct 27 15:21:43 2004
  Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
  Port number: sender 1 receiver 47977 protocol 0
  PATH rcvfrom: 10.1.36.1 (so-0/0/3.0) 7 pkts
  Adspec: received MTU 1500
  PATH sentto: localclient
  RESV rcvfrom: localclient
  Record route: 10.1.13.1 10.1.36.1 <self>
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Checklist for Determining LSP Status

Purpose This checklist provides the steps and commands to verify the state of a label-switched path (LSP) in an MPLS network. The checklist includes links to more detailed information about the commands to verify the LSP and supporting protocols. Table 53 on page 1409 provides commands for determining the LSP state.

Table 53: Checklist for Determining the LSP State

Tasks	Command or Action
"Determining LSP Status" on page 1572	
1. Check the Status of the LSP on page 1572	**show mpls lsp**
2. Display Extensive Status About the LSP on page 1573	**show mpls lsp extensive**
"Determining LSP Statistics" on page 1409	**show rsvp session detail**

Determining LSP Statistics

Purpose Display detailed information about RSVP objects to assist the diagnosis of an LSP problem.

Action To verify RSVP objects, enter the following Junos OS CLI operational mode command:

```
user@host> show rsvp session detail
```

Sample Output

```
user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

10.0.0.6
  From: 10.0.0.1, LSPstate: Up, ActiveRoute: 1
  LSPname:  R1-to-R6 , LSPpath:  Primary
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent:  100064
  Resv style: 1 FF, Label in: -, Label out: 100064
  Time left:    -, Since: Tue Aug 17 12:22:52 2004
  Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
  Port number: sender 12 receiver 44251 protocol 0
  PATH rcvfrom: localclient
  Adspec: sent MTU 1500
  PATH sentto: 10.1.13.2 (so-0/0/2.0) 182 pkts
  RESV rcvfrom: 10.1.13.2 (so-0/0/2.0) 159 pkts
  Explct route: 10.1.13.2 10.1.36.2
  Record route: <self> 10.1.13.2 10.1.36.2
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions

10.0.0.1
  From:  10.0.0.6 , LSPstate: Up, ActiveRoute: 0
  LSPname: R6-to-R1, LSPpath: Primary
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent: -
  Resv style: 1 FF, Label in: 3, Label out: -
  Time left:  135, Since: Tue Aug 17 12:23:14 2004
  Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
  Port number: sender 1 receiver 39024 protocol 0
  PATH rcvfrom: 10.1.15.2 (so-0/0/1.0) 158 pkts
  Adspec: received MTU 1500
  PATH sentto: localclient
  RESV rcvfrom: localclient
  Record route: 10.1.56.2 10.1.15.2 <self>
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output shows that there is one ingress and one egress RSVP session. The ingress session has a source address of **10.0.0.1** (**R1**), and the session is up, with one active route. The LSP name is **R1-to-R6** and it is the primary path for the LSP.

The recovery label (**100064**) is sent by a graceful restart router to its neighbor to recover a forwarding state. It is probably the old label that the router advertised before it went down.

This session is using the fixed filter (**FF**) reservation style (**Resv style**). Since this is an ingress router, there is no inbound label. The outbound label (provided by the next downstream router) is **100064**.

The **Time Left** field provides the number of seconds remaining in the RSVP session, and the **Tspec** object provides information about the controlled load rate (**rate**) and maximum burst size (**peak**), an infinite value (**Infbps**) for the guaranteed delivery option, and the indication that packets smaller than 20 bytes are treated as 20 bytes, while packets larger than 1500 bytes are treated as 1500 bytes.

The port number is the IPv4 tunnel ID, while the sender/receiver port number is the LSP ID. The IPv4 tunnel ID is unique for the life of the LSP, while the sender/receiver LSP ID can change, for example, with an SE style reservation.

The **PATH rcvfrom** field includes the source of the path message. Since this is the ingress router, the local client originated the path message.

The **PATH sentto** field includes the path message destination (**10.1.13.2**) and outgoing interface (**so-0/0/2.0**). The **RESV rcvfrom** field includes both the source of the Resv message received (**10.1.13.2**) and the incoming interface (**so-0/0/2.0**).

The RSVP explicit route and the route record values are identical: **10.1.13.2** and **10.1.36.2**. In most cases, the explicit route and the record route values are identical. Differences indicate that some path rerouting has occurred, typically during Fast-Reroute.

The **Total** fields indicate the total number of ingress, egress, and transit RSVP sessions, with the total being equal to the sum of the up and down sessions. In this example, there is one ingress session, one egress session, and no transit RSVP sessions.

Checklist for Verifying LSP Use

Purpose This checklist provides the steps and commands to verify the use of the LSP in an MPLS network. The checklist includes links to more detailed information about verifying the LSP on the ingress and transit routers in the network.

This checklist describes how to verify the availability and valid use of a label-switched path (LSP) in your network.

Table 54: Checklist for Verifying LSP Use

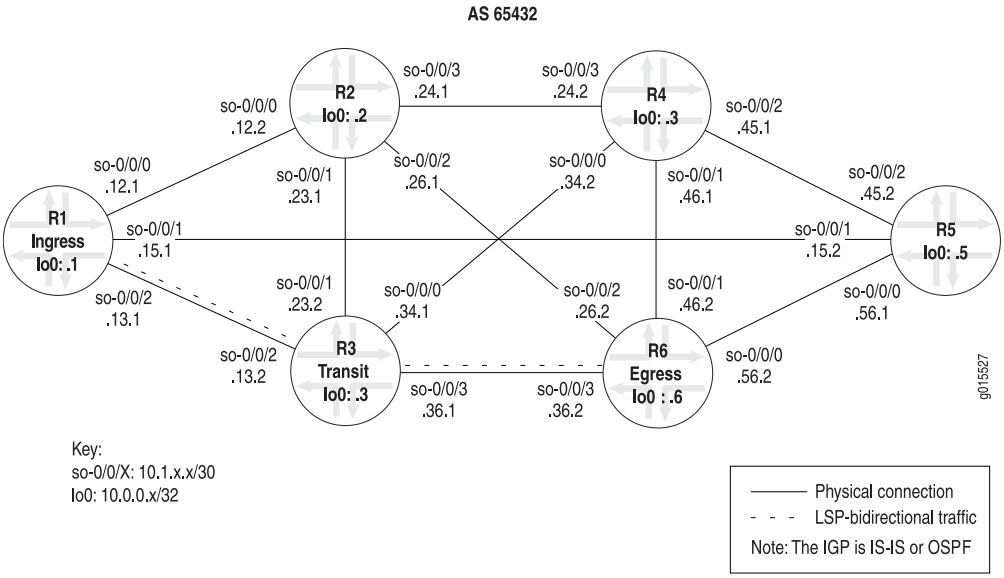
Tasks	Command or Action
Action	
"Verifying LSP Use in Your Network" on page 1412	
"Verifying an LSP on the Ingress Router" on page 1412	**show route table inet.3**
"Verifying an LSP on a Transit Router" on page 1414	**show route table mpls.0**

Table 54 on page 1411 provides commands for verifying LSP use.

Verifying LSP Use in Your Network

Purpose When you verify the valid use of an LSP on the ingress and transit routers in your network, you can determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network. Figure 120 on page 1412 describes the example network used in this topic.

Figure 120: MPLS Topology for Verifying LSP Use



The MPLS network in Figure 120 on page 1412 illustrates a router-only network with SONET interfaces that consist of the following components:

- A full-mesh interior Border Gateway Protocol (IBGP) topology, using AS 65432
- MPLS and Resource Reservation Protocol (RSVP) enabled on all routers
- A **send-statics** policy on routers R1 and R6 that allows a new route to be advertised into the network
- An LSP between routers R1 and R6

The network shown in Figure 120 on page 1412 is a Border Gateway Protocol (BGP) full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

To verify LSP use in your network, follow these steps:

1. Verifying an LSP on the Ingress Router on page 1412
2. Verifying an LSP on a Transit Router on page 1414

Verifying an LSP on the Ingress Router

Purpose You can verify the availability of an LSP when it is up by examining the **inet.3** routing table on the ingress router. The **inet.3** routing table contains the host address of each LSP's

egress router. This routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses.

Action To verify an LSP on an ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show route table inet.3
```

Sample Output

```
user@R1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[RSVP/7] 4w0d 22:40:57, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6
```

Meaning The sample output shows the **inet.3** routing table. By default, only BGP and MPLS virtual private networks (VPNs) can use the **inet.3** route table to resolve next-hop information. One destination is listed in the route table, **10.0.0.6**. This destination (**10.0.0.6**) is signaled by RSVP, and is the current active path, as indicated by the asterisk (*****). The protocol preference for this route is **7**, and the metric associated with it is **20**. The label-switched path is **R1-to-R6**, through interface **so-0/0/2.0**, which is the physical next-hop transit interface.

Typically, the penultimate router in the LSP either pops the packet's label or changes the label to a value of 0. If the penultimate router pops the top label and an IPv4 packet is underneath, the egress router routes the IPv4 packet, consulting the IP routing table **inet.0** to determine how to forward the packet. If another type of label (such as one created by Label Distribution Protocol (LDP) tunneling or VPNs, but not IPv4) is underneath the top label, the egress router does not examine the **inet.0** routing table. Instead, it examines the **mpls.0** routing table for forwarding decisions.

If the penultimate router changes the packet's label to a value of 0, the egress router strips off the 0 label, indicating that an IPv4 packet follows. The packet is examined by the **inet.0** routing table for forwarding decisions.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or whether this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the **inet.0** and **inet.3** routing tables, seeking the next hop with the lowest preference; for example, RSVP preference 7 is preferred over OSPF preference 10. The RSVP signaled LSP is used to reach the BGP next hop. This is the default when the BGP next hop equals the LSP egress address. Once the BGP next hop is resolved through an LSP, the BGP traffic uses the LSP to forward BGP transit traffic.

Verifying an LSP on a Transit Router

Purpose You can verify the availability of an LSP when it is up by examining the **mpls.0** routing table on a transit router. MPLS maintains the **mpls.0** routing table, which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Action To verify an LSP on a transit router, enter the following Junos OS CLI operational mode command:

```
user@host> show route table mpls.0
```

Sample Output

```
user@R3> show route table mpls.0
mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
1                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
2                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
100064             *[RSVP/7] 2w1d 04:17:36, metric 1
                    > via so-0/0/3.0, label-switched-path R1-to-R6
100064 (S=0)        *[RSVP/7] 2w1d 04:17:36, metric 1
                   > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning The sample output from transit router **R3** shows route entries in the form of MPLS label entries, indicating that there is only one active route, even though there are five active entries.

The first three MPLS labels are reserved MPLS labels defined in RFC 3032. Packets received with these label values are sent to the Routing Engine for processing. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label and Label 2 is the IPv6 explicit null label.

The two entries with the **100064** label are for the same LSP, **R1-to-R6.** There are two entries because the stack values in the MPLS header may be different. The second entry, **100064 (S=0)**, indicates that the stack depth is not 1 and additional label values are included in the packet. In contrast, the first entry of **100064** has an inferred S=1 which indicates a stack depth of 1 and makes it the last label in the packet. The dual entry indicates that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

The incoming label is the MPLS header of the MPLS packet, and is assigned by RSVP to the upstream neighbor. Juniper Networks routers dynamically assign labels for RSVP traffic-engineered LSPs in the range from 100,000 through 1,048,575.

The router assigns labels starting at label 100,000, in increments of 16. The sequence of label assignments is 100,000, 100,016, 100,032, 100,048, and so on. At the end of the assigned labels, the label numbers start over at 100001, incrementing in units of 16. Juniper Networks reserves labels for various purposes. Table 55 on page 1415 lists the various label range allocations for incoming labels.

Table 55: MPLS Label Range Allocations

Incoming Label	Status
0 through **15**	Reserved by IETF
16 through **1023**	Reserved for static LSP assignment
1024 through **9999**	Reserved for internal use (for example, CCC labels)
10,000 through **99,999**	Reserved for static LSP assignment
100,000 through **1,048,575**	Reserved for dynamic label assignment

Verifying an LSP on the Ingress Router

Purpose You can verify the availability of an LSP when it is up by examining the **inet.3** routing table on the ingress router. The **inet.3** routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses.

Action To verify an LSP on an ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show route table inet.3
```

Sample Output

```
user@R1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32        *[RSVP/7] 4w0d 22:40:57, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6
```

Meaning The sample output shows the **inet.3** routing table. By default, only BGP and MPLS virtual private networks (VPNs) can use the **inet.3** route table to resolve next-hop information. One destination is listed in the route table, **10.0.0.6**. This destination (**10.0.0.6**) is signaled by RSVP, and is the current active path, as indicated by the asterisk (*). The protocol

preference for this route is **7**, and the metric associated with it is **20**. The label-switched path is **R1-to-R6**, through interface **so-0/0/2.0**, which is the physical next-hop transit interface.

Typically, the penultimate router in the LSP either pops the packet's label or changes the label to a value of 0. If the penultimate router pops the top label and an IPv4 packet is underneath, the egress router routes the IPv4 packet, consulting the IP routing table **inet.0** to determine how to forward the packet. If another type of label (such as one created by Label Distribution Protocol (LDP) tunneling or VPNs, but not IPv4) is underneath the top label, the egress router does not examine the **inet.0** routing table. Instead, it examines the **mpls.0** routing table for forwarding decisions.

If the penultimate router changes the packet's label to a value of 0, the egress router strips off the 0 label, indicating that an IPv4 packet follows. The packet is examined by the **inet.0** routing table for forwarding decisions.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or whether this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the **inet.0** and **inet.3** routing tables, seeking the next hop with the lowest preference; for example, RSVP preference 7 is preferred over OSPF preference 10. The RSVP signaled LSP is used to reach the BGP next hop. This is the default when the BGP next hop equals the LSP egress address. Once the BGP next hop is resolved through an LSP, the BGP traffic uses the LSP to forward BGP transit traffic.

Verifying an LSP on a Transit Router

Purpose You can verify the availability of an LSP when it is up by examining the **mpls.0** routing table on a transit router. MPLS maintains the **mpls.0** routing table, which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Action To verify an LSP on a transit router, enter the following Junos OS CLI operational mode command:

```
user@host> show route table mpls.0
```

Sample Output

```
user@R3> show route table mpls.0
mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
1                  *[MPLS/0] 7w3d 22:20:56, metric 1
                    Receive
2                  *[MPLS/0] 7w3d 22:20:56, metric 1
```

```
                   Receive
100064             * [RSVP/7] 2w1d 04:17:36, metric 1
                   > via so-0/0/3.0, label-switched-path R1-to-R6
100064 (S=0)         * [RSVP/7] 2w1d 04:17:36, metric 1
                   > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning The sample output from transit router **R3** shows route entries in the form of MPLS label entries, indicating that there is only one active route, even though there are five active entries.

The first three MPLS labels are reserved MPLS labels defined in RFC 3032. Packets received with these label values are sent to the Routing Engine for processing. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label and Label 2 is the IPv6 explicit null label.

The two entries with the **100064** label are for the same LSP, **R1-to-R6.** There are two entries because the stack values in the MPLS header may be different. The second entry, **100064 (S=0)**, indicates that the stack depth is not 1 and additional label values are included in the packet. In contrast, the first entry of **100064** has an inferred S=1 which indicates a stack depth of 1 and makes it the last label in the packet. The dual entry indicates that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

The incoming label is the MPLS header of the MPLS packet, and is assigned by RSVP to the upstream neighbor. Juniper Networks routers dynamically assign labels for RSVP traffic-engineered LSPs in the range from 100,000 through 1,048,575.

The router assigns labels starting at label 100,000, in increments of 16. The sequence of label assignments is 100,000, 100,016, 100,032, 100,048, and so on. At the end of the assigned labels, the label numbers start over at 100001, incrementing in units of 16. Juniper Networks reserves labels for various purposes. Table 55 on page 1415 lists the various label range allocations for incoming labels.

Table 56: MPLS Label Range Allocations

Incoming Label	Status
0 through **15**	Reserved by IETF
16 through **1023**	Reserved for static LSP assignment
1024 through **9999**	Reserved for internal use (for example, CCC labels)
10,000 through **99,999**	Reserved for static LSP assignment
100,000 through **1,048,575**	Reserved for dynamic label assignment

Verify That Load Balancing Is Working

Purpose After configuring load balancing, check that traffic is load-balanced equally across paths. In this section, the command output reflects the load-balancing configuration of the example network shown in "Load-Balancing Network Topology" on page 1421. The **clear** commands are used to reset LSP and interface counters to zero so that the values reflect the operation of the load-balancing configuration.

Action To verify load balancing across interfaces and LSPs, use the following command on the ingress router:

```
user@host# show configuration
```

To verify load balancing across interfaces and LSPs, use the following commands on a transit router:

```
user@host# show route
user@host# show route forwarding-table
user@host# show mpls lsp statistics
user@host# monitor interface traffic
user@host# clear mpls lsp statistics
user@host# clear interface statistics
```

Sample Output

The following sample output is for the configuration on ingress router **R1**:

```
user@R1> show configuration | no-more
[...Output truncated...]
routing-options {
    [...Output truncated...]
     forwarding-table {
         export lbpp;
    }
}
[...Output truncated...]
policy-options {
      policy-statement lbpp {
          then {
               load-balance per-packet;
          }
    }
}
```

Meaning The sample output for the **show configuration** command on ingress router **R1** shows that load balancing is correctly configured with the **lbpp** policy statement. Also, the **lbpp** policy is exported into the forwarding table at the **[edit routing-options]** hierarchy level.

Sample Output The following sample output is from transit router R2:

```
user@R2> show route 192.168.0.1 terse

inet.0: 25 destinations, 27 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
A Destination        P Prf   Metric 1   Metric 2  Next hop        AS path
* 192.168.0.1/32     O  10          3             so-0/0/1.0
                                                 >so-0/0/2.0
[...Output truncated...]
```

Meaning The sample output for the **show route** command issued on transit router **R2** shows the two equal-cost paths (**so-0/0/1** and **so-0/0/2)** through the network to the loopback address to **R0** (**192.168.0.1**). Even though the right angle bracket (>) usually indicates the active route, in this instance it does not, as shown in the following four sample outputs.

Sample Output The following sample output is from transit router R2:

```
user@R2> monitor interface traffic

R2                                Seconds: 65                 Time: 11:41:14

Interface    Link  Input packets        (pps)     Output packets        (pps)
 so-0/0/0      Up               0          (0)                  0          (0)
 so-0/0/1      Up             126          (0)             164659       (2128)
 so-0/0/2      Up           85219       (1004)             164598       (2128)
 so-0/0/3      Up               0          (0)                  0          (0)
 fe-0/1/0      Up          328954       (4265)              85475       (1094)
 fe-0/1/1      Up               0          (0)                  0          (0)
 fe-0/1/2      Up               0          (0)                  0          (0)
 fe-0/1/3      Up               0          (0)                  0          (0)
[...Output truncated...]
```

Meaning The sample output for the **monitor interface traffic** command issued on transit router **R2** shows that output traffic is evenly distributed across the two interfaces **so-0/0/1** and **so-0/0/2**.

Sample Output The following sample output is from transit router R2:

```
user@R2> show mpls lsp statistics
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 5 sessions
To              From            State     Packets            Bytes LSPname
192.168.0.1     192.168.1.1     Up          87997    17951388 lsp1
192.168.0.1     192.168.1.1     Up          87997    17951388 lsp2
192.168.0.1     192.168.1.1     Up          87997    17951388 lsp3
192.168.0.1     192.168.1.1     Up          87997    17951388 lsp4
192.168.6.1     192.168.0.1     Up              0           0 r0-r1
Total 5 displayed, Up 5, Down 0
```

Meaning The sample output for the **show mpls lsp statistics** command issued on transit router **R2** shows that output traffic is evenly distributed across the four LSPs configured on ingress router **R6**.

Sample Output The following sample output is from transit router R2:

```
user@R2> show route forwarding-table destination 10.0.90.14
Routing table: inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
10.0.90.12/30      user     0                     ulst 262144    6
                                                  ucst   345    5 so-0/0/1.0
                                                  ucst   339    2 so-0/0/2.0
```

Meaning The sample output for the **show route forwarding-table destination** command issued on transit router **R2** shows **ulst** in the **Type** field, which indicates that load balancing is working. The two unicast (**ucst**) entries in the **Type** field are the two next hops for the LSPs.

Sample Output The following sample output is from transit router R2:

```
user@R2> show route forwarding-table | find mpls
Routing table: mpls
MPLS:
Destination        Type RtRef Next hop           Type Index NhRef Netif
default            perm     0                    dscd    38     1
0                  user     0                    recv    37     3
1                  user     0                    recv    37     3
2                  user     0                    recv    37     3
100112             user     0                  Swap 100032       so-0/0/1.0
100128             user     0                  Swap 100048       so-0/0/1.0
100144             user     0 10.0.12.13       Swap 100096       fe-0/1/0.0
100160             user     0                  Swap 100112       so-0/0/2.0
100176             user     0                  Swap 100128       so-0/0/2.0
```

Meaning The sample output for the **show route forwarding-table | find mpls** command issued on transit router R2 shows the MPLS routing table that contains the labels received and used by this router to forward packets to the next-hop router. This routing table is used mostly on transit routers to route packets to the next router along an LSP. The first three labels in the **Destination** column (Label 0, Label 1, and Label 2) are automatically entered by MPLS when the protocol is enabled. These labels are reserved MPLS labels defined in RFC 3032. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label, and Label 2 is the IPv6 explicit null label.

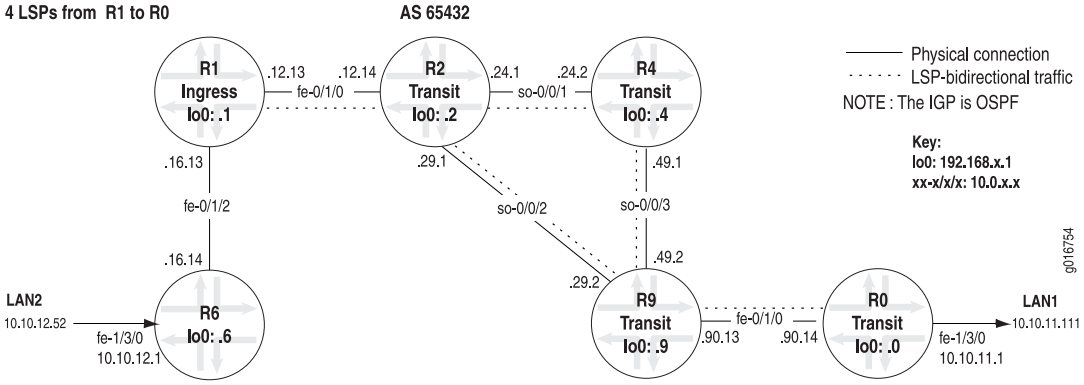
The remaining five labels in the **Destination** column are nonreserved labels that the router uses to forward traffic, and the last column **Netif**, shows the interfaces used to send the labeled traffic. For nonreserved labels, the second **Type** column shows the operation performed on matching packets. In this example, all non-reserved packets are swapped for outgoing packet labels. For example, packets with the label **100112** have their label swapped for **100032** before they are pushed out of interface **so-0/0/1.0**.

Example: Load-Balanced MPLS Network

When you configure several RSVP LSPs to the same egress router, the LSP with the lowest metric is selected and carries all traffic. If all of the LSPs have the same metric, one of the LSPs is selected at random and all traffic is forwarded over it. To distribute traffic equally across all LSPs, you can configure load balancing on the ingress or transit routers, depending on the type of load balancing configured.

Figure 121 on page 1422 illustrates an MPLS network with four LSPs configured to the same egress router (**R0**). Load balancing is configured on ingress router **R1**. The example network uses Open Shortest Path First (OSPF) as the interior gateway protocol (IGP) with OSPF area **0.0.0.0**. An IGP is required for the Constrained Shortest Path First (CSPF) LSP, which is the default for the Junos OS. In addition, the example network uses a policy to create BGP traffic.

Figure 121: Load-Balancing Network Topology



The network shown in Figure 121 on page 1422 consists of the following components:

- A full-mesh interior BGP (IBGP) topology, using AS 65432
- MPLS and RSVP enabled on all routers
- A send-statics policy on routers **R1** and **R0** that allows a new route to be advertised into the network
- Four unidirectional LSPs between **R1** and **R0**, and one reverse direction LSP between **R0** and **R1**, which allows for bidirectional traffic
- Load balancing configured on ingress router **R1**

The network shown in Figure 121 on page 1422 is a BGP full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

For complete configurations for all routers in the example MPLS network, see "Router Configurations for the Load-Balanced MPLS Network" on page 1422.

For a description of the situation before and after load balancing is configured in the network to use all four LSPs to forward traffic, see "Traffic Flows Before Load Balancing" on page 1433.

Router Configurations for the Load-Balanced MPLS Network

Purpose The configurations in this topic are for the six routers in the example network illustrated in "Load-Balancing Network Topology" on page 1421.

Action To display the configuration of a router, use the following Junos OS CLI operational mode command:

```
user@host> show configuration | no-more
```

Sample Output 1 The following configuration output is for edge router **R6**.

```
user@R6> show configuration | no-more

            }
            then accept;
        }
    }
}
```

Meaning Sample Outputs 1 through 6 show the base interfaces, routing options, protocols, and policy options configurations for all six routers in the example network illustrated in "Load-Balancing Network Topology" on page 1421.

All routers in the network have MPLS, RSVP, and BGP enabled. OSPF is configured as the IGP, and relevant interfaces have basic IP information and MPLS support.

In addition, all routers have the router ID (RID) configured manually at the **[edit routing-options]** hierarchy level to avoid duplicate RID problems. The **passive** statement is included in the OSPF configuration to ensure that protocols are not run over the loopback (**lo0**) interface and that the loopback (**lo0**) interface is advertised correctly throughout the network.

Sample Outputs 1, 3, 4, and 5 for **R6**, **R2**, **R4**, and **R9** show the base configuration for transit label-switched routers. The base configuration includes all interfaces enabled for MPLS, the RID manually configured, and the relevant protocols (RSVP, MPLS, BGP, and OSPF).

Sample Output 2 from ingress router **R1** shows the base configuration plus four LSPs (**lsp1** through **lsp4**) configured to **R0**. The four LSPs are configured with different primary paths that specify a loose hop through **R4** for **lsp1** and **lsp4**, and through **R2** for **lsp2** and **lsp3**.

To create traffic, **R1** has a static route (**100.100.1.0/24**) configured at the **[edit routing-options static route]** hierarchy level. The prefix is included in the send-statics policy at the **[edit policy-options send statics]** hierarchy level so the routes can become BGP routes.

In addition, on the ingress router **R1**, load balancing is configured using the **per-packet** option, and the policy is exported at the **[edit routing-options forwarding-table]** hierarchy level.

Sample Output 6 from egress router **R0** shows one LSP (**r0-r6**) to **R6** used to create bidirectional traffic. OSPF requires bidirectional LSP reachability before it will advertise the LSP into the IGP. Although the LSP is advertised into the IGP, no hello messages or routing updates occur over the LSP—only user traffic is sent over the LSP. The router uses its local copy of the IGP database to verify bidirectional reachability.

In addition, **R0** has a static route (**100.100.10.0/24**) configured at the **[edit routing-options static route]** hierarchy level. The prefix is included in the send-statics policy at the **[edit policy-options send statics]** hierarchy level so the routes can become BGP routes.

Traffic Flows Before Load Balancing

Purpose The following sample output illustrates the details to look for when you issue different **show** commands to check if traffic is balanced. The following output is before load balancing is configured and is taken from transit router R2 in the network shown in "Load-Balancing Network Topology" on page 1421.

Action To check the distribution of traffic across interfaces and LSPs, use the following CLI operational mode commands:

```
user@host> show route | find mpls
user@host> monitor interface traffic
user@host> show mpls lsp statistics
```

Sample Output 1

```
user@R2> show route | find mpls

mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                  *[MPLS/0] 1d 00:12:08, metric 1
                      Receive
1                  *[MPLS/0] 1d 00:12:08, metric 1
                      Receive
2                  *[MPLS/0] 1d 00:12:08, metric 1
                      Receive
100112             *[RSVP/7] 13:10:36, metric 1
                    > via so-0/0/1.0, label-switched-path lsp1
100128             *[RSVP/7] 13:01:08, metric 1
                    > via so-0/0/1.0, label-switched-path lsp4
100144             *[RSVP/7] 00:26:49, metric 1
                    > to 10.0.12.13 via fe-0/1/0.0, label-switched-path r0-r6
100160             *[RSVP/7] 00:23:25, metric 1
                    > via so-0/0/2.0, label-switched-path lsp2
100176             *[RSVP/7] 00:23:25, metric 1
                    > via so-0/0/2.0, label-switched-path lsp3
```

Sample Output 2

```
user@R2> monitor interface traffic

R2                                 Seconds: 89                  Time: 14:33:09

Interface    Link  Input packets        (pps)     Output packets        (pps)
 so-0/0/0      Up              0          (0)                  0          (0)

192.168.6.1     192.168.0.1     Up              0                0 r0-r6
Total 5 displayed, Up 5, Down 0
```

Meaning Sample Outputs 1 through 3 from transit router **R2** show that traffic is not balanced across LSPs or interfaces.

Sample Output 1 for the **show route** command shows that all LSPs have the same metric (**1**) to the destination, even though they are traversing different interfaces. **lsp1** and **lsp4** are using **so-0/0/1**, while **lsp2** and **lsp3** are using **so-0/0/2**.

Sample Output 2 for the **monitor interface traffic** command shows that traffic is not evenly balanced across interfaces **so-0/0/1** and **so-0/0/2**. Almost all traffic is going out **so-0/0/2**.

Sample Output 3 for the **show mpls lsp statistics** command shows that traffic across LSPs is not balanced. All traffic is going over **lsp1**.

Verify the Operation of Uneven Bandwidth Load Balancing

Purpose When a router is performing unequal-cost load balancing between LSPs paths, the **show route detail** command displays a balance field associated with each next hop being used.

Action To verify that an RSVP LSP is unevenly load-balanced, use the following Junos OS CLI operational mode commands:

```
user@host> show route protocol rsvp detail
user@host> show mpls lsp statistics
```

Sample Output

```
user@R1> show route protocol rsvp detail

inet.0: 25 destinations, 25 routes (25 active, 0 holddown, 0 hidden)

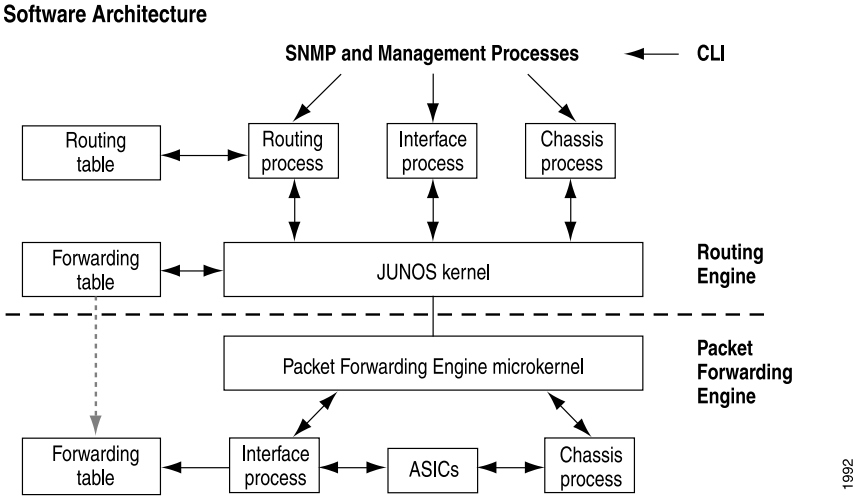
2. Clear the NVRAM Contents on page 1457	**start shell** **su** **root password** **vty *component-executable-name*** **clear nvram**
3. Check Packet Forwarding Engine Microkernel Core Files on page 1458	**file list detail /var/crash**
4. Collect and Send Routing Engine Crash Data to JTAC on page 1449	
a. List the Core Files Generated by the Crash on page 1458	**start shell** **su** ***root password*** **cd /var/crash** **ls -l**
b. Compress the Core Files on page 1459	**gzip *filename***
c. Log Software Version Information on page 1444	**show version**
d. Open a Case with JTAC on page 1442	Send an e-mail to **support@juniper.net** .

Understand Crash Data Collection

A crash can occur in one of three areas in the Junos OS architecture (see Figure 122 on page 1439):

- Routing Engine kernel
- Routing Engine daemons (processes)
- Packet Forwarding Engine microkernel

Figure 122: Three Areas Where a Software Crash Can Occur



Collect Crash Data for a Routing Engine Kernel

Purpose When a Routing Engine kernel crashes, the Routing Engine automatically reboots. By default, the Juniper Networks router does not attempt to dump a core if the Routing Engine kernel crashes. As a result, there is no crash data on the router to help investigate the crash. In addition, the system log messages are similar to those generated when the router is powered down and restarted, so you cannot tell if the Routing Engine restart was caused by a kernel crash or a normal power restart.

To collect crash data for a Routing Engine kernel crash, follow these steps:

1. Check the Routing Engine Core Files on page 1439
2. List the Core Files on page 1440
3. Compress the vmcore File on page 1441
4. Log Software Version Information on page 1441
5. Open a Case with JTAC on page 1442

Check the Routing Engine Core Files

Purpose If you observe disruption to the Routing Engine kernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action To check the **/var/crash** directory, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
total 1577912
drwxr-x---   2 root  wheel        512 Sep  9 11:59 ./
drwxr-xr-x  22 root  wheel        512 Oct 29  2001 ../
-rw-r--r--   1 root  wheel          2 Jul 20 01:11 bounds
-rw-r--r--   1 root  wheel    2166913 Jul 20 01:11 kernel.0
-rw-r--r--   1 root  wheel          5 Feb 15  2002 minfree
-rw-------   1 root  wheel  805306368 Jul 20 01:11 vmcore.0
```

Meaning The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any kernel core files created around the time of the crash. In the example above, two core files are listed: **kernel.0** and **vmcore.0**.

List the Core Files

Purpose To list the core files, follow these steps:

Action

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

   ```
   % su
   Password: ****
   ```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

   ```
   root@host% cd /var/crash
   root@host% ls -l
   ```

4. Look for any core files created around the time of the crash.

Sample Output

```
user@host> start shell
%  su
Password:  ****
```

```
root@host%  cd /var/crash
root@host%  ls -l
total 1577908
-rw-r--r--  1 root  wheel          2 Jul 20 01:11 bounds
-rw-r--r--  1 root  wheel    2166913 Jul 20 01:11 kernel.0
-rw-r--r--  1 root  wheel          5 Feb 15  2002 minfree
-rw-------  1 root  wheel  805306368 Jul 20 01:11 vmcore.0
```

Meaning The sample output lists the contents of the **/var/crash** directory and shows the current core files **kernel.0** and **vm.core.0**.

Compress the vmcore File

Purpose The gzip compression utility is used to compress files. Compress the **vmcore** file if it is larger than 50 MB. Files created using the **gzip** command end with the file extension **.gz**.

NOTE: Use lowercase for the gzip command when you are in the shell.

Action To compress the **vmcore** file with gzip, use the following command from the shell:

```
root@host% gzip vmcore .number
```

To unzip the **vmcore** file with gzip, use the following command from the shell:

```
root@host% gzip -d vmcore .number.gz
```

Meaning The contents of the **vmcore** file are compressed into a single compressed file named **vmcore.*number*.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose To log the Junos OS version information.

Action To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output `user@host>` **show version**

```
Hostname: host
Model: m10

Meaning The sample output shows the hostname, router model, and the different Junos OS packages, processes, and documents.

Open a Case with JTAC

Problem **Description:** To open a case with JTAC, call one of the Support phone numbers or create a case via Case Manager.

Check the Routing Engine Core Files

Purpose If you observe disruption to the Routing Engine kernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action To check the **/var/crash** directory, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
total 1577912
drwxr-x---   2 root  wheel        512 Sep  9 11:59 ./
drwxr-xr-x  22 root  wheel        512 Oct 29  2001 ../
-rw-r--r--   1 root  wheel          2 Jul 20 01:11 bounds
-rw-r--r--   1 root  wheel    2166913 Jul 20 01:11 kernel.0
-rw-r--r--   1 root  wheel          5 Feb 15  2002 minfree
-rw-------   1 root  wheel  805306368 Jul 20 01:11 vmcore.0
```

Meaning The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any kernel core files created around the time of the crash. In the example above, two core files are listed: **kernel.0** and **vmcore.0**.

List the Core Files

Purpose To list the core files, follow these steps:

Action

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

   ```
   % su
   Password: ****
   ```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

   ```
   root@host% cd /var/crash
   root@host% ls -l
   ```

4. Look for any core files created around the time of the crash.

Sample Output

```
user@host> start shell
%  su
Password:  ****
root@host%  cd /var/crash
root@host%  ls -l
total 1577908
-rw-r--r--  1 root  wheel          2 Jul 20 01:11 bounds
-rw-r--r--  1 root  wheel    2166913 Jul 20 01:11 kernel.0
```

```
-rw-r--r--  1 root  wheel          5 Feb 15  2002 minfree
-rw-------  1 root  wheel  805306368 Jul 20 01:11 vmcore.0
```

Meaning The sample output lists the contents of the **/var/crash** directory and shows the current core files **kernel.0** and **vm.core.0**.

Compress the vmcore File

Purpose The gzip compression utility is used to compress files. Compress the **vmcore** file if it is larger than 50 MB. Files created using the **gzip** command end with the file extension **.gz**.

NOTE: **Use lowercase for the gzip command when you are in the shell.**

Action To compress the **vmcore** file with gzip, use the following command from the shell:

```
root@host% gzip vmcore .number
```

To unzip the **vmcore** file with gzip, use the following command from the shell:

```
root@host% gzip -d vmcore .number.gz
```

Meaning The contents of the **vmcore** file are compressed into a single compressed file named **vmcore.*number*.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose To log the JUNOS software version information.

Action To log the JUNOS software version information, use the following JUNOS CLI operational mode command:

```
user@host> show version
```

Sample Output `user@host>` **show version**

```

Meaning The sample output shows the hostname, router model, and the different JUNOS software packages, processes, and documents.

Open a Case with JTAC

Problem **Description:** To open a case with JTAC, call one of the Support phone numbers or create a case via Case Manager.

Collect Crash Data for Routing Engine Daemons

To collect crash data for Routing Engine daemons, follow these steps:

1. Check for Daemon Core Files on page 1446
2. List the Daemon Core Files on page 1447
3. Compress the Daemon Core Files on page 1448
4. Log Software Version Information on page 1448
5. Open a Case with JTAC on page 1449

Check for Daemon Core Files

Purpose If you observe disruption to routing protocol operation, system log operation, Simple Network Management Protocol (SNMP) operation, or other operations handled by Routing Engine daemons, check the **/var/tmp** directory for any daemon core files created around the time of the crash.

Action To check the **/var/tmp** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/tmp
```

Sample Output

```
user@host> file list detail /var/tmp
total 1292622
drwxrwxrwt   3 root  field        512 Dec 31 06:48 ./
drwxr-xr-x  21 root  field       512 Mar  5  1999 ../
-rw-rw----   1 root  field  119713792 Nov 17 21:58 rpd.core.0
-rw-rw----   1 root  field  120782848 Nov 17 22:12 rpd.core.1
```

Meaning The sample output lists the contents of the **/var/tmp/** directory. Look for any daemon core files created around the time of the crash. In the example above, two core files are listed: **rpd.core.0** and **rpd.core.1**.

Table 58 on page 1446 lists the major Routing Engine daemons supported by the Junos OS.

Table 58: Major Routing Engine Daemons

Executable Name	Definition	Description
rpd	Routing protocol daemon	Provides routing protocol intelligence (Border Gateway Protocol [BGP], Intermediate System-to-Intermediate System [ISIS], Open Shortest Path First [OSPF], and so on).
dcd	Device control daemon	Manages all interface devices.
mgd	Management daemon	Provides user configuration access to the system. The CLI is a client of **mgd**.
snmpd	Simple Network Management Protocol daemon	Provides remote network management information to the network management system.
chassisd	Chassis daemon	Monitors and manages Flexible PIC Concentrator (FPC) slots and other environmental components.
alarmd	Alarm daemon	Manages system alarm notifications.

Table 58: Major Routing Engine Daemons (continued)

Executable Name	Definition	Description
apsd	Automatic protection switching daemon	Provides SONET Automatic Protection Switching (APS) functionality.
sampled	Traffic sampling daemon	Gathers traffic sampling information.
vrrpd	Virtual Router Redundancy Protocol daemon	Provides Virtual Router Redundancy Protocol (VRRP) functionality.
syslogd	System log daemon	Manages the router system logging operation.
mib2d	MIB2 daemon	Management Information Base (MIB) subagent for MIB2.

List the Daemon Core Files

Purpose To list the daemon core files.

Action To list the daemon core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Change the directory to **/var/tmp** and type **ls -l**, for example:

   ```
   root@host% cd /var/tmp
   root@host% ls -l
   ```

4. Look for any daemon core files created around the time of the crash.

Sample Output

```
user@host> start shell
% su
Password: ****
root@host% cd /var/tmp
root@host% ls -l
total 1292618
```

```
-rw-rw----  1 root  field  119713792 Nov 17 21:58  rpd.core.0
-rw-rw----  1 root  field  120782848 Nov 17 22:12  rpd.core.1
```

Meaning The sample output lists the contents of the **/var/tmp** directory and shows the current core file (**rpd.core.1**) and one previous core file (**rpd.core.0**) for the routing protocol daemon (**rpd**). For each daemon, you can have a total of five core files in the **/var/tmp** directory: the current core file and the four previous core files numbered 0 through 4 (from oldest to newest).

Compress the Daemon Core Files

Purpose The gzip compression utility is used to compress the files if they are large. Files created using the **gzip** command end with the file extension .**gz**. Compress the core file if it is over 50 MB.

NOTE: Use lowercase for the gzip command when you are in the shell.

You only need to compress the daemon core files when the tarball file is not created.

Action To compress the daemon core file with gzip, use the following command from the shell:

```
root@host% gzip daemon-executable-name.core.number
```

Sample Output

```
root@host% gzip rpd.core.0
gzip rpd.core.0
```

Meaning The contents of the daemon core file are compressed into a single compressed file named **daemon.*number*.gz.** The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose To log the Junos OS version information.

Action To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output `user@host>` **show version**

```
Hostname: host

Check for Daemon Core Files

Purpose If you observe disruption to routing protocol operation, system log operation, Simple Network Management Protocol (SNMP) operation, or other operations handled by Routing Engine daemons, check the **/var/tmp** directory for any daemon core files created around the time of the crash.

Action To check the **/var/tmp** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/tmp
```

Sample Output

```
user@host> file list detail /var/tmp
total 1292622
drwxrwxrwt   3 root  field        512 Dec 31 06:48 ./
drwxr-xr-x  21 root  field       512 Mar  5  1999 ../
-rw-rw----   1 root  field  119713792 Nov 17 21:58 rpd.core.0
-rw-rw----   1 root  field  120782848 Nov 17 22:12 rpd.core.1
```

Meaning The sample output lists the contents of the **/var/tmp/** directory. Look for any daemon core files created around the time of the crash. In the example above, two core files are listed: **rpd.core.0** and **rpd.core.1**.

Table 58 on page 1446 lists the major Routing Engine daemons supported by the Junos OS.

Table 59: Major Routing Engine Daemons

Executable Name	Definition	Description
rpd	Routing protocol daemon	Provides routing protocol intelligence (Border Gateway Protocol [BGP], Intermediate System-to-Intermediate System [ISIS], Open Shortest Path First [OSPF], and so on).
dcd	Device control daemon	Manages all interface devices.
mgd	Management daemon	Provides user configuration access to the system. The CLI is a client of **mgd**.

Table 59: Major Routing Engine Daemons (continued)

Executable Name	Definition	Description
snmpd	Simple Network Management Protocol daemon	Provides remote network management information to the network management system.
chassisd	Chassis daemon	Monitors and manages Flexible PIC Concentrator (FPC) slots and other environmental components.
alarmd	Alarm daemon	Manages system alarm notifications.
apsd	Automatic protection switching daemon	Provides SONET Automatic Protection Switching (APS) functionality.
sampled	Traffic sampling daemon	Gathers traffic sampling information.
vrrpd	Virtual Router Redundancy Protocol daemon	Provides Virtual Router Redundancy Protocol (VRRP) functionality.
syslogd	System log daemon	Manages the router system logging operation.
mib2d	MIB2 daemon	Management Information Base (MIB) subagent for MIB2.

List the Daemon Core Files

Purpose To list the daemon core files.

Action To list the daemon core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Change the directory to **/var/tmp** and type **ls -l**, for example:

   ```
   root@host% cd /var/tmp
   root@host% ls -l
   ```

4. Look for any daemon core files created around the time of the crash.

Sample Output

```
user@host> start shell
% su
Password: ****
root@host% cd /var/tmp
root@host% ls -l
total 1292618
-rw-rw----  1 root  field  119713792 Nov 17 21:58  rpd.core.0
-rw-rw----  1 root  field  120782848 Nov 17 22:12  rpd.core.1
```

Meaning The sample output lists the contents of the **/var/tmp** directory and shows the current core file (**rpd.core.1**) and one previous core file (**rpd.core.0**) for the routing protocol daemon (**rpd**). For each daemon, you can have a total of five core files in the **/var/tmp** directory: the current core file and the four previous core files numbered 0 through 4 (from oldest to newest).

Compress the Daemon Core Files

Purpose The gzip compression utility is used to compress the files if they are large. Files created using the **gzip** command end with the file extension .**gz**. Compress the core file if it is over 50 MB.

NOTE: Use lowercase for the **gzip** command when you are in the shell.

You only need to compress the daemon core files when the tarball file is not created.

Action To compress the daemon core file with gzip, use the following command from the shell:

```
root@host% gzip daemon-executable-name.core.number
```

Sample Output

```
root@host% gzip rpd.core.0
gzip rpd.core.0
```

Meaning The contents of the daemon core file are compressed into a single compressed file named **daemon.*number*.gz.** The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Collect Crash Data for the Packet Forwarding Engine Microkernel

Purpose Each of the following Packet Forwarding Engine components of a Juniper Networks router runs a microkernel:

- Flexible PIC Concentrator (FPC) on M-series platforms except for the M5 and M10 Internet routers
- Gibson Flexible PIC Concentrator (GFPC) on T640 and T320 Internet routing nodes
- Switched Printed Mezzanine Board (SPMB) on T640 and T320 Internet routing nodes
- Forwarding Engine Board (FEB) on M5 and M10 Internet routers
- System Switching Board (SSB) on an M20 Internet router
- System Control Board (SCB) on an M40 Internet router
- Switching and Forwarding Module (SFM) on M160 and M40e Internet routers

When a crash occurs, crash stack traceback and registration information is placed into nonvolatile random access memory (NVRAM) on the different components. Table 60 on page 1453 shows where the NVRAM is located for the components for each router.

Table 60: NVRAM Location on the Microkernel of the Packet Forwarding Engine Components

Router Type	NVRAM Location
M5 and M10	FEB
M20	SSB and crash stack traceback and register information for the FPC
M40	SCB and crash stack traceback and register information for the FPC
M40e	FPC SFM
M160	FPC SFM
T320	GFPC SPMB
T640	GFPC SPMB

To collect crash data for the Packet Forwarding Engine microkernel, follow these steps:

1. Display the Crash Stack Traceback and Registration Information on page 1454
2. Clear the NVRAM Contents on page 1457
3. Check Packet Forwarding Engine Microkernel Core Files on page 1458

4. List the Core Files Generated by the Crash on page 1458
5. Compress the Core Files on page 1459
6. Log Software Version Information on page 1459
7. Open a Case with JTAC on page 1460

Display the Crash Stack Traceback and Registration Information

Purpose To display the crash stack traceback and registration information.

Action To display the crash stack traceback and registration information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Establish a vty session to the appropriate component. Use the **vty** command followed by the executable name for the component; for example, **scb**, **ssb0**, **ssb1**, **fpc0**, or **fpc1**:

   ```
   root@host% vty sfm0
   ```

   NOTE: For the M40e and M160 routers, you can also create a **cty** session to the components if the components are not online.

4. Type the **show nvram** command to view the NVRAM information.
5. Type the **show syslog messages** command to view the system log messages.

Sample Output 1

```
user@host> start shell
% su
Password: ****
root@host% vty sfm0

FPC1(host vty)# show syslog messages
[0+00:00:00.780 LOG: Info] Version 4.0R5 by tlim on 2000-08-10 04:45:54 UTC
[0+00:00:00.780 LOG: Info] On-board NVRAM contains diagnostic information.
[0+00:00:03.175 LOG: Info] PFEMAN: Established connection to Master
[Jan 30 21:53:05.804 LOG: Info] SNTPD: Initial time of day set.
```

Meaning Sample output 1 and 2 show the stack trace from the microkernel crash. Save the output from the **show nvram** and **show syslog** commands so that you can send them to JTAC when you open a case.

Clear the NVRAM Contents

Purpose Currently the storage area for the logs on the NVRAM is limited to 4 KB. You need to delete old NVRAM logs to make room for new ones.

Action To clear the content of the NVRAM after you have captured the necessary information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Establish a vty session to the appropriate component. Use the **vty** command followed by the abbreviation for the component, for example:

   ```
   root@host% vty sfm0
   SFM3(host vty)#
   FPC1(host vty)#
   ```

4. Type the **clear nvram** command, for example:

   ```
   SFM3(host vty)# clear nvram
   FPC1(host vty)# clear nvram
   ```

Check Packet Forwarding Engine Microkernel Core Files

Purpose If you observe disruption to the Packet Forwarding Engine microkernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action To check the **/var/crash** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
var/crash:
total 456630
-rw-r--r--   1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--   1 root  wheel   65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--   1 root  wheel   65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--   1 root  wheel   65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any core files created around the time of the crash. In the example above, four core files are listed.

List the Core Files Generated by the Crash

Purpose To list the core files generated by the crash.

Action To list the core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

   ```
   root@host% cd /var/crash
   root@host% ls -l
   ```

4. Look for any core files created around the time of the crash.

Sample Output

```
user@host> start shell
% su
Password: ****
root@host% cd /var/crash
root@host% ls -l
total 456630
-rw-r--r--   1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--   1 root  wheel   65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--   1 root  wheel   65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--   1 root  wheel   65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning The sample output shows the current core files for the different components on the router; for example, **core-FPC4.100111808032** and **core-SCB.100111004570.**

Compress the Core Files

Purpose gzip is a compression utility used to compress the core files. Files created using the **gzip** command end with the file extension .**gz**. Compress the core files if they are larger than 50 MB.

Action To compress the core files with gzip, use the following command from the shell:

```
root@host% gzip filename
```

Sample Output

```
root@host% gzip core-SCB.101010920452
```

Meaning The contents of the core file are compressed into a single compressed file named **core-SCB.10101092045.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose To log the Junos OS version information.

Action To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output `user@host>` **show version**

```
Hostname: host

```

Meaning The sample output shows the hostname, router model, and the different Junos OS packages, processes, and documents.

Open a Case with JTAC

Problem **Description:** To open a case with JTAC, call one of the Support phone numbers or create a case via Case Manager.

Display the Crash Stack Traceback and Registration Information

Purpose To display the crash stack traceback and registration information.

Action To display the crash stack traceback and registration information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and prompt is **%** instead of **>**, for example:

```
% su
Password: ****
```

3. Establish a vty session to the appropriate component. Use the **vty** command followed by the executable name for the component; for example, **scb**, **ssb0**, **ssb1**, **fpc0**, or **fpc1**:

```
root@host% vty sfm0
```

NOTE: For the M40e and M160 routers, you can also create a **cty** session to the components if the components are not online.

4. Type the **show nvram** command to view the NVRAM information.
5. Type the **show syslog messages** command to view the system log messages.

Sample Output 1

```
user@host> start shell
% su
Password: ****
root@host% vty sfm0

SFM platform (266Mhz PPC 603e processor, 64Mb memory, 512Kb flash)
SFM3(host vty)# show nvram

FPC1(host vty)# show syslog messages
[0+00:00:00.780 LOG: Info] Version 4.0R5 by tlim on 2000-08-10 04:45:54 UTC
[0+00:00:00.780 LOG: Info] On-board NVRAM contains diagnostic information.
[0+00:00:03.175 LOG: Info] PFEMAN: Established connection to Master
[Jan 30 21:53:05.804 LOG: Info] SNTPD: Initial time of day set.
```

Meaning Sample output 1 and 2 show the stack trace from the microkernel crash. Save the output from the **show nvram** and **show syslog** commands so that you can send them to JTAC when you open a case.

Clear the NVRAM Contents

Purpose Currently the storage area for the logs on the NVRAM is limited to 4 KB. You need to delete old NVRAM logs to make room for new ones.

Action To clear the content of the NVRAM after you have captured the necessary information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Establish a vty session to the appropriate component. Use the **vty** command followed by the abbreviation for the component, for example:

   ```
   root@host% vty sfm0
   SFM3(host vty)#
   FPC1(host vty)#
   ```

4. Type the **clear nvram** command, for example:

   ```
   SFM3(host vty)# clear nvram
   FPC1(host vty)# clear nvram
   ```

Check Packet Forwarding Engine Microkernel Core Files

Purpose If you observe disruption to the Packet Forwarding Engine microkernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action To check the **/var/crash** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
var/crash:
total 456630
-rw-r--r--   1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
```

```
-rw-r--r--   1 root  wheel   65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--   1 root  wheel   65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--   1 root  wheel   65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any core files created around the time of the crash. In the example above, four core files are listed.

List the Core Files Generated by the Crash

Purpose To list the core files generated by the crash.

Action To list the core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

   ```
   user@host> start shell
   ```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

   ```
   % su
   Password: ****
   ```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

   ```
   root@host% cd /var/crash
   root@host% ls -l
   ```

4. Look for any core files created around the time of the crash.

Sample Output

```
user@host> start shell
% su
Password: ****
root@host% cd /var/crash
root@host% ls -l
total 456630
-rw-r--r--   1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--   1 root  wheel   65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--   1 root  wheel   65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--   1 root  wheel   65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning The sample output shows the current core files for the different components on the router; for example, **core-FPC4.100111808032** and **core-SCB.100111004570.**

Compress the Core Files

Purpose gzip is a compression utility used to compress the core files. Files created using the **gzip** command end with the file extension .**gz**. Compress the core files if they are larger than 50 MB.

Action To compress the core files with gzip, use the following command from the shell:

```
root@host% gzip filename
```

Sample Output

```
root@host% gzip core-SCB.101010920452
```

Meaning The contents of the core file are compressed into a single compressed file named **core-SCB.101010092045.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Configure a Primary Path

Action To configure a primary path with an ERO list, bandwidth, and priority, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols mpls
   ```

2. Configure the primary ERO list:

   ```
   [edit protocols mpls]
   user@host# set path path-name address strict
   ```

   For example:

   ```
   [edit protocols mpls]
   user@R1# set path via-r2 10.0.12.14 strict
   user@R1# set path via-r2 10.0.24.2 strict
   ```

3. Configure the LSP:

   ```
   [edit protocols mpls]
   user@host# set label-switched-path lsp-path-name to destination;
   ```

   For example:

   ```
   [edit protocols mpls]
   user@R1# set label-switched-path r1-to-r5 to 192.168.5.1;
   ```

4. Configure the primary path:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r5]
user@R1# set primary via-r2
```

5. Configure the bandwidth:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name bandwidth bandwidth
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r5]
user@R1# set primary via-r2 bandwidth 35m
```

6. Configure the priority value:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name priority reservation-priority setup-priority
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r5]
user@R1# set primary via-r2 priority 6 6
```

7. Verify and commit the configuration:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# show
user@host# commit
```

Sample Output The sample output below illustrates the configuration of the primary path on ingress router **R1**.

```
[edit protocols mpls]
user@R1# show
label-switched-path r1-to-r5 {
    to 192.168.5.1;
    primary via-r2 {   #  Bandwidth and priority configured at the primary path

        bandwidth 35m; #  level of the hierarchy
        priority 6 6; #  Priority setup and hold values
    }
}
path via-r2 { #  Primary ERO list
    10.0.12.14 strict;
    10.0.24.2 strict;
[...Output truncated...]

[edit protocols mpls]
user@R1# commit
commit complete
```

Meaning The sample output shows a label-switched path (LSP) with bandwidth and priority applied to only one primary path. The same parameters specified one level up in the hierarchy, at the **[edit protocols mpls label-switched-path *lsp-path-name*]** hierarchy level, affect all paths.

The path, **via-r2**, specifies the complete strict path from the ingress to the egress routers through **10.0.12.14**, **10.0.24.2**, in that order. There cannot be any intermediate routers except the ones specified. However, there can be intermediate routers between **10.0.24.2** and the egress router because the egress router is not specifically listed in the path statement. To prevent intermediate routers before egress, configure the egress router as the last router, with a strict type.

Ensuring That Secondary Paths Establish When Resources Are Diminished

The Junos OS does not require that a primary and secondary path share the same parameters. You may decide to configure your primary paths with strict resource requirements, and configure your secondary paths with less strict requirements, allowing your secondary paths to establish more readily during periods of diminished resources.

Action To ensure that secondary paths establish when resources are diminished, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit protocols mpls]
   user@host# edit label-switched-path lsp-path-name
   ```

   For example:

```
[edit protocols mpls]
user@R1# edit label-switched-path r1-to-r4
```

2. Configure the bandwidth for the primary path, and do not configure any bandwidth for the secondary path:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name bandwidth bandwidth
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r4]
user@R1# set primary via-r2 bandwidth 35m
```

3. Verify and commit the configuration:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# show
user@host# commit
```

Sample Output The sample output below illustrates a bandwidth configuration on ingress router R1.

```
[edit protocols mpls]
user@R1# show
label-switched-path r1-to-r4 {
    to 192.168.4.1;
     primary via-r2 {
         bandwidth 35m;
    }
    secondary via-r7 { #  In this example, bandwidth is not configured for the
secondary path.
        standby;       #  However you could configure a bandwidth value different
 from
    }                   #  that on the primary path.
}
[...Output truncated...]
```

Meaning The sample output shows the primary path **via-r2** requires 35 Mbps of bandwidth, while secondary path **via-r7** has no constraints. The primary path is configured with strict resource requirements, while the secondary path is configured with no bandwidth requirements, allowing the secondary path to establish more readily during periods of diminished resources. One thing to keep in mind when configuring a secondary path without bandwidth requirements is that it can be subject to traffic loss due to congestion.

One-to-One Backup Overview

Fast reroute or one-to-one backup is a short-term solution to reduce packet loss associated with a particular LSP. One-to-one backup is appropriate under the following circumstances:

- Protection of a small number of LSPs relative to the total number of LSPs.
- Path selection criteria, such as bandwidth, priority, and link coloring for detour paths is critical.
- Control of individual LSPs is important.

In one-to-one backup, the ingress router adds the fast reroute object to the RSVP Path message requesting that downsteam routers establish detours. Downstream routers generate Path messages and establish detours to avoid the downstream link or node. Detours are always calculated to avoid the immediate downstream link and node, providing against both link and node failure, as shown in Figure 123 on page 1470.

Figure 123: One-to-One Backup Detours

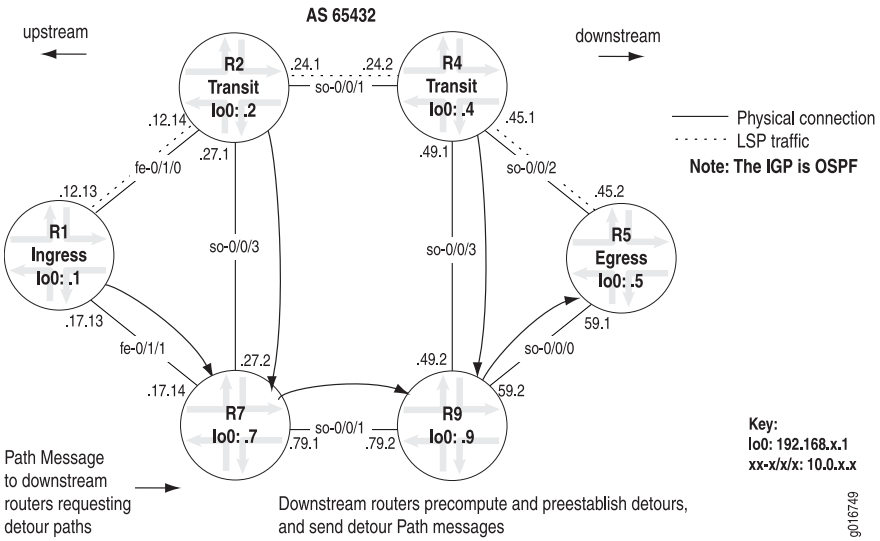

Figure 123 on page 1470 shows a network with one LSP configured from the ingress router **R1** to the egress router **R5**, transiting **R2** and **R4**. The following detours are established:

- **R1** creates a detour to **R5** via **R7** and **R9**
- **R2** creates a detour to **R5** via **R7** and **R9**
- **R4** creates a detour to **R5** via **R9**

Each detour is dedicated to a particular LSP traversing the router (one detour to one LSP). If the network topology has insufficient links and nodes, it may be impossible to establish a detour. Also, detour paths are not meant for long-term use because they may provide inadequate bandwidth and can result in congestion on the links. As soon as the ingress router calculates a new path avoiding the failure, traffic is redirected along the new path, detours are torn down, and new detours established.

Configure Link Protection

Purpose Configuring link protection is a two-part process. The first part involves configuring link protection on the RSVP interface, and the second part sets link protection for any LSPs traversing the protected link that require use of the bypass path.

Action To configure link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@R1# edit protocols rsvp interface type-fpc/pic/port
   ```

   For example:

   ```
   [edit]
   user@R1# edit protocols rsvp interface fe-0/1/0
   ```

2. Configure link protection for the interface:

   ```
   [edit protocols rsvp interface type-fpc/pic/port]
   user@R1# set link-protection
   ```

3. Verify the link protection configuration for the interface:

   ```
   [edit protocols rsvp interface type-fpc/pic/port]
   user@R1# show
   ```

4. Configure link protection for LSPs requiring use of the bypass path:

   ```
   [edit protocols rsvp interface fe-0/1/0.0]
   user@R1# top
   [edit]
   user@R1# edit protocols mpls label-switched-path lsp-path-name
   ```

   For example:

   ```
   [edit]
   user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
   ```

5. Configure link protection for the LSP:

   ```
   [edit protocols mpls label-switched-path lsp-path-name]
   user@R1# set link-protection
   ```

6. Verify and the link protection configuration for the LSP:

   ```
   [edit protocols mpls label-switched-path lsp-path-name]
   user@R1# show
   user@R1# commit
   ```

Sample Output The following sample output illustrates the configuration of the link protection on ingress router R1 in the network shown in Figure 107 on page 1270:

```
[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
     link-protection; #Protection for the RSVP interface
}

[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
label-switched-path lsp2-r1-to-r5  { #Path level of the hierarchy
    #to 192.168.5.1;
    link-protection;

[edit protocols mpls]
user@R1# commit
commit complete
```

Meaning The sample output shows link protection for a specific interface. After link protection is configured, a bypass path is signaled to avoid that link in case of a failure. Having a bypass path available does not in itself provide protection for LSPs that traverse the protected link. You must configure link protection on the ingress router for each LSP that will benefit from the bypass path.

Configuring and Verifying Link Protection

The following sections describe the steps you must take to configure and verify link protection (many-to-one backup):

1. Configure Link Protection on page 1472
2. Verify That Link Protection Is Up on page 1474

Configure Link Protection

Purpose Configuring link protection is a two-part process. The first part involves configuring link protection on the RSVP interface, and the second part sets link protection for any LSPs traversing the protected link that require use of the bypass path.

Action To configure link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@R1# edit protocols rsvp interface type-fpc/pic/port
   ```

   For example:

```
[edit]
user@R1# edit protocols rsvp interface fe-0/1/0
```

2. Configure link protection for the interface:

```
[edit protocols rsvp interface type-fpc/pic/port]
user@R1# set link-protection
```

3. Verify the link protection configuration for the interface:

```
[edit protocols rsvp interface type-fpc/pic/port]
user@R1# show
```

4. Configure link protection for LSPs requiring use of the bypass path:

```
[edit protocols rsvp interface fe-0/1/0.0]
user@R1# top
[edit]
user@R1# edit protocols mpls label-switched-path lsp-path-name
```

   For example:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
```

5. Configure link protection for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# set link-protection
```

6. Verify and the link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
user@R1# commit
```

Sample Output The following sample output illustrates the configuration of the link protection on ingress router R1 in the network shown in Figure 107 on page 1270:

```
[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
     link-protection; #Protection for the RSVP interface
}

[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
label-switched-path lsp2-r1-to-r5  { #Path level of the hierarchy
    #to 192.168.5.1;
    link-protection;

[edit protocols mpls]
user@R1# commit
commit complete
```

Meaning The sample output shows link protection for a specific interface. After link protection is configured, a bypass path is signaled to avoid that link in case of a failure. Having a bypass path available does not in itself provide protection for LSPs that traverse the protected link. You must configure link protection on the ingress router for each LSP that will benefit from the bypass path.

Verify That Link Protection Is Up

Purpose When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in Figure 107 on page 1270, a bypass path should be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

Action To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface
```

Sample Output

```
user@R1> show mpls lsp extensive | no-more
Ingress LSP: 1 sessions

```

Meaning The sample output from ingress router **R1** shows that **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have link protection up, and both LSPs are using the bypass path, **10.0.12.14**. However, the **show mpls lsp** command does not list the bypass path. For information about the bypass path, use the **show rsvp session** command.

```

Meaning The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the **show mpls lsp** command. However, because link protection is an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass >** ***interface-address***, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1** (**lsp2-r1-to-r5)** is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0.** Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
fe-0/1/0.0  Up           2    100%  100Mbps     100Mbps     0bps        35Mbps
fe-0/1/1.0  Up           1    100%  100Mbps     100Mbps     0bps        0bps
fe-0/1/2.0  Up           0    100%  100Mbps     100Mbps     0bps        0bps
so-0/0/3.0  Up           1    100%  155.52Mbps  155.52Mbps  0bps        0bps
```

Meaning The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

Configure Node-Link Protection

Configuring node-link protection is a two-part process. The first part involves configuring node-link protection for any LSPs traversing the protected node that require use of the bypass path, and the second part sets link protection on the outgoing RSVP interface on routers in the LSP.

Action To configure node-link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@R1# edit protocols mpls label-switched-path lsp-path-name
   ```

   For example:

   ```
   [edit]
   user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
   ```

2. Configure node-link protection for the LSP:

   ```
   [edit protocols mpls label-switched-path lsp-path-name]
   user@R1# set node-link-protection
   ```

3. Verify the node-link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
```

4. Configure link protection for the interface:

```
[edit protocols]
user@R1# edit protocols rsvp interface interface-name
```

For example:

```
[edit protocols]
user@R1# edit protocols rsvp interface fe-0/1/0
```

5. Configure link protection:

```
[edit protocols rsvp interface interface-name]
user@R1# set link-protection
```

6. Verify the link protection configuration for the interface, and commit both configurations:

```
[edit protocols rsvp interface interface-name]
user@R1# show
user@R1# commit
```

7. Repeat Step 1 through Step 3 on any other ingress routers that have LSPs requiring use of the bypass path.
8. Repeat Step 4 and Step 5 on routers with outgoing interfaces in the LSP.

Sample Output The following sample output shows the configuration of node-link protection on ingress router R1 in the network shown in Figure 107 on page 1270:

```
[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
label-switched-path lsp2-r1-to-r5  { #Label-switched-path level of the hierarchy

     to 192.168.5.1;
     node-link-protection; #LSP node-link protection

[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
     link-protection; #Link protection for the RSVP interface
}

[edit protocols rsvp]
user@R1# commit
commit complete
```

Meaning The sample output shows the configuration of node-link protection for an LSP. After node-link protection is configured, bypass paths are signaled to avoid the protected link or node in case of failure. Having bypass paths available does not in itself provide protection for LSPs that traverse the protected node. You must include the **node-link-protection** statement on the ingress router for each LSP that will benefit from the bypass path.

Configuring and Verifying Node-Link Protection

The following section describes the steps you must take to configure and verify many-to-one backup.

1. Configure Node-Link Protection on page 1480
2. Verify That Node-Link Protection Is Up on page 1482

Configure Node-Link Protection

Configuring node-link protection is a two-part process. The first part involves configuring node-link protection for any LSPs traversing the protected node that require use of the bypass path, and the second part sets link protection on the outgoing RSVP interface on routers in the LSP.

Action To configure node-link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   ```

```
user@R1# edit protocols mpls label-switched-path lsp-path-name
```

For example:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
```

2. Configure node-link protection for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# set node-link-protection
```

3. Verify the node-link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
```

4. Configure link protection for the interface:

```
[edit protocols]
user@R1# edit protocols rsvp interface interface-name
```

For example:

```
[edit protocols]
user@R1# edit protocols rsvp interface fe-0/1/0
```

5. Configure link protection:

```
[edit protocols rsvp interface interface-name]
user@R1# set link-protection
```

6. Verify the link protection configuration for the interface, and commit both configurations:

```
[edit protocols rsvp interface interface-name]
user@R1# show
user@R1# commit
```

7. Repeat Step 1 through Step 3 on any other ingress routers that have LSPs requiring use of the bypass path.
8. Repeat Step 4 and Step 5 on routers with outgoing interfaces in the LSP.

Sample Output The following sample output shows the configuration of node-link protection on ingress router R1 in the network shown in Figure 107 on page 1270:

```
[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
label-switched-path lsp2-r1-to-r5  { #Label-switched-path level of the hierarchy

     to 192.168.5.1;
     node-link-protection; #LSP node-link protection

[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
     link-protection; #Link protection for the RSVP interface
}

[edit protocols rsvp]
user@R1# commit
commit complete
```

Meaning The sample output shows the configuration of node-link protection for an LSP. After node-link protection is configured, bypass paths are signaled to avoid the protected link or node in case of failure. Having bypass paths available does not in itself provide protection for LSPs that traverse the protected node. You must include the **node-link-protection** statement on the ingress router for each LSP that will benefit from the bypass path.

Verify That Node-Link Protection Is Up

Purpose After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in Figure 6 on page 112, two bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

Action To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

show mpls lsp (See Sample Output on page ?)
show mpls lsp extensive (See Sample Output on page 1260)
show rsvp interface (See Sample Output on page 1261)
show rsvp interface extensive (See Sample Output on page 1262)
show rsvp session detail (See Sample Output on page 1263)

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
192.168.5.1     192.168.1.1     Up     0 via-r2           *      lsp2-r1-to-r5
Total 1 displayed,  Up 1 , Down 0

Total 2 displayed, Up 2, Down 0
```

Meaning Sample output from **R1** for the **show mpls lsp** command shows a brief description of the state of configured and active LSPs for which **R1** is the ingress, transit, and egress router. All LSPs are up. **R1** is the ingress router for **lsp2-r1-to-r5**, and the egress router for return LSP **r5-to-r1**. Two LSPs transit **R1**, **lsp1-r6-to-r0** and the return LSP **r0-to-t6**. For more detailed information about the LSP, include the **extensive** option when you issue the **show mpls lsp** command.

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

192.168.5.1

Meaning Sample output from **R1** for the **show mpls lsp extensive** command shows detailed information about all LSPs for which **R1** is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass **LSP Bypass->10.0.12.14->10.0.24.2.**

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater

```

Meaning Sample output from **R1** for the **show rsvp interface** command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5.** Interface **fe-0/1/0.0** is the connecting interface between R1 and R2, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the **show rsvp interface extensive** command.

Sample Output

```
user@R1> show rsvp interface extensive
RSVP interface: 3 active

Meaning

Sample output from **R1** for the **show rsvp interface extensive** command shows more detailed information about the activity on all RSVP interfaces (**3**). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14**is a link protection bypass path (**Type: LP**), protecting the link between **R1** and **R2 fe-0/1/0.0.** The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding **R2** in case of node failure.

Sample Output

Meaning Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5)** originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

Conclusion Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection

provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment. Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

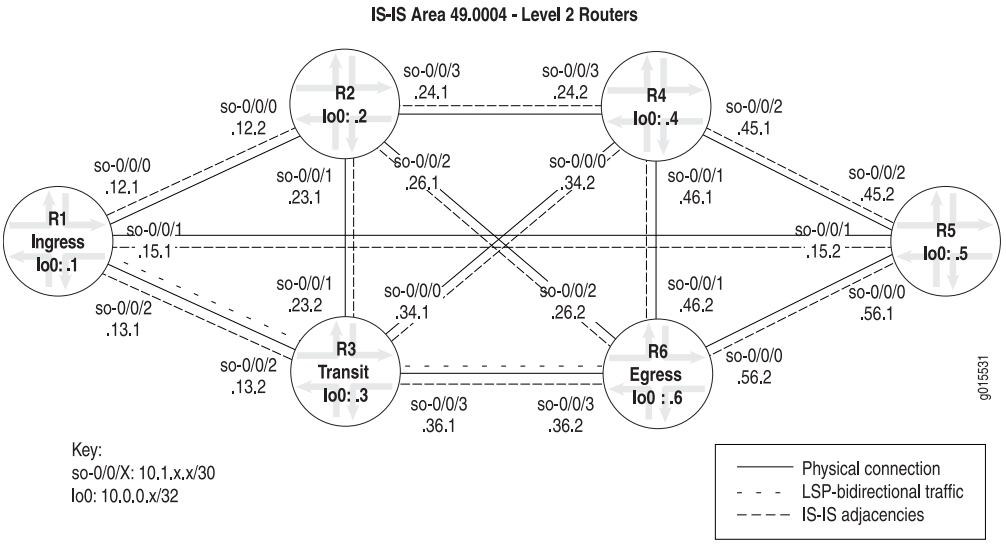
Configure IS-IS as the IGP

Before you can run MPLS on your network, you should have an IGP running on all specified routers and interfaces. The IGP can be either IS-IS or OSPF. For the steps to configure OSPF, see "Configure OSPF as the IGP" on page 1497.

Figure 124: IS-IS Network Topology



The IS-IS IGP in the MPLS network in Figure 124 on page 1489 consists of the following:

- All routers are configured for Level 2, therefore default CSPF LSPs can occur.
- All routers are in IS-IS area 49.0004. However, the routers in this network could be in any area because Level 2 adjacencies occur between all directly connected Level 2 routers regardless of which area they are in.

- Level 2 adjacencies between all directly connected Level 2 routers as follows:
  - R1 is adjacent to R2, R3, and R5
  - R2 is adjacent to R1, R3, R4, and R6
  - R3 is adjacent to R1, R2, R4, and R6
  - R4 is adjacent to R2, R3, R5, and R6
  - R5 is adjacent to R1, R4, and R6
  - R6 is adjacent to R2, R3, R4, and R5

When you configure IS-IS as the IGP, you must enable IS-IS on the router, configure International Organization for Standardization (ISO) addressing, and enable IS-IS on all router interfaces.

You can enable IS-IS throughout the rest of the network by repeating Step 1, "Enable IS-IS on Routers in Your Network" on page 1490 through Step 3, "Enable IS-IS on Router Interfaces" on page 1494 as appropriate on other routers until all routers and interfaces establish IS-IS adjacencies.

To configure IS-IS and establish IS-IS adjacencies, follow these steps:

1. Enable IS-IS on Routers in Your Network on page 1490
2. Configure ISO Addressing on page 1493
3. Enable IS-IS on Router Interfaces on page 1494
4. Verify That IS-IS Adjacencies Are Established on page 1495

Enable IS-IS on Routers in Your Network

Action To enable IS-IS on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols isis
```

2. Disable Level 1 if appropriate for your network:

```
[edit protocols isis]
user@host# set level 1 disable
```

3. Configure the interface:

```
[edit protocols isis]
user@host# edit interface type-fpc/pic/port level level-number metric metric
```

4. Disable the management interface if you have included the **interface all** statement, as shown in Sample Output 2 on page 1491:

```
[edit protocols isis]
user@host# set interface fxp0.0 disable
```

5. Include the loopback interface (**lo0**) if you have listed all interfaces separately, as shown in Sample Output 1 on page 1491:

```
[edit protocols isis]
user@host# set interface lo0.0
```

6. Set the loopback interface (**lo0**) to passive:

```
[edit protocols isis]
user@R1# set interface lo0 passive
```

7. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output 1

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols isis

[edit protocols isis]
user@R1# set level 1 disable

[edit protocols isis]
user@host# edit interface all level 2 metric 10

[edit protocols isis]
user@host# set interface lo0.0

[edit protocols isis]
user@host# set interface lo0 passive

[edit protocols isis]
user@R1# show
level 1 disable;
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface lo0.0;
     passive;
}

[edit protocols isis]
user@R1# commit
commit complete
```

Sample Output 2

```
[edit protocols isis]
user@R6# show
```

```
level 1 disable;
interface all  {
     level 2 metric 15;
}
interface fxp0.0  {
    disable;
}
interface lo0.0 {
     passive;
}
```

Meaning Sample Output 1 shows that IS-IS Level 1 is disabled, making this a Level 2 router. When all routers in the network are running at one IS-IS level (Level 2), default CSPF LSPs can occur.

Because **R1** in Sample Output 1 has all IS-IS enabled interfaces listed, including the loopback interface (**lo0**), you do not need to include the **disable** statement for the management interface (**fxp0**). All interfaces have unit number **0**, the default if a unit number is not specified. When you configure an interface at the [**edit protocols isis**] hierarchy level, and you do not include the logical unit, the default **0** is appended to the interface name, for example, **so-0/0/1.0.**

Sample Output 2 does not list the interfaces configured with IS-IS; instead, all interfaces are configured, including the loopback interface (**lo0**) and the management interface (**fxp0**). Therefore, you do not need to include a separate statement for the loopback (**lo0**) interface. However, in this instance, it is best practice to disable the management interface (**fxp0**) so that IS-IS packets are not sent over it. If you do not disable the management interface (**fxp0**) when you include the **interface-all** statement, the IS-IS protocol can form adjacencies over the management backbone, but traffic does not flow because transit traffic does not go out of the management interface.

Sample Output 2 also shows that all interfaces on **R6** are configured with a metric of **15**. A metric is not required to configure IS-IS on your interfaces. The default metric value is **10** (with the exception of the loopback [**lo0**] interface, which has a default metric of **0**). A metric is included to demonstrate that you can configure a metric for IS-IS if the default (**10**) is not appropriate for your network.

Both sample outputs show the **passive** statement included in the configuration of the loopback (**lo0**) interface. Including the **passive** statement is considered best practice and ensures the following:

- Protocols are not run over the loopback (**lo0**) interface
- When the router ID (RID) is configured manually, ensures that the loopback (**lo0**) interface is advertised to other networks.

NOTE: **It is considered best practice to configure the RID manually to avoid duplicate RID problems.**

Configure ISO Addressing

Purpose For a router to support IS-IS, you must configure an ISO network entity title (NET) address on one of the router's interfaces, preferably the loopback interface (**lo0**).

Action To configure ISO addressing, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Include a NET address for the loopback interface:

```
[edit interfaces]
user@host#  set lo0 unit number family iso address address
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set lo0 unit 0 family iso address 49.0004.1000.0000.0001.00

[edit interfaces]
userR1# show
[...Output truncated...]
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.1/32;
        }
         family iso {
            address 49.0004.1000.0000.0001.00;
        }
    }
}

[edit interfaces]
user@R1# commit
commit complete
```

Meaning The sample output shows that the loopback (**lo0**) interface is configured with the NET address **49.0004.1000.0000.0001.00**. The loopback interface (**lo0**) becomes a point of connection from the router to the IS-IS network. Every router in an IS-IS network must have at least one ISO NET address that identifies a point of connection to the IS-IS network. The NET address is generally configured on the loopback **(lo0**) interface. Routers that participate in multiple areas can have multiple NET addresses.

All the routers in the network share a Level 2 database containing identical information. A common Level 2 database occurs in this case because all adjacencies are Level 2, and all routers are within the same IS-IS area (**49.0004**). Level 2 LSP flooding reaches all routers in the network due to the presence of a single level. For more information on determining the NET address, see the *Junos Routing Protocols Configuration Guide*.

Enable IS-IS on Router Interfaces

Purpose Enable reception and transmission of ISO protocol data units (PDUs) on each router interface in the network with the **family** statement, which identifies which protocol packets are accepted into the interfaces. For example, valid IS-IS packets are dropped if the interface is not configured with the **family iso** statement.

Action To configure support for IS-IS on router interfaces in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure IS-IS:

```
[edit interfaces]
user@host# set type-fpc/pic/port unit number  family iso
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set so-0/0/2 unit 0 family iso

[edit interfaces]
```

```
userR1# show
[...Output truncated...]
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.13.1/30;
        }
         family iso;
    }
}

[edit interfaces]
user@R1# commit
commit complete
```

Meaning The sample output shows that the interface **so-0/0/2** is configured with IS-IS.

Verify That IS-IS Adjacencies Are Established

Purpose After configuring IS-IS, you must verify that neighboring routers have formed adjacencies with each other.

Action To verify IS-IS adjacencies, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show isis adjacency
```

Sample Output

```
user@R1> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R2             2 Up                   25
so-0/0/1.0            R5             2 Up                   23
so-0/0/2.0            R3             2 Up                   20

user@R3> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R4             2 Up                   25
so-0/0/1.0            R2             2 Up                   25
so-0/0/2.0            R1             2 Up                   26
so-0/0/3.0            R6             2 Up                   25

user@R6> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R5             2 Up                   19
so-0/0/1.0            R4             2 Up                   22
so-0/0/2.0            R2             2 Up                   22
so-0/0/3.0            R3             2 Up                   19
```

Sample Output

```
user@R1> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R2             2 Up                   25
so-0/0/1.0            R5             2 Up                   23
so-0/0/2.0            R3             2 Up                   20

user@R3> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R4             2 Up                   25
so-0/0/1.0            R2             2 Up                   25
so-0/0/2.0            R1             2 Up                   26
so-0/0/3.0            R6             2 Up                   25

user@R6> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R5             2 Up                   19
so-0/0/1.0            R4             2 Up                   22
so-0/0/2.0            R2             2 Up                   22
so-0/0/3.0            R3             2 Up                   19
```

Meaning The sample output from the ingress, transit, and egress routers shows that all routers in the network have formed IS-IS adjacencies.

Verify That IS-IS Adjacencies Are Established

Purpose After configuring IS-IS, you must verify that neighboring routers have formed adjacencies with each other.

Action To verify IS-IS adjacencies, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show isis adjacency
```

Sample Output

```
user@R1> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R2             2 Up                   25
so-0/0/1.0            R5             2 Up                   23
so-0/0/2.0            R3             2 Up                   20

user@R3> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R4             2 Up                   25
so-0/0/1.0            R2             2 Up                   25
so-0/0/2.0            R1             2 Up                   26
so-0/0/3.0            R6             2 Up                   25

user@R6> show isis adjacency
```

```
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R5             2 Up                   19
so-0/0/1.0            R4             2 Up                   22
so-0/0/2.0            R2             2 Up                   22
so-0/0/3.0            R3             2 Up                   19
```

Sample Output

```
user@R1> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R2             2 Up                   25
so-0/0/1.0            R5             2 Up                   23
so-0/0/2.0            R3             2 Up                   20

user@R3> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R4             2 Up                   25
so-0/0/1.0            R2             2 Up                   25
so-0/0/2.0            R1             2 Up                   26
so-0/0/3.0            R6             2 Up                   25

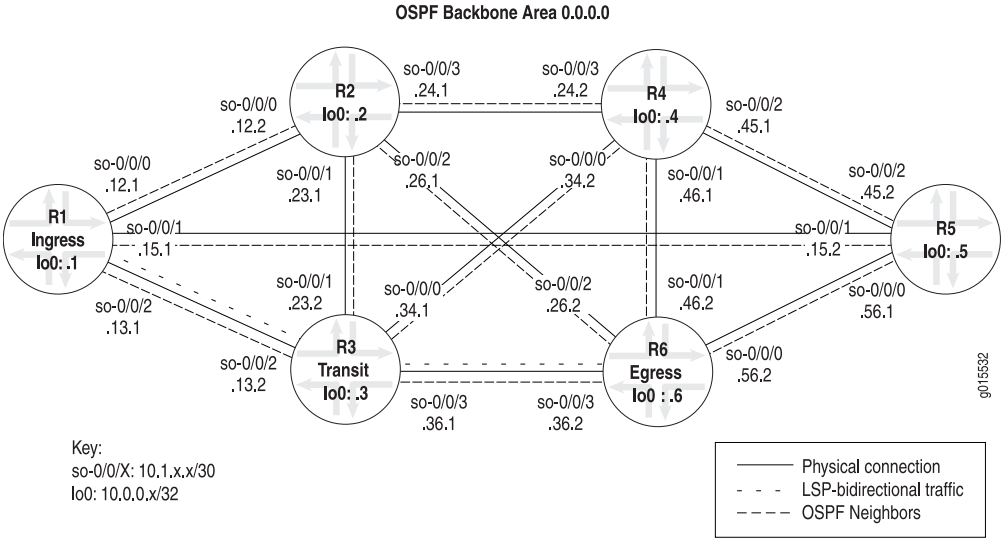
user@R6> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R5             2 Up                   19
so-0/0/1.0            R4             2 Up                   22
so-0/0/2.0            R2             2 Up                   22
so-0/0/3.0            R3             2 Up                   19
```

Meaning The sample output from the ingress, transit, and egress routers shows that all routers in the network have formed IS-IS adjacencies.

Configure OSPF as the IGP

Before you can run MPLS on your network, you must have an IGP running on all specified routers and interfaces. The IGP can be either OSPF or IS-IS. For the steps to configure IS-IS, see "Configure IS-IS as the IGP" on page 1489.

Figure 125: OSPF Network Topology



The OSPF IGP in the MPLS network in Figure 124 on page 1489 consists of the following:

- All routers are configured for the backbone OSPF area 0.0.0.0.
- All routers have the RID manually configured to avoid possible problems when the OSPF RID changes; for example, when multiple loopback addresses are configured.
- All routers have traffic engineering enabled. When traffic engineering is enabled for OSPF, the SPF algorithm takes into account the various LSPs configured under MPLS and configures OSPF to generate link-state advertisements (LSAs) that carry traffic engineering parameters. These routes are installed into the primary routing table **inet.0**,but the LSPs are installed by default into the **inet.3** routing table.
- Adjacencies between all OSPF neighbors are as follows:
  - R1 is adjacent to R2, R3, and R5
  - R2 is adjacent to R1, R3, R4, and R6
  - R3 is adjacent to R1, R2, R4, and R6
  - R4 is adjacent to R2, R3, R5, and R6
  - R5 is adjacent to R1, R4, and R6
  - R6 is adjacent to R2, R3, R4, and R5

When you configure OSPF as the IGP, you must enable OSPF and traffic engineering on the router. We also recommend that you manually configure the RID and include the loopback interface (**lo0**) at the [**edit protocols ospf**] hierarchy level.

You can enable OSPF throughout the rest of the network by repeating this step as appropriate on other routers until all routers and interfaces establish OSPF neighbors.

To configure OSPF and establish OSPF neighbors, follow these steps:

1. Enable OSPF on Routers in Your Network on page 1499
2. Verify That OSPF Neighbors Are Established on page 1501

Enable OSPF on Routers in Your Network

Action To enable OSPF on routers in your MPLS network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host#  edit protocols ospf
```

2. Configure the area and the interface:

```
[edit protocols ospf]
user@host#  set area area-id interface type-fpc/pic/port
```

3. Disable the management interface if you have included the **interface all** statement in the previous step:

```
[edit protocols ospf]
user@host# set interface  fxp0.0 disable
```

4. Include the loopback (**lo0**) interface if you intend to manually configure the RID:

```
[edit protocols ospf]
user@host#  set area 0.0.0.0 interface lo0
```

5. Set the loopback interface (**lo0**) to passive:

```
[edit protocols ospf]
user@host#  set area 0.0.0.0 interface lo0 passive
```

6. Configure traffic engineering:

```
[edit protocols ospf]
user@host#  set traffic-engineering
```

7. Manually configure the RID at the [**routing-options**] hierarchy level:

```
[edit]
user@host# edit routing-options
[edit routing-options]
user@host#  set router-id router-id
```

8. Verify and commit the entire configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols ospf

[edit protocols ospf]
user@R6# set area 0.0.0.0 interface so-0/0/0.0

[edit protocols ospf]
user@R6# set area 0.0.0.0 interface lo0

[edit protocols ospf]
user@R6# set area 0.0.0.0 interface lo0 passive

[edit protocols ospf]
user@R6# set traffic-engineering

[edit protocols ospf]
user@R6# show
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
    interface so-0/0/3.0;
    interface lo0.0 {
         passive;
}

[edit protocols ospf]
user@R6# commit
commit complete

[edit]
user@R6# edit routing-options

[edit routing-options]
user@R6# set router-id 10.0.0.6

[edit routing-options]
user@R6# show
[...Output truncated...]
router-id 10.0.0.6;
autonomous-system 65432;

[edit routing-options]
user@R6# commit
commit complete
```

Meaning The sample output shows that OSPF, with traffic engineering, is enabled on the interfaces on egress router **R6**. In addition, the RID is configured manually to avoid possible problems

when the OSPF RID changes; for example, when multiple loopback addresses are configured. The RID uniquely identifies the router within the OSPF network. It is transmitted within the LSAs used to populate the link-state database and calculate the shortest-path tree. In a link-state network, it is important that two routers do not share the same RID value, otherwise IP routing problems may occur.

The sample outputs also shows the **passive** statement included in the configuration of the loopback (**lo0**) interface. Including the **passive** statement is considered best practice and ensures the following:

- Protocols are not run over the loopback (**lo0**) interface
- When the router ID (RID) is configured manually, ensures that the loopback (**lo0**) interface is advertised to other networks.

Verify That OSPF Neighbors Are Established

Purpose After configuring OSPF, you must verify that neighboring routers have formed adjacencies with each other.

Action To verify OSPF neighbors, enter the following Junos OS CLI operational mode command:

```
user@host> show ospf neighbor
```

Sample Output

```
user@R1> show ospf neighbor
  Address          Interface              State      ID               Pri  Dead
10.1.12.2          so-0/0/0.0             Full       10.0.0.2         128   37
10.1.15.2          so-0/0/1.0             Full       10.0.0.5         128   35
10.1.13.2          so-0/0/2.0             Full       10.0.0.3         128   38

user@R3> show ospf neighbor
  Address          Interface              State      ID               Pri  Dead
10.1.34.2          so-0/0/0.0             Full       10.0.0.4         128   38
10.1.23.1          so-0/0/1.0             Full       10.0.0.2         128   35
10.1.13.1          so-0/0/2.0             Full       10.0.0.1         128   37
10.1.36.2          so-0/0/3.0             Full       10.0.0.6         128   36

user@R6> show ospf neighbor
  Address          Interface              State      ID               Pri  Dead
10.1.56.1          so-0/0/0.0             Full       10.0.0.5         128   39
10.1.46.1          so-0/0/1.0             Full       10.0.0.4         128   37
10.1.26.1          so-0/0/2.0             Full       10.0.0.2         128   36
10.1.36.1          so-0/0/3.0             Full       10.0.0.3         128   37
```

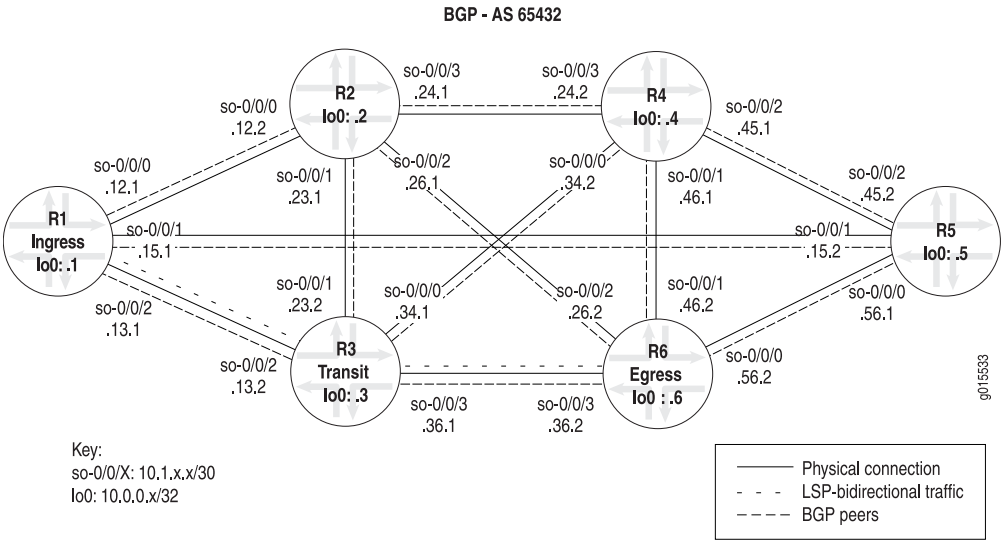
Meaning The sample output from the ingress, transit, and egress routers shows that all routers in the network have formed OSPF neighbor adjacencies.

Set Up BGP on Routers in Your Network

Before BGP can function in your MPLS network, you must define the autonomous system (AS) number on the routers in your network, and configure at least one group that includes at least one peer.

Optionally, you can configure a routing policy. The routing policy allows you to control the information shared with BGP neighbors and provides the opportunity to filter and modify the information you receive.

Figure 126: BGP Network Topology



The BGP configuration in the MPLS network in Figure 126 on page 1502 consists of the following:

- A full-mesh IBGP topology, using AS 65432.
- All IBGP sessions peer between loopback addresses because significant stability advantages are gained.
- All routers are configured with one group, **group internal**.
- A **send-statics** policy on routers R1 and R6 allows a new route to be advertised into the network.

The example network uses IS-IS Level 2 and a policy to create routes that are reachable through the LSP. However, IS-IS Level 1 or an OSPF area can be used and the policy omitted if the network has existing BGP traffic.

You can set up BGP throughout the rest of the network by repeating Step 1, "Define the Local Autonomous System" on page 1503 through Step 3, "Configure a Simple Routing Policy" on page 1505 as appropriate on other routers until all routers are set up with BGP.

To set up BGP on routers in your network, follow these steps:

Define the Local Autonomous System

Purpose Before BGP can function, you need to define a local AS number on the routers in your network. In the example network in Figure 126 on page 1502, all routers are in AS 65432.

Action To define an AS number on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit routing-options
```

2. Configure all interfaces to a specific AS:

```
[edit routing-options]
user@host# set autonomous-system as-number
```

3. Verify the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit routing-options

[edit routing-options]
user@R1# set autonomous-system 65432

[edit routing-options]
user@R1# show
[...Output truncated...]
autonomous-system 65432;

[edit routing-options]
```

```
user@R6# commit
commit complete
```

Meaning The output shows that router **R1** resides in **AS 65432**. All other routers in the example network shown in Figure 126 on page 1502 also reside in **AS 65432**.

Configure BGP Neighbor Connections

Purpose You must configure at least one group that includes at least one peer for BGP to run in your network. First determine which neighbors are internal or external to your local AS boundary. Internal neighbors are inside your local AS boundary. In the example network shown in Figure 126 on page 1502, all the routers are in one AS and are therefore internal. In this example, all IBGP sessions peer between loopback addresses because significant stability advantages are gained. For more information about configuring BGP neighbor connections, see the *Junos Routing Protocols Configuration Guide*.

Action To configure BGP neighbor connections, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols bgp
   ```

2. Configure the group and peer's IP address:

   ```
   [edit protocols bgp]
   user@host# set group group-name type type neighbor neighbor-address
   ```

   NOTE: For external neighbors, use the following form of the command that includes the peer's AS number:

   ```
   user@host# set group group-name neighbor neighbor-address peer-as
     peer-as-number
   ```

3. Configure the local address:

   ```
   [edit protocols bgp]
   user@host# set group group-name local-address local-address
   ```

4. Verify and commit the configuration:

   ```
   user@host# show
   ```

   ```
   user@host# commit
   ```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols bgp

[edit protocols bgp]
user@R1# set group internal type internal neighbor 10.0.0.2

[edit protocols bgp]
users@R1# set group internal local-address 10.0.0.1

[edit protocols bgp]
user@R1# show
group internal  {
    type internal;
     local-address 10.0.0.1;
     neighbor 10.0.0.2;
    neighbor 10.0.0.3;
    neighbor 10.0.0.5;
    neighbor 10.0.0.4;
    neighbor 10.0.0.6;
}

[edit protocols bgp]
user@R1# commit
commit complete
```

Meaning The sample output shows that router **R1** is in an internal group with five BGP neighbors. The **local-address** statement is included in this example configuration because IBGP is used. It is considered best practice to configure a local address when you use an IBGP. BGP messages are sourced from the loopback address because the **local-address** statement is included in the configuration. Generally, you would not configure a local address when external BGP is configured.

Configure a Simple Routing Policy

Purpose Routing policy allows you to control the information shared with BGP neighbors and provides the opportunity to filter and modify the information you receive. Typically, a network is injected into BGP using a policy. This may also be done through a static route. In the network in Figure 126 on page 1502, a static route export policy is used to inject routes into BGP.

Action To configure a simple routing policy, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit routing-options
   ```

2. Configure a static route for redistribution to other autonomous systems:

```
[edit routing-options]
user@host# set static route destination/24 reject
```

3. Configure a routing policy that matches and accepts the configured static routes into BGP updates:

```
[edit]
user@host# edit policy-options
[edit policy-options]
user@host# set policy-statement policy-name term term-name from route-filter
  address exact
user@host# set policy-statement policy-name term term-name then accept
```

4. Apply the policy created in Step 3 to all BGP neighbors:

```
[edit]
user@host# edit protocols bgp
[edit protocols bgp]
user@host#  set export policy-name
```

5. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit routing-options

[edit routing-options]
user@R1# set static route 100.100.1.0/24 reject

[edit routing-options]
user@R1# show
[...Output truncated...]
    route 100.100.1.0/24 reject;
}
router-id 10.0.0.1;
autonomous-system 65432;

[edit routing-options]
user@R1# top

[edit]
user@R1# edit policy-options

[edit policy-options]
user@R1# set policy-statement send-statics term statics from route-filter 100.100.1.0/24 exact

[edit policy-options]
```

```
user@R1# set policy-statement send-statics term statics then accept

[edit policy-options]
user@R1# top

[edit]
user@R1# edit protocols bgp

[edit protocols bgp]
user@R1# set export send-statics

[edit protocols bgp]
user@R1# show
export send-statics;
group internal {
    type internal;
    local-address 10.0.0.1;
    neighbor 10.0.0.2;
    neighbor 10.0.0.3;
    neighbor 10.0.0.5;
    neighbor 10.0.0.4;
    neighbor 10.0.0.6;
}

[edit protocols bgp]
user@R1# commit
commit complete
```

Meaning The sample output shows that routing policy **send-statics** is configured on the router. The routing policy matches and accepts the configured static routes into the routing table and injects the routes into BGP updates. Typically, a routing policy is applied at the group level, although it can be applied at the global level, as shown in this example.

Verify That BGP Sessions Are Up

Purpose After configuring BGP, you must verify that BGP peers are established and the sessions are up.

Action To verify BGP peers and sessions, enter the following Junos OS CLI operational mode command:

```
user@host> show bgp summary
```

Sample Output

```
user@R1> show bgp summary
Groups: 1 Peers: 5 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
inet.0                 1          1          0          0          0          0

10.0.0.5        65432       1347       1350       0       0    11:13:50 0/0/0                0/0/0
```

Meaning The sample output from the ingress, transit, and egress routers shows that all routers in the network shown in Figure 126 on page 1502 have BGP peers established and sessions up.

Define the Local Autonomous System

Purpose Before BGP can function, you need to define a local AS number on the routers in your network. In the example network in Figure 126 on page 1502, all routers are in AS 65432.

Action To define an AS number on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit routing-options
   ```

2. Configure all interfaces to a specific AS:

   ```
   [edit routing-options]
   user@host#  set autonomous-system as-number
   ```

3. Verify the configuration:

   ```
   user@host# show
   ```

   ```
   user@host# commit
   ```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit routing-options

[edit routing-options]
user@R1# set autonomous-system 65432

[edit routing-options]
user@R1# show
[...Output truncated...]
autonomous-system 65432;

[edit routing-options]
user@R6# commit
commit complete
```

Meaning The output shows that router **R1** resides in **AS 65432**. All other routers in the example network shown in Figure 126 on page 1502 also reside in **AS 65432**.

Enable MPLS and RSVP

You can enable MPLS and RSVP throughout the rest of the network by repeating Step 1, "Enable MPLS and RSVP on Routers" on page 1509 and Step 2, "Enable MPLS on Transit Router Interfaces" on page 1511 as appropriate on other routers until all routers are enabled with MPLS and RSVP.

1. Enable MPLS and RSVP on Routers on page 1509
2. Enable MPLS on Transit Router Interfaces on page 1511

Enable MPLS and RSVP on Routers

Action To enable MPLS and RSVP on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols
   ```

2. Configure MPLS and RSVP:

   ```
   [edit protocols]
   user@host#  set mpls interface all
   user@host#  set rsvp interface all
   ```

3. Disable the management interface for MPLS and RSVP:

   ```
   [edit protocols mpls]
   user@host# set interface  fxp0.0 disable
   ```

```
[edit protocols rsvp]
user@host# set interface  fxp0.0 disable
```

4. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols

[edit protocols]
user@R1# set mpls interface all

[edit protocols]
user@R1# set rsvp interface all

[edit protocols]
user@R1# show
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    interface all;
    interface fxp0.0 {
        disable;
    }
}

[edit protocols]
user@R1# commit
commit complete
```

Meaning

The sample output shows that router **R1** has MPLS and RSVP enabled on all interfaces, except for the management interface (**fxp0.0**), which is disabled. It is considered best practice to disable the management interlace (**fxp0.0**) for MPLS and RSVP to preempt any problems.

Typically every interface that you want to use is listed. For an example of a router configured with specific interfaces, see "Enable IS-IS on Routers in Your Network" on page 1490.

Enable MPLS on Transit Router Interfaces

Purpose Even though transit interfaces are enabled with MPLS when you include the **family mpls** statement in the configuration, MPLS as a whole is not configured on your router or in your network. You must complete all five steps in this topic to have the MPLS protocol running on your network.

NOTE: The management interface (fxp0) and the loopback interface (lo0) are not transit interfaces.

Action To configure transit interfaces to support MPLS, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure MPLS:

```
[edit interfaces]
user@host# set type-fpc/pic/port unit number  family mpls
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set so-0/0/2 unit 0 family mpls

[edit interfaces]
user@R1# show
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.13.1/30;
        }
        family iso;
         family mpls;
    }
}

[edit interfaces]
user@R1# commit
commit complete
```

Meaning The sample output shows that the interface **so-0/0/2** is configured to support MPLS. The **family** statement identifies which protocol packets are accepted into the interfaces. For example, valid MPLS packets are dropped if the interface is not configured with the MPLS protocol.

Enable MPLS and RSVP on Routers

Action To enable MPLS and RSVP on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols
   ```

2. Configure MPLS and RSVP:

   ```
   [edit protocols]
   user@host#  set mpls interface all
   user@host#  set rsvp interface all
   ```

3. Disable the management interface for MPLS and RSVP:

   ```
   [edit protocols mpls]
   user@host# set interface  fxp0.0 disable
   [edit protocols rsvp]
   user@host# set interface  fxp0.0 disable
   ```

4. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols

[edit protocols]
user@R1# set mpls interface all

[edit protocols]
user@R1# set rsvp interface all

[edit protocols]
user@R1# show
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    interface all;
    interface fxp0.0 {
        disable;
    }
}

[edit protocols]
user@R1# commit
commit complete
```

Meaning The sample output shows that router **R1** has MPLS and RSVP enabled on all interfaces, except for the management interface (**fxp0.0**), which is disabled. It is considered best practice to disable the management interlace (**fxp0.0**) for MPLS and RSVP to preempt any problems.

Typically every interface that you want to use is listed. For an example of a router configured with specific interfaces, see "Enable IS-IS on Routers in Your Network" on page 1490.

Enable MPLS on Transit Router Interfaces

Purpose Even though transit interfaces are enabled with MPLS when you include the **family mpls** statement in the configuration, MPLS as a whole is not configured on your router or in

your network. You must complete all five steps in this topic to have the MPLS protocol running on your network.

NOTE: The management interface (fxp0) and the loopback interface (lo0) are not transit interfaces.

Action To configure transit interfaces to support MPLS, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure MPLS:

```
[edit interfaces]
user@host# set type-fpc/pic/port unit number  family mpls
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set so-0/0/2 unit 0 family mpls

[edit interfaces]
user@R1# show
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.13.1/30;
        }
        family iso;
         family mpls;
    }
}

[edit interfaces]
user@R1# commit
commit complete
```

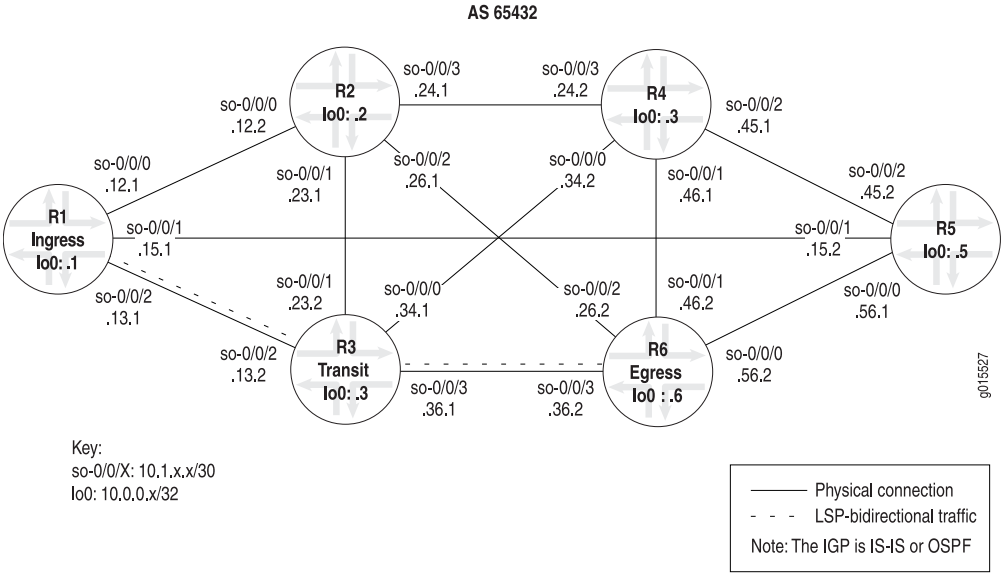
Meaning The sample output shows that the interface **so-0/0/2** is configured to support MPLS. The **family** statement identifies which protocol packets are accepted into the interfaces. For example, valid MPLS packets are dropped if the interface is not configured with the MPLS protocol.

Verifying the MPLS Configuration

After configuring MPLS on your network, you must verify the correct configuration of both the MPLS and RSVP protocols. Incorrect configuration of either protocol prevents successful LSP creation.

Figure 127 on page 1516 illustrates the network with the example configurations used in this topic.

Figure 127: MPLS Network Topology



To verify the MPLS configuration, follow these steps:

1. Verify MPLS Interfaces on page 1516
2. Verify the RSVP Protocol on page 1518
3. Verify RSVP Interfaces on page 1519
4. Verify Protocol Families on page 1521

Verify MPLS Interfaces

Purpose If the MPLS protocol is not configured correctly on the routers in your network, the interfaces are not able to perform MPLS switching.

Action To verify MPLS interfaces, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls interface
```

Sample Output 1

The following sample output is for all routers in the network shown in *MPLS Network Topology*.

```
user@R1> show mpls interface
Interface           State       Administrative groups
so-0/0/0.0          Up          <none>
so-0/0/1.0          Up          <none>
so-0/0/2.0          Up          <none>

user@R2> show mpls interface
Interface           State       Administrative groups
```

```
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>

user@R3> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>

user@R4> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>

user@R5> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>

user@R6> show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/2.0        Up          <none>
so-0/0/3.0        Up          <none>
```

Sample Output 2

```
user@R6>  show mpls interface
Interface         State       Administrative groups
so-0/0/0.0        Up          <none>
so-0/0/1.0        Up          <none>
so-0/0/3.0        Up          <none>        # so-0/0/2.0 is missing
```

Sample Output 3

```
user@host> show mpls interface
MPLS not configured
```

Meaning Sample Output 1 shows that all MPLS interfaces on all routers in the network are enabled (**Up**) and can perform MPLS switching. If you fail to configure the correct interface at the [**edit protocols mpls**] hierarchy level or include the **family mpls** statement at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level, the interface cannot perform MPLS switching, and does not appear in the output for the **show mpls interface** command.

Administrative groups are not configured on any of the interfaces shown in the example network in *MPLS Network Topology*. However, if they were, the output would indicate which affinity class bits are enabled on the router.

Sample Output 2 shows that interface **so-0/0/2.0** is missing and therefore might be incorrectly configured. For example, the interface might not be included at the [**edit protocols mpls**] hierarchy level, or the **family mpls** statement might not be included at the [**edit interfaces** *type-fpc/pic/port* **unit** *number*] hierarchy level. If the interface is configured correctly, RSVP might not have signaled over this interface yet. For more information on determining which interface is incorrectly configured, see "Verify Protocol Families" on page 1521.

Sample Output 3 shows that the MPLS protocol is not configured at the [**edit protocols mpls**] hierarchy level.

Verify the RSVP Protocol

Purpose If the RSVP protocol is not enabled on the routers in your network, the interface cannot signal LSPs.

Action To verify that the RSVP protocol is enabled, enter the following Junos OS CLI command:

```
user@host> show rsvp version
```

Sample Output

```
user@R1> show rsvp version
Resource ReSerVation Protocol, version 1. rfc2205
   RSVP protocol           =  Enabled
   R(refresh timer)        = 30 seconds
   K(keep multiplier)      = 3
   Preemption              = Normal
   Soft-preemption cleanup = 30 seconds
   Graceful restart        = Disabled
   Restart helper mode     = Enabled
   Restart time            = 0 msec
```

Meaning The sample output shows that the RSVP protocol is enabled on **R1**. The supported RSVP protocol is version 1, as defined in RFC 2205.

The RSVP refresh timer is set to 30 seconds, indicating that every 30 seconds, plus or minus 50 percent, the router will refresh the RSVP state with its directly connected neighbors by sending either a **Path** or a **Resv** message. The variable refresh time helps prevent harmonic oscillations in network traffic caused by periodic protocol updates.

The keepalive multiplier, **K(keep multiplier)**, is input to a formula that helps determine the lifetime of an RSVP session. The session lifetime is reset each time the state is updated. The lifetime represents the duration of an RSVP session that does not receive any state updates (**Path** or **Resv** messages). The formula is:

RSVP session lifetime = (keep-multiplier + 0.5) * 1.5 * refresh-time

The RSVP **preemption** state is currently configured for normal preemption, indicating that only an LSP with a stronger priority can preempt an existing session; that is, the setup value of the new LSP is lower than the hold value of the existing LSP. Other options include **aggressive** preemption, which always preempts when there is insufficient bandwidth, and **disabled**, which prevents any preemption, regardless of LSP priority values.

Graceful restart is currently disabled and **Restart helper mode** is enabled. There are four combinations for **Graceful restart** and **restart helper mode**:

1. Both **Graceful restart** and **Restart helper mode** are enabled.
2. **Graceful restart** is enabled but **Restart helper mode** is disabled. An LSR with this configuration can restart gracefully but cannot help a neighbor with its restart and recovery procedures.
3. **Graceful restart** is disabled but **Restart helper mode** is enabled. An LSR with this configuration can only help a restarting neighbor. It cannot restart gracefully itself.
4. **Graceful restar**t and **Restart helper mode** are both disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). It is the same as an LSR that is not supported by RSVP graceful restart.

Restart time is the estimated time (in milliseconds) for an LSR to restart the RSVP traffic engineering component. In the example output, the restart time is 0 milliseconds, indicating that it is disabled.

The output is identical for all routers in the network shown in *MPLS Network Topology*.

Verify RSVP Interfaces

Purpose If the RSVP protocol is not configured correctly on the routers in your network, the interfaces cannot signal LSPs.

Action To verify RSVP interfaces, enter the following Junos OS CLI operational mode command:

```
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show rsvp interface
RSVP interface: 4 active
                  Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
so-0/0/0.0  Up         2   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/1.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/2.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps

user@R2> show rsvp interface
```

```
RSVP interface: 5 active
                Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
so-0/0/0.0  Up         1   100%  155.52Mbps  155.52Mbps  0bps        0bps

so-0/0/0.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/1.0  Up         1    100%  155.52Mbps  155.52Mbps  0bps        0bps

so-0/0/2.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/3.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
```

Sample Output 2

```
user@R6> show rsvp interface
RSVP interface: 3 active
                Active Subscr- Static      Available   Reserved    Highwater
Interface   State resv   iption  BW          BW          BW          mark
so-0/0/0.0  Up         1   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/1.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
so-0/0/2.0  Up         0   100%  155.52Mbps  155.52Mbps  0bps        0bps
#so-0/0/3.0 is missing
```

Sample Output 3

```
user@host# show rsvp interface
RSVP not configured
```

Meaning Sample Output 1 shows that all interfaces on all routers in the network are enabled with RSVP, including the management interface (**fxp0**). The output for all routers in the network includes similar information, so we will examine R6 in detail.

R6 has five interfaces enabled with RSVP (**Up**). Interface **so-0/1/1.0** has a single active RSVP reservation (**Active resv**) that did not change the default subscription percentage of 100 percent (**Subscription**). Interface **so-0/1/1.0** did not assign a static bandwidth (**Static BW**) to the logical unit and therefore inherited 100 percent of the physical interface rate as the bandwidth available (**Available BW**) for RSVP sessions. Interface **so-0/1/1.0** has no bandwidth assigned (**Reserved BW**), and no RSVP bandwidth allocation at any single instant in time (**Highwater mark**).

Sample Output 2 shows that interface **so-0/0/3.0** is missing. If you do not configure the correct interface at the [**edit protocols rsvp**] hierarchy level, the interface cannot signal LSPs, and does not appear in the output for the **show rsvp interface** command.

Sample Output 3 shows that the RSVP protocol is not configured at the [**edit protocols rsvp**] hierarchy level.

Verify Protocol Families

Purpose If a logical interface does not have MPLS enabled, it cannot perform MPLS switching. This step allows you to quickly determine which interfaces are configured with MPLS and other protocol families.

Action To verify the protocol families configured on the routers in your network, enter the following Junos OS CLI operational mode command:

```
user@host> show interfaces terse
```

Sample Output 1

```
user@R1> show interfaces terse
Interface               Admin Link Proto Local                 Remote

                                  mpls
```

Meaning Sample Output 1 shows the interface, the administrative status of the link (**Admin**), the data link layer status of the link (**Link**), the protocol families configured on the interface (**Proto**), and the local and remote addresses on the interface.

All interfaces on all routes in the network shown in Figure 127 on page 1516 are administratively enabled and functioning at the data link layer with MPLS and IS-IS, and have an **inet** address. All are configured with an IPv4 protocol family (**inet**), and have the IS-IS (**iso**) and MPLS (**mpls**) protocol families configured at the [**edit interfaces** ***type-fpc/pic/port*** **unit** ***number***] hierarchy level.

Sample Output 2 shows that interface **so-0/0/2.0** on **R6** does not have the **mpls** statement included at the [**edit interfaces** ***type-fpc/pic/port*** **unit** ***number***] hierarchy level.

Verify the RSVP Protocol

Purpose If the RSVP protocol is not enabled on the routers in your network, the interface cannot signal LSPs.

Action To verify that the RSVP protocol is enabled, enter the following Junos OS CLI command:

```
user@host> show rsvp version
```

Sample Output

```
user@R1> show rsvp version
Resource ReSerVation Protocol, version 1. rfc2205
   RSVP protocol           =  Enabled
   R(refresh timer)        = 30 seconds
   K(keep multiplier)      = 3
   Preemption              = Normal
   Soft-preemption cleanup = 30 seconds
   Graceful restart        = Disabled
   Restart helper mode     = Enabled
   Restart time            = 0 msec
```

Meaning The sample output shows that the RSVP protocol is enabled on **R1**. The supported RSVP protocol is version 1, as defined in RFC 2205.

The RSVP refresh timer is set to 30 seconds, indicating that every 30 seconds, plus or minus 50 percent, the router will refresh the RSVP state with its directly connected neighbors by sending either a **Path** or a **Resv** message. The variable refresh time helps prevent harmonic oscillations in network traffic caused by periodic protocol updates.

The keepalive multiplier, **K(keep multiplier)**, is input to a formula that helps determine the lifetime of an RSVP session. The session lifetime is reset each time the state is updated. The lifetime represents the duration of an RSVP session that does not receive any state updates (**Path** or **Resv** messages). The formula is:

RSVP session lifetime = (keep-multiplier + 0.5) * 1.5 * refresh-time

The RSVP **preemption** state is currently configured for normal preemption, indicating that only an LSP with a stronger priority can preempt an existing session; that is, the setup value of the new LSP is lower than the hold value of the existing LSP. Other options include **aggressive** preemption, which always preempts when there is insufficient bandwidth, and **disabled**, which prevents any preemption, regardless of LSP priority values.

Graceful restart is currently disabled and **Restart helper mode** is enabled. There are four combinations for **Graceful restart** and **restart helper mode**:

1. Both **Graceful restart** and **Restart helper mode** are enabled.
2. **Graceful restart** is enabled but **Restart helper mode** is disabled. An LSR with this configuration can restart gracefully but cannot help a neighbor with its restart and recovery procedures.
3. **Graceful restart** is disabled but **Restart helper mode** is enabled. An LSR with this configuration can only help a restarting neighbor. It cannot restart gracefully itself.
4. **Graceful restar**t and **Restart helper mode** are both disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). It is the same as an LSR that is not supported by RSVP graceful restart.

Restart time is the estimated time (in milliseconds) for an LSR to restart the RSVP traffic engineering component. In the example output, the restart time is 0 milliseconds, indicating that it is disabled.

The output is identical for all routers in the network shown in *MPLS Network Topology*.

Define a Load-Balancing Policy

Purpose On the ingress or transit router, you can include a policy statement that performs load balancing on all routes. For information on including a policy statement that performs load balancing on specific routes, see “Configuring Per-Packet Load Balancing” in the *Junos Routing Protocols Configuration Guide*.

Action On the ingress or transit router, to define a load-balancing policy for all routes, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit policy-options
```

2. Define the load-balance policy and action:

```
[edit policy-options]
user@host# set policy-statement policy-name then load-balance per-packet
```

3. Verify and commit the configuration:

```
user@host# show
user@host# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit policy-options

[edit policy-options]
user@R6# set policy-statement load-balance-traffic then load-balance per-packet

[edit policy-options]
user@R6# show
policy-statement load-balance-traffic {
    then {
        load-balance per-packet;
    }
}

[edit policy-options]
user@R6# commit
commit complete
```

Meaning

The sample output from ingress router **R6** shows the process for configuring load balancing. On an Internet Processor I ASIC, packets with the same parameters are spread across multiple equal-cost next hops; while an Internet Processor II ASIC sends packets with the same parameters to the same next hop, since they are in the same flow. The Junos OS command to turn on load balancing uses the action **load-balance per-packet**, which is misnamed in relation to the Internet Processor II ASIC. On the Internet Processor II ASIC, this command actually enables per-flow load balancing.

Use the traceroute Command to Verify MPLS Labels

Purpose

You can use the **traceroute** command to verify that packets are being sent over the LSP.

Action

To verify MPLS labels, enter the following Junos OS CLI operational mode command, where ***host-name*** is the IP address or the name of the remote host:

```
user@host> traceroute host-name
```

Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.861 ms  0.718 ms  0.679 ms
      MPLS Label=100048 CoS=0 TTL=1 S=1
 2  10.1.24.2 (10.1.24.2)  0.822 ms  0.731 ms  0.708 ms
```

```
     MPLS Label=100016 CoS=0 TTL=1 S=1
3  10.1.46.2 (10.1.46.2)  0.571 ms !N  0.547 ms !N  0.532 ms !N
```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.605 ms  0.548 ms  0.503 ms
 2  10.0.0.6 (10.0.0.6)  0.761 ms  0.676 ms  0.675 ms
```

Meaning Sample Output 1 shows that MPLS labels are used to forward packets through the network. Included in the output is a label value (**MPLS Label=100048**), the time-to-live value (**TTL=1**), and the stack bit value (**S=1**).

The **MPLS Label** field is used to identify the packet to a particular LSP. It is a 20-bit field, with a maximum value of (2^^20-1), or approximately 1,000,000.

The TTL value contains a limit on the number of hops that this MPLS packet can travel through the network (1). It is decremented at each hop, and if the TTL value drops below one, the packet is discarded.

The bottom of the stack bit value (**S=1**) indicates that is the last label in the stack and that this MPLS packet has one label associated with it. The MPLS implementation in the Junos OS supports a stacking depth of 3 on the M-series routers and up to 5 on the T-series platforms. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

MPLS labels appear in Sample Output 1 because the **traceroute** command is issued to a BGP destination where the BGP next hop for that route is the LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 shows that MPLS labels do not appear in the output for the **traceroute** command. If the BGP next hop does not equal the LSP egress address or the destination is an IGP route, the BGP traffic does not use the LSP. Instead of using the LSP, the BGP traffic is using the IGP (IS-IS, in this case) to reach the egress address (**R6**).

Apply the Load-Balancing Policy to the Forwarding Table

Purpose Apply the policy configured in Step 1 to routes exported from the routing table to the forwarding table.

Action To apply a load-balancing policy to the forwarding table, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   ```

```
user@host# edit routing-options
```

2. Define a load-balance per packet action:

```
[edit routing-options]
user@host#set forwarding-table export policy-name
```

3. Verify and commit the configuration:

```
user@host# show
user@host# commit
```

Sample Output

```
[edit]
user@R6# edit routing-options

[edit routing-options]
user@R6# set forwarding-table export load-balance-traffic

[edit routing-options]
user@R6# show
static {
[...Output truncated...]
}
router-id 192.168.6.1;
autonomous-system 65432;
forwarding-table {
    export load-balance-traffic;
}

[edit routing-options]
user@R6# commit
commit complete
```

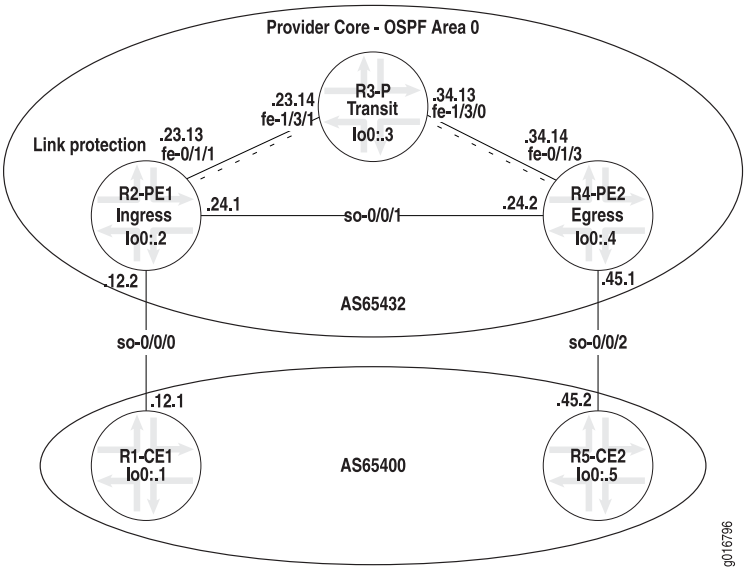
Meaning The sample output shows the process for applying a load-balancing policy to export routes from the routing table to the forwarding table.

Fast Reroute Problem Overview

Problem **Description:** Incorrect configuration is a common mistake when trying to establish protection for an MPLS LSP. Protection with either fast reroute or link protection requires a **per-packet load-balance policy** exported at the **[edit routing-options forwarding-table]** hierarchy level. Correctly configured protection for an MPLS LSP results in two next-hop forwarding table entries per destination, either an incoming MPLS label or an IP destination.

Figure 128 on page 1529 illustrates a network topology with link protection and load balancing enabled to ensure that routes are correctly placed in to the forwarding table.

Figure 128: Fast Reroute Problem Network



The network shown in Figure 128 on page 1529 illustrates an MPLS-based VPN with traffic protection and load balancing, consisting of the following:

- All physical interfaces addresses are from the 10.0.x.x/30 address space.
- All loopback addresses are from the 192.168.x.1/32 block.
- The IGP is a single-area (Area 0) OSPF.
- RSVP is deployed as the MPLS signaling protocol between PE routers.
- LSPs (**r2-r4** and **r4-r2**) established between PE routers.
- MP-IBGP mesh between PE routers, loopback peering, and VPN-IPv4 NLRI.
- CE-PE link running EBGP.
- Full-mesh Layer 3 VPN between CE1 and CE2.
- Traffic protection for the link between the PE1 and P routers.
- Load balancing on PE1.

The overall goal of this network is to provide point-to-point connectivity between the two CE routers and traffic protection in the core of the network.

Symptom In the network shown in Figure 128 on page 1529, the external symptom is that local repair is taking about one second to complete, which is slow. Use the **show route forwarding-table vpn vpn-a destination** command to check that the correct routes are included in the forwarding table. In the example output below, there is only one route installed in the forwarding table, when for fast local repair, there should be multiple next hops installed.

Sample Output

```
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive

Routing table: vpn-a.inet [Index 2]
Internet:

Destination:  192.168.5.0/24
  Route type: user
  Route reference: 0                   Route interface-index: 0
  Flags: sent to PFE, prefix load balance
  Next-hop type: indirect              Index: 262142   Reference: 2
  Next-hop type: Push 100160
   Next-hop interface: so-0/0/1.0 #Only one next hop in the forwarding table.
```

Cause Slow local repair is caused by the forwarding table not including the necessary next-hops to support local repair. The forwarding table shows only a single next-hop, when local repair requires additional next-hops for fast recovery.

Troubleshooting Commands The Junos OS includes commands that are useful when troubleshooting a problem. This topic provides a brief description of each command followed by sample output, and a discussion of the output in relation to the problem.

The following commands can be used when troubleshooting a fast reroute error in an MPLS-VPN network:

```
user@R2-PE1> show configuration routing-instances vpn-a
user@R2-PE1> show configuration routing-options
user@R2-PE1> show bgp summary instance vpn-a
user@R2-PE1> show configuration protocols mpls
user@R2-PE1> show mpls lsp ingress
user@R2-PE1> show rsvp session ingress
user@R2-PE1> show rsvp session ingress detail
user@R2-PE1> show route table vpn-a 192.168.5.1 detail
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive
```

Sample Output The **show configuration *statement-path*** command is used to display a specific configuration hierarchy; in this case, to verify the correct configuration of a specific routing instance named **vpn-a**.

```
user@R2-PE1> show configuration routing-instances vpn-a
instance-type  vrf ;
interface  so-0/0/0.0 ;
vrf-target {
    import target:65432:100;
    export target:65432:100;
}
protocols {
    bgp {
        group CE1 {
            type external;
             peer-as 65400;
             neighbor 10.0.12.1 ;
        }
    }
}
```

Meaning The sample output for the **show configuration** command shows the current running configuration of the specific routing instance named **vpn-a** configured on the ingress PE1 router. The **vpn-a** instance configuration has a VRF table that supports EBGP routing on the PE-CE link (**so-0/0/0.0**). This interface is the correct interface for the CE1-PE1 link in the network topology shown in Figure 128 on page 1529.

The VRF instance is linked to a VFR target community configured at the [edit policy-options] hierarchy level, allowing advertising of L3 VPN routes between PE routers. (See the PE1 configuration in "Router Configurations" on page 1538 for the policy options configuration.) The import statement places, into the vpn-a.inet.0 table, all received L3 VPN MP-BGP routes tagged with the correct target community. The export statement advertises and tags all routes in the vpn-a.inet.o table with the listed target community to all MP-BGP peers.

The BGP protocols configuration within the routing instance applies the BGP import and export policies to the exchange of BGP routes on the PE-CE routing instance.

Sample Output The **show bgp summary** command is used to display summary information about BGP and its neighbors to determine if routes are received from peers in the autonomous system (AS). In this case, information for the specified instance **vpn-a** is displayed.

```
user@R2-PE1> show bgp summary instance vpn-a
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
vpn-a.inet.0          11          7          0          0          0          0
Peer               AS      InPkt     OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Damped...
10.0.12.1   65400   2471   2473   0   0  20:35:20 Establ
  vpn-a.inet.0: 5/5/0
```

Meaning The sample output for the **show bgp summary instance vpn-a** command shows that the peering session between the CE1 and PE1 routers is established, indicating that the peers are exchanging update messages.

Sample Output The **show configuration *statement-path*** command is used to display a specific configuration hierarchy; in this case, the MPLS hierarchy.

```
user@R2-PE1> show configuration protocols mpls
label-switched-path r2-r4  {
    to 192.168.4.1;
     link-protection  ;
     primary direct  ;
}
path direct {
    10.0.24.2 strict;
}
interface all;
interface fxp0.0 {
    disable;
}
```

Meaning The sample output for the **show configuration protocols mpls** command shows the current running MPLS configuration on the ingress PE1 router. The configuration include the LSP **r2-r4**, link protection, and the strict primary path **direct**.

Sample Output The **show mpls lsp** command is used to display summarized information about the configured and active LSPs on a router; in this case, the command shows only the ingress LSPs on the ingress PE1 router.

```
user@R2-PE1> show mpls lsp ingress
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
192.168.4.1     192.168.2.1     Up     0 direct           *     r2-r4
Total 1 displayed, Up 1, Down 0
```

Meaning The sample output for the **show mpls lsp ingress** command shows that the ingress LSP **r2-r4** is up and following the configured path **direct**.

Sample Output The **show rsvp session** command is used to display summarized information about active RSVP sessions on a router; in this case, the command shows summarized information about ingress RSVP sessions on the PE1 router

```
user@R2-PE1> show rsvp session ingress
Ingress RSVP: 2 sessions
To              From            State   Rt Style Labelin Labelout LSPname
192.168.4.1     192.168.2.1     Up       0  1  SE        -        3  r2-r4
192.168.4.1     192.168.2.1     Up       0  1  SE        -   100064
Bypass->10.0.24.2
Total 2 displayed, Up 2, Down 0
```

Meaning The sample output for the **show rsvp session ingress** command shows two RSVP sessions are up; the main LSP **r2-r4** and a bypass path protecting the main LSP. Both RSVP sessions are in the Shared Explicit (**SE**) style, creating a shared reservation among for the two paths.

Sample Output The **show rsvp session ingress detail** command is used to display more detailed information about the two ingress RSVP sessions on the PE1 router.

```
user@R2-PE1> show rsvp session ingress detail
Ingress RSVP: 2 sessions

192.168.4.1
   From: 192.168.2.1, LSPstate: Up , ActiveRoute: 0

  Recovery label received: -, Recovery label sent: 100064
  Resv style: 1 SE, Label in: -, Label out: 100064
  Time left:    -, Since: Fri Mar  9 14:05:58 2007
  Tspec: rate 0bps size 0bps peak Infbps m 20 M 1500
  Port number: sender 1 receiver 63396 protocol 0
   Type: Bypass LSP
      Number of data route tunnel through: 1
    Number of RSVP session tunnel through: 0
  PATH rcvfrom: localclient
  Adspec: sent MTU 1500
  Path MTU: received 1500
  PATH sentto: 10.0.23.14 (fe-0/1/1.0) 2001 pkts
  RESV rcvfrom: 10.0.23.14 (fe-0/1/1.0) 1736 pkts
   Explct route: 10.0.23.14 10.0.34.14
  Record route: <self> 10.0.23.14 10.0.34.14
Total 2 displayed, Up 2, Down 0
```

Meaning The sample output for the **show rsvp session ingress detail** command shows the RSVP session for the ingress LSP and the bypass path, which appears as a separate RSVP ingress session for the protected interface **10.0.24.2**. The bypass path is automatically generated. By default, the name appears as **Bypass > *interface-address,*** where the interface address is the next downstream router's interface (**10.0.24.2**). The explicit route **10.0.23.14 10.0.34.14** for the session shows **R3** as the transit node and **R4** as the egress node.

Sample Output The **show route table*routing-table-name*** command is used to display information about a particular routing table. In this case, the **vpn-a.inet.0** routing table.

```
user@R2-PE1> show route table vpn-a 192.168.5.1 detail
vpn-a.inet.0: 9 destinations, 13 routes (9 active, 0 holddown, 0 hidden)
192.168.5.0/24 (1 entry, 1 announced)
        *BGP    Preference: 170/-101
                Route Distinguisher: 192.168.4.1:4
                Next-hop reference count: 11
                Source: 192.168.4.1
                Next hop: via so-0/0/1.0 weight 0x1, selected
                Label-switched-path r2-r4
                Label operation: Push 100160
                Next hop: 10.0.23.14 via fe-0/1/1.0 weight 0x8001
                Label-switched-path r2-r4
                Label operation: Push 100160, Push 100064(top)
                Protocol next hop: 192.168.4.1
                Push 100160
                Indirect next hop: 8791000 262142
                State: <Secondary Active Int Ext>
                Local AS: 65432 Peer AS: 65432
                Age: 1d 5:22:31         Metric2: 1
                Task: BGP_65432.192.168.4.1+2056
                Announcement bits (1): 0-KRT
                AS path: 65400 I
                Communities: target:65432:100
                VPN Label: 100160
                Localpref: 100
                Router ID: 192.168.4.1
                Primary Routing Table bgp.l3vpn.0
```

Meaning The sample output for the **show route table vpn-a 192.168.5.1 detail** command shows routes associated with the remote PE-CE location as indicated by the loopback address of the PE2 router **192.168.5.1**. In this case, there are different next hops with unequal weights (**0x1** and **0x8001**) associated with the remote location. For correct traffic protection, those two routes must appear in the forwarding table.

Sample Output The **show route forwarding-table** command displays the route entries in the kernel's forwarding table. This is the version of the forwarding table in the Routing Engine. The Routing Engine copies this table to the Packet Forwarding Engine. In this case, the set of routes installed in the forwarding table to verify that the routing protocol process (rpd) has relayed the correct information to the forwarding table for the specified destination.

```
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1
extensive
Routing table: vpn-a.inet [Index 2]
Internet:

Destination:  192.168.5.0/24
  Route type: user
  Route reference: 0                    Route interface-index: 0
  Flags: sent to PFE, prefix load balance
  Next-hop type: indirect               Index: 262142   Reference: 2
  Next-hop type: Push 100160
  Next-hop interface: so-0/0/1.0
```

Meaning The sample output for the **show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive** command shows only one next hop **so-0/0/1.0** is installed in the forwarding table, indicating that the information in the forwarding table is not correct. We would expect to see the same paths installed in the forwarding table as appear in the routing table in the output for the **show route table vpn-a 192.168.5.1 detail**.

Solution The solution is to enable load-balancing and ensure that multiple next-hop forwarding table entries appear in the forwarding table for each destination. The forwarding-table entries can be an incoming MPLS label or an IP destination.

A load-balancing policy applied to the forwarding-table is the same mechanism required for ECMP (equal-cost multipath) load-balancing to install multiple next-hops into the forwarding-table. The extra paths installed for local repair are not used for load-balancing, because the paths are differently weighted, as demonstrated in the sample output for the **show routing table** and the **show route forwarding-table** commands.

NOTE: **The load-balancing policy must be applied to all provider (P) and provider-edge (PE) routers that are required to support local repair.**

The following sample output shows an example load-balancing configuration and the commands used to verify that the required two next-hop entries appear in the forwarding table.

Sample Output Use the following two **show configuration *statement-path*** commands to display a specific configuration hierarchy; in this case, policy-options and routing-options.

```
user@R2-PE1> show configuration policy-options
policy-statement lbpf {
    then {
         load-balance per-packet ;
    }
}
[...Output truncated...]

user@R2-PE1> show configuration routing-options
static {
    [...Output truncated...]
    route 100.100.1.0/24 reject;
}
router-id 192.168.2.1;
route-distinguisher-id 192.168.2.1;
autonomous-system 65432;
forwarding-table {
    export lbpf ;
}
```

Meaning The sample output for the **show configuration policy-options** and **show configuration routing-options** commands shows the two parts required to configure a load balancing policy. The **lbpf** policy includes the **load-balance per-packet** statement. The policy is then applied at the **[edit routing options forwarding-table]** hierarchy level with the **export lbpf** statement. Enabling load balancing results in the export of routes from the routing table to the forwarding table, and a solution to the problem.

NOTE: The **load-balance per-packet** statement is named ***per-packet*** for historical reasons. When the Packet Forwarding Engine was an IP Processor-I (before Junos 4.0), Junos supported only per-packet load balancing. When the IP Processor-II was introduced the behavior was changed to per-flow load balancing without changing the statement.

Sample Output Use the **show route forwarding-table** command to display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. In this case, the option **vpn** ***vpn*** is used to display routing table entries for the specified VPN **vpn-a**.

```
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive

Routing table: vpn-a.inet [Index 2]
Internet:

Destination:  192.168.5.0/24
  Route type: user
  Route reference: 0                    Route interface-index: 0
  Flags: sent to PFE
  Next-hop type: indirect               Index: 262142   Reference: 2
  Next-hop type: unilist                Index: 262146   Reference: 1
  Next-hop type: Push 100160
  Next-hop interface: so-0/0/1.0    Weight: 0x1
  Nexthop: 10.0.23.14
  Next-hop type: Push 100160, Push 100064(top)
  Next-hop interface: fe-0/1/1.0    Weight: 0x8001
```

Meaning The sample output for the **show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive** command shows the correct two routes were relayed from the routing table to the forwarding table.

Conclusion In conclusion, a load balancing policy is required for link protection to work effectively. The principles are the same for the configuration of the **fast reroute** and the **node-link protection** statements.

Router Configurations The following output shows the configurations of all routers in the network. The **no-more** option entered after the pipe **(|)** prevents the output from being paginated if the output is longer than the length of the terminal screen.

Sample Output The following sample output is for the customer edge (CE) 1 router:

```
user@R1-CE1> show configuration | no-more

Problem Establishing a GRE Tunnel Checklist

Problem **Description:** This checklist provides the links and commands for troubleshooting a case study about a problem establishing a Generalized Multiprotocol Label Switching (GMPLS) label-switched path (LSP). Specifically, the configuration of the data channel is incorrect because the configuration includes different interface types at both ends of the tunnel. The principles and solution used in this case study also apply to control channel configuration.

The checklist includes the links to a brief summary of GRE tunnels within the context of GMPLS, an example network scenario, and more detailed information about the commands used to troubleshoot and resolve the problem.

The troubleshooting process described in this case study should not be followed rigidly; it is a basis from which you can develop your own process to suit your particular situation. (See Table 61 on page 1550

Table 61: Problem Establishing a GRE Tunnel Checklist

Solution

Tasks	Command or Action
"Troubleshooting GMPLS and GRE Tunnel" on page 1551	
"Symptom" on page 1553	**show mpls lsp** **show rsvp session**
"Cause" on page 1554	The cause of the problem with the GMPLS LSP is the configuration of different interface types at both ends of the GMPLS data channel.

Table 61: Problem Establishing a GRE Tunnel Checklist (continued)

Tasks	Command or Action
"Troubleshooting Commands" on page 1554	**show mpls lsp extensive** **show rsvp session detail** **show link-management peer** **show link-management te-link** **show configuration protocols mpls** **monitor start *filename*** **show log *filename***
"Solution" on page 1560	Configure both ends of the data channel with the same switching type. **show configuration protocols link-management** **show mpls lsp** **show link-management te-link**
"Conclusion" on page 1561	Both ends of a GMPLS data must be the same encapsulation or interface type.
"Router Configurations" on page 1561	**show configuration | no-more**

Troubleshooting GMPLS and GRE Tunnel

Problem **Description:** The logical control channel for GMPLS must be a point-to-point link and must have some form of IP reachability. On broadcast interfaces or when there are multiple hops between control channel peers, use a GRE tunnel for the control channel. For more detailed information on GMPLS and GRE tunnels see the *Junos MPLS Applications Configuration Guide* and the *Junos Feature Guide*.

A tunnel PIC is *not* required to configure a GRE tunnel for the GMPLS control channel. Instead, use the software-based **gre** interface, rather than the hardware-based **gr-*fpc/pic/port*** interface.

CAUTION: Due to restrictions to the software-based gre interface, the GMPLS control channel is the only supported use of the software-based gre interface. Any other use is expressly unsupported and might cause an application failure.

The following example shows a basic **gre** interface configuration. In this case, the tunnel source is the loopback address of the local router and the destination address is the loopback destination of the remote router. Traffic that has a next hop of the tunnel destination will use the tunnel. The tunnel is not automatically used by all the traffic passing through the interface. Only traffic with the tunnel destination as the next hop uses the tunnel.

Sample Output

```
user@R1> show configuration interfaces
[...Output truncated...]
gre {
    unit 0 {
        tunnel {
            source 10.0.12.13;
            destination 10.0.12.14;
        }
        family inet {
            address 10.35.1.6/30;
        }
        family mpls;
    }
}
```

Sample Output

The following sample output for the show interfaces command shows the encapsulation type and header, the maximum speed, packets through the logical interface, the destination, and logical address.

```
user@R1> show interfaces gre
Physical interface: gre, Enabled, Physical link is Up
  Interface index: 10, SNMP ifIndex: 8
   Type: GRE, Link-level type: GRE,  MTU: Unlimited, Speed: Unlimited
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
    Input packets : 0
    Output packets: 0

  Logical interface gre.0 (Index 70) (SNMP ifIndex 47)
    Flags: Point-To-Point SNMP-Traps 0x4000
     IP-Header 10.0.12.14:10.0.12.13:47:df:64:0000000000000000
     Encapsulation: GRE-NULL
    Input packets : 171734
    Output packets: 194560
    Protocol inet, MTU: 1476
      Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
          Destination: 10.35.1.4/30, Local: 10.35.1.6, Broadcast: 10.35.1.7
    Protocol mpls, MTU: 1464
      Flags: None
```

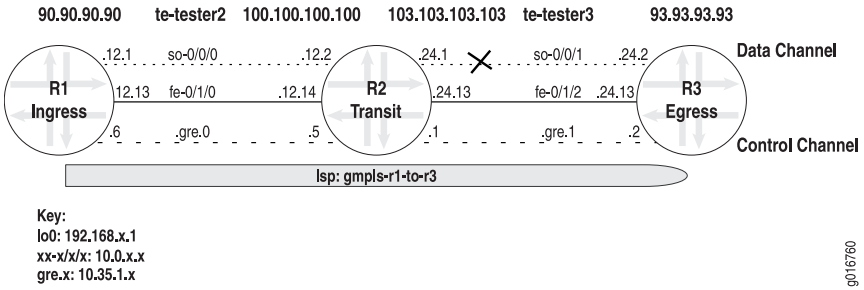
The following are various requirements when you configure a GMPLS LSP using a GRE tunnel:

- The data channel must start and end on the same type of interface.
- The control channel can be a GRE tunnel that starts and ends on the same or different interface type.
- The GRE tunnel must be configured indirectly with the **peer-interface** *peer-name* statement at the **[edit protocol ospf]** hierarchy level.
- The GRE interface must be disabled at the **[edit protocols ospf]** and **[edit protocols rsvp]** hierarchy levels.

- Data and control channels must be defined correctly in the LMP configuration .
- It is optional to disable Constrained Shortest Path First (CSPF) with the **no-cspf** statement.

This case focuses on the incorrect configuration of the endpoints of the GRE tunnel. However, you can use a similar process and commands to diagnose other GRE tunnel problems. Figure 129 on page 1553 illustrates a network topology with MPLS tunneled through a GRE interface.

Figure 129: GMPLS Network Topology



The MPLS network topology in Figure 129 on page 1553 shows Juniper Networks routers configured with a GRE tunnel that consists of the following components:

- A strict GMPLS LSP path from the ingress router to the egress router.
- On the ingress router, CSPF disabled with the **no-cspf** statement at the [**edit protocol mpls label-switched-path *lsp-name***] hierarchy level.
- Traffic-engineering links and control channels within the **peer** statement at the [**edit protocols link-management**] hierarchy level on all routers.
- OSPF and OSPF traffic engineering configured on all routers.
- A reference to the **peer-interface** in both OSPF and RSVP on all routers.
- A switching-type problem between **R2** and **R3**.

Symptom The LSP in the network shown in Figure 129 on page 1553 is down, as indicated by the output from the **show mpls lsp** and **show rsvp session** commands, which display very similar information. The **show mpls lsp** command shows all LSPs configured on the router, as well as all transit and egress LSPs. The **show rsvp session** command displays summary information about RSVP sessions. You can use either command to verify the state of the LSP. In this case, LSP **gmpls-r1-to-r3** is down (**Dn**).

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
192.168.4.1  192.168.1.1  Dn   0 -         gmpls-r1-to-r3
Bidir
Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R1>   show rsvp session
Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
192.168.4.1  192.168.1.1  Dn    0 0 -   -    - gmpls-r1-to-r3
Bidir
Total 1 displayed, Up 0, Down 1

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Cause The cause of the problem with the GMPLS LSP is the configuration of different interface types at both ends of the GMPLS data channel.

Troubleshooting Commands The Junos OS includes commands that are useful when troubleshooting a problem. This topic provides a brief description of each command, followed by sample output, and a discussion of the output in relation to the problem.

You can use the following commands when troubleshooting a GMPLS problem:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show link-management peer
user@host> show link-management te-link
user@host> show configuration protocols mpls
user@host> monitor start filename
user@host> show log filename
```

Sample Output Use the show mpls lsp extensive command on transit router R1 to display detailed information about all LSPs transiting, terminating, and configured on the router.

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

192.168.4.1
  From: 192.168.1.1, State: Dn, ActiveRoute: 0, LSPname: gmpls-r1-to-r3
```

```
  Bidirectional
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: SDH/SONET, Switching type: PSC-1, GPID: IPv4
  Primary   p1               State: Dn
    SmartOptimizeTimer: 180
    8 Dec 20 18:08:02 192.168.4.1: MPLS label allocation failure [3 times]
    7 Dec 20 18:07:53 Originate Call
    6 Dec 20 18:07:53 Clear Call
    5 Dec 20 18:07:53 Deselected as active
    4 Dec 20 18:06:13 Selected as active path
    3 Dec 20 18:06:13 Record Route:  100.100.100.100 93.93.93.93
    2 Dec 20 18:06:13 Up
    1 Dec 20 18:06:13 Originate Call
  Created: Wed Dec 20 18:06:12 2006
Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output for the **show mpls lsp extensive** command shows an error message (**MPLS label allocation failure)** in the log section of the output. This LSP event indicates that the MPLS protocol or the **family mpls** statement were not configured properly. When the LSP event is preceded by an IP address, the address is typically the router that has the MPLS configuration error. In this case, it appears that the router with the **lo0** address of **192.168.4.1** (**R3**) has an MPLS configuration error.

Sample Output Use the show rsvp session detail command to display detailed information about RSVP sessions.

```
user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

192.168.4.1
  From: 192.168.1.1,  LSPstate: Dn, ActiveRoute: 0
   LSPname: gmpls-r1-to-r3, LSPpath: Primary
  Bidirectional, Upstream label in: 21253, Upstream label out: -
  Suggested label received: -,  Suggested label sent: 21253
  Recovery label received: -, Recovery label sent: -
   Resv style: 0 - , Label in: -, Label out: -
  Time left:    -, Since: Wed Dec 20 18:07:53 2006
  Tspec: rate 0bps size 0bps peak 155.52Mbps m 20 M 1500
  Port number: sender 2 receiver 46115 protocol 0
  PATH rcvfrom: localclient
  Adspec: sent MTU 1500
  Path MTU: received 0
  PATH sentto: 10.35.1.5 (tester2) 3 pkts
   Explct route: 100.100.100.100 93.93.93.93
   Record route: <self> ...incomplete
Total 1 displayed, Up 0, Down 1
```

```
Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output for the **show rsvp session detail** command shows that LSP **gmpls-r1-to-r3** is down (**LSPstate: Dn**). The route record is incomplete, indicating a problem with the explicit route **100.100.100.100 93.93.93.93**. The address **100.100.100.100** is the data channel on **R2 so-0/0/0**, and the address **93.93.93.93** is the data channel on **R3**.

Sample Output Use the show link-management peer command to display MPLS peer link information.

```
user@R1> show link-management peer
Peer name: tester2, System identifier: 48428
  State: Up, Control address:  10.35.1.5
   Control-channel                  State
   gre.0                             Active
  TE links:
   tester2

user@R2> show link-management peer
Peer name: tester2, System identifier: 48428
 State: Up, Control address: 10.35.1.6
   Control-channel                  State
   gre.0                             Active
  TE links:
   te-tester2

Peer name: tester3 , System identifier: 48429
  State: Up , Control address: 10.35.1.2
   Control-channel                  State
   gre.1                             Active
  TE links:
   te-tester3

user@R3> show link-management peer
Peer name: tester3, System identifier: 48429
  State: Up, Control address: 10.35.1.1
   Control-channel                  State
   gre.0                             Active
  TE links:
   te-tester3
```

Meaning The sample output from all routers in the example network in Figure 129 on page 1553 for the **show link-management peer** command shows that all control channels are up and active. A detailed analysis of the output shows the following information:

- Name of the peer, **tester2** or **tester3**, which is the same on neighboring routers for ease of troubleshooting.
- Internal identifier for the peer, **48428** for **tester2** and **48429** for **tester3**. The internal identifier is a range of values from 0 through 64,000.
- The state of the peer, which can be up or down. In this case, all peers are up.
- The address to which a control channel is established, for example, **10.35.1.5.**
- The state of the control channel, which can be up, down, or active.
- The traffic-engineered links that are managed by their peer, indicating that control channel **gre.0** is managed by **tester3**.

Sample Output Use the show link-management te-link command to display the resources used to set up Multiprotocol Label Switching (MPLS) traffic-engineered forwarding paths.

```
user@R1> show link-management te-link
TE link name:  tester2, State: Up
  Local identifier: 2005, Remote identifier: 21253, Local address: 90.90.90.90,
Remote address: 100.100.100.100,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth  Used   LSP-name
     so-0/0/0  Up    21253   21253      155.52Mbps    Yes   gmpls-r1-to-r3

user@R2> show link-management te-link
 TE link name:  te-tester2,  State: Up
  Local identifier: 7002, Remote identifier: 22292, Local address: 100.100.100.100,
 Remote address: 90.90.90.90,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth  Used   LSP-name
    so-0/0/0    Up       21253      21253     155.52Mbps   Yes   gmpls-r1-to-r3
TE link name:  te-tester3, State: Up
  Local identifier: 7003, Remote identifier: 21254, Local address: 103.103.103.103,
 Remote address: 93.93.93.93,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth  Used   LSP-name
    so-0/0/1    Up       21252      21252     155.52Mbps   Yes  gmpls-r1-to-r3

user@R3> show link-management te-link
 TE link name:  te-tester3, State: Up
  Local identifier: 7003, Remote identifier: 21254,  Local address: 93.93.93.93,
Remote address: 103.103.103.103,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 0bps, Maximum
bandwidth: 0bps, Total bandwidth: 0bps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth Used  LSP-name
    so-0/0/1  Dn       21252      21252     155.52Mbps     No
```

Meaning The sample output for the **show link-management te-link** command issued on the three routers in the network in Figure 129 on page 1553 shows the resources allocated to the traffic-engineered links **te-tester2** and **te-tester3**. The resources are the SONET interfaces **so-0/0/0** and **so-0/0/1.** On **R1** and **R2, t**he SONET interfaces are used for the LSP **gmpls-r1-to-r3**, as indicated by **Yes** in the **Used** field.However, the SONET interface **so-0/0/1** on **R3** is down (**Dn**) and is not used for the LSP (**Used No**). Further investigation is required to discover why the SONET interface on **R3** is down.

Sample Outut Use the show log *filename* command to display the contents of the specified log file. In this case, the log file rsvp.log is configured at the [edit protocols rsvp traceoptions] hierarchy level. When the log file is configured, you must issue the monitor start *filename* command to begin logging messages to the file.

```
user@R1> show configuration protocols rsvp
traceoptions {
    file rsvp.log size 3m world-readable;
    flag state detail;
    flag error detail;
    flag packets detail;
}

user@R1> monitor start rsvp.log
```

NOTE: The find Error option entered after the pipe (|) searches the output for an instance of the term *Error*.

Sample Output

```
user@R3>
show log rsvp.log | find Error

```

Meaning

The sample output from the egress router **R3** for the **show log rsvp.log** command is a snippet taken from the log file. The snippet shows a Link Management Protocol (LMP) resource request for the LSP **gmpls-r1-to-r3.** The request has problems with the encoding type (SDH/SONET), indicating a possible error with the SONET interface connecting **R2** and **R3**. Further investigation of the configuration of the LMP on **R2** and **R3** is required.

Sample Output

Use the show configuration *statement-path* command to display a specific configuration hierarchy; in this instance, link-management.

```
user@R2> show configuration protocols link-management
te-link te-tester2 {
    local-address 100.100.100.100;
    remote-address 90.90.90.90;
    remote-id 22292;
    interface so-0/0/0 {
        local-address 100.100.100.100;
        remote-address 90.90.90.90;
        remote-id 21253;
    }
}
te-link te-tester3  {
    local-address 103.103.103.103;
    remote-address 93.93.93.93;
    remote-id 21254;
     interface so-0/0/1  {
        local-address 103.103.103.103;
```

```
        remote-address 93.93.93.93;
        remote-id 21252;
    }
}
peer tester2 {
    address 10.35.1.6;
    control-channel gre.0;
    te-link te-tester2;
}
peer tester3 {
    address 10.35.1.2;
    control-channel gre.1;
    te-link te-tester3;
}

user@R3> show configuration protocols link-management
te-link te-tester3  {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
    }
     interface at-0/3/1 {
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}
```

Meaning The sample output from transit router **R2** and ingress router **R3** for the **show configuration protocols link-management** command shows that the interface type on the two routers is different. The resource allocated to **te-tester3** on transit router **R2** is a SONET interface, while the resource allocated to **te-tester3** on egress router **R3** is an ATM interface. The interface type on each end of the data or control channels must be of the same type. In this case, both ends should be SONET or ATM.

Solution The solution to the problem of different interface or encapsulation types at either end of the GMPLS LSP is to make sure that the interface type is the same at both ends. In this case, the ATM interface was deleted from the link-management configuration on **R3**, and a SONET interface was configured instead.

The following commands illustrate the correct configuration and commands to verify that the GMPLS LSP is up and using the data channel:

```
user@R3> show configuration protocols link-management
user@R3> show mpls lsp
user@R3> show link-management te-link
```

Sample Output

```
user@R3> show configuration protocols link-management
te-link te-tester3 {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
     interface so-0/0/1 { # SONET interface replaces the incorrect ATM interface
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}

user@R3> show mpls lsp
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
Egress LSP: 1 sessions

192.168.4.1   192.168.1.1   Up    0 1 FF  21252    - gmpls-r1-to-r3
Bidir
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R3> show link-management te-link
 TE link name: te-tester3, State: Up
  Local identifier: 7003, Remote identifier: 21254, Local address: 93.93.93.93,
Remote address: 103.103.103.103,
  Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
  Available bandwidth: 0bps
    Name        State Local ID  Remote ID      Bandwidth Used  LSP-name
     so-0/0/1  Up    21252   21252   155.52Mbps Yes gmpls-r1-to-r3
```

Meaning The sample output for the **show protocols link-management**, **show mpls lsp**, and **show link-management te-link** commands from ingress router **R3** show that the problem is solved. LMP is correctly configured, and the LSP **gmpls-r1-to-r3** is up and using the data channel **so-0/0/1**.

Conclusion In conclusion, both ends of a GMPLS data channel must be the same encapsulation or interface type. This case illustrates the correct configuration of the data channel. The principles are the same for the control channel.

Router Configurations Output that shows the configurations of the ingress router in the network. The **no-more** option entered after the pipe **(|)** prevents the output from being paginated if the output is longer than the length of the terminal screen.

Sample Output The following sample output is for ingress router R1:

```
user@R1>  show configuration | no-more

```

Verify Protocol Families

Purpose If a logical interface does not have MPLS enabled, it cannot perform MPLS switching. This step allows you to quickly determine which interfaces are configured with MPLS and other protocol families.

Action To verify the protocol families configured on the routers in your network, enter the following Junos OS CLI operational mode command:

```
user@host> show interfaces terse
```

Sample Output 1

```
user@R1> show interfaces terse
Interface               Admin Link Proto Local                 Remote
so-0/0/0                up    up
so-0/0/0.0              up  up  inet  10.1.12.1/30
                                  iso
                                  mpls

                                    mpls
```

Meaning Sample Output 1 shows the interface, the administrative status of the link (**Admin**), the data link layer status of the link (**Link**), the protocol families configured on the interface (**Proto**), and the local and remote addresses on the interface.

All interfaces on all routes in the network shown in Figure 127 on page 1516 are administratively enabled and functioning at the data link layer with MPLS and IS-IS, and have an **inet** address. All are configured with an IPv4 protocol family (**inet**), and have the IS-IS (**iso**) and MPLS (**mpls**) protocol families configured at the [**edit interfaces** ***type-fpc/pic/port*** **unit** ***number***] hierarchy level.

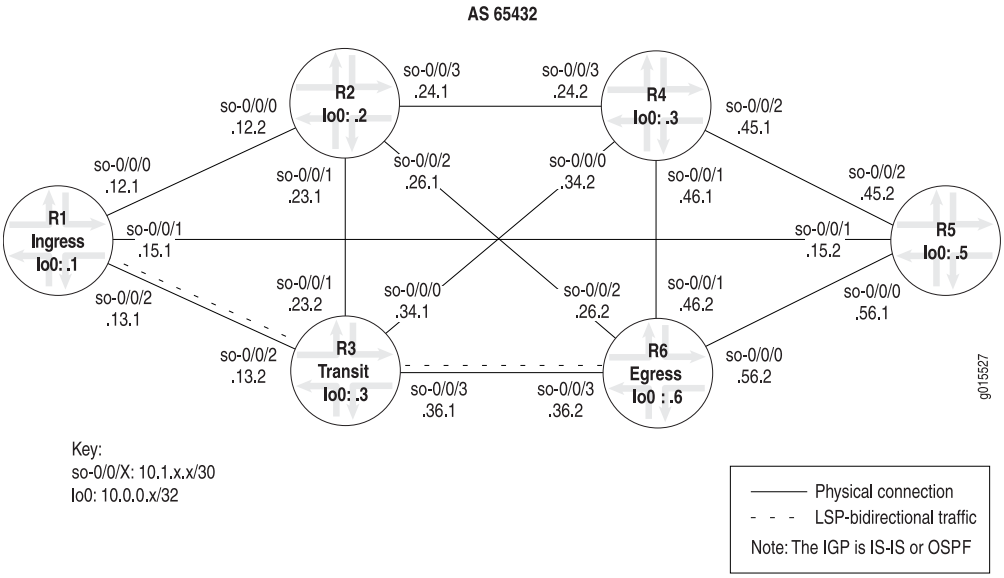
Sample Output 2 shows that interface **so-0/0/2.0** on **R6** does not have the **mpls** statement included at the [**edit interfaces** ***type-fpc/pic/port*** **unit** ***number***] hierarchy level.

Determining LSP Status

Display detailed information about Resource Reservation Protocol (RSVP) objects and the label-switched path (LSP) history to pinpoint a problem with the LSP.

Figure 130 on page 1572 illustrates the network topology used in this topic.

Figure 130: MPLS Network Topology



To determine the LSP state, follow these steps:

1. Check the Status of the LSP on page 1572
2. Display Extensive Status About the LSP on page 1573

Check the Status of the LSP

Purpose Display the status of the label-switched pathe (LSP).

Action To determine the LSP status, on the ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp
```

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
10.0.0.6    10.0.0.1    Up  1       *  R1-to-R6
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State Rt  Style   Labelin  Labelout LSPname
10.0.0.1    10.0.0.6    Up   0 1 FF    3    - R6-to-R1
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information. Ingress information is for the sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1** (**10.0.0.1**) to **R6** (**10.0.0.6**). This route is currently up, and is an active route installed in the routing table (**Rt**). The LSP **R1-to-R6** is the primary path (**P**) as opposed to the secondary path, and is indicated by an asterisk (*****). The route to **R6** does not contain a named path (**ActivePath**).

There is one egress LSP from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see "Checklist for Working with the Layered MPLS Troubleshooting Model" on page 1293.

Display Extensive Status About the LSP

Purpose Display extensive information about LSPs, including all past state history and the reasons why an LSP might have failed.

Action To display extensive information about LSPs, on the ingress router, enter the following Junos OS CLI operational mode command:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information in detail, including all past state history and the reasons why an LSP failed. Ingress information is for sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1** (**10.0.0.1**) to **R6** (**10.0.0.6**). This route is currently up (**State**), with one route actively using the LSP, **R1-to-R6**. The LSP active path is the primary path. Even if the LSP does not contain a **primary** or **secondary** keyword, the router still treats the LSP as a primary LSP, indicating that if the LSP fails, the router will attempt to signal inactive LSPs at 30-second intervals, by default.

Load balancing is **Random**, which is the default, indicating that when selecting the physical path for an LSP, the router randomly selects among equal-cost paths that have an equal hop count. Other options that you can configure are **Least-fill** and **Most-fill**. **Least-fill** places the LSP over the least utilized link of the equal-cost paths with equal hop count. **Most-fill** places the LSP over the most utilized link of the equal-cost paths sharing an equal hop count. Utilization is based on the percentage of available bandwidth.

The **Encoding type** field shows Generalized MPLS (GMPLS) signaling parameters (**Packet)**, indicating IPv4. The **Switching type** is **Packet**, and the Generalized Payload Identifier (**GPID**) is IPv4.

The primary path is the active path, as indicated by an asterisk (*). The state of the LSP is **Up**.

The Explicit Route Object (**ERO**) includes the Constrained Shortest Path First (CSPF) cost (**20**) for the physical path that the LSP follows. The presence of the CSPF metric indicates that this is a CSPF LSP. The absence of the CSPF metric indicates a no-CSPF LSP.

The field **10.1.13.2 S** indicates the actual ERO. The RSVP signaling messages went to **10.1.13.2** strictly (as a next hop) and finished at **10.1.36.2** strictly. All ERO addresses are strict hops when the LSP is a CSPF LSP. Loose hops can only display in a no-CSPF LSP.

The received Record Route Object (**RRO**) has the following protection flags:

- **0x01**—Local protection available. The link downstream of this node is protected by a local repair mechanism. This flag can only be set if the Local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding path message.
- **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).
- **0x04**— Bandwidth protection. The downstream router has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.
- **0x08**—Node protection. The downstream router has a backup path providing protection against link and node failure on the corresponding path section. If the downstream router can set up only a link-protection backup path, the “Local protection available” bit is set but the “Node protection” bit is cleared.
- **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engineered LSP. This indicates to the ingress label edge router (LER) of this LSP that it should be rerouted.

For more information on protection flags, see the *Junos Routing Protocols and Policies Command Reference.*

The field **10.1.13.2.10.1.36.2** is the actual received record route (**RRO**). Note that the addresses in the **RRO** field match those in the **ERO** field. This is the normal case for CSPF LSPs. If the RRO and ERO addresses do not match for a CSPF LSP, the LSP has to reroute or detour.

The lines numbered 91 through 42 contain the 49 most recent entries to the history log. Each line is time stamped. The most recent entries have the largest log history number and are at the top of the log, indicating that line 91 is the most recent history log entry. When you read the log, start with the oldest entry (**42**) to the most recent (**91**).

The history log was started on July 10, and displays the following sequence of activities: an LSP was selected as active, was found to be down, MPLS label allocation failed several times, was deleted several times, was preempted because of an ResvTear, was deselected

as active, and was cleared. In the end, the router computed a CSPF ERO, signaled the call, the LSP came up with the listed RRO (line 90), and was listed as active.

For more information on error messages, see the *Junos MPLS Network Operations Guide Log Reference.*

The total number of ingress LSPs displayed is **1**, with **1** up and **0** down. The number in the **Up** field plus the number in the **Down** field should equal the total.

There is one egress LSP session from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see "Checklist for Working with the Layered MPLS Troubleshooting Model" on page 1293.

Check the Status of the LSP

Purpose Display the status of the label-switched pathe (LSP).

Action To determine the LSP status, on the ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp
```

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
10.0.0.6    10.0.0.1    Up  1       *  R1-to-R6
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State Rt  Style   Labelin  Labelout LSPname

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information. Ingress information is for the sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1** (**10.0.0.1**) to **R6** (**10.0.0.6**). This route is currently up, and is an active route installed in the routing table (**Rt**). The LSP **R1-to-R6** is the primary path (**P**) as opposed to the secondary path, and is indicated by an asterisk (*****). The route to **R6** does not contain a named path (**ActivePath**).

There is one egress LSP from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see "Checklist for Working with the Layered MPLS Troubleshooting Model" on page 1293.

Display Extensive Status About the LSP

Purpose Display extensive information about LSPs, including all past state history and the reasons why an LSP might have failed.

Action To display extensive information about LSPs, on the ingress router, enter the following Junos OS CLI operational mode command:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive

Meaning The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information in detail, including all past state history and the reasons why an LSP failed. Ingress information is for sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1** (**10.0.0.1**) to **R6** (**10.0.0.6**). This route is currently up (**State**), with one route actively using the LSP, **R1-to-R6**. The LSP active path is the primary path. Even if the LSP does not contain a **primary** or **secondary** keyword, the router still treats the LSP as a primary LSP, indicating that if the LSP fails, the router will attempt to signal inactive LSPs at 30-second intervals, by default.

Load balancing is **Random**, which is the default, indicating that when selecting the physical path for an LSP, the router randomly selects among equal-cost paths that have an equal hop count. Other options that you can configure are **Least-fill** and **Most-fill**. **Least-fill** places the LSP over the least utilized link of the equal-cost paths with equal hop count. **Most-fill** places the LSP over the most utilized link of the equal-cost paths sharing an equal hop count. Utilization is based on the percentage of available bandwidth.

The **Encoding type** field shows Generalized MPLS (GMPLS) signaling parameters (**Packet)**, indicating IPv4. The **Switching type** is **Packet**, and the Generalized Payload Identifier (**GPID**) is IPv4.

The primary path is the active path, as indicated by an asterisk (*). The state of the LSP is **Up**.

The Explicit Route Object (**ERO**) includes the Constrained Shortest Path First (CSPF) cost (**20**) for the physical path that the LSP follows. The presence of the CSPF metric indicates that this is a CSPF LSP. The absence of the CSPF metric indicates a no-CSPF LSP.

The field **10.1.13.2 S** indicates the actual ERO. The RSVP signaling messages went to **10.1.13.2** strictly (as a next hop) and finished at **10.1.36.2** strictly. All ERO addresses are strict hops when the LSP is a CSPF LSP. Loose hops can only display in a no-CSPF LSP.

The received Record Route Object (**RRO**) has the following protection flags:

- **0x01**—Local protection available. The link downstream of this node is protected by a local repair mechanism. This flag can only be set if the Local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding path message.
- **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).
- **0x04**— Bandwidth protection. The downstream router has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.

- **0x08**—Node protection. The downstream router has a backup path providing protection against link and node failure on the corresponding path section. If the downstream router can set up only a link-protection backup path, the "Local protection available" bit is set but the "Node protection" bit is cleared.
- **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engineered LSP. This indicates to the ingress label edge router (LER) of this LSP that it should be rerouted.

For more information on protection flags, see the *Junos Routing Protocols and Policies Command Reference.*

The field **10.1.13.2.10.1.36.2** is the actual received record route (**RRO**). Note that the addresses in the **RRO** field match those in the **ERO** field. This is the normal case for CSPF LSPs. If the RRO and ERO addresses do not match for a CSPF LSP, the LSP has to reroute or detour.

The lines numbered 91 through 42 contain the 49 most recent entries to the history log. Each line is time stamped. The most recent entries have the largest log history number and are at the top of the log, indicating that line 91 is the most recent history log entry. When you read the log, start with the oldest entry (**42**) to the most recent (**91**).

The history log was started on July 10, and displays the following sequence of activities: an LSP was selected as active, was found to be down, MPLS label allocation failed several times, was deleted several times, was preempted because of an ResvTear, was deselected as active, and was cleared. In the end, the router computed a CSPF ERO, signaled the call, the LSP came up with the listed RRO (line 90), and was listed as active.

For more information on error messages, see the *Junos MPLS Network Operations Guide Log Reference.*

The total number of ingress LSPs displayed is **1**, with **1** up and **0** down. The number in the **Up** field plus the number in the **Down** field should equal the total.

There is one egress LSP session from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see "Checklist for Working with the Layered MPLS Troubleshooting Model" on page 1293.

Checking That RSVP Path Messages Are Sent and Received

Purpose The presence or absence of various RSVP messages can help determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network. For example, if path messages occur in the output without Resv messages, it might indicate that label-switched paths (LSPs) are not being created.

Action To check that RSVP Path messages are sent and received, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show rsvp statistics
```

Sample Output

```
user@R1> show rsvp statistics
  PacketType              Total                 Last 5 seconds
                    Sent      Received        Sent      Received

  No path information               0                       0
  Resv style conflict               0                       0
  Port conflict                     0                       0
  Resv no interface                 0                       0
  PathErr to client       15                        0
  ResvErr to client                 0                       0
  Path timeout                      0                       0
  Resv timeout                      0                       0
  Message out-of-order              0                       0
  Unknown ack msg                   0                       0
  Recv nack                         0                       0
  Recv duplicated msg-id            0                       0
  No TE-link to recv Hop            0                       0
```

Meaning The sample output shows RSVP messages sent and received. The total number of RSVP Path messages is 11,4532 sent and 80,185 received. Within the last 5 seconds, no messages have been sent or received.

A total of 5 **PathErr** messages were sent and 10 received. When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. In this case, **R1** sent at least 10 path messages with an error, as indicated by the 10 PathErr messages that **R1** has received.

The downstream router sent **R1** five path messages with an error, as indicated by the five PathErr messages that **R1** has sent. PathErr messages transmit in the opposite direction to path messages.

A total of 12 **PathTear** messages were sent and 6 received, none in the last 5 seconds. In contrast to PathErr messages, PathTear messages travel in the same direction as path messages. Since path messages are both sent and received, PathTear messages are also sent and received. However, if only path messages are sent, then only the PathTear messages that are sent appear in the output.

A total of 80,515 reservation (**Resv**) messages with the fixed filter (**FF**) reservation style were sent and 111,476 received, none in the last 5 seconds. An **FF** reservation style indicates that within each session, each receiver establishes its own reservation with each upstream sender, and that all selected senders are listed. No messages for the wildcard filter (**WF**) or shared explicit (**SE**) reservation styles are sent or received. For more information on RSVP reservation styles, see the *Junos MPLS Applications Configuration Guide*.

Other RSVP message types are not sent or received. For information on the ResvErr, ResvTear, and Resvconf message types, see the *Junos MPLS Applications Configuration Guide*.

Ack and summary refresh (SRefresh) messages do not appear in the output. Ack and summary refresh messages are defined in RFC 2961 and are part of the RSVP extensions. Ack messages are used to reduce the amount of RSVP control traffic in the network.

A total of 915,851 hello messages were sent and 915,881 received, with none transmitted or received in the last 5 seconds. The RSVP hello interval is 9 seconds. If more than one hello message is sent or received in the last 5 seconds, it implies that more than one interface supports RSVP.

EndtoEnd RSVP messages are legacy RSVP messages that are not used for RSVP traffic engineering. These counters increment only when RSVP forwards legacy RSVP messages issued by a virtual private network (VPN) customer for transit across the backbone to the other site(s) in the VPN. They are called end-to-end messages because they are intended for the opposite side of the network and only have meaning at the two ends of the provider network.

The **Errors** section of the output shows statistics about RSVP packets with errors. A total of 15 **PathErr to client** packets were sent to the Routing Engine. The total combines the sent and received **PathErr** packets. For more information about error statistics and packets, see the *Junos System Basics and Services Command Reference.*

Determining the Current RSVP Neighbor State

Purpose Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors.

Action To determine the current RSVP neighbor state, enter the following Junos OS CLI operational mode command:

```
user@host>  show rsvp neighbor
```

Sample Output

```
user@R6> show rsvp neighbor
RSVP neighbor:  2  learned
Address   Idle Up/Dn LastChange   HelloInt  HelloTx/Rx     MsgRcvd
10.1.36.1    5  1/0  1w5d 6:30:50    9      116734/116734   23558
10.1.56.1   10  1/0  2w2d 23:44:15   9      161600/161600   23570
```

Meaning The sample output shows that **R6** has learned about two different RSVP neighbors. Each neighbor has one line of output that includes the neighbor RSVP address, the length of time the interface was idle, the current interface up/down counter, the time of the last interface state change, the current RSVP hello interval, the total number of RSVP hello messages transmitted and received, and the total number of RSVP messages received on the interface.

The **show rsvp neighbor** command only indicates a neighbor after a session is established. Once an interface is displayed in this command output, it always appears, even if the RSVP neighbor state is down.

The RSVP neighbor **10.1.36.1** was idle for 5 seconds, came up once and has not gone down, indicating that the interface is currently in an **Up** state. As long as the up counter is one greater than the down counter, the RSVP interface is up. If the up/down counters are equal, the interface is down.

The last state change occurred 6 hours and 30 minutes ago. The current hello interval is 9 seconds. A total of 116,734 hello messages were transmitted and received on this interface, and a total of 23,558 RSVP Path/Resv messages were processed.

The RSVP neighbor **10.1.56.1** was idle for 10 seconds, came up once and has not gone down, indicating that the interface is currently in an **Up** state. The last state change occurred 23 hours and 44 minutes ago. The current Hello interval is 9 seconds. A total of 161,600 hello messages were transmitted and received on this interface, and a total of 23,570 RSVP Path/Resv messages were processed.

Take Appropriate Action

Problem **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the routers are configured to function at different levels of the IS-IS protocol.

Solution To correct the error in this example, enter the following commands:

Sample Output

```
[edit protocols isis]
user@R6# show
level 2 disable;
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
    disable;
}
interface lo0.0; {
passive

[edit protocols isis]
user@R6# delete level 2

[edit protocols isis]
user@R6# set level 1 disable

[edit protocols isis]
user@R6# show
level 1 disable;
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
    disable;
}
interface lo0.0; {
passive

[edit protocols isis]
user@R6# commit
commit complete

[edit protocols isis]
user@R6# run show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R5             2 Up                   22
so-0/0/1.0            R4             2 Up                   22
so-0/0/2.0            R2             2 Up                   22
so-0/0/3.0            R3             2 Up                   22
```

Meaning

The sample output shows that the configuration error on egress router R6 has been corrected, and IS-IS adjacencies are now established.

Related Documentation

Examine BGP Routes

Purpose You can examine the BGP path selection process to determine the single, active path when BGP receives multiple routes to the same destination. In this step, we examine the reverse LSP **R6-to-R1**, making **R6** the ingress router for that LSP.

Action To examine BGP routes and route selection, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix detail
```

Sample Output 1

```
user@R6> show route 100.100.1.1 detail
inet.0: 30 destinations, 46 routes (29 active, 0 holddown, 1 hidden)
100.100.1.0/24 (1 entry, 1 announced)
        *BGP    Preference: 170/-101
                Source: 10.1.13.1
                Next hop: via so-0/0/3.0, selected
                 Protocol next hop: 10.1.13.1  Indirect next hop: 8671594 304
                State: <Active Int Ext>
                Local AS: 65432 Peer AS: 65432
                Age: 4d 5:15:39         Metric2: 2
                Task: BGP_65432.10.1.13.1+3048
                Announcement bits (2): 0-KRT 4-Resolve inet.0
                AS path: I
                Localpref: 100
                 Router ID: 10.0.0.1
```

Sample Output 2

```
user@R6> show route 100.100.1.1 detail
inet.0: 30 destinations, 46 routes (29 active, 0 holddown, 1 hidden)
100.100.1.0/24 (1 entry, 1 announced)
        *BGP    Preference: 170/-101
                Source: 10.0.0.1
                Next hop: via so-0/0/3.0 weight 1, selected
                 Label-switched-path R6-to-R1
                Label operation: Push 100000
                 Protocol next hop: 10.0.0.1  Indirect next hop: 8671330 301
                State: <Active Int Ext>
                Local AS: 65432 Peer AS: 65432
                Age: 24:35      Metric2: 2
                Task: BGP_65432.10.0.0.1+179
                Announcement bits (2): 0-KRT 4-Resolve inet.0
                AS path: I
                Localpref: 100
                 Router ID: 10.0.0.1
```

Meaning Sample Output 1 shows that the BGP next hop (**10.1.13.1**) does not equal the LSP destination address (**10.0.0.1**) in the **to** statement at the [**edit protocols mpls**

label-switched-path *label-switched-path-name*] hierarchy level when the BGP configuration of **R6** and **R1** is incorrect.

Sample Output 2, taken after the configurations on R1 and R6 are corrected, shows that the BGP next hop (**10.0.0.1**) and the LSP destination address (**10.0.0.1**) are the same, indicating that BGP can use the LSP to forward BGP traffic.

CLI Operational Mode Top-Level Commands

In operational mode, you enter commands to monitor and diagnose the software, network connectivity, and the router. When you log in to the router and the CLI starts, you are at the top level of the CLI operational mode. At this level, there are several broad groups of CLI commands. Table 62 on page 1587 lists the top-level CLI operational mode commands and describes the options available for each command. The commands are listed in alphabetical order.

Table 62: CLI Operational Mode Top-Level Commands

Command	Description
clear	Clear statistics and protocol database information. Syntax: **clear (arp | bgp | firewall | helper | igmp | ike | ilmi | interfaces | ipsec | ipv6 | isis | ldp | log | mpls | msdp | multicast | ospf | pim | rip | ripng | route | rsvp | snmp | system | vrrp)**
configure	Enter CLI configuration mode. Alternative commands: **configure <exclusive> <private>**
file	Perform file manipulation operations, such as copy, delete, list, rename, and show. Syntax: **file (compare | copy | delete | list | rename | show)**
help	Provide help information. Syntax: **help (reference | syslog | topic)**
monitor	Monitor a log file or interface traffic in real time. Syntax: **monitor (interface | list | start | stop | traffic)**
mtrace	Display trace information about a multicast path from a source to a receiver. Syntax: **mtrace (from-source | monitor | to-gateway)**

Table 62: CLI Operational Mode Top-Level Commands (continued)

Command	Description
ping	Verify IP connectivity to another IP host or Asynchronous Transfer Mode (ATM) connectivity (ping ATM) using Operation Administration and Maintenance (OAM) cells to an ATM endstation. Syntax: **ping** *host* <**interface** *source-interface* > <**bypass-routing**> <**count** *requests* > <**do-not-fragment**> <**interval** *seconds* > <**pattern** *string* > <**record-route**> <**routing-instance** *routing-instance-name* > <**size** *bytes* > <**strict**> <**tos** *type-of-service* > <**ttl** *value* > <**via** *route* > <**rapid** | **detail**> Syntax: **ping atm interface** *interface* <**count** *count* > <**end-to-end** | **segment**> <**interval** *interval*> <**sequence-number** *sequence-number* > <**vci** *vci* > <**brief**> Syntax: **ping vpn-interface** *vpn-interface host* <**local** *echo-address*>
pipe	Filter the output of an operational mode or configuration mode command. Syntax: | **(compare** | **count** | **display** <**detail** | **inheritance** | **xml**> | **except** *pattern* | **find** *pattern* | **last** *lines* | **match** *pattern* | **no-more** | **resolve** <*file-names*> | **save** *filename* | **trim** *columns)*
quit	Log out from the CLI process. Syntax: **quit**
request	Make system-level requests, such as halt or reboot the router, load software packages, and back up the router's file systems. Syntax: **request system (halt** | **reboot** | **snapshot** | **software)**
restart	Restart the router hardware or software processes. Syntax: **restart (fpc** | **class-of-service** | **gracefully** | **immediately** | **interface-control** | **mib-process** | **network-access-service** | **remote-operations** | **routing** | **sampling** | **sfm** | **snmp** | **soft)**
set	Set CLI properties, the router's date and time, and the craft interface display text. Syntax: **set (chassis** | **cli** | **date)**
show	Show information about all aspects of the software, including interfaces and routing protocols. Syntax: **show (accounting** | **aps** | **arp** | **as-path** | **bgp** | **chassis** | **cli** | **configuration** | **connections** | **dvmrp** | **firewall** | **helper** | **host** | **igmp** | **ike** | **ilmi** | **interfaces** | **ipsec** | **ipv6** | **isis** | **l2circuit** | **l2vpn** | **ldp** | **link-management** | **log** | **mpls** | **msdp** | **multicast** | **ntp** | **ospf** | **pfe** | **pim** | **policer** | **policy** | **rip** | **ripng** | **route** | **rsvp** | **sap** | **snmp** | **system** | **task** | **ted** | **version** | **vrrp)**
ssh	Open a secure shell to another host. Syntax: **ssh** *host* <**bypass-routing**> <**routing-instance** *routing-instance-name* > <**source** *address* > <**vpn-interface** *vpn-interface* > <**v1** | **v2**>
start	Start a software process. Syntax: **start shell**

Table 62: CLI Operational Mode Top-Level Commands (continued)

Command	Description
telnet	Start a telnet session to another host. Syntax: **telnet** *host* <8bit> <bypass-routing> <inet | inet6> <noresolve> <port *port* > <interface *interface-name*> <routing-instance *routing-instance-name* > <source *address* > <vpn-interface *vpn-interface*>
test	Run various diagnostic debugging commands. Syntax: **test (configuration | interface | msdp | policy)**
traceroute	Trace the route to a remote host. Syntax: **traceroute** *host* <as-number-lookup> <bypass-routing> <gateway *address* > <inet | inet6> <noresolve> <routing-instance *routing-instance-name*><*source address* > <tos *value* > <ttl *value* > <vpn-interface *vpn-interface* > <wait *seconds*>

CLI Keyboard Shortcuts

In the CLI, you can use keyboard sequences to move around and edit a command line. You can also use keyboard sequences to scroll through a list of recently executed commands.

Table 15 on page 23 lists some of the CLI keyboard sequences.

Table 63: CLI Keyboard Shortcuts

Keyboard sequence	Action
Ctrl+b	Move the cursor back one character.
Esc+b or **Alt+b**	Move the cursor back one word.
Ctrl+f	Move the cursor forward one character.
Esc+f or **Alt+f**	Move the cursor forward one word.
Ctrl+a	Move the cursor to the beginning of the command line.
Ctrl+e	Move the cursor to the end of the command line.
Ctrl+h, **Delete, or Backspace**	Delete the character before the cursor.
Ctrl+d	Delete the character at the cursor.
Ctrl+k	Delete the all characters from the cursor to the end of the command line.
Ctrl+u or **Ctrl+x**	Delete the all characters from the command line.
Ctrl+w, **Esc+Backspace**, or **Alt+Backspace**	Delete the word before the cursor.

Table 63: CLI Keyboard Shortcuts (continued)

Keyboard sequence	Action
Esc+d or **Alt+d**	Delete the word after the cursor.
Ctrl+y	Insert the most recently deleted text at the cursor.
Ctrl+l	Redraw the current line.
Ctrl+p	Scroll backward through the list of recently executed commands.
Ctrl+n	Scroll forward through the list of recently executed commands.
Ctrl+r	Search the CLI history incrementally in reverse order for lines matching the search string.
Esc+/ or **Alt+/**	Search the CLI history for words for which the current word is a prefix.
Esc-1 through **Esc-9** or **Alt-1** through **Alt-9**	Specify the number of times to execute a keyboard sequence.

Manage Output at the ---(more)--- Prompt

If the output is longer than the screen length, it appears one screen at a time with the UNIX **---(more)--** prompt at the end of the screen. The **---(more)---** prompt indicates that more output is available. The following table lists the keyboard sequences you can use at the **--(more)---** prompt.

Table 64: Keyboard Shortcuts at the ---(more)--- Prompt

Keyboard Shortcut	Action
Enter, **Return**, **k**, **Ctrl+m**, **Ctrl+n**, or **down arrow**	Scroll down one line.
Tab, **d**, **Ctrl+d**, or **Ctrl+x**	Scroll down one-half screen.
Space or **Ctrl+f**	Scroll down one whole screen.
Ctrl+e or **g**	Scroll down to the bottom of the output.
n (or **no-more**)	Display the output all at once instead of one screen at a time.
j, **Ctrl-h**, **Ctrl-p**, or **up arrow**	Scroll up one line.
u or **Ctrl-u**	Scroll up one-half screen.
b or **Ctrl-b**	Scroll up one whole screen.
Ctrl-a or **g**	Scroll up to the bottom of the output.
/string	Search forward for a string.

Table 64: Keyboard Shortcuts at the ---(more)--- Prompt (continued)

Keyboard Shortcut	Action
?*string*	Search backward for a string.
n	Repeat previous search for a string.
m or **M** (or **| match *string***)	Find a text string. You are prompted for the string to match
e or E (or | except *string*)	Find, ignoring a text string. You are prompted for the string to ignore.
Ctrl-C, **q**, **Q**, or **Ctrl-k**	Interrupt the display of output.
H (Same as specifying **| hold**)	Hold the CLI at the **—more-** prompt after displaying all output.
c or **C**	Clear any match conditions and display the complete output.
Ctrl-l	Redraw the output on the screen.
s or **S** (or **| save *filename***)	Save the command output to a file. You are prompted for a filename.

Working with Problems on Your Network

Problem **Description:** This checklist provides links to troubleshooting basics, an example network, and includes a summary of the commands you might use to diagnose problems with the router and network.

Solution

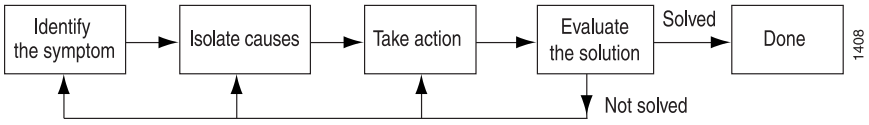
Table 65: Checklist for Working with Problems on Your Network

Tasks	Command or Action
"Isolating a Broken Network Connection" on page 1592	
1. *Identifying the Symptoms of a Broken Network Connection*	**ping (*ip-address* | *hostname*)** **show route (*ip-address* | *hostname*)** **traceroute (*ip-address* | *hostname*)**
2. *Isolating the Causes of a Network Problem*	**show < configuration | interfaces | protocols | route >**
3. *Taking Appropriate Action for Resolving the Network Problem*	**[edit]** **delete routing options static route *destination-prefix*** **commit and-quit** **show route *destination-prefix***
4. *Evaluating the Solution to Check Whether the Network Problem Is Resolved*	**show route (*ip-address* | *hostname*)** **ping (*ip-address* | *hostname*) count 3** **traceroute (*ip-address* | *hostname*)**

Isolating a Broken Network Connection

By applying the standard four-step process illustrated in Figure 131 on page 1592, you can isolate a failed node in the network. Note that the functionality described in this section is not supported in versions 15.1X49, 15.1X49-D30, or 15.1X49-D40.

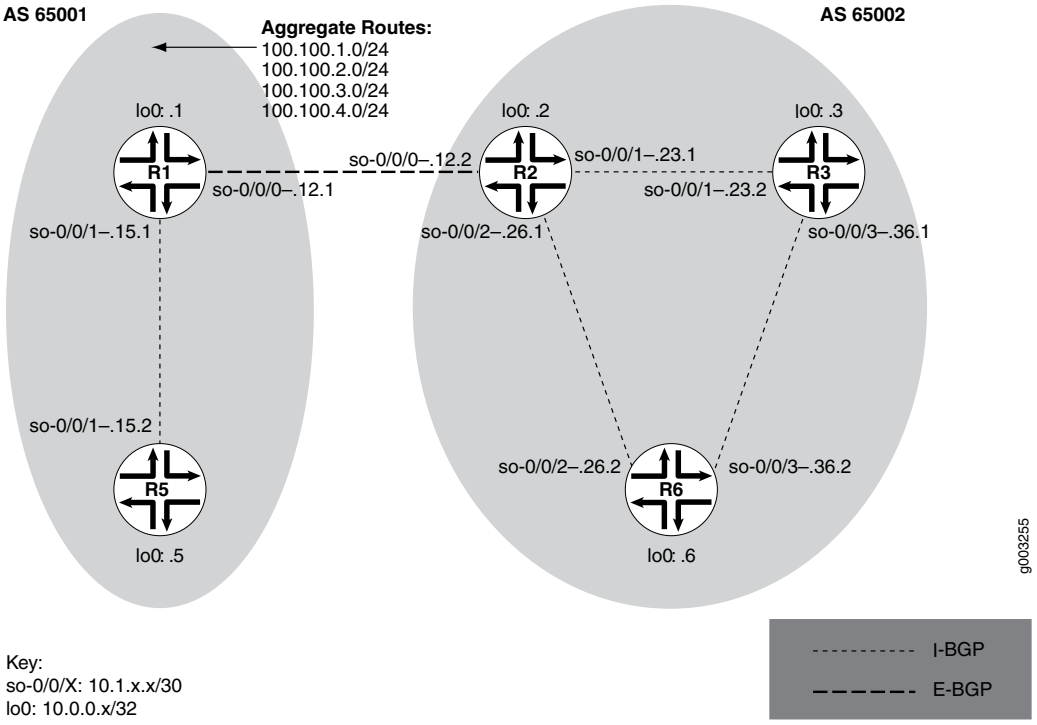
Figure 131: Process for Diagnosing Problems in Your Network



Before you embark on the four-step process, however, it is important that you are prepared for the inevitable problems that occur on all networks. While you might find a solution to a problem by simply trying a variety of actions, you can reach an appropriate solution more quickly if you are systematic in your approach to the maintenance and monitoring of your network. To prepare for problems on your network, understand how the network functions under normal conditions, have records of baseline network activity, and carefully observe the behavior of your network during a problem situation.

Figure 132 on page 1592 shows the network topology used in this topic to illustrate the process of diagnosing problems in a network.

Figure 132: Network with a Problem



The network in Figure 132 on page 1592 consists of two autonomous systems (ASs). AS 65001 includes two routers, and AS 65002 includes three routers. The border router (**R1**) in AS 65001 announces aggregated prefixes **100.100/24** to the AS 65002 network. The

problem in this network is that **R6** does not have access to **R5** because of a loop between **R2** and **R6**.

To isolate a failed connection in your network, follow the steps in these topics:

- *Identifying the Symptoms of a Broken Network Connection*
- *Isolating the Causes of a Network Problem*
- *Taking Appropriate Action for Resolving the Network Problem*
- *Taking Appropriate Action for Resolving the Network Problem*
- *Evaluating the Solution to Check Whether the Network Problem Is Resolved*

Display Junos OS Information

Purpose Display Junos OS information and status to determine if the version of Junos OS that you are running supports particular features or hardware. You can also determine whether particular software bugs will affect your version of Junos OS.

Action To display Junos OS information, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show version
```

Sample Output `user@host>` **show version**

COSD release 5.5R2.3 built by builder on 2002-11-21 22:33:50 UTC
KMD release 5.5R2.3 built by builder on 2002-11-21 22:35:29 UTC
FSAD release 5.5R2.3 built by builder on 2002-11-21 22:34:14 UTC
SERVICED release 5.5R2.3 built by builder on 2002-11-21 22:43:07 UTC
IRSD release 5.5R2.3 built by builder on 2002-11-21 22:35:21 UTC
NASD release 5.5R2.3 built by builder on 2002-11-21 22:36:47 UTC
FUD release 5.5R2.3 built by builder on 2002-11-21 22:34:17 UTC
PPMD release 5.5R2.3 built by builder on 2002-11-21 22:36:58 UTC
LMPD release 5.5R2.3 built by builder on 2002-11-21 22:36:01 UTC
RTSPD release 5.5R2.3 built by builder on 2002-11-21 22:42:58 UTC
SMARTD release 5.5R2.3 built by builder on 2002-11-21 22:47:50 UTC
jkernel-dd release 5.5R2.3 built by builder on 2002-11-21 22:27:20 UTC
jroute-dd release 5.5R2.3 built by builder on 2002-11-21 22:27:34 UTC
jcrypto-dd release 5.5R2.3 built by builder on 2002-11-21 22:27:46 UTC
```

Meaning The sample output shows the hostname, the version information for the Junos OS packages installed on the machine, and the version information for each software process.

Display Version Information for Junos OS Packages

Purpose Display version information for Junos OS packages to determine if they support particular features or hardware. You can also determine whether particular software bugs will affect your version of Junos OS.

Action To display brief information and status for the kernel and Packet Forwarding Engine, use the following CLI operational mode command:

```
user@host> show version brief
```

The following sample output is for worldwide nonencrypted Junos OS:

Sample Output

```
user@host> show version brief
 Hostname: my-router.net
Model: m10
JUNOS Base OS boot [5.5R2.3]
JUNOS Base OS Software Suite [5.5R2.3]
JUNOS Kernel Software Suite [5.5R2.3]
JUNOS Packet Forwarding Engine Support [5.5R2.3]
JUNOS Routing Software Suite [5.5R2.3]
JUNOS Online Documentation [5.5R2.3]
```

The following sample output is for Canada and USA encrypted Junos OS:

```
user@host> show version brief
Hostname: my-router.net
Model: m10
JUNOS Base OS boot [5.5R2.3]
JUNOS Base OS Software Suite [5.5R2.3]
JUNOS Kernel Software Suite [5.5R2.3]
JUNOS Packet Forwarding Engine Support [5.5R2.3]
JUNOS Routing Software Suite [5.5R2.3]
JUNOS Online Documentation [5.5R2.3]
JUNOS Crypto Software Suite [5.5R2.3]
```

Meaning The sample output shows version information for the Junos OS packages installed on the router. If the **Junos Crypto Software Suite** is listed, the router has Canada and USA encrypted Junos OS. If the **Junos Crypto Software Suite** is not listed, the router is running worldwide nonencrypted Junos OS.

Display the Current Active Router Configuration

Purpose Examine the current active router configuration.

Action To display the current, active router configuration, use the following command-line interface (CLI) operational mode command:

```
user@host> show configuration
```

Sample Output

```
user@host> show configuration
version "10.4R2";
groups {
    global {
        system {
            host-name potter;
```

```
            domain-name harry.potter.net;
            domain-search [ harry.potter.net potter.net hryptr.net ];

```

Meaning The sample output shows the current, active configuration for the router. When displaying the configuration, the CLI indents each subordinate hierarchy level, inserts braces to indicate the beginning and end of each hierarchy level, and places semicolons at the end of statements that are at the lowest level of the hierarchy.

The configuration statements appear in a fixed order. Interfaces appear alphabetically by type, and then in numerical order by slot number, Physical Interface Card (PIC) number, and port number.

Copy Junos OS to the Router

Action Copy the software packages from the server to the router. We recommend that you copy them to the **/var/tmp** directory, which is on the rotating medium (hard disk) and is a large file system. Use the following CLI command:

```
user@host> file copy ftp://username: prompt@ftp.hostname.
  net/jinstall-package-name/var/tmp/jinstall-package-name
```

Add New Software

Action To add new software packages, use the following Junos OS CLI operational mode command:

```
user@host> request system software add /var/tmp/jinstall-package--name
```

package-name is the full URL to the file and *release-number* is the major software release number; for example, 4.2R1. Before the new software is added, the existing software is automatically deleted.

NOTE: Even though you are adding the new software, the changes do not take effect until the router has completed rebooting.

Sample Output

```
user@host> request system software add /var/tmp/jinstall-5.2R2.3-domestic.tgz
Installing package '/var/tmp/jinstall-5.2R2.3-domestic.tgz
Auto-deleting old jroute...
Auto-deleting old jdocs...
Auto-deleting old jpfe...
Auto-deleting old jkernel...
Adding JUNOS base software 5.2R2.3
Adding jkernel...
Adding jpfe...
Adding jdocs...
Adding jroute...
NOTICE: uncommitted changes have been saved in
/var/db/config/juniper.conf.pre-install
Saving package file in /var/sw/pkg/jinstall-5.2R2.3-domestic.tgz
```

Compare Information Logged Before and After the Upgrade

Purpose Compare the operation of the system before and after the upgrade to ensure that everything is working as expected.

Action To obtain system information, use the following Junos OS CLI operational mode commands:

```
user@host> show version
user@host> show chassis hardware
user@host> show configuration
user@host> show interface terse
user@host> show bgp summary
user@host> show isis adjacency brief
user@host> show ospf neighbor brief
user@host> show system storage
```

Compare the information from these commands with the information you logged before the upgrade.

Displaying LSP Status Events

Purpose Display extensive information about LSPs, including the 50 most recent history events and the reasons why an LSP might have failed.

Action To examine status messages, enter the following Junos OS command-line interface (CLI) operational mode command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

   (flag=0x01) 10.35.40.2 (flag=0x01) 10.35.41.1 (flag=0x01)
[...Output truncated...]
```

Meaning Sample Output 1 from ingress router R1 shows extensive ingress LSP information, including LSP events that led to an LSP failure and the 50 most recent state events.

LSP events in bold are described in this topic. Descriptions include sample output of the LSP event, an explanation of what the event means, the possible cause of the event, and any possible actions that you can take.

For completeness, events not included in this example output are also described in this topic to show LSP events that did not occur in the example network configuration, but might occur in your network. The LSP events are organized alphabetically.

Sample Output 2 shows the state of the route received in the Received Record Route (**Received RRO**) created by fast reroute configurations in the network. The **Received RRO** indicates a series of hops. Each hop has an address followed by a flag. For more information on flags, see the *Junos MPLS Network Operations Guide*. In most cases, the **Received RRO** is the same as the computed Explicit Route Object (ERO).

Sample Output 3 shows a **Computed ERO** and a **Received RRO**. In this instance they are the same. However, if **Received RRO** is different from the **Computed ERO**, there is a topology change in the network, and the route is taking a detour.

Call Was Cleared by RSVP Event

LSP Event Call was cleared by RSVP

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
ActivePath: (none)
LoadBalance: Random
Encoding type: Packet, Switching type: Packet, GPID: IPv4
Primary State: Dn
Will be enqueued for recomputation in 10 second(s).
11 Jan 26 14:58:32 CSPF failed: no route toward 10.0.0.6
10 Jan 26 14:58:25 Deselected as active
9 Jan 26 14:58:25 CSPF failed: no route toward 10.0.0.6
8 Jan 26 14:58:25  Call was cleared by RSVP
7 Jan 26 14:58:25 Session preempted
6 Jan 26 14:58:25 Down
[...Output truncated...]
```

Meaning This LSP event indicates that the Resource Reservation Protocol (RSVP) session corresponding to the LSP path was preempted and the corresponding RSVP state deleted.

Cause This LSP event is occurs when you issue the **clear rsvp session** command or trigger preemption of an RSVP session at the ingress router. Depending on the timer value, Constrained Shortest Path First (CSPF) recomputes the path and the LSP comes up again.

Action Not applicable.

Change in Active Path Event

LSP Event Change in active path

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
13 Sep 19 00:02:20 Deselected as active
12 Sep 19 00:02:20 ResvTear received
11 Sep 19 00:02:20 Down
10 Sep 19 00:02:20  Change in active path
9 Sep 19 00:02:20
8 Sep 19 00:02:20 10.222.28.2: Explicit Route: bad strict routeChange in active
path
7 Sep 19 00:02:20 CSPF failed: no route toward 192.168.32.1
6 Sep 19 00:02:20 10.222.28.2: No Route toward dest
5 Sep 19 00:00:54 Selected as active path
4 Sep 19 00:00:54 Record Route: 10.222.28.2 10.222.4.2 10.222.44.2
3 Sep 19 00:00:54 Up
2 Sep 19 00:00:54 Originate Call
1 Sep 19 00:00:54 CSPF: computation result accepted
[...Output truncated...]
```

Meaning This LSP event indicates that even though the active physical path has changed, the LSP stays up. Because this network configuration has an alternate (fast-reroute) path available, the event is a **Change in active path** rather than a **Session preempted** event.

Cause The active path might have failed.

Action Not applicable.

Clear Call Event

LSP Event Clear call

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   65 Jan  5 09:58:33  Clear Call
   64 Jan  5 09:58:33 Session preempted
   63 Jan  5 09:58:33 Down
[...Output truncated...]
```

Meaning This LSP event indicates that the LSP was disconnected and restarted.

Cause The **clear mpls lsp** command was issued on the ingress router to disconnect existing RSVP sessions, release the routes and states associated with the LSP, and then start a new LSP. Issuing this command might impact traffic travelling along the LSP, because a time lag might occur between tearing down the old path and setting up a new path.

Action Not applicable.

Deselected as Active Event

LSP Event Deselected as active

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   Will be enqueued for recomputation in 18 second(s).
   53 Jan  4 18:11:28 CSPF failed: no route toward 10.0.0.6[2 times]
   52 Jan  4 18:10:44  Deselected as active
   51 Jan  4 18:10:44 CSPF failed: no route toward 10.0.0.6
   50 Jan  4 18:10:44 CSPF: link down/deleted
[...Output truncated...]
```

Meaning This LSP event indicates that the LSP is no longer the active path.

Cause Typically, other events, similar to those in lines 50 and 51, indicate the reason that the LSP is no longer the active path.

Action Refer to events on either side of this event to determine the appropriate action.

Link Protection Down Event

LSP Event Link protection down

Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
     link-protection;
}
interface fxp0.0 {
    disable;
}
interface all;
```

Sample Output 2

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Up, ActiveRoute: 1, LSPname: R1-to-R6
  ActivePath:  (primary)

    48 Feb 10 10:48:32 Link-protection Up
    47 Feb 10 10:48:32 Selected as active path
[...Output truncated...]
```

Meaning Sample Output 1 shows the MPLS link-protection configuration on R1 for the LSP **R1-to-R6**.

Sample Output 2 shows that link protection came up and down several times. Link protection comes up when the LSP signals. Line 60 shows the result when RSVP is disabled on all alternate paths out of R6. Lines 68 to 70 are the result when the **clear mpls lsp** command is issued.

Cause This LSP event is caused by a failure or configuration change that deletes or resignals the bypass LSP. For example, you clear the LSP using the **clear mpls lsp** command, or you disable RSVP on all alternate paths for the LSP. The bypass LSP does not use the primary path, instead it looks for an alternate path.

Action Include the **family mpls** statement for all alternate paths for the LSP at the [**edit interfaces type-fpc/pic/port.unit**] hierarchy level.

Originate Call Event

LSP Event Originate call

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   43 Jan  4 18:06:09 Record Route:  10.1.13.2 10.1.36.2
   42 Jan  4 18:06:09 Up
   41 Jan  4 18:06:09  Originate Call
   40 Jan  4 18:06:09 CSPF: computation result accepted
   39 Jan  4 18:05:40 CSPF failed: no route toward 10.0.0.6[2 times]
[...Output truncated...]
```

Meaning This LSP event indicates that the router is issuing an RSVP Path message.

Cause A Path message is transmitted by the ingress router toward the egress router to establish an LSP.

Action To analyze the contents of the Path message, enable RSVP tracing. To configure RSVP tracing, include the **traceoptions** statement at the [**edit protocols rsvp**] hierarchy level. Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**. To examine the contents of the **rsvp-log** file, issue the **file show /var/log/rsvp-log** command.

ResvTear Received Event

LSP Event ResvTear received

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
    23 Dec 28 13:46:39 CSPF failed: no route toward 10.0.0.6
   22 Dec 28 13:46:39 Clear Call
   21 Dec 28 13:46:39  ResvTear received
   20 Dec 28 13:46:39 Down
   19 Dec 28 13:46:39 10.1.13.2: Session preempted
   18 Dec 28 13:42:07 Selected as active path
[...Output truncated...]
```

Meaning This LSP event indicates that an RSVP ResvTear message was received. ResvTear messages remove RSVP reservation states along a path. These messages travel upstream toward senders of the session. This message usually appears in the middle of a run of messages that tear the LSP down.

Cause In some cases, an ResvTear event is received because a router's reservation state times out. In other cases, when the downstream link fails, the upstream node must eliminate all RSVP states and initiates a ResvTear event. If you are running Fast ReRoute, the upstream node initiates a PathErr message, not a ResvTear message. It is beyond the scope of this document to include all possible reasons for an ResvTear event.

Action Analyze the status to determine if this is the required behavior. If this is not the required behavior, verify the surrounding LSP events to identify the cause of the problem.

Session Preempted Event

LSP Event Session preempted

Sample Output 1

```
user@R1> show mpls lsp extensive
[...Output truncated...]
    21 Dec 28 13:46:39 ResvTear received
   20 Dec 28 13:46:39 Down
   19 Dec 28 13:46:39  10.1.13.2: Session preempted
   18 Dec 28 13:42:07 Selected as active path
   17 Dec 28 13:42:07 Record Route:  10.1.13.2 10.1.36.2
[...Output truncated...]
```

Sample Output 2

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   66 Jan  5 09:58:33 CSPF failed: no route toward 10.0.0.6
   65 Jan  5 09:58:33 Clear Call
   64 Jan  5 09:58:33  Session preempted
   63 Jan  5 09:58:33 Down
   62 Jan  5 09:58:32  CSPF failed
 : no route toward 10.0.0.6[2 times]
61 Jan  5 09:57:55 10.1.36.2: Explicit Route: wrong delivery
   60 Jan  5 09:57:34 CSPF failed: no route toward 10.0.0.6[2 times]
   59 Jan  5 09:57:28 CSPF: link down/deleted
10.1.36.1(R3.00/10.0.0.3)->10.1.36.2(R6.00/10.0.0.6)
[...Output truncated...]
```

Meaning This LSP event indicates that the LSP session was taken over. Sample Output 1 shows the IP address (**10.1.13.2**) included with the event, indicating the IP address of the router that sent the message. Sample Output 2 does not include an IP address, indicating that the message originated on the ingress router.

Cause The state of the network might have changed, as shown in Sample Output 1, or an LSP with a higher priority might be using the bandwidth of the LSP.

Action Refer to the events preceding this event in the history log for more information on what might have caused the preemption. For example, in line 62, the **CSPF failed** message may indicate that you specified a disable constrained-path (**no-cspf**) LSP and an explicit route address that is strict and not directly connected. Additionally, the egress router might have changed its configuration, making the destination address unreachable.

Displaying General LSP Error Events

Purpose Display extensive information about LSPs, including the 50 most recent history events and the possible reasons why an LSP failed.

Action To examine error messages, enter the following Junos OS command-line interface (CLI) operational mode command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn, No-decrement-ttl
    Bandwidth: 100Mbps
   14 Jan 21 15:43:39 Requested bandwidth unavailable[3 times]
   13 Jan 21 15:43:21 Deselected as active
   12 Jan 21 15:43:21  Requested bandwidth unavailable
   11 Jan 21 15:43:21 Clear Call
   10 Jan 21 15:42:32 Selected as active path
    9 Jan 21 15:42:32 Record Route:  10.1.12.2 10.1.26.2
    8 Jan 21 15:42:32 Up
[...Output truncated...]
```

Meaning The sample output from ingress router R1 is a section from the complete output. Typically, the output includes LSP events that led to an LSP failure and the 50 most recent state events. Only one example of a general LSP error event is displayed because it is impossible to provide all of the events described in this topic in one sequence of log history.

For completeness, events not generated by the example network used throughout this book are described to show LSP events that might occur in your network. The output for these events includes the prompt **user@host** rather than the usual **user@R1** prompt.

Admission Control Failure Event

LSP Event Admission control failure

Sample Output Not available.

Meaning This LSP error event indicates that a Resource Reservation Protocol (RSVP) Admission control failure occurred along the LSP path. This event is logged because of on an error notification (PathErr message) received from RSVP for the label-switched path.

Cause This LSP event is caused by inadequate bandwidth on a link along the LSP path. The available bandwidth could not satisfy the requested traffic parameters and no other sessions were pre-emptied to accommodate this request.

Action This error event is not generated by Juniper Networks routers. However, when this event is received by a Juniper Networks router, it appears in the log output of the **show mpls lsp extensive** command.

Explicit Route: Bad Loose Route Event

LSP Event Explicit Route: bad loose route

Sample Output 1

```
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
From: 10.0.0.1, State: up, ActiveRoute: 0, LSPname: R1-R6-3

}
path R6-3-1 {
10.1.12.2;
}
interface fxp0.0 {
disable;
}
interface all;
```

Meaning This LSP error event indicates that there is an error in the loose hop specified in the Explicit Route Object (ERO) of a Path message received by a label-switched router (LSR) along the LSP path, indicating an LSP setup failure.

Cause This LSP error event is caused by control plane unreachability or data plane incompatibility.

Action Check the LSP configuration at the [**edit protocols mpls**] hierarchy level.

Explicit Route: Bad Strict Route Event

LSP Event Explicit route: bad strict route

Sample Output 1

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   36 Jan  4 18:04:57 CSPF: link down/deleted 10.1.13.1(R1.00/10.0.0.1)

[...Output truncated...]
```

Meaning This LSP event indicates that a poorly formed ERO was generated. Sample Outputs 1 and 2 show that this LSP event was caused by different situations described below.

Cause This LSP event can be caused by several factors:

- A strict hop address specified for an LSP on a link that does not have RSVP enabled.
- The **no-cspf** statement included in the LSP configuration.
- An error with the configuration of constraints on a Constrained Shortest Path First (CSPF) LSP generates the **CSPF: No route towards dest** message, followed by the **Explicit Route: bad strict route** event.
- An ERO that causes a routing loop. See Sample Output 2.

Action Examine the strict hop address, remove the **no-cspf** statement, or examine the path and verify that RSVP is enabled on each interface.

Explicit Route: Format Error Event

LSP Event Explicit route: format error

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary   to-R6            State: Dn, No-decrement-ttl
    5 Jan 21 14:37:06 10.1.34.2:  Explicit Route: format error [2 times]
    4 Jan 21 14:37:03 Originate Call
    3 Jan 21 14:37:03 Clear Call
[...Output truncated...]
```

Meaning This LSP event indicates an LSP setup failure in which a Path message error in the the ERO was received by a router along the LSP path.

Cause This LSP event can be caused by several factors:

- An incorrectly formed ERO in the RSVP Path message.
- A strict hop address specified in the middle of an ERO that is not contiguous.
- An unsupported subobject in the ERO of a router along the LSP path.
- The hop indicated by the RSVP hop object does not match the hop indicated by the ERO.

Action Examine the strict hop address configuration and make any necessary changes.

Explicit Route: Wrong Delivery Event

LSP Event Explicit route: wrong delivery

Sample Output 1

```
user@host> show mpls lsp extensive
[...Output truncated...]
Primary use-TOKYO State: Dn, No-decrement-ttl
   3 Sep 19 00:25:45  10.222.45.2: Explicit Route: wrong delivery
   2 Sep 19 00:25:34 No Route[8 times]
   1 Sep 19 00:23:01 Originate Call
[...Output truncated...]
```

Sample Output 2

```
user@host> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary   to-R6            State: Dn
   40 Jan 26 16:35:26  10.1.36.2: Explicit Route: wrong delivery [2 times]
   39 Jan 26 16:35:23 Originate Call
   38 Jan 26 16:35:23 Clear Call
[...Output truncated...]
```

Sample Output 3

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
    no-cspf;
    primary to-R6;
}
path to-R6 {
    10.1.13.2 strict;
     10.1.56.1 strict;      <<< IP address not directly connected to 10.1.13.2
    10.1.26.1 strict;
```

Meaning This LSP event indicates that a RSVP message with an ERO arrived at the wrong router, even though a strict route was specified. The receiving router determines that the address is inconsistent with the ERO, and generates the error message. Note that the IP address of the sending router precedes the error event; for example, **10.222.45.2** in Sample Output 1, and **10.1.36.2** in Sample Output 2.

Cause This LSP event can be caused by several factors:

- The loopback (**lo0**) interface on the ingress router is not configured at the [**edit protocols isis**] hierarchy level. After the loopback (**lo0**) interface is included in the Intermediate System-to-Intermediate System (IS-IS) configuration, and while IS-IS is forming adjacencies, an RSVP packet is forwarded to an incorrect destination, **10.222.45.2**, as shown in Sample Output 1.
- A strict path is configured to a directly connected router, then another strict path is configured to an IP address that is not directly connected. For example, Sample Output 3 shows that the path **to-R6** includes three IP addresses, one of which (**10.1.56.1)** is not directly connected to the other IP addresses in the path.

Action Take appropriate action. On the ingress router, include the loopback (**lo0**) interface at the [**edit protocols isis**] hierarchy level, change the definition of the strict path at the [**edit protocols mpls path** ***path-name***] hierarchy level, or verify the validity of all IP addresses listed in the named path referenced by the LSP hop by hop.

Invalid Destination Address Event

LSP Event Invalid Dest addr

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.1
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Metric: 100
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                    State: Dn
    4 Apr 22 10:22:15  Invalid Dest Addr
    3 Apr 22 10:22:15 Originate Call
    2 Apr 22 10:22:15 Invalid Dest Addr
    1 Apr 22 10:22:15 Originate Call
  Created: Fri Apr 22 10:22:16 2005
Total 1 displayed, Up 0, Down 1
```

Meaning This LSP event indicates that the **to** address configured at the [**edit protocols mpls labeled-switched-path** ***name***] hierarchy level is invalid.

Cause This LSP event is caused when the **to** address of the LSP is the loopback address of the ingress router. A contributing factor may be that the **no-cspf** statement is included in the LSP configuration.

Action Verify that the LSP destination address is not the local router's loopback address, and check that the addresses on the local router are correctly configured.

Invalid Filter for Policing Event

LSP Event Invalid filter for policing

Sample Output Not available. This LSP event indicates an abnormal condition and is difficult to recreate.

Meaning Although a policer was configured on the LSP, the corresponding firewall filter index was not found, indicating a failure in the routing protocol process (rpd) or the firewall process (dfwd).

Cause A possible cause is that the routing protocol process (rpd) or the firewall process (dfwd) were restarted in a situation in which the LSP was established.

Action Not applicable.

MPLS Graceful Restart: Recovery Failed Event

LSP Event MPLS graceful restart: recovery failed

Sample Output Not available.

Meaning This LSP event indicates unsuccessful recovery of an LSP path after graceful restart, resulting in potential traffic loss.

Cause This LSP event is caused by several factors:

- MPLS graceful restart procedures may have been aborted by this LSR.
- MPLS graceful restart is disabled, by configuration, during the recovery period.
- An MPLS LSP path is disabled either due to a configuration change or due to an error during the recovery period.
- CSPF computation failed for the restarted LSP path with parameters and constraints preserved across the restart.
- A signaling failure occurred and an RSVP PathErr was received on the LSP path signaled after a restart.
- A network failure occurred on some hop that the LSP was traversing during the recovery period.

Action Check the MPLS logs for more details about the failure.

MPLS Label Allocation Failure Event

LSP Event MPLS label allocation failure

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   24 Jan 20 09:25:35 CSPF failed: no route toward 10.0.0.6
   23 Jan 20 09:25:35 Clear Call
   22 Jan 20 09:25:35 Deselected as active
   21 Jan 20 09:25:35  10.1.13.1: MPLS label allocation failure
   20 Jan 20 09:25:34  MPLS label allocation failure
   19 Jan 20 09:25:34 Down
[...Output truncated...]
```

Meaning This LSP event indicates that the MPLS protocol or the **family mpls** statement were not configured properly. When the LSP event is preceded by an IP address, the address is typically the router that has the MPLS configuration error.

Cause This LSP event is caused by the omission of interfaces at the [**edit protocols mpls**] hierarchy level or failure to configure the **family mpls** statement at the [**edit interfaces** ***type-fpc/pic/port***] hierarchy level. The **family mpls** statement specifies to the interface ASICs to permit protocol code 0x8847 (unicast MPLS) into the router.

Action Include interfaces at the **[edit protocols mpls]** hierarchy level, or include the **family mpls** statement at the [**edit interfaces** ***type-fpc/pic/port***] hierarchy level. You must configure the **family mpls** statement, in the same way that you must configure the **family iso** statement for IS-IS.

NOTE: Do not configure the family mpls statement on the loopback (lo0) interface.

Non-RSVP Capable Router Detected Event

LSP Event Non-RSVP capable router detected

Sample Output

```
user@host> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn, No-decrement-ttl
   19 Jan 21 15:05:37 10.1.24.2:  Non-RSVP capable router detected
   18 Jan 21 15:04:52 10.1.26.2:  Non-RSVP capable router detected [4 times]
   17 Jan 21 15:04:34 Originate Call
   16 Jan 21 15:04:34 Clear Call
[...Output truncated...]
```

Meaning This LSP event indicates that a router, forwarding packets to the egress router, was not configured for RSVP.

Cause This LSP event might be caused when a router not configured for RSVP forwards an RSVP packet toward the egress router without decrementing the **Send_TTL** value in the RSVP common header. The next downstream router detects that the **Send_TTL** value and the **IP_TTL** value are different, and generates this LSP event. Note that two different routers generated the same error message at different times.

Action Configure the router in question with RSVP.

No Route Toward Destination Event

LSP Event No route toward destination

Sample Output 1

```
user@R1> show mpls lsp extensive
[...Output truncated...]
   35 Oct 26 22:48:36 Down
   34 Oct 26 22:48:29 CSPF failed: no route toward 10.0.0.1[4 times]
   33 Oct 26 22:47:25 CSPF: link down/deleted
10.1.13.2(R3.00/10.0.0.3)->10.1.13.1(R1.00/10.0.0.1)
   32 Oct 26 22:47:25 CSPF failed: no route toward 10.0.0.1
   31 Oct 26 22:47:25  10.1.36.1: No Route toward dest
   30 Oct 26 22:33:54 Selected as active path
   29 Oct 26 22:33:53 Record Route:  10.1.36.1 10.1.13.1
[...Output truncated...]
```

Sample Output 2

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
   From: 10.0.0.1 , State: Dn, ActiveRoute: 0, LSPname: R1-to-R6

  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn
    Will be enqueued for recomputation in 7 second(s).
   13 Oct 25 16:29:28 Deselected as active
   12 Oct 25 16:29:27 CSPF failed: no route toward 10.0.0.6
   11 Oct 25 16:29:27 CSPF: link down/deleted
10.1.13.1(R1.00/10.0.0.1)->10.1.13.2(R3.00/10.0.0.3)
   10 Oct 25 16:29:27 CSPF failed: no route toward 10.0.0.6
    9 Oct 25 16:29:27 Clear Call
    8 Oct 25 16:29:27 Explicit Route: bad strict route
    7 Oct 25 16:29:27  No Route toward dest
    6 Oct 25 16:29:27 Down
[...Output truncated...]
```

Meaning This LSP event indicates that the router at address **10.1.36.1** in Sample Output 1 does not have a route to the specified destination. Sample Output 2 shows that the local router, ingress router **10.0.0.1,** does not have a route to the specified destination.

Cause This LSP event is caused by different factors. The egress interface of a transit router might not have RSVP enabled, or IP reachability to the destination (either the egress router or the next address in the ERO) does not exist.

Action Enable RSVP on the transit router's egress interface, or examine the IP configuration of the relevant router.

Unsupported Traffic Class Event

LSP Event Unsupported traffic class

Sample Output Not available. This LSP event indicates an abnormal condition and is difficult to recreate.

Meaning This LSP error event is a Juniper Networks proprietary error, indicating that a DiffServ-traffic engineering (TE) LSP was signaled with one or more traffic classes with values greater than the four traffic classes currently supported.

Cause Not available.

Action Not available.

CSPF: Computation Result Accepted Event

LSP Event CSPF: computation result accepted

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
  57 Jan  5 09:54:37 Record Route:  10.1.13.2 10.1.36.2
   56 Jan  5 09:54:37 Up
   55 Jan  5 09:54:37 Originate Call
   54 Jan  5 09:54:37  CSPF: computation result accepted
[...Output truncated...]
```

Meaning This LSP event indicates that CSPF pruned the traffic engineering database of noncompliant links and found a shortest path. CSPF generated an ERO, which was then passed to the RSVP.

Cause Not applicable.

Action Not applicable

CSPF: Reroute Due to Re-Optimization Event

LSP Event CSPF: Reroute due to re-optimization

Sample Output

```
user@host> show mpls lsp extensive
[...Output truncated...]
9 Dec 11 17:32:35  Up
    8 Dec 11 17:32:35  Clear Call
    7 Dec 11 17:32:35  CSPF: computation result accepted
    6 Dec 11 17:32:35   CSPF: Reroute due to re-optimization
    5 Dec 11 17:28:29  CSPF: computation result ignored
    4 Dec 11 17:24:23  Record Route:  10.35.38.2 S 192.168.135.29 S
10.35.39.1 S 10.35.40.2 S 10.35.41.1 S
    3 Dec 11 17:24:23  Up
[...Output truncated...]
```

Meaning This LSP event indicates that CSPF found an optimal path for LSP traffic, and switched over to the new path.

Cause This is a periodic or one-time reoptimization event.

Action Not applicable.

Retry Limit Exceeded Event

LSP Event Retry limit exceeded

Sample Output 1

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn
     RetryCount: 13
     RetryLimit: 1
    12 Jan 14 15:39:30 Clear Call
    11 Jan 14 15:39:30  Retry limit exceeded
    10 Jan 14 15:39:10 10.1.12.1: MPLS label allocation failure[11 times]
[...Output truncated...]
```

Sample Output 2

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                   State: Dn
    14 Jan 14 15:44:07 10.1.12.1: MPLS label allocation failure[3 times]
    13 Jan 14 15:43:58 Originate Call
    12 Jan 14 15:39:30 Clear Call
    11 Jan 14 15:39:30  Retry limit exceeded
    10 Jan 14 15:39:10 10.1.12.1: MPLS label allocation failure[11 times]
[...Output truncated...]
```

Meaning This LSP event indicates that the number of CSPF path computations for a particular path exceeded a configured retry limit. After this point, the path is not recomputed or signaled, unless the user intervenes.

Cause The number of CSPF path computations for an LSP path exceeded the configured non-zero retry limit. Sample Output 1 shows that a configured retry limit of 1 was exceeded by the retry count of 13.

Action Enter the **clear mpls lsp** command to disconnect and restart the LSP. Sample Output 2 shows that events 13 and 14 were generated after the **clear mpls lsp** command was issued. This operation disconnects existing RSVP sessions on the ingress router, releases the routes and states associated with the LSPs, and starts a new LSP. Issuing this command might impact traffic travelling along the LSP, because of a time lag that can occur between the old path being torn down and the new path being set up.

Log the Software Version Information

Purpose The purpose of this action is to log the Junos OS version information.

Action Use the following Junos OS CLI operational mode command:

```
user@host> show version | save filename
```

Sample Output

```
user@host> show version | save test
Wrote 39 lines of output to 'test'

user@host> show version
Hostname:  my-router.net
Model: m10
JUNOS Base OS boot [5.0R5]
JUNOS Base OS Software Suite [5.0R5]

```

Meaning The sample output shows the hostname, router model, and the different Junos OS packages, processes, and documents.

Related Documentation

-

Log the Hardware Version Information

Purpose You should log hardware version information in the rare event that a router cannot successfully reboot and you cannot obtain the Routing Engine serial number. The Routing Engine serial number is necessary for Juniper Networks Technical Assistance Center (JTAC) to issue a return to manufacturing authorization (RMA). Without the Routing Engine serial number, an onsite technician must be dispatched to issue the RMA.

Action To log the router chassis hardware version information, use the following Junos OS CLI operational mode command:

```
user@host> show chassis hardware | save filename
```

Sample Output The output for the M-series routers varies depending on the chassis components of each router. All routers have a chassis, midplanes or backplanes, power supplies, and Flexible PIC Concentrators (FPCs). Refer to the hardware guides for information about the different chassis components.

```
user@host> show chassis hardware | save test
Wrote 43 lines of output to 'test'

user@host> show chassis hardware
Item             Version  Part number  Serial number     Description

Meaning The sample output shows the initial messages generated by the system kernel upon boot. This is the content of the **/var/run/dmesg.boot** file.

Log the BGP, IS-IS, and OSPF Adjacency Information

Purpose The following commands log useful information about Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), and Open Shortest Path First (OSPF) protocols. If you have other protocols installed, such as Multiprotocol Label Switching (MPLS), Resource Reservation Protocol (RSVP), or Protocol Independent Multicast (PIM), you also might log summary information for them.

Action To log the protocol peer information, use the following Junos OS CLI operational mode commands:

```
user@host> show bgp summary | save filename
user@host> show isis adjacency brief | save filename
user@host> show ospf neighbor brief | save filename
```

Sample Output 1

```
user@host> show bgp summary | save test
Wrote 45 lines of output to 'test'

user@host> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
inet.0                 4          4          0          0          0          0

so-5/0/0.0 ranier         2 Up                   17
```

Sample Output 3

```
user@host> show ospf neighbor brief | save test
Wrote 10 lines of output to 'test'

user@host> show ospf neighbor brief
  Address         Intf              State      ID              Pri  Dead
10.168.254.225   fxp3.0            2Way       10.250.240.32   128    36
10.168.254.230   fxp3.0            Full       10.250.240.8    128    38
10.168.254.229   fxp3.0            Full       10.250.240.35   128    33
10.1.1.129       fxp2.0            Full       10.250.240.12   128    37
10.1.1.131       fxp2.0            Full       10.250.240.11   128    38
10.1.2.1         fxp1.0            Full       10.250.240.9    128    32
10.1.2.81        fxp0.0            Full       10.250.240.10   128    33
```

Meaning Sample output 1 displays summary information about BGP and its neighbors. Sample output 2 displays information about IS-IS neighbors. Sample output 3 displays information about all OSPF neighbors.

Back Up the Currently Running and Active File System

Action To back up the currently running and active file system so that you can recover to a known, stable environment in case there is a problem during the reinstall, use the following Junos OS CLI operational mode command:

```
user@host> request system snapshot
```

Sample Output

```
user@host> request system snapshot
umount: /altroot: not currently mounted
Copying / to /altroot.. (this may take a few minutes)
umount: /altconfig: not currently mounted
Copying /config to /altconfig.. (this may take a few minutes)
The following filesystems were archived: / /config
```

Meaning The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Reinstall Junos OS

Action To reinstall Junos OS, follow these steps:

1. Insert the removable medium (boot floppy) into the router.
2. Reboot the router, either by power-cycling it or by issuing the **request system reboot** command from the CLI.
3. At the following prompt, type **y**:

   ```
   WARNING: The installation will erase the contents of your disk. Do you wish
   to continue (y/n)?
   ```

   The router copies the software from the removable medium onto your system, occasionally displaying status messages. This can take up to 10 minutes.
4. Remove the removable medium when prompted.

   The router reboots from the primary boot device on which the software is installed. When the reboot is complete, the router displays the login prompt.

Reconfigure Junos OS

After you have reinstalled the software, you must copy the router's configuration files back to the router. (You also can configure the router from scratch, as described in *Junos System Basics Configuration Guide*) However, before you can copy the configuration files, you must establish network connectivity.

To reconfigure the software, follow these steps:

1. Configure Host Names, Domain Names, and IP Addresses on page 1633
2. Protecting Network Security by Configuring the Root Password on page 1635
3. Check Network Connectivity on page 1637
4. Copy Backup Configurations to the Router on page 1637

Configure Host Names, Domain Names, and IP Addresses

To configure the machine name, domain name, and various addresses, follow these steps:

1. Log in as **root**. There is no password.
2. Start the CLI:

```
root# cli
root@>
```

3. Enter configuration mode:

```
cli> configure
[edit]
root@#
```

4. Configure the name of the machine. If the name includes spaces, enclose the entire name in quotation marks (" "):

```
[edit]
root@# set system host-name host-name
```

5. Configure the machine's domain name:

```
[edit]
root@# set system domain-name domain-name
```

6. Configure the IP address and prefix length for the router's management Ethernet interface:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address / prefix-length
```

7. Configure the IP address of a default router. This system is called the backup router because it is used only while the routing protocol process is not running.

```
[edit]
root@#  set system backup-router address
```

8. Configure the IP address of a Domain Name Server (DNS) server:

```
[edit]
root@# set system name-server  address
```

Protecting Network Security by Configuring the Root Password

Configuring the root password on your Junos OS-enabled router helps prevent unauthorized users from making changes to your network. The root user (also referred to as superuser) has unrestricted access and full permissions within the system, so it is crucial to protect these functions by setting a strong password when setting up a new router.

After a new router is initially powered on, you log in as the user **root** with no password. Junos OS requires configuration of the root password before it accepts a commit operation. On a new device, the root password must always be a part of the configuration submitted with your initial commit.

To set the root password, you have a few options as shown in Step 1 of the following procedure.

- Enter a plain-text password that Junos OS encrypts.
- Enter a password that is already encrypted.
- Enter a secure shell (ssh) public key string.

The most secure options of these three are using an already encrypted password or an ssh public key string. Pre-encrypting your password or using a ssh public key string means the plain-text version of your password will never be transferred over the internet, protecting it from being intercepted by a man-in-the-middle attack.

BEST PRACTICE: **Optionally, instead of configuring the root password at the [edit system] hierarchy level, you can use a configuration group to strengthen security, as shown in Step 2 of this procedure. This step uses a group called global as an example.**

To set the root password:

1. Use one of these methods to configure the root password:

   - To enter a plain-text password that the system encrypts for you:

     ```
     [edit groups global system]
     root@# set root-authentication plain-text-password
     New Password: type password here
     Retype new password: retype password here
     ```

     If you use a plain-text password, Junos OS displays the password as an encrypted string so that users viewing the configuration cannot see it. As you enter the password in plain text, Junos OS encrypts it immediately. You do not have to configure Junos OS to encrypt the password as in some other systems. Plain-text passwords are hidden and marked as **## SECRET-DATA** in the configuration.

   - To enter a password that is already encrypted:

     

     CAUTION: Do not use the **encrypted-password** option unless the password is *already* encrypted, and you are entering the encrypted version of the password.

     If you accidentally configure the **encrypted-password** option with a plain-text password or with blank quotation marks (" "), you will not be able to log in to the device as root, and you will need to complete the root password recovery process.

     ```
     [edit groups global system]
     root@# set root-authentication encrypted-password password
     ```

   - To enter an ssh public key string:

     ```
     [edit groups global system]
     root@# set root-authentication (ssh-dsa | ssh-ecdsa | ssh-rsa key)
     ```

2. (Optional) Strengthen security by only allowing root access from the console port.

   ```
   [edit groups global system]
   root@# set services ssh root-login deny
   ```

3. If you used a configuration group in Step 2, apply the configuration group, substituting **global** with the appropriate group name.

   ```
   [edit]
   user@host# set apply-groups global
   ```

4. Commit the changes.

   ```
   root@# commit
   ```

Check Network Connectivity

Purpose Establish that the router has network connectivity.

Action To check that the router has network connectivity, issue a **ping** command to a system on the network:

```
root@> ping address
```

If there is no response, verify that there is a route to the ***address*** using the **show route** command. If the address is outside your **fxp0** subnet, add a static route. Once the backup configuration is loaded and committed, the static route is no longer needed and should be deleted.

Copy Backup Configurations to the Router

To copy backup configurations to the router, follow these steps:

1. To copy the existing configuration and any backup configurations back onto the router, use the **file copy** command. Place the files in the **/var/tmp** directory.

   ```
   user@host> file copy var/tmp/filename
   ```

2. Load and activate the desired configuration:

   ```
   root@> configure
   [edit]
   root@# load merge/config/filename or load replace/config/filename
   [edit]
   root@# commit
   ```

Configure Host Names, Domain Names, and IP Addresses

To configure the machine name, domain name, and various addresses, follow these steps:

1. Log in as **root**. There is no password.
2. Start the CLI:

   ```
   root# cli
   root@>
   ```

3. Enter configuration mode:

```
cli> configure
[edit]
root@#
```

4. Configure the name of the machine. If the name includes spaces, enclose the entire name in quotation marks (" "):

```
[edit]
root@# set system host-name host-name
```

5. Configure the machine's domain name:

```
[edit]
root@# set system domain-name domain-name
```

6. Configure the IP address and prefix length for the router's management Ethernet interface:

```
[edit]
root@#  set interfaces fxp0 unit 0 family inet address address / prefix-length
```

7. Configure the IP address of a default router. This system is called the backup router because it is used only while the routing protocol process is not running.

```
[edit]
root@# set system backup-router address
```

8. Configure the IP address of a Domain Name Server (DNS) server:

```
[edit]
root@# set system name-server address
```

Check Network Connectivity

Purpose Establish that the router has network connectivity.

Action To check that the router has network connectivity, issue a **ping** command to a system on the network:

```
root@> ping address
```

If there is no response, verify that there is a route to the ***address*** using the **show route** command. If the address is outside your **fxp0** subnet, add a static route. Once the backup configuration is loaded and committed, the static route is no longer needed and should be deleted.

Automatic Autobandwidth Adjustment Failed Event

LSP Event Autobw adjustment failed

Sample Output 1

```
user@R1> show configuration protocols mpls
statistics {
    file auto-bw.log;
    interval 5;
    auto-bandwidth;
}
label-switched-path R1-to-R6 {
    to 10.0.0.6;
    auto-bandwidth {
        adjust-interval 300;
        adjust-threshold 10;

  Created: Thu Feb 17 15:36:23 2005
[...Output truncated...]
```

Meaning This LSP event indicates that a periodic (timer-based) autobandwidth adjustment for the LSP is triggered at the end of the adjust interval. The adjustment fails, and the LSP stays up on the existing path with its current bandwidth.

Cause Adjustment failure may be due to a path CSPF computation failure with the adjust bandwidth or a signaling failure on the new path.

At the end of the time interval specified at the **[edit protocols mpls label-switched-path auto-bandwidth]** hierarchy level, the current maximum average bandwidth usage is compared to the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

Action Take action appropriate to the situation:

- Verify the MPLS and RSVP configuration on all available paths to the LSP endpoint.
- Check available bandwidth on alternate paths using the **show rsvp interface** command. If not enough bandwidth is available on any available paths, adjust the minimum-bandwidth parameter for the LSP in order to establish or adjust the priority to allow the LSP to preempt another LSP of lesser priority. For an LSP to be preempted, its hold priority must be lower than the LSP you are trying to establish.

Configuring Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth, and this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

At the end of the automatic bandwidth allocation time interval, the current maximum average bandwidth usage is compared with the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

NOTE: In calculating the value for Max AvgBW (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

If you have configured link and node protection for the LSP and traffic has been switched to the bypass LSP, the automatic bandwidth allocation feature continues to operate and

take bandwidth samples from the bypass LSP. For the first bandwidth adjustment cycle, the maximum average bandwidth usage taken from the original link and node-protected LSP is used to resignal the bypass LSP if more bandwidth is needed. (Link and node protection are not supported on QFX Series switches.)

If you have configured fast-reroute for the LSP, you might not be able to use this feature to adjust the bandwidth. Because the LSPs use a fixed filter (FF) reservation style, when a new path is signaled, the bandwidth might be double-counted. Double-counting can prevent a fast-reroute LSP from ever adjusting its bandwidth when automatic bandwidth allocation is enabled. (Fast reroute is not supported on QFX Series switches.)

To configure automatic bandwidth allocation, complete the steps in the following sections:

- Configuring Automatic Bandwidth Allocation on LSPs on page 1641
- Requesting Automatic Bandwidth Allocation Adjustment on page 1647

NOTE: On the QFX10000 switches, you can only configure automatic bandwidth allocation at the **edit protocols mpls** hierarchy level. Logical systems are not supported.

Configuring Automatic Bandwidth Allocation on LSPs

To enable automatic bandwidth allocation on an LSP, include the **auto-bandwidth** statement:

```
auto-bandwidth (MPLS Tunnel) {
  adjust-interval seconds;
  adjust-threshold percent;
  adjust-threshold-overflow-limit number;
  adjust-threshold-underflow-limit number;
  maximum-bandwidth bps;
  minimum-bandwidth bps;
  minimum-bandwidth-adjust-interval
  minimum-bandwidth-adjust-threshold-change
  minimum-bandwidth-adjust-threshold-value
  monitor-bandwidth;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path *lsp-name*]
- **[edit logical-systems** *logical-system-name* **protocols mpls** label-switched-path *lsp-name*]

If an LSP has an automatic bandwidth configuration, you can disable automatic bandwidth adjustments on a particular path (either primary or secondary) by configuring a static bandwidth value and by disabling the CSPF computation (using the **no-cspf** statement).

For example:

```
user@host> show protocols mpls
label-switched-path primary-path {
   to 192.168.0.1;
   ldp-tunneling;
   optimize-timer 3571;
   least-fill;
   link-protection;
   adaptive;
   auto-bandwidth {
      adjust-interval 7177;
      adjust-threshold 5;
      minimum-bandwidth 1m;
      maximum-bandwidth 2500000000;
      adjust-threshold-overflow-limit 2;
      resignal-minimum-bandwidth;
   }
   primary primary-path;
   secondary secondary-path {
      bandwidth 0;
      no-cspf;
      priority 0 0;
   }
}
```

The statements configured at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level are optional and explained in the following sections:

- Configuring the Automatic Bandwidth Allocation Interval on page 1642
- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 1643
- Configuring the Automatic Bandwidth Adjustment Threshold on page 1644
- Configuring a Limit on Bandwidth Overflow and Underflow Samples on page 1645
- Configuring Passive Bandwidth Utilization Monitoring on page 1647

Configuring the Automatic Bandwidth Allocation Interval

At the end of the automatic bandwidth allocation interval, the automatic bandwidth computation and new path setup process is triggered.

NOTE: To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (**interval** statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (**adjust-interval** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level). See also "Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs" on page 451.

To specify the bandwidth reallocation interval in seconds for a specific LSP, include the **adjust-interval** statement:

```
adjust-interval seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]**

Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth

You can maintain the LSP's bandwidth between minimum and maximum bounds by specifying values for the **minimum-bandwidth** and **maximum-bandwidth** statements.

NOTE: For a label-swtiched path (LSP) that has both **bandwidth** and **minimum-bandwidth** for autobandwidth configured under the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the maximum bandwidth.

To specify the minimum amount of bandwidth allocated for a specific LSP, include the **minimum-bandwidth** statement:

```
minimum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

To specify the maximum amount of bandwidth allocated for a specific LSP, include the **maximum-bandwidth** statement:

```
maximum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

Configuring the Automatic Bandwidth Adjustment Threshold

Use the **adjust-threshold** statement to specify the sensitivity of the automatic bandwidth adjustment of an LSP to changes in bandwidth utilization. You can set the threshold for when to trigger automatic bandwidth adjustments. When configured, bandwidth demand for the current interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the specified **adjust-threshold** percentage, the LSP's bandwidth is adjusted to the current bandwidth demand.

For example, assume that the current bandwidth allocation is 100 megabits per second (Mbps) and that the percentage configured for the **adjust-threshold** statement is 15 percent. If the bandwidth demand increases to 110 Mbps, the bandwidth allocation is not adjusted. However, if the bandwidth demand increases to 120 Mbps (20 percent over the current allocation) or decreases to 80 Mbps (20 percent under the current allocation), the bandwidth allocation is increased to 120 Mbps or decreased to 80 Mbps, respectively.

To configure the threshold for automatic bandwidth adjustment, include the **adjust-threshold** statement:

```
adjust-threshold percent;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

Configuring a Limit on Bandwidth Overflow and Underflow Samples

The automatic bandwidth adjustment timer is a periodic timer which is triggered every adjust interval to determine whether any bandwidth adjustments are required on the LSP's active path. This interval is typically configured as a long period of time, usually hours. If, at the end of adjust interval, the change in bandwidth is above a certain adjust threshold, the LSP is resignaled with the new bandwidth.

During the automatic bandwidth adjustment interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Every statistics interval, the router samples the average bandwidth utilization of an LSP and if this has exceeded the current maximum average bandwidth utilization, the maximum average bandwidth utilization is updated.

During each sample period, the following conditions are also checked:

- Is the current average bandwidth utilization above the active bandwidth of the path?
- Has the difference between the average bandwidth utilization and the active bandwidth exceeded the adjust threshold (bandwidth utilization has changed significantly)?

If these conditions are true, it is considered to be one bandwidth overflow sample. Using the **adjust-threshold-overflow-limit** statement, you can define a limit on the number of bandwidth overflow samples such that when the limit is reached, the current automatic bandwidth adjustment timer is expired and a bandwidth adjustment is triggered. Once this adjustment is complete, the normal automatic bandwidth adjustment timer is reset to expire after the periodic adjustment interval.

To specify a limit on the number of bandwidth overflow samples before triggering an automatic bandwidth allocation adjustment, configure the **adjust-threshold-overflow-limit** statement:

```
adjust-threshold-overflow-limit number;
```

Similarly, if the current average bandwidth utilization is below the active bandwidth of the path by the configured adjusted threshold (meaning that bandwidth utilization has gone down significantly), the sample is considered to be an underflow sample. The adjusted (new signaling) bandwidth after an adjustment due to underflow is the maximum average bandwidth among the underflow samples. Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

You can specify a limit on the number of bandwidth underflow samples before triggering an automatic bandwidth allocation adjustment by configuring the **adjust threshold-underflow-limit** statement:

```
adjust-threshold-underflow-limit number;
```

These statements can be configured at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

You must configure the **adjust-threshold** and **minimum-bandwidth** statements whenever you configure the **adjust-threshold-underflow-limit** statement. You must configure the **adjust-threshold** and **maximum-bandwidth** statements whenever you configure the **adjust-threshold-overflow-limit** statement

- You must configure a nonzero value for the **adjust-threshold** statement if you configure the **adjust-threshold-overflow-limit** or **adjust-threshold-underflow-limit** statement.
- Any bandwidth increase or decrease below the value configured for the **adjust-threshold** statement does not constitute an overflow or underflow condition.
- To prevent unlimited increases in LSP bandwidth (to limit overflow beyond a certain bandwidth), you must also configure the **maximum-bandwidth** statement when you configure the **adjust-threshold-overflow-limit** statement.

The following describes the other aspects of the **adjust-threshold-overflow-limit** statement:

- It only applies to bandwidth overflows. If the bandwidth is decreasing, the normal automatic bandwidth adjustment interval is used.
- It does not affect manually triggered automatic bandwidth adjustment.
- It applies to single-class DiffServ-TE LSPs.
- Because the **adjust-threshold-overflow-limit** statement can trigger a bandwidth adjustment, it cannot be enabled at the same time as the **monitor-bandwidth** statement (for information about that statement, see "Configuring Passive Bandwidth Utilization Monitoring" on page 449).
- You cannot configure automatic bandwidth adjustments to occur more often than every 300 seconds. The **adjust-threshold-overflow-limit** statement is subject to the same minimum value with regard to the minimum frequency of adjustment allowed. Overflow condition based adjustments can occur no sooner than 300 seconds from the start of the overflow condition. Therefore it is required that:

  sample interval x adjust-threshold-overflow-limit >= 300s

  These values are checked during the commit operation. An error is returned if the value is less than 300 seconds.
- If you change the value of the **adjust-threshold-overflow-limit** statement on a working router, you can expect the following behavior:
  - If you increase the current value of the **adjust-threshold-overflow-limit** statement, the old value is replaced with the new one.

- If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is less than the new value, the old value is replaced with the new one.
- If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is greater than the new value, the adjustment timer is immediately expired and a bandwidth adjustment is initiated.

Configuring Passive Bandwidth Utilization Monitoring

Use the **monitor-bandwidth** statement to switch to a passive bandwidth utilization monitoring mode. In this mode, no automatic bandwidth adjustments are made, but the maximum average bandwidth utilization is continuously monitored and recorded.

To configure passive bandwidth utilization monitoring, include the **monitor-bandwidth** statement:

```
monitor-bandwidth;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**
- **[edit logical-systems** ***logical-system-name*** **protocols mpls** label-switched-path ***lsp-name*** auto-bandwidth (MPLS Tunnel)**]**

If you have configured an LSP with primary and secondary paths, the automatic bandwidth allocation statistics are carried over to the secondary path if the primary path fails. For example, consider a primary path whose adjustment interval is half complete and whose maximum average bandwidth usage is currently calculated as 50 Mbps. If the primary path suddenly fails, the time remaining for the next adjustment and the maximum average bandwidth usage are carried over to the secondary path.

Requesting Automatic Bandwidth Allocation Adjustment

For MPLS LSP automatic bandwidth allocation adjustment, the minimum value for the adjustment interval is 5 minutes (300 seconds). You might find it necessary to trigger a bandwidth allocation adjustment manually, for example in the following circumstances:

- When you are testing automatic bandwidth allocation in a network lab.
- When the LSP is configured for automatic bandwidth allocation in monitor mode (the **monitor-bandwidth** statement is included in the configuration as described in "Configuring Passive Bandwidth Utilization Monitoring" on page 449), and want to initiate an immediate bandwidth adjustment.

To use the **request mpls lsp adjust-autobandwidth** command, the following must be true:

- Automatic bandwidth allocation must be enabled on the LSP.
- The criteria required to trigger a bandwidth adjustment have been met (the difference between the adjust bandwidth and the current LSP path bandwidth is greater than the threshold limit).

A manually triggered bandwidth adjustment operates only on the active LSP path. Also, if you have enabled periodic automatic bandwidth adjustment, the periodic automatic bandwidth adjustment parameters (the adjustment interval and the maximum average bandwidth) are not reset after a manual adjustment.

For example, suppose the periodic adjust interval is 10 hours and there are currently 5 hours remaining before an automatic bandwidth adjustment is triggered. If you initiate a manual adjustment with the **request mpls lsp adjust-autobandwidth** command, the adjust timer is not reset and still has 5 hours remaining.

To manually trigger a bandwidth allocation adjustment, you need to use the **request mpls lsp adjust-autobandwidth** command. You can trigger the command for all affected LSPs on the router, or you can specify a particular LSP:

```
user@host> request mpls lsp adjust-autobandwidth
```

Once you execute this command, the automatic bandwidth adjustment validation process is triggered. If all the criteria for adjustment are met, the LSP's active path bandwidth is adjusted to the adjusted bandwidth value determined during the validation process.

Release History Table

Release	Description
14.1R9	Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

Displaying DiffServ-Aware Traffic-Engineered LSP Events

Purpose

A DiffServ-aware traffic-engineered LSP is configured with a bandwidth reservation for a specific class type, and carries traffic for a single class type. On the packets, the class type is specified by the experimental (EXP) bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, instead of being signaled in Resource Reservation Protocol (RSVP).

The class type must be configured consistently across the DiffServ domain, and must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link. For more information about forwarding classes and class of service, see the Junos Class

of Service Configuration Guide. For more information about differentiated services, see RFC 3270, *MPLS Applications Feature Guide Support of Differentiated Services.*

When the configuration of a DiffServ-aware traffic-engineered LSP is incorrect, an even or error message might occur in the output of the **show mpls lsp extensive** command.

Action To display LSP events that can occur with a DiffServ-aware LSP, enter the following Junos OS command-line interface (CLI) operational mode command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output

Not available.

Unsupported Traffic Class Event

LSP Event Unsupported traffic class

Sample Output Not available.

Meaning This LSP error event is a Juniper Networks proprietary error indicating that a Diffserv traffic engineering LSP was signaled with one or more traffic classes with values greater than the four traffic classes currently supported by the Junos OS.

Cause Not available.

Action Not available.

Traffic Class Value Out of Allowed Range Event

LSP Event Traffic class value out of allowed range

Sample Output Not available.

Meaning This LSP error event is a Juniper Networks proprietary error indicating that a single class, IETF-style DiffServ traffic engineering LSP was signaled with a traffic class value of zero, which is invalid.

Cause Not available.

Action Not available.

The Combination of Setup Priority and Traffic Class Is Not One of the Configured TE Classes Event

LSP Event The combination of setup-priority and traffic class is not one of the configured TE-classes

Sample Output Not available.

Meaning This LSP error event is a Juniper Networks proprietary error that indicates the setup priority signaled in the Path message for the LSP does not match the supported Diffserv traffic engineering classes configured on a label-switching router (LSR) along the LSP path.

Cause This LSP error event is caused by incorrect configuration of the LSP setup priority on the ingress LSR, or the incorrect configuration of a DiffServ traffic engineering class on an LSR along the LSP path.

Action Correct the configuration depending on the supported traffic engineering classes.

RSVP Error, Subcode 7, Signal Type Does Not Match Link Encoding Event

LSP Event RSVP error, subcode 7, signal-type does not match link encoding

Sample Output Not available

Meaning This LSP error event is a Juniper Networks proprietary error reported for GMPLS LSPs when the configured signal bandwidth does not match the encoding type of the traffic engineering link selected on the first hop.

Cause An incorrect Sender Tspec is used with a particular LSP switching or encoding type.

Action Not available.

Unacceptable Label Value Event

LSP Event Unacceptable label value event

Sample Output Not available.

Meaning This LSP error event indicates that the label value signaled in either the Path or Resv message was unacceptable to a label-switched router (LSR) along the LSP path.

Cause For GMPLS LSPs, this LSP error event is generated by incorrect label mapping configured on one of the LSRs, or by deletion of a resource that was being used by an LSP.

Action Not available.

Unsupported Switching Type Event

LSP Event Unsupported switching type

Sample Output Not available.

Meaning This LSP error event indicates that the switching type requested in the generalized label request for a GMPLS LSP is unsupported on the corresponding selected traffic engineering link.

Cause Not available.

Action Not available.

Gather Component Alarm Information

Purpose When you obtain information about component alarms and error messages, you determine when a problem with a component first appeared and the details of the situation.

To gather component alarm information, follow these steps:

1. Display the Current Router Alarms on page 1651
2. Display Error Messages in the Messages Log File on page 1652
3. Display Error Messages in the Chassis Process Log File on page 1652

Display the Current Router Alarms

Purpose To determine the details of the alarms and when they first appeared in the component.

Action To display the current router component alarms, use the following CLI command:

```
user@host> show chassis alarms
```

The command output displays the number of alarms currently active, the time when the alarm began, the severity level, and an alarm description. Note the date and time of an alarm so that you can correlate it with error messages in the **messages** system log file.

For examples of sample output, see the *Junos System Basics and Services Command Reference.*

Display Error Messages in the Messages Log File

Purpose To determine the details of the error messages in the Messages Log File.

Action To display router component error messages in the **messages** system log file, use the following CLI command:

```
user@host> show log messages
```

The **messages** system log file records the time the failure or event occurred, the severity level, a code, and a message description. Error messages in the **messages** system log file are logged at least 5 minutes before and after the alarm event.

To search for specific information in the log file, use the | **match** ***component-name*** command; for example, use **show log messages** | **match fpc**. If there is a space in the component name, enclose the component name in quotation marks; for example, | **match "power supply"**.

To search for multiple items in the log file, use the **| match** command followed by the multiple items, separated by the **|** (pipe), and enclosed in quotation marks; for example, **| match "fpc | sfm | kernel | tnp"**.

To monitor the **messages** file in real time, use the **monitor start messages** CLI command. This command displays the new entries in the file until you stop monitoring by using the **monitor stop messages** CLI command.

For more information about system log messages, see the *Junos System Log Messages Reference.*

Display Error Messages in the Chassis Process Log File

Purpose To determine the details of the error messages in the Chassis Process Log File.

Action To display router component errors in the chassis process (**chassisd**) system log file, use the following CLI command:

```
user@host> show log chassisd
```

The chassis process (**chassisd**) log file tracks the state of each chassis component. For examples of sample output, see the *Junos System Basics and Services Command Reference*.

To search for specific information in the log file, use the **| match component-name** command; for example, **show log messages | match fpc**. If there is a space in the component name, enclose the component name in quotation marks; for example, **| match "power supply"**.

To search for multiple items in the log file, use the **| match** command followed by the multiple items, separated by the **|** (pipe), and enclosed in quotation marks; for example, **| match "fpc | sfm | kernel | tnp"**.

To monitor the **chassisd** file in real time, use the **monitor start chassisd** CLI command. This command displays the new entries in the file until you stop monitoring by using the **monitor stop chassisd** CLI command.

Case Study for a CSPF Failure

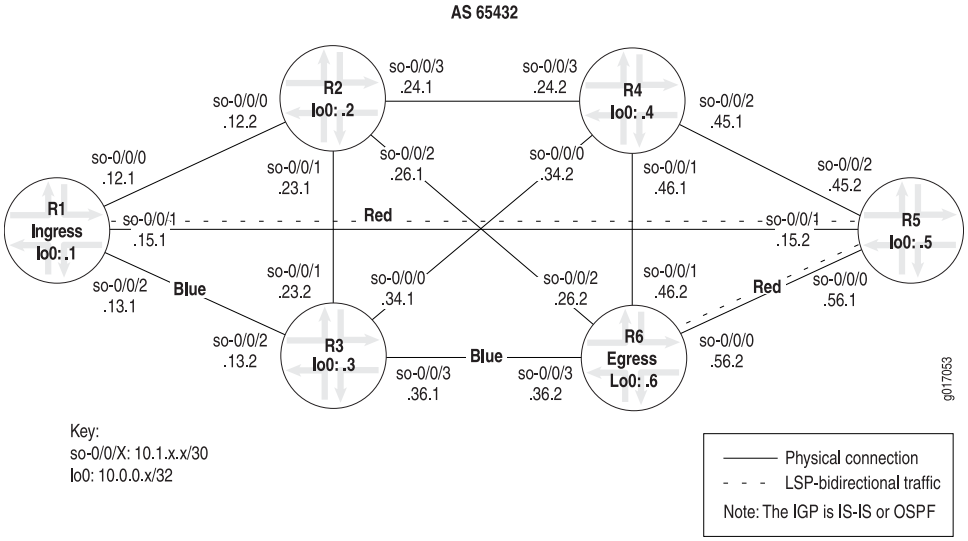
Purpose This case study presents a Multiprotocol Label Switching (MPLS) network topology and CSPF failure scenario designed to demonstrate techniques and commands that are particularly useful when addressing CSPF problems in your network. The focus of the study is the incorrect association of user-provided constraints, specifically administrative groups (also known as link coloring).

When calculating a path, the CSPF algorithm factors in user–provided constraints. The ingress router determines the physical path for each LSP by applying a CSPF algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first (SPF) algorithm that has been modified to take into account constraints when calculating the shortest path across the network. Links that do not comply with the restrictions are removed from the tree and cannot be factored into the resulting SPF calculations.

CSPF integrates topology link-state information that is learned from interior gateway protocol (IGP) traffic engineering extensions and is maintained in the traffic engineering database. The information stored in the traffic engineering database includes attributes associated with the state of network resources.

The network topology shown in Figure 133 on page 1654 illustrates a network in which the LSP is constrained by administrative group coloring (also known as link coloring), and CSPF tracing is configured on the ingress router **R1**. In this example, the LSP is forced to transit **R5** in accordance with the restrictions imposed.

Figure 133: CSPF Topology with Administrative Group Coloring



The network shown in Figure 133 on page 1654 is an MPLS router-only network with SONET interfaces.

The MPLS network shown in Figure 133 on page 1654 is configured with administrative group coloring as follows:

- The LSP **R1-to-R6** is established with **R1** as the ingress router and **R6** as the egress router.
- The required path to **R6** transits **R5** on the redlinks. The inclusion of red coloring is not strictly necessary. To force the LSP to transit **R5**,you could color the links on **R3** and **R2** blue and then exclude the blue links.
- Both red and blue colors are used with the **include** and **exclude** statements to ensure that the LSP always transits **R5**. For information on configuring administrative group coloring, see the *MPLS Applications Feature Guide*.

To check that the network is configured correctly and the LSP is established, follow these steps:

1. Verify That the LSP Is Established on page 1654
2. Check the Administrative Group Configuration on page 1656

Verify That the LSP Is Established

Purpose Check that the LSP shown in Figure 133 on page 1654 is established and traversing the path from **R1** to **R6** through the red links.

Action To verify that the LSP is established, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp extensive
```

```
user@host> show mpls lsp
```

Sample Output

```
user@R1>  show mpls lsp extensive | no-more
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Up, ActiveRoute: 1, LSPname: R1-to-R6
  ActivePath:  (primary)

To              From            State   Rt Style Labelin Labelout LSPname
10.0.0.1        10.0.0.6        Up       1  1 FF  100352        3 R6-to-R1
10.0.0.6    10.0.0.1    Up    1 1 FF 100384    3 R1-to-R6
Total 2 displayed, Up 2, Down 0
```

Meaning Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** is successfully established as indicated by the Explicit Route Object (ERO) **10.1.15.2 S 10.1.56.2 S**, the log message **CSPF: computation result accepted**, and **State: Up**. Also, the LSP is routing packets correctly over the red links, avoiding the blue links or the links without any coloring.

Sample Output 2 from transit router **R5** shows that LSP **R1-to-R6** is transiting **R5** as expected.

Check the Administrative Group Configuration

Purpose Check that the administrative group coloring is correct and the relevant interfaces are associated with each administrative group correctly

Action To check the administrative group configuration, enter the following Junos OS CLI operational mode commands, or issue the **show** command at the [**edit protocols mpls**] hierarchy level, as shown in the example below:

```
user@host> show configuration protocols mpls
user@host> show mpls interface
user@host> show ted database extensive nodeID
```

Sample Output 1

```
[edit protocols mpls]

```

Meaning Sample Output 1 shows that administrative group coloring is correctly configured on all relevant routers. Administrative groups redand blue are configured at the [**edit protocols mpls**] hierarchy level, and relevant interfaces are associated with each administrative group correctly.

R3 is configured with blue coloring and the **include** and **exclude** statements are included in the configuration of **R1** to ensure that LSP **R1-to-R6** always transits **R5**. The inclusion of red coloring is not strictly necessary. To force the LSP to transit **R5**,you could color the links on **R2** and **R3** blue and then exclude the blue links. Red coloring is included in this example to demonstrate the fact that the CSPF algorithm excludes links that do not have a color configured, when the **include** statement is configured at the [**edit protocols mpls**] hierarchy level.

In addition, ingress router **R1** has CSPF tracing configured in preparation for gathering information when the CSPF algorithm fails later in this example.

Sample Output 2 shows that the correct interfaces are associated with the red and blue administration groups on **R1**, **R3**, **R5**, and **R6**.

Sample Output 3 confirms that link coloring is correctly reported in the traffic engineering database for **R1**. Not shown is the traffic engineering database output for the remaining routers, which is similar to the **R1** output, and correct.

Examining a CSPF Failure

When a local CSPF failure indicates that no path meets the constraints configured for the LSP, you must perform CSPF-based tracing and be familiar with the contents of the traffic engineering database to resolve the problem. See "Examine the Traffic Engineering Database" on page 1663 for an analysis of the traffic engineering database.

NOTE: If an LSP does not establish immediately, wait at least a minute or so before taking diagnostic or corrective action. This is because the RSVP retry timer is set to a 30-second default, resulting in a slight delay before the correct state of the LSP is available.

To examine a CSPF failure, follow these steps:

1. Verify the CSPF Failure on page 1660
2. Examine the CSPF Log File on page 1661
3. Examine the Traffic Engineering Database on page 1663
4. Check the Administrative Group Configuration on R5 on page 1666

Verify the CSPF Failure

Purpose To simulate a configuration error on the network, router **R5** has the administrative group coloring removed from interface **so-0/0/0**. The result is a CSPF failure at **R5** because there is no longer a path between **R1** and **R6** that includes the red color.

Action To confirm that the LSP is down and verify the configuration on routers **R1** and **R5**, enter the following Junos OS CLI operational mode commands:

```
user@host> clear mpls lsp
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> clear mpls lsp
[edit protocols mpls]
user@R1#  run show mpls lsp extensive
Ingress LSP: 1 sessions

Total 1 displayed, Up 1
 , Down 0
```

Meaning Sample Output 1 from ingress router **R1** shows that the **clear mpls lsp** command was issued to confirm that **R1** cannot reestablish LSP **R1-to-R6.** The sample output from the **show mpls lsp extensive** command shows that LSP **R1-to-R6** is down, **State: Dn** and **ActivePath: (None)**; and that the CSPF has failed, **CSPF failed: no route toward 10.0.0.6**.

Sample Output 2 from transit router **R5** shows that LSP **R1-to-R6** is not included in the output, indicating that the LSP is not transiting **R5**.

Most network problems appear as a local CSPF failure, as shown in the sample output. The CSPF failure indicates that no path meeting the constraints for the LSP can be found in the router's traffic engineering database. To resolve these problems effectively, use CSPF tracing on the ingress router, and analyze the traffic engineering database to locate the node that should meet the constraints.

Examine the CSPF Log File

Purpose After you have confirmed that the LSP is down, obtain more information about the possible cause of the failure.

NOTE: To obtain useful information from the CSPF log file, make sure that CSPF tracing is configured on the ingress router.

Action To examine the CSPF log file, enter the following Junos OS CLI operational mode commands:

```
user@host> monitor start filename
user@host> show log filename
```

NOTE: To stop monitoring CSPF, issue the **monitor stop** command.

Sample Output

```
user@R1> monitor start cspf

[edit protocols mpls]
user@R1#  run show log cspf-failed3

monitor stop
```

Meaning The sample output shows that the **monitor start cspf** command was issued to start displaying entries in the **cspf** log file in real time. The **cspf** log file is generated by the routing protocol process after the file is configured with the **traceoptions** statement at the [**edit protocols mpls**] hierarchy level. In this example, the **cspf** log file is configured with the **cspf**, **cspf-node**, and **cspf-link** flags to provide the most granular information about the steps taken by the CSPF algorithm.

The only link that passes the color constraint is between **R1** and **R5**, **10.1.15.0/32.** The CSPF algorithm is a locally run algorithm, which makes its calculations on a given router. When the CSPF algorithm runs on **R5**, it prunes **10.1.15.2** and selects **10.1.56.1** to send the message to **R6**.The link between **R5** and **R6 10.1.56.0/32** does not pass the color constraints, indicating a problem with **R5**. At this stage, it is useful to examine the traffic engineering database to determine which link on **R5** should be associated with the red color.

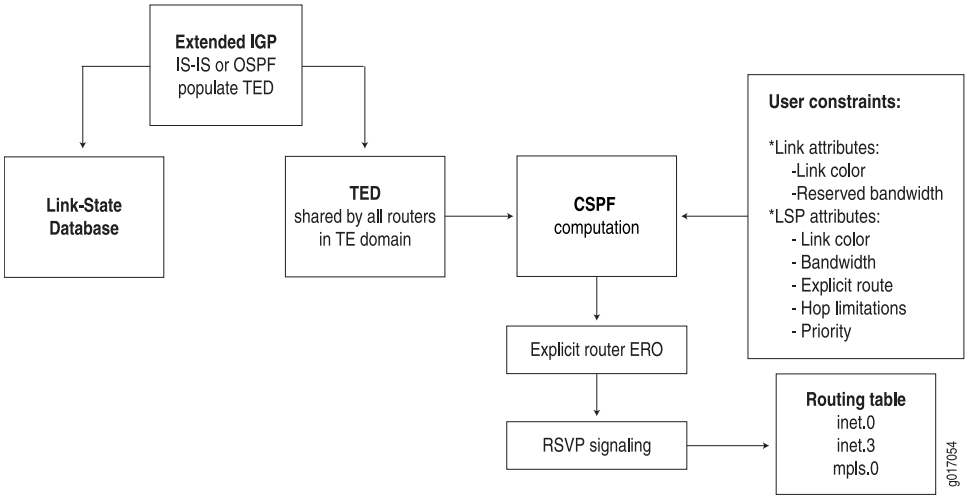
Examine the Traffic Engineering Database

Purpose Examining the traffic engineering database is another way to locate the node that should meet the constraints but does not. Once identified, you can concentrate your troubleshooting efforts on why that node is not being represented accurately in the database.

The contents of the traffic engineering database are consistent among all routers within a given traffic engineering domain. Therefore, you can issue the **show ted database** command from any router in the same traffic engineering domain to obtain more granular information about the CSPF failure.

CSPF integrates topology link-state information that is learned from the IGP traffic engineering extensions and maintained in the traffic engineering database. The information stored in the traffic engineering database includes attributes associated with the state of the network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color). When calculating a path, the CSPF algorithm factors in user–provided information such as bandwidth requirements, maximum allowed hop count, and administrative groups, all of which are obtained from user configuration. (See Figure 134 on page 1664).

Figure 134: User–Provided Constraints



Action To examine the traffic engineering database, enter the following Junos OS CLI operational mode commands:

```
user@host>  show ted database extensive
user@host> show ted database extensive NodeID | match "(NodeID|To:|Color)"
```

```

Meaning Sample Output 1 from ingress router **R1** shows a wealth of information on each node in the network, although only a portion is included in this example. The output shows the total number of IS-IS and INET nodes in the traffic engineering domain. The portion of the traffic engineering database shown represents a node (**R5**), and the **Type** field indicates **Rtr** (router). The **Type** field could also indicate Net (network) if the node were a pseudo node. The node (**R5**) has three input and output links that are running IS-IS Level 2, **Protocol: IS-IS(2)**. The links lead to nodes **R1**, **R4**, and **R6**. The local address and remote address for each link is specified. The information on each node includes administrative groups (**Color:**), metrics, static bandwidth, reservable bandwidth, and available bandwidth priority level. The information contained in the traffic engineering database should be the same across all routers in the same traffic engineering domain.

For a detailed description of the fields in the output of the **show ted database extensive** command, see the *Junos Routing Protocols and Policies Command Reference*.

Sample Output 2 shows filtered output that allows you to focus on exactly what is missing or incorrect.

Both outputs confirm that the link between **R1** and **R5**, **10.1.15.0/32**, is associated with the red color, while the link between **R5** and **R6**, **10.1.56.0/32**, is not associated with a color. In the network shown in Figure 133 on page 1654, for the LSP to establish correctly, link **10.1.56.1** must be associated with the red color.

Check the Administrative Group Configuration on R5

Purpose Focus on R5 to determine which interfaces are associated with the red color, and make any necessary corrections.

Action To check the administrative group configuration on R5 and make any necessary corrections, enter the following Junos OS CLI commands:

```
user@R5> edit
[edit protocols mpls]
user@R5# show
user@R5# delete interface so-0/0/1 admin-group
user@R5# set interface so-0/0/0 admin-group red
user@R5# show
user@R5# commit
```

Sample Output 1

```
user@R5> edit
Entering configuration mode

[edit protocols mpls]
user@R5# show
admin-groups {
    red 8;
}
interface fxp0.0 {
    disable;
}
interface so-0/0/0.0;
interface so-0/0/1.0 { <<<incorrect interface configured with admin-group
    admin-group red;
}
interface so-0/0/2.0;
```

Sample Output 2

```
[edit protocols mpls]
user@R5# delete interface so-0/0/1 admin-group
```

```
[edit protocols mpls]
user@R5# set interface so-0/0/0 admin-group red

[edit protocols mpls]
user@R5# show
admin-groups {
    red 8;
    blue 4;
}
interface fxp0.0 {
    disable;
}
interface so-0/0/0.0 { <<<correct interface configured with admin-group
    admin-group red;
}
interface so-0/0/1.0;
interface so-0/0/2.0;

[edit protocols mpls]
user@R5# commit
commit complete
```

Sample Output 3

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To              From            State Rt ActivePath       P     LSPname
10.0.0.6    10.0.0.1    Up  1       *  R1-to-R6
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.0.0.1        10.0.0.6        Up       0  1 FF       3        - R6-to-R1
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from transit router **R5** shows that at the [**edit protocols mpls**] hierarchy level, interface **so-0/0/1** is incorrectly configured with the **admin-group red** statement. The **so-0/0/0** interface should be configured with the **admin-group red** statement.

Sample Output 2 shows the steps taken to correct the configuration. The administration group has been deleted from **so-0/0/1** and **so-0/0/0** is now associated with the red color.

Sample Output 3 shows that LSP **R1-to-R6** is established.

Verify the CSPF Failure

Purpose To simulate a configuration error on the network, router **R5** has the administrative group coloring removed from interface **so-0/0/0**. The result is a CSPF failure at **R5** because there is no longer a path between **R1** and **R6** that includes the red color.

Action To confirm that the LSP is down and verify the configuration on routers **R1** and **R5**, enter the following Junos OS CLI operational mode commands:

```
user@host> clear mpls lsp
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> clear mpls lsp
[edit protocols mpls]
user@R1#  run show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6

10.0.0.1        10.0.0.6        Up       1  1 FF  100352        3 R6-to-R1
Total 1 displayed, Up 1
 , Down 0
```

Meaning Sample Output 1 from ingress router **R1** shows that the **clear mpls lsp** command was issued to confirm that **R1** cannot reestablish LSP **R1-to-R6.** The sample output from the

show mpls lsp extensive command shows that LSP **R1-to-R6** is down, **State: Dn** and **ActivePath: (None)**; and that the CSPF has failed, **CSPF failed: no route toward 10.0.0.6**.

Sample Output 2 from transit router **R5** shows that LSP **R1-to-R6** is not included in the output, indicating that the LSP is not transiting **R5**.

Most network problems appear as a local CSPF failure, as shown in the sample output. The CSPF failure indicates that no path meeting the constraints for the LSP can be found in the router's traffic engineering database. To resolve these problems effectively, use CSPF tracing on the ingress router, and analyze the traffic engineering database to locate the node that should meet the constraints.

Examining the Hello Message

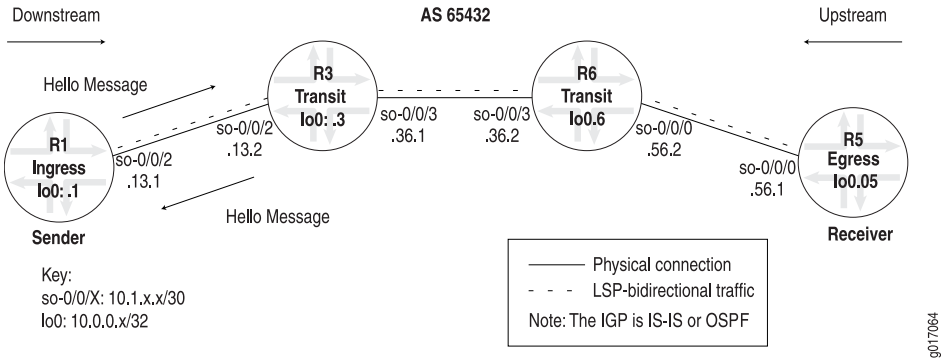
Purpose RSVP monitors the status of the interior gateway protocol (IGP) (Intermediate System-to-Intermediate System [ISIS] or Open Shortest Path First [OSPF]) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because Hello messages are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

RSVP Hello messages are exchanged between neighbors. The destination address is the neighbor node. RSVP Hello messages are used to determine loss of interface more quickly than determined by the RSVP state timeout.

NOTE: **RSVP Hello messages are required to establish the protocol or to maintain adjacency information. RSVP Hello messages do not establish state.**

Figure 135 on page 1669 shows two RSVP Hello messages exchanged between routers **R1** and **R3**.

Figure 135: RSVP Hello Message



To ensure that Hello messages are displayed in the output, include the **packets** flag at the [**edit protocols rsvp traceoptions**] hierarchy level.

Action To examine the Hello message, enter the following Junos OS CLI command:

```
user@R1> monitor start filename
```

Sample Output 1

```
[edit protocols rsvp]
user@R1# show
traceoptions {
    file rsvp-log;
    flag packets detail;
}
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
```

Sample Output 2

```
user@R1> clear log rsvp-log

user@R1> monitor start rsvp-log

user@R1>
*** rsvp-log ***
[...Output truncated...]
Jun 29 15:48:59  RSVP send Hello New 10.1.13.1->10.1.13.2 Len=32 so-0/0/2.0
Jun 29 15:48:59   HelloReq Len 12
Jun 29 15:48:59   RestartCap Len 12 restart time 0, recovery time 0
Jun 29 15:48:59  RSVP recv Hello New 10.1.13.2->10.1.13.1 Len=32 so-0/0/2.0
Jun 29 15:48:59   HelloRply Len 12
Jun 29 15:48:59   RestartCap Len 12 restart time 0, recovery time 0
monitor stop
```

Meaning Sample Output 1 shows the configuration of RSVP tracing on ingress router **R1**. The **packets** flag is included at the [**edit protocols rsvp traceoptions**] hierarchy level to provide information about RSVP traffic. The **detail** option is included to show granular details about the configured flag.

Sample Output 2 shows **clear** commands, the output for the **rsvp-log** file, and that monitoring was started and then stopped. The **rsvp-log** output shows two RSVP Hello messages exchanged between **R1** and **R3**.

The first Hello message in the **rsvp-log** output is a request sent from **R1** (**10.1.13.1**) to **R3** (**10.1.13.2**). The outgoing interface is **so-0/0/2.0** on **R1**. The second Hello message was a reply sent from **R3** to **R1**, also through the outgoing interface **so-0/0/2.0** on **R3**.

The next two lines of output indicate object values for the two Hello messages, and are indented in the output. To facilitate this discussion, each line of output for each object is displayed before the corresponding explanation.

- **HelloReq Len 12**

The Hello request (**HelloReq**) object indicates that this is a Hello request. RFC 3209 defines the RSVP Hello message. An RSVP Hello message can either be a request or a reply. Every request should generate a reply.

- **RestartCap Len 12 restart time 0, recovery time 0**

  The restart object (**RestartCap**) indicates the graceful restart capability of the sender node. The restart time of 0 milliseconds is the length of time that this node takes to restart its RSVP traffic engineering functionality. At the end of this time, the node can send and receive RSVP messages again. The recovery time of 0 milliseconds indicates the length of time the LSR retains MPLS forwarding information. A recovery time of 0 in this case indicates that no forwarding state was preserved across a restart. Because both values are set to 0, graceful restart was not enabled for this RSVP session.

- **HelloRply Len 12**

  The **Hello** reply (**HelloRply**) object indicates that this is an RSVP Hello message sent from **R3** to **R1** out of interface **so-0/0/2.0**.

In standard RSVP, node failure detection occurs as a consequence of the RSVP soft-state timeout model. However, detection typically requires several minutes to time out the soft state. Hello packets allow the detection of the neighboring node state changes more quickly.

In Junos OS, RSVP Hello messages are optional and are backward-compatible with RSVP implementations that do not support Hello messages. For neighboring routers that do not support Hello messages or on which RSVP Hello is disabled, RSVP uses the soft-state timeout for loss detection and cannot benefit from fast IGP Hello detection.

Configuring a short time for the IS-IS or OSPF Hello timers allows these protocols to detect node failures more quickly. RSVP also benefits from early detection by the IGP protocols. It is not necessary to explicitly configure a short RSVP Hello timer. If you do configure the RSVP Hello timer, you can configure a longer value and can still expect the failure of a neighboring router to be quickly detected by IGP.

Between Hello-capable neighbors, Hello messages are sent unicast toward each other. A loss of (2 x keep-multiplier + 1) consecutive Hello messages causes the neighbor's state to go down, and all RSVP sessions to and from that neighbor are declared to be down.

By default, RSVP sends Hello messages every 9 seconds.

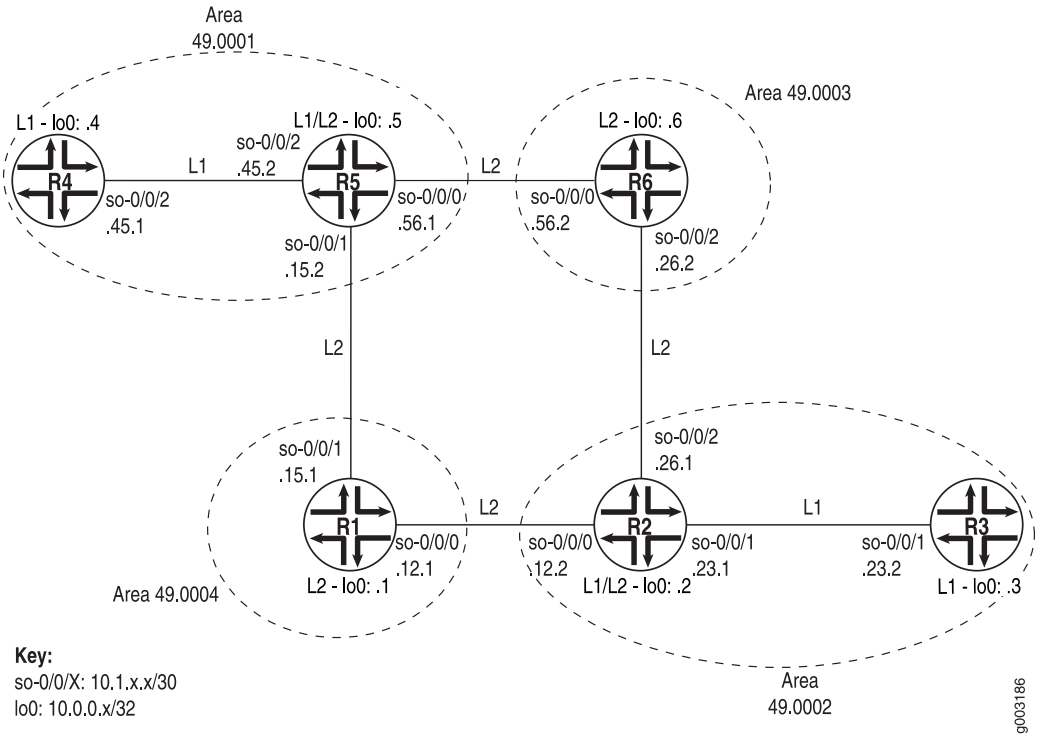
Displaying the Status of IS-IS Adjacencies

Purpose

Assuming that all the routers are correctly configured for IS-IS, you can verify which neighbors are adjacent and able to exchange IS-IS data. In addition, you can examine the set of routes installed in the forwarding table to verify that the routing protocol process (rpd) has relayed the correct information into the forwarding table.

Figure 136 on page 1672 illustrates the example IS-IS topology used for the procedures in this topic.

Figure 136: IS-IS Network Topology



The network consists of Level 1 and Level 2 adjacencies. Level 1 adjacencies are within areas 49.0001 and 49.0002. Level 2 adjacencies occur between all directly connected Level 2 routers regardless of which area they are in. For example, R5 is in area 49.0001, R6 is in area 49.0003, R1 is in area 49.0004, and R2 is in area 49.0002. The network in Figure 136 on page 1672 should have the following adjacencies:

- Level 2 adjacencies between all directly connected Level 2 routers (R1, R2, R5, and R6).
- Level 1 adjacencies between routers in area 49.0001 (R4 and R5) and between routers in area 49.0002 (R2 and R3).

To verify that routers are adjacent and able to exchange IS-IS data, follow these steps:

1. Verifying Adjacent Routers on page 1672
2. Examine the Forwarding Table on page 1674

Verifying Adjacent Routers

Purpose Verify that routers are adjacent and able to exchange IS-IS data.

Action To verify that routers are adjacent and able to exchange IS-IS data, enter the following CLI operational mode command:

```
user@host> show isis adjacency
```

The following sample output shows the adjacencies that formed for all routers shown in "Displaying the Status of IS-IS Adjacencies" on page 1671.

Sample Output

```
user@R1> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R2             2 Up                   19
so-0/0/1.0            R5             2 Up                   18

user@R2> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R1             2 Up                   19
so-0/0/1.0            R3             1 Up                   26
so-0/0/2.0            R6             2 Up                   21

user@R3> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/1.0            R2             1 Up                   24

user@R4> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/2.0            R5             1 Up                   23

user@R5> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R6             2 Up                   22
so-0/0/1.0            R1             2 Up                   20
so-0/0/2.0            R4             1 Up                   20

user@R6> show isis adjacency
Interface             System         L State       Hold (secs) SNPA
so-0/0/0.0            R5             2 Up                   21
so-0/0/2.0            R2             2 Up                   20
```

Meaning The sample output shows the adjacencies that formed in the network illustrated in "Displaying the Status of IS-IS Adjacencies" on page 1671. The Level 1/Level 2 routers (R2 and R5) formed Level 1 adjacencies with Level 1 routers (R3 and R4), and Level 2 adjacencies with the Level 2 routers (R1 and R6). To view the status of the adjacency, examine the State column. In this example, all adjacencies in the network are up.

If the state is not **Up** for a particular neighbor, you must first examine the IS-IS configuration for the particular interface. Make sure that the NET address is correct and that the loopback interface (lo0) is configured. Use the **show isis interface** or **show isis interface detail** command to display the IS-IS parameters for all interfaces configured with IS-IS. With these two commands, you can see which interfaces are configured for IS-IS, whether they are configured for Level 1 or Level 2, the IS-IS metric, and other IS-IS information.

See Also

Examine the Forwarding Table

Purpose You can display the set of routes installed in the forwarding table to verify that the routing protocol process (rpd) has relayed the correct information into the forwarding table. This is especially important when there are network problems, such as connectivity. In this procedure, you verify that the routes displayed in Step 2 appear in the forwarding table for Router R5.

Action To examine the forwarding table for a router, enter the following CLI command:

```
user@host> show route forwarding-table destination destination-prefix
```

Sample Output

```
user@R5> show route forwarding-table destination 10.0.0.3
Routing table: inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
10.0.0.3/32        user     0 10.1.15.0          ucst   285     7  so-0/0/1.0
user@R5> show route forwarding-table destination 10.0.0.3
Routing table: inet
Internet:
Destination        Type RtRef Next hop           Type Index NhRef Netif
10.0.0.3/32        user     0 10.1.56.0          ucst   281     9  so-0/0/0.0
```

Meaning The sample output shows the selected next hop between Routers R5 and R3 sent from the inet routing table and installed into the forwarding table. The first instance shows the route through Router R1, and the second instance shows the route through Router R6. In both instances, the preferred route displayed in Step 2 is installed in the forwarding table.

In general, the sample output includes the destination address and destination type, the next-hop address and next-hop type, the number of references to the next hop, an index number into an internal next-hop database, and the interface used to reach the next hop.

Check OSPF on a Stub Router

Purpose To verify the OSPF configuration on a stub router.

Action To verify the OSPF configuration on a stub router in your network, enter the following commands:

```
user@host> show configuration
user@host> show ospf interface
```

The following sample output is for an OSPF configuration on **R5**, a stub router:

Sample Output

```
user@R5> show configuration
[...Output truncated...]
interfaces {
     so-0/0/2  {
        unit 0 {
             family inet  {
                address 10.1.45.2/30;
            }
        }
    }
     lo0 {
        unit 0 {
             family inet {
                address 10.0.0.5/32;
            }
        }
    }
}
routing-options {
     router-id 10.0.0.5;
}
protocols {
    ospf {
         area 0.0.0.2 {
             stub;
            interface so-0/0/2.0;
            interface lo0.0 {
                passive;
            }
        }
    }
}

user@R5> show ospf interface
Interface         State     Area            DR ID           BDR ID       Nbrs
lo0.0             DRother   0.0.0.2         0.0.0.0         0.0.0.0         0
so-0/0/2.0         PtToPt   0.0.0.2          0.0.0.0         0.0.0.0         1
```

Meaning The sample output shows a basic OSPF configuration at the [**edit protocols ospf**] and [**edit interfaces**] hierarchy levels on **R5**, a stub router.

R5 has two interfaces included at the [**edit protocols ospf**] hierarchy level, and those interfaces have the **family inet** statement included at the [**edit interfaces**] hierarchy level. Both interfaces, **so-0/0/2.0** and the loopback interface (**lo0**), are in the stub area (**0.0.0.2**).

R5 has the router ID configured manually to avoid possible problems when the OSPF router ID (RID) changes; for example, when multiple loopback addresses are configured. The RID uniquely identifies the router within the OSPF network. It is transmitted within

the LSAs used to populate the link-state database and calculate the shortest-path tree. In a link-state network, it is important that two routers do not share the same RID value, otherwise IP routing problems may occur.

A stub area does not allow AS external advertisements to flood within that area. **R5** relies on a default route (**0.0.0.0/0**) to reach destinations outside the AS. The default route can be statically configured on **R5** or advertised by an ABR (**R4**). In this network, the default LSA is advertised by **R4.**

A stub area is useful if you want to reduce the size of the topological database and therefore the amount of memory required from the routers in the stub area. However, some restrictions apply to a stub area. You cannot create a virtual link through a stub area, and a stub area cannot contain an ASBR.

Checklist for Verifying the BGP Protocol and Peers

Purpose Table 66 on page 1676 provides links and commands for verifying whether the Border Gateway Protocol (BGP) is configured correctly on a Juniper Networks router in your network, the internal Border Gateway Protocol (IBGP) and exterior Border Gateway Protocol (EBGP) sessions are properly established, the external routes are advertised and received correctly, and the BGP path selection process is working properly.

Action

Table 66: Checklist for Verifying the BGP Protocol and Peers

Tasks	Command or Action

3. Examine the EBGP over IBGP Selection on page 1685	**show route *destination-prefix* < detail >**

Table 66: Checklist for Verifying the BGP Protocol and Peers (continued)

Tasks	Command or Action
4. Examine the IGP Cost Selection on page 1692	**show route *destination-prefix* < detail >**
"Examine Routes in the Forwarding Table" on page 1697	**show route forwarding-table**

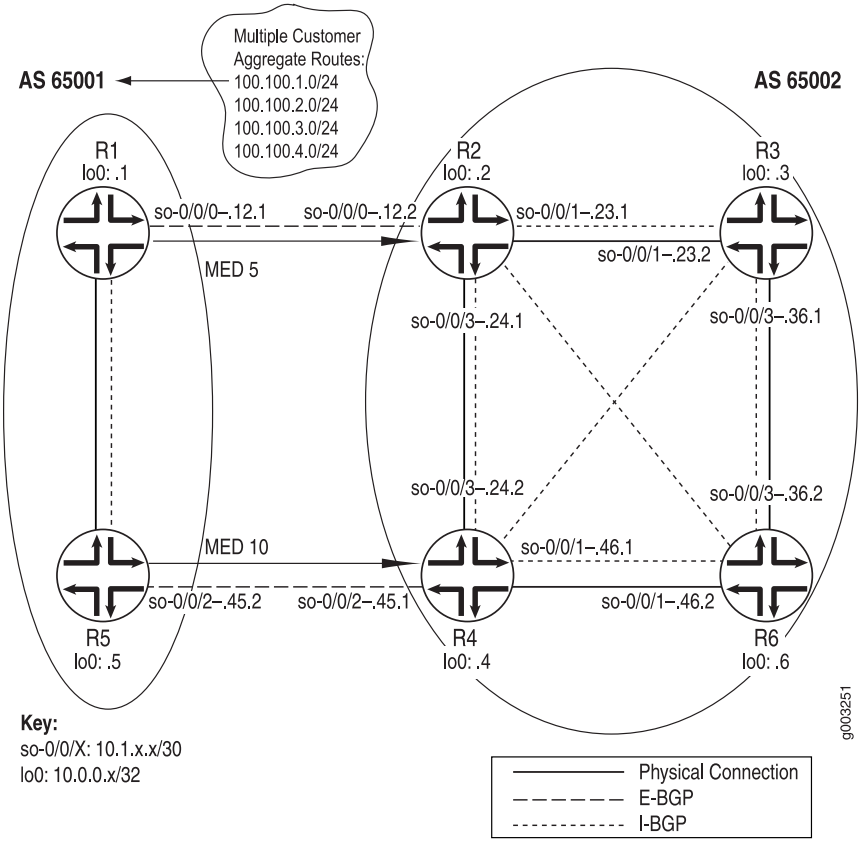
Verify BGP Peers

Purpose

Assuming that all the routers are correctly configured for BGP, you can verify if IBGP and EBGP sessions are properly established, external routes are advertised and received correctly, and the BGP path selection process is working properly.

Figure 137 on page 1677 illustrates an example BGP network topology used in this topic.

Figure 137: BGP Network Topology



The network consists of two directly connected ASs consisting of external and internal peers. The external peers are directly connected through a shared interface and are running EBGP. The internal peers are connected through their loopback (**lo0**) interfaces through IBGP. AS 65001 is running OSPF and AS 65002 is running IS-IS as its underlying

IGP. IBGP routers do not have to be directly connected, the underlying IGP allows neighbors to reach one another.

The two routers in AS 65001 each contain one EBGP link to AS 65002 (**R2** and **R4**) over which they announce aggregated prefixes: **100.100.1.0**, **100.100.2.0**, **100.100.3.0**, and **100.100.4.0**. Also, **R1** and **R5** are injecting multiple exit discriminator (MED) values of 5 and 10, respectively, for some routes.

The internal routers in both ASs are using a full mesh IBGP topology. A full mesh is required because the networks are not using confederations or route reflectors, so any routes learned through IBGP are not distributed to other internal neighbors. For example, when **R3** learns a route from **R2**, **R3** does not distribute that route to **R6** because the route is learned through IBGP, so **R6** must have a direct BGP connection to **R2** to learn the route.

In a full mesh topology, only the border router receiving external BGP information distributes that information to other routers within its AS. The receiving router does not redistribute that information to other IBGP routers in its own AS.

From the point of view of AS 65002, the following sessions should be up:

- The four routers in AS 65002 should have IBGP sessions established with each other.
- **R2** should have an EBGP session established with **R1**.
- **R4** should have an EBGP session established with **R5**.

To verify BGP peers, follow these steps:

1. Verify BGP on an Internal Router on page 1678
2. Verify BGP on a Border Router on page 1681
3. Verify Advertised BGP Routes on page 1684
4. Verify That a Particular BGP Route Is Received on Your Router on page 1684
5. Examine the EBGP over IBGP Selection on page 1685

Verify BGP on an Internal Router

Purpose To verify the BGP configuration of an internal router.

Action To verify the BGP configuration of an internal router, enter the following Junos OS command-line interface (CLI) command:

```
user@host> show configuration
```

The following sample output is for a BGP configuration on R3, as shown in *Verify the BGP Protocol*:

Sample Output

```
user@R3> show configuration
[...Output truncated...]
```

```
interfaces {
    so-0/0/1 {
        unit 0 {
             family inet {
                address 10.1.23.2/30;
            }
            family iso;

```

Meaning The sample output shows a basic BGP configuration on routers **R3** and **R6**. The local AS (65002) and one group (**internal**) are configured on both routers. **R3** has three internal peers—**10.0.0.2**, **10.0.0.4**, and **10.0.0.6**—included at the [**protocols bgp group *group***] hierarchy level. **R6** also has three internal peers: **10.0.0.2**, **10.0.0.3**, and **10.0.0.4**. The underlying IGP protocol is Intermediate System-to-Intermediate System (IS-IS), and relevant interfaces are configured to run IS-IS.

Note that in this configuration the router ID is manually configured to avoid any duplicate router ID problems.

Verify BGP on a Border Router

Purpose To verify the BGP configuration of a border router.

Action To verify the BGP configuration of a border router, enter the following Junos OS CLI operational mode command:

```
user@host> show configuration
```

Sample Output

The following sample output is for a BGP configuration on two border routers from AS 65002 (R2 and R4 as shown in *Verify the BGP Protocol*):

```
user@R2> show configuration
[...Output truncated...]
interfaces {
    so-0/0/0 {
        unit 0 {
            family inet {
                address 10.1.12.2/30;
            }
            family iso;
        }
    }
    so-0/0/1 {
        unit 0 {
             family inet {

                next-hop self;
            }
```

```
        }
    }
```

Meaning The sample output shows a basic BGP configuration on border routers **R2** and **R4**. Both routers have the AS (65002) included at the [**routing-options**] hierarchy level. Each router has two groups included at the [**protocols bgp group** *group*] hierarchy level. External peers are included in the external group, either *toR1* or **toR5**, depending on the router. Internal peers are included in the **internal** group. The underlying IGP protocol is IS-IS on both routers, and relevant interfaces are configured to run IS-IS.

Note that in the configuration on both routers, the router ID is manually configured to avoid duplicate router ID problems, and the **next-hop-self** statement is included to avoid any BGP next-hop reachability problems.

Verify Advertised BGP Routes

Purpose You can determine if a particular route that you have configured is being advertised to a neighbor.

Action To verify the routing information as it has been prepared for advertisement to the specified BGP neighbor, enter the following Junos OS CLI operational mode command:

```
user@host> show route advertising-protocol bgp neighbor-address
```

Sample Output

```
user@R2> show route advertising-protocol bgp 10.0.0.4\

inet.0: 20 destinations, 22 routes (20 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 100.100.1.0/24          Self                 5       200        65001 I
* 100.100.2.0/24          Self                 5       100        65001 I
* 100.100.3.0/24          Self                         100        65001 I
* 100.100.4.0/24          Self                         100        65001 I
```

Meaning The sample output shows the BGP routes advertised from **R2** to its neighbor, **10.0.0.4** (**R4**). Out of 22 total routes in the **inet.0** routing table, 20 are active destinations . No routes are **hidden** or in the **hold-down** state. Routes reside in the **hold-down** state prior to being declared active, and routes rejected by a routing policy can be placed into the **hidden** state. The information displayed reflects the routes that the routing table exported to the BGP routing protocol.

Verify That a Particular BGP Route Is Received on Your Router

Purpose Display the routing information as it is received through a particular BGP neighbor and advertised by the local router to the neighbor.

Action To verify that a particular BGP route is received on your router, enter the following Junos OS CLI operational mode command:

```
user@host> show route receive-protocol bgp neighbor-address
```

Sample Output

```
user@R6> show route receive-protocol bgp 10.0.0.2
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 100.100.1.0/24    10.0.0.2     5   200    65001 I
* 100.100.2.0/24    10.0.0.2     5   100    65001 I
  100.100.3.0/24          10.0.0.2                     100        65001 I
  100.100.4.0/24          10.0.0.2                     100        65001 I
iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)

user@R6> show route receive-protocol bgp 10.0.0.4
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
  Prefix                  Nexthop              MED     Lclpref    AS path
* 100.100.3.0/24          10.0.0.4                    100        65001 I
* 100.100.4.0/24          10.0.0.4                    100        65001 I
iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
```

Meaning The sample output shows four BGP routes from **R2** and two from **R4**. Of the four routes from **R2**, only two are active in the routing table, as indicated by the asterisk (*), while both routes received from **R4** are active in the routing table. All BGP routes came through AS 65001.

Examine the EBGP over IBGP Selection

Purpose To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path.

Action To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.3.0 detail
inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.3.0/24 (2 entries, 1 announced)
        *BGP     Preference: 170/-101
                 Source: 10.1.45.2
                Next hop: 10.1.45.2 via so-0/0/2.0, selected
                State: <Active Ext>
                 Local AS: 65002 Peer AS: 65001
                Age: 5d 0:31:25
                Task: BGP_65001.10.1.45.2+179
```

```
              Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0

              AS path: 65001 I
              Localpref: 100
              Router ID: 10.0.0.5
        BGP   Preference: 170/-101
               Source: 10.0.0.2
              Next hop: 10.1.24.1 via so-0/0/3.0, selected
              Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
              State: <NotBest Int Ext>
               Inactive reason: Interior > Exterior > Exterior via Interior
              Local AS: 65002 Peer AS: 65002
              Age: 2:48:18    Metric2: 10
              Task: BGP_65002.10.0.0.2+179
              AS path: 65001 I
              Localpref: 100
              Router ID: 10.0.0.2
```

Meaning The sample output shows that **R4** received two instances of the **100.100.3.0** route: one from **10.1.45.2** (**R5**) and one from **10.0.0.2** (**R2**). **R4** selected the path from **R5** as its active path, as indicated by the asterisk (*). The selection is based on a preference for routes learned from an EBGP peer over routes learned from an IBGP. **R5** is an EBGP peer.

You can determine if a path is received from an EBGP or IBGP peer by examining the **Local As** and **Peer As** fields. For example, the route from **R5** shows the local AS is 65002 and the peer AS is 65001, indicating that the route is received from an EBGP peer. The route from **R2** shows that both the local and peer AS is 65002, indicating that it is received from an IBGP peer.

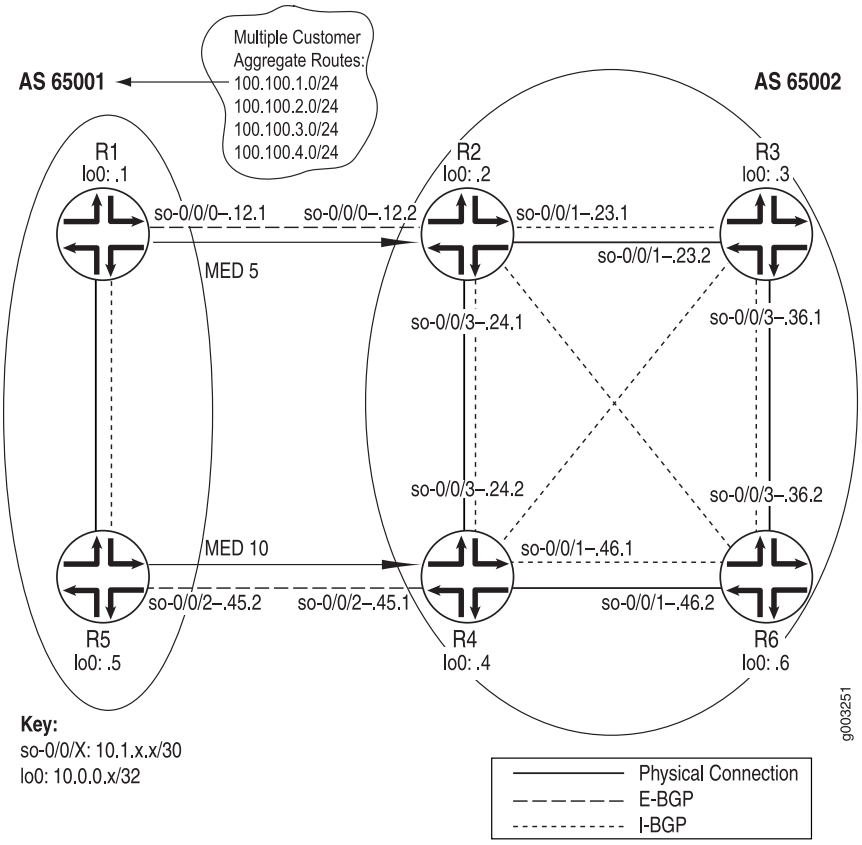
The reason that the inactive path is not selected is displayed in the **Inactive reason** field, in this case, **Interior > Exterior > Exterior via Interior**. The wording of this reason shows the order of preferences applied when the same route is received from two routers. The route received from a strictly internal source (IGP) is preferred first, the route received from an external source (EBGP) is preferred next, and any route which comes from an external source and is received internally (IBGP) is preferred last.

Examine BGP Routes and Route Selection

Purpose

You can examine the BGP path selection process to determine the single, active path when BGP receives multiple routes to the same destination prefix.

Figure 138: BGP Network Topology



The network in Figure 138 on page 1687 shows that **R1** and **R5** announce the same aggregate routes to **R2** and **R4,** which results in **R2** and **R4** receiving two routes to the same destination prefix. The route selection process on **R2** and **R4** determines which of the two BGP routes received is active and advertised to the other internal routers (**R3** and **R6**).

Before the router installs a BGP route, it must make sure that the BGP **next-hop** attribute is reachable. If the BGP next hop cannot be resolved, the route is not installed. When a BGP route is installed in the routing table, it must go through a path selection process if multiple routes exist to the same destination prefix. The BGP path selection process proceeds in the following order:

1. Route preference in the routing table is compared. For example, if an OSPF and a BGP route exist for a particular destination, the OSPF route is selected as the active route because the OSPF route has a default preference of 110, while the BGP route has a default preference of 170.
2. Routes are compared for local preference. The route with the highest local preference is preferred. For example, see "Examine the Local Preference Selection" on page 1688.
3. The AS path attribute is evaluated. The shorter AS path is preferred.
4. The origin code is evaluated. The lowest origin code is preferred (**I (IGP) < E (EGP) < ? (Incomplete)**).

5. The MED value is evaluated. By default, if any of the routes are advertised from the same neighboring AS, the lowest MED value is preferred. The absence of a MED value is interpreted as a MED of 0. For an example, see "Examine the Multiple Exit Discriminator Route Selection" on page 1689.
6. The route is evaluated as to whether it is learned through EBGP or IBGP. EBGP learned routes are preferred to IBGP learned routes. For an example, see "Examine the EBGP over IBGP Selection" on page 1685
7. If the route is learned from IBGP, the route with the lowest IGP cost is preferred. For an example, see "Examine the IGP Cost Selection" on page 1692. The physical next hop to the IBGP peer is installed according to the following three rules:
    a. After BGP examines the **inet.0** and **inet.3** routing tables, the physical next hop of the route with the lowest preference is used.
    b. If the preference values in the **inet.0** and the **inet.3** routing tables are a tie, the physical next hop of the route in the **inet.3** routing table is used.
    c. When a preference tie exists in the same routing table, the physical next hop of the route with more paths is installed.
8. The route reflection cluster list attribute is evaluated. The shortest length cluster list is preferred. Routes without a cluster list are considered to have a cluster list length of 0.
9. The router ID is evaluated. The route from the peer with the lowest router ID is preferred (usually the loopback address).
10. The peer address value is examined. The peer with the lowest peer IP address is preferred.

To determine the single, active path when BGP receives multiple routes to the same destination prefix, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

The following steps illustrate the inactive reason displayed when BGP receives multiple routes to the same destination prefix and one route is selected as the single, active path:

1. Examine the Local Preference Selection on page 1688
2. Examine the Multiple Exit Discriminator Route Selection on page 1689
3. Examine the EBGP over IBGP Selection on page 1690
4. Examine the IGP Cost Selection on page 1692

Examine the Local Preference Selection

Purpose To examine a route to determine if local preference is the selection criteria for the single, active path.

Action To examine a route to determine if local preference is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.1.0 detail

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.1.0/24 (2 entries, 1 announced)
        *BGP    Preference: 170/-201
                Source: 10.0.0.2
                Next hop: 10.1.24.1 via so-0/0/3.0, selected
                Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
                State: <Active Int Ext>

                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.5
```

Meaning The sample output shows that **R4** received two instances of the **100.100.1.0** route: one from **10.0.0.2** (**R2**) and one from **10.1.45.2** (**R5**). **R4** selected the path from **R2** as its active path, as indicated by the asterisk (*). The selection is based on the local preference value contained in the **Localpref** field. The path with the *highest* local preference is preferred. In the example, the path with the higher local preference value is the path from **R2**, 200.

The reason that the route from **R5** is not selected is in the **Inactive reason** field, in this case, **Local Preference**.

Note that the two paths are from the same neighboring network: AS 65001.

Examine the Multiple Exit Discriminator Route Selection

Purpose To examine a route to determine if the MED is the selection criteria for the single, active path.

Action To examine a route to determine if the MED is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.2.0 detail

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.2.0/24 (2 entries, 1 announced)
        *BGP    Preference: 170/-101
                Source: 10.0.0.2
                Next hop: 10.1.24.1 via so-0/0/3.0, selected
                Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
                State: <Active Int Ext>
                Local AS: 65002 Peer AS: 65002
                Age: 2:32:01    Metric: 5       Metric2: 10
                Task: BGP_65002.10.0.0.2+179
                Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0

                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.2
        BGP     Preference: 170/-101
                Source: 10.1.45.2
                Next hop: 10.1.45.2 via so-0/0/2.0, selected
                State: <NotBest Ext>
                Inactive reason: Not Best in its group
                Local AS: 65002 Peer AS: 65001
                Age: 2w0d 1:37:58       Metric: 10
                Task: BGP_65001.10.1.45.2+179
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.5
```

Meaning The sample output shows that **R4** received two instances of the **100.100.2.0** route: one from **10.0.0.2** (**R2**), and one from **10.1.45.2** (**R5**). **R4** selected the path from **R2** as its active route, as indicated by the asterisk (*). The selection is based on the MED value contained in the **Metric:** field. The path with the lowest MED value is preferred. In the example, the path with the lowest MED value (5) is the path from **R2**. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path is not selected is displayed in the **Inactive reason:** field, in this case, **Not Best in its group**. The wording is used because the Junos OS uses the process of deterministic MED selection, by default.

Examine the EBGP over IBGP Selection

Purpose To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path.

Action To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.3.0 detail

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.3.0/24 (2 entries, 1 announced)
        *BGP    Preference: 170/-101
                Source: 10.1.45.2
                Next hop: 10.1.45.2 via so-0/0/2.0, selected
                State: <Active Ext>
                Local AS: 65002 Peer AS: 65001
                Age: 5d 0:31:25
                Task: BGP_65001.10.1.45.2+179
                Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0

                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.5
        BGP     Preference: 170/-101
                Source: 10.0.0.2
                Next hop: 10.1.24.1 via so-0/0/3.0, selected
                Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
                State: <NotBest Int Ext>
                Inactive reason: Interior > Exterior > Exterior via Interior
                Local AS: 65002 Peer AS: 65002
                Age: 2:48:18    Metric2: 10
                Task: BGP_65002.10.0.0.2+179
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.2
```

Meaning The sample output shows that **R4** received two instances of the **100.100.3.0** route: one from **10.1.45.2** (**R5**) and one from **10.0.0.2** (**R2**). **R4** selected the path from **R5** as its active path, as indicated by the asterisk (*). The selection is based on a preference for routes learned from an EBGP peer over routes learned from an IBGP. **R5** is an EBGP peer.

You can determine if a path is received from an EBGP or IBGP peer by examining the **Local As** and **Peer As** fields. For example, the route from **R5** shows the local AS is 65002 and the peer AS is 65001, indicating that the route is received from an EBGP peer. The route from **R2** shows that both the local and peer AS is 65002, indicating that it is received from an IBGP peer.

The reason that the inactive path is not selected is displayed in the **Inactive reason** field, in this case, **Interior > Exterior > Exterior via Interior**. The wording of this reason shows the order of preferences applied when the same route is received from two routers. The route received from a strictly internal source (IGP) is preferred first, the route received from an external source (EBGP) is preferred next, and any route which comes from an external source and is received internally (IBGP) is preferred last.

Examine the IGP Cost Selection

Purpose To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path.

Action To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R6> show route 100.100.4.0 detail

inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
100.100.4.0/24 (2 entries, 1 announced)
        *BGP    Preference: 170/-101
                Source: 10.0.0.4
                Next hop: 10.1.46.1 via so-0/0/1.0, selected
                Protocol next hop: 10.0.0.4 Indirect next hop: 864c000 276
                State: <Active Int Ext>
                Local AS: 65002 Peer AS: 65002
                Age: 2:16:11    Metric2: 10
                Task: BGP_65002.10.0.0.4+4120
                Announcement bits (2): 0-KRT 4-Resolve inet.0
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.4
         BGP    Preference: 170/-101
                Source: 10.0.0.2
                Next hop: 10.1.46.1 via so-0/0/1.0, selected
                Next hop: 10.1.36.1 via so-0/0/3.0
                Protocol next hop: 10.0.0.2 Indirect next hop: 864c0b0 278
                State: <NotBest Int Ext>
                Inactive reason: IGP metric
                Local AS: 65002 Peer AS: 65002
                Age: 2:16:03    Metric2: 20
                Task: BGP_65002.10.0.0.2+179
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.2
```

Meaning The sample output shows that **R6** received two instances of the **100.100.4.0** route: one from **10.0.0.4** (**R4**) and one from **10.0.0.2** (**R2**). **R6** selected the path from **R4** as its active route, as indicated by the asterisk (*). The selection is based on the IGP metric, displayed in the **Metric2** field. The route with the lowest IGP metric is preferred. In the example, the path with the lowest IGP metric value is the path from **R4**, with an IGP metric value of 10, while the path from **R2** has an IGP metric of 20. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path was not selected is displayed in the **Inactive reason** field, in this case, **IGP metric**.

Examine the Local Preference Selection

Purpose To examine a route to determine if local preference is the selection criteria for the single, active path.

Action To examine a route to determine if local preference is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.1.0 detail

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.1.0/24 (2 entries, 1 announced)
        *BGP    Preference: 170/-201
                Source: 10.0.0.2
                Next hop: 10.1.24.1 via so-0/0/3.0, selected
                Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
                State: <Active Int Ext>
                Local AS: 65002 Peer AS: 65002
                Age: 2:22:34    Metric: 5       Metric2: 10
                Task: BGP_65002.10.0.0.2+179
                Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0

                AS path: 65001 I
                Localpref: 200
                Router ID: 10.0.0.2
        BGP     Preference: 170/-101
                Source: 10.1.45.2
                Next hop: 10.1.45.2 via so-0/0/2.0, selected
                State: <Ext>
                Inactive reason: Local Preference
                Local AS: 65002 Peer AS: 65001

                State: <Active Int Ext>
                Local AS: 65002 Peer AS: 65002
                Age: 2:32:01     Metric: 5       Metric2: 10
                Task: BGP_65002.10.0.0.2+179
                Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0

                  AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.2
         BGP    Preference: 170/-101
                  Source: 10.1.45.2
                Next hop: 10.1.45.2 via so-0/0/2.0, selected
                State: <NotBest Ext>
                  Inactive reason: Not Best in its group
                Local AS: 65002 Peer AS: 65001
                Age: 2w0d 1:37:58        Metric: 10
                Task: BGP_65001.10.1.45.2+179
                  AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.5
```

Meaning The sample output shows that **R4** received two instances of the **100.100.2.0** route: one from **10.0.0.2** (**R2**), and one from **10.1.45.2** (**R5**). **R4** selected the path from **R2** as its active route, as indicated by the asterisk (*). The selection is based on the MED value contained in the **Metric:** field. The path with the lowest MED value is preferred. In the example, the path with the lowest MED value (5) is the path from **R2**. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path is not selected is displayed in the **Inactive reason:** field, in this case, **Not Best in its group**. The wording is used because the Junos OS uses the process of deterministic MED selection, by default.

Examine the EBGP over IBGP Selection

Purpose To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path.

Action To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.3.0 detail

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.3.0/24 (2 entries, 1 announced)
         *BGP     Preference: 170/-101
                  Source: 10.1.45.2
                Next hop: 10.1.45.2 via so-0/0/2.0, selected
                State: <Active Ext>
                 Local AS: 65002 Peer AS: 65001
                Age: 5d 0:31:25
                Task: BGP_65001.10.1.45.2+179
                Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0

                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.5
         BGP    Preference: 170/-101
                  Source: 10.0.0.2
                Next hop: 10.1.24.1 via so-0/0/3.0, selected
                Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
                State: <NotBest Int Ext>
                 Inactive reason: Interior > Exterior > Exterior via Interior
                Local AS: 65002 Peer AS: 65002
                Age: 2:48:18    Metric2: 10
                Task: BGP_65002.10.0.0.2+179
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.2
```

Meaning The sample output shows that **R4** received two instances of the **100.100.3.0** route: one from **10.1.45.2** (**R5**) and one from **10.0.0.2** (**R2**). **R4** selected the path from **R5** as its active path, as indicated by the asterisk (*). The selection is based on a preference for routes learned from an EBGP peer over routes learned from an IBGP. **R5** is an EBGP peer.

You can determine if a path is received from an EBGP or IBGP peer by examining the **Local As** and **Peer As** fields. For example, the route from **R5** shows the local AS is 65002 and the peer AS is 65001, indicating that the route is received from an EBGP peer. The route from **R2** shows that both the local and peer AS is 65002, indicating that it is received from an IBGP peer.

The reason that the inactive path is not selected is displayed in the **Inactive reason** field, in this case, **Interior > Exterior > Exterior via Interior**. The wording of this reason shows the order of preferences applied when the same route is received from two routers. The route received from a strictly internal source (IGP) is preferred first, the route received from an external source (EBGP) is preferred next, and any route which comes from an external source and is received internally (IBGP) is preferred last.

Examine the IGP Cost Selection

Purpose To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path.

Action To examine a route to determine if EBGP is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R6> show route 100.100.4.0 detail

inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
100.100.4.0/24 (2 entries, 1 announced)
        *BGP    Preference: 170/-101
                Source: 10.0.0.4
                Next hop: 10.1.46.1 via so-0/0/1.0, selected
                Protocol next hop: 10.0.0.4 Indirect next hop: 864c000 276
                State: <Active Int Ext>
                Local AS: 65002 Peer AS: 65002
                Age: 2:16:11    Metric2: 10
                Task: BGP_65002.10.0.0.4+4120
                Announcement bits (2): 0-KRT 4-Resolve inet.0
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.4
         BGP    Preference: 170/-101
                Source: 10.0.0.2
                Next hop: 10.1.46.1 via so-0/0/1.0, selected
                Next hop: 10.1.36.1 via so-0/0/3.0
                Protocol next hop: 10.0.0.2 Indirect next hop: 864c0b0 278
                State: <NotBest Int Ext>
                Inactive reason: IGP metric
                Local AS: 65002 Peer AS: 65002
                Age: 2:16:03    Metric2: 20
                Task: BGP_65002.10.0.0.2+179
                AS path: 65001 I
                Localpref: 100
                Router ID: 10.0.0.2
```

Meaning The sample output shows that **R6** received two instances of the **100.100.4.0** route: one from **10.0.0.4** (**R4**) and one from **10.0.0.2** (**R2**). **R6** selected the path from **R4** as its active route, as indicated by the asterisk (*). The selection is based on the IGP metric, displayed

in the **Metric2** field. The route with the lowest IGP metric is preferred. In the example, the path with the lowest IGP metric value is the path from **R4**, with an IGP metric value of 10, while the path from **R2** has an IGP metric of 20. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path was not selected is displayed in the **Inactive reason** field, in this case, **IGP metric**.

Examine Routes in the Forwarding Table

Purpose When you run into problems, such as connectivity problems, you may need to examine routes in the forwarding table to verify that the routing protocol process has relayed the correct information into the forwarding table.

Action To display the set of routes installed in the forwarding table, enter the following Junos OS CLI operational mode command:

```
user@host> show route forwarding-table
```

Sample Output

```
user@R2> show route forwarding-table
Routing table: inet
Internet:
Destination        Type RtRef Next hop           Type  Index NhRef Netif
default            perm     0                    rjct     10     1
10.0.0.2/32        intf     0 10.0.0.2           locl    256     1
10.0.0.3/32        user     1 10.1.23.0          ucst    282     4 so-0/0/1.0
10.0.0.4/32        user     1 10.1.24.0          ucst    290     7 so-0/0/3.0

10.1.24.0/32       dest     0 10.1.24.0          recv    292     1 so-0/0/3.0
10.1.24.1/32       intf     0 10.1.24.1          locl    289     1
10.1.24.3/32       dest     0 10.1.24.3          bcst    291     1 so-0/0/3.0
10.1.36.0/30       user     0 10.1.23.0          ucst    282     4 so-0/0/1.0
10.1.46.0/30       user     0 10.1.24.0          ucst    290     7 so-0/0/3.0
100.100.1.0/24     user     0 10.1.12.0          ucst    278     6 so-0/0/0.0
100.100.2.0/24     user     0 10.1.12.0          ucst    278     6 so-0/0/0.0
100.100.3.0/24     user     0 10.1.12.0          ucst    278     6 so-0/0/0.0
100.100.4.0/24     user     0 10.1.12.0          ucst    278     6 so-0/0/0.0
[...Output truncated...]
```

Meaning The sample output shows the network-layer prefixes and their next hops installed in the forwarding table. The output includes the same next-hop information as in the **show route detail** command (the next-hop address and interface name). Additional information includes the destination type, the next-hop type, the number of references to this next hop, and an index into an internal next-hop database. (The internal database contains additional information used by the Packet Forwarding Engine to ensure proper encapsulation of packets sent out an interface. This database is not accessible to the user.

For detailed information about the meanings of the various flags and types fields, see the *Routing Policies, Firewall Filters, and Traffic Policers.*

Ping the Egress Router

Purpose Ping the egress router to confirm that communication over the network is operational.

Action To ping the egress router, enter the following Junos OS CLI operational mode command:

```
user@host>  ping ip-address-interface
```

Sample Output

```
[edit protocols mpls]
user@R1# run ping 10.1.56.1
PING 10.1.56.1 (10.1.56.1): 56 data bytes
64 bytes from 10.1.56.1: icmp_seq=0 ttl=255 time=0.837 ms
64 bytes from 10.1.56.1: icmp_seq=1 ttl=255 time=0.792 ms
64 bytes from 10.1.56.1: icmp_seq=2 ttl=255 time=0.856 ms
^C
--- 10.1.56.1 ping statistics ---
3 packets transmitted, 3 packets received,  0% packet loss
round-trip min/avg/max/stddev = 0.792/0.828/0.856/0.027 ms
```

Meaning The sample output confirms that communication between router **R1** and the IP address of the relevant interface on router **R5** (**10.1.56.1**) is operational.

View the RSVP Log File on Transit Routers

Purpose Transit router messages that appear in the RSVP log file can help you analyze the problem with an RSVP session. You may need to issue the **clear rsvp session** and **clear log *filename*** commands to ensure that your records are current. However, if your network is large with many RSVP sessions, this may not be advisable because it may take a while for all sessions to reestablish. However, the **clear rsvp session** command has various options you can include to minimize the effect on your network. For more information about the **clear rsvp session** command, see the *Junos Routing Protocols and Policies Command Reference.*

Action To view the RSVP log file, enter the following Junos OS CLI operational mode commands:

```
user@host> clear rsvp session (Optional)
user@host> clear log filename (Optional)
user@host> show log  filename
```

Sample Output 1

```
user@R3> clear rsvp session

user@R3> clear log rsvp-log

user@R3> show log rsvp-log

Jul 21 17:01:23    RecRoute Len 28 10.1.56.2 10.1.36.1 10.1.13.1
```

Meaning Sample Output 1 from transit router **R3** shows that **R3** (**so-0/0/2.0**) correctly received a Path request message (**recv Path**) from **R1**, and correctly sent the Path message (**send Path**) through interface **so-0/0/3.0** to **R6**. The route record object (**RecRoute**) indicates the list of addresses this Path message transited, in this case, **10 1.36.1** and **10.1.13.1**.

Sample Output 2 from transit router **R6** shows that **R6** (**so-0/0/3.0**) correctly received a Path request message (**recv Path**) from **R3**, and correctly sent the Path message (**send Path**) through interface **so-0/0/0** to **R5**. The route record object (**RecRoute**) indicates the list of addresses this Path message transited, in this case, **10.1.56.2**, **10 1.36.1**, and **10.1.13.1**.

With the information above, the focus shifts to egress router **R5** as the source of the problem, with indications that **R5** ignored the RSVP message.

Check the RSVP Log File on the Egress Router

Purpose After placing an RSVP tracing configuration on router **R5** similar to that on routers **R3** and **R6**, display the RSVP log file for useful information about the problem on router **R5**.

Action To check the RSVP log file, enter the following Junos OS CLI operational mode command:

```
user@host>  show log rsvp-log
```

Sample Output

```
user@R5>  show log rsvp-log
Jul 21 10:53:16 R5 clear-log[40071]: logfile cleared
Jul 21 11:02:37 trace_on: Tracing to "/var/log/rsvp-log" started
Jul 21 11:03:07 RSVP error, send to  DISABLED interface  ? Hello New
10.1.56.1->10.1.56.2 Len=8  so-0/0/0.0
```

Meaning The sample output shows that **R5** did not receive the Path message because of a disabled interface, **so-0/0/0.0**.

Determine and Correct the Problem on the Egress Router

Problem **Description:** Check the configuration of interface **so-0/0/0.0** on egress router **R5** to determine the reason it was disabled.

Solution To determine the problem on **R5**, enter the following Junos OS CLI commands:

```
user@R5> show configuration protocols rsvp
user@R5> edit
[edit protocols rsvp]
user@R5# rename interface so-0/0/3 to interface so-0/0/0
user@R5# show
user@R5# commit
user@R5# run show rsvp session ingress detail
```

Sample Output 1

```
user@R5> show configuration protocols rsvp
traceoptions {
    file rsvp-log;
    flag error detail;
    flag path detail;
    flag pathtear detail;
}
interface so-0/0/3.0;       <<< so-0/0/3 incorrectly included
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
```

Sample Output 2

```
[edit protocols rsvp]
user@R5# rename interface so-0/0/3 to interface so-0/0/0

[edit protocols rsvp]
user@R5# show
traceoptions {
    file rsvp-log;
    flag packets detail;
    flag error detail;
}
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

[edit protocols rsvp]
user@R5# commit
commit complete
```

Sample Output 3

```
[edit protocols mpls]
user@R5# run show rsvp session ingress detail
Ingress RSVP: 1 sessions
To              From            State   Rt Style Labelin Labelout LSPname
10.0.0.1        10.0.0.5        Up       1  1 FF       -   103104 R5-to-R1
Total 1 displayed, Up 1, Down 0
Egress RSVP: 1 sessions
To      From      State  Rt Style Labelin Labelout LSPname
10.0.0.5    10.0.0.1    Up    0 1 FF    3    - R1-to-R5
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning Sample Output 1 from egress router **R5** shows three interfaces configured at the [**edit**

protocols rsvp] hierarchy level, non of which is **so-0/0/0.0**. On examination of the network topology, it is apparent that the **so-0/0/0.0** interface was configured incorrectly as **so-0/0/3.0**.

Sample Output 2 shows the correct configuration of interfaces at the [**edit protocols rsvp**] hierarchy level, and the **rename** command issued to correct the configuration error.

Sample Output 3 shows that the RSVP-signaled LSP (**R1-to-R5**) is correctly established after the changes to the RSVP configuration are committed.

Check the Routing CPU Memory Usage

Purpose Software processes on the router can consume a considerable amount of CPU and memory. The routing protocol process (rpd) can consume enormous amounts of memory to store information needed for the operation of routing and related protocols, such as Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), Intermediate System-to-Intermediate System (ISIS), Resource Reservation Protocol (RSVP), Label Distribution Protocol (LDP), and Multiprotocol Label Switching (MPLS).

To verify the traffic passing through the router and check memory utilization, follow these steps:

1. Check Overall CPU and Memory Usage on page 1703
2. Check Routing Protocol Process (rpd) Memory Usage on page 1705
3. Display Tasks on page 1708

Check Overall CPU and Memory Usage

Purpose You can display exhaustive system process information about software processes that are running on the router and have controlling terminals. This command is equivalent to the UNIX **top** command. However, the UNIX **top** command shows real-time memory usage, with the memory values constantly changing, while the **show system processes extensive** command provides a snapshot of memory usage in a given moment.

Action To check overall CPU and memory usage, enter the following Junos OS command-line interface (CLI) command:

```
user@host> show system processes extensive
```

Sample Output

```
user@R1> show system processes extensive
last pid:  5251;  load averages:  0.00,  0.00,  0.00  up 4+20:22:16    10:44:41

```

Meaning The sample output shows the amount of virtual memory used by the Routing Engine and software processes. For example, 118 MB of physical memory is free and 512 MB of the swap file is free, indicating that the router is not short of memory. The **processes** field shows that most of the 58 processes are in the **sleeping** state, with 1 in the **running** state. The process or command that is running is the **top** command.

The **commands** column lists the processes that are currently running. For example, the chassis process (chassisd**)** has a process identifier (**PID**) of 4480, with a current priority (**PRI**) of 2. A lower priority number indicates a higher priority.

The processes are listed according to level of activity, with the most active process at the top of the output. For example, the chassis (chassisd) process is consuming the largest amount of CPU resource at 2.34 percent.

The memory field (**Mem**) shows the virtual memory managed by the Routing Engine and used by processes. The value in the memory field is in KB and MB, and is broken down as follows:

- **Active**—Memory that is allocated and actually in use by programs.
- **Inact**—Memory that is either allocated but not recently used or memory that was freed by programs. Inactive memory is still mapped in the address space of one or more processes and, therefore, counts toward the resident set size of those processes.
- **Wired**—Memory that is not eligible to be swapped, and is usually used for Routing Engine memory structures or memory physically locked by a process.
- **Cache**—Memory that is not associated with any program and does not need to be swapped before being reused.
- **Buf**—The size of the memory buffer used to hold data recently called from disk.
- **Free**—Memory that is not associated with any programs. Memory freed by a process can become **Inactive**, **Cache**, or **Free**, depending on the method used by the process to free the memory.

When the system is under memory pressure, the pageout process reuses memory from the free, cache, inactive and, if necessary, active pages.

The **Swap** field shows the total swap space available and how much is unused. In the example, the output shows 512 MB of total swap space and 512 MB of free swap space.

Finally, the memory usage of each process is listed. The **SIZE** field indicates the size of the virtual address space, and the **RES** field indicates the amount of the program in physical memory, which is also known as RSS or Resident Set Size. In the sample output, the chassis (chassisd) process has 3728 KB of virtual address space and 1908 KB of physical memory.

Check Routing Protocol Process (rpd) Memory Usage

Purpose When you notice a lot of memory usage, you can obtain detailed information about the memory utilization of routing tasks to get an idea of what is going on. The routing process (rpd) is the main task that uses Routing Engine memory.

Action To check routing process memory usage, enter the following Junos OS CLI operational mode commands:

```
user@host> show route summary
user@host> show task memory detail
```

Sample Output

```
user@host> show route summary
Autonomous system number: 209
Router ID: 205.175.0.170
inet.0: 179783 destinations, 898393 routes (179771 active, 146 holddown, 157
hidden)
              Direct:     17 routes,     17 active
               Local:     18 routes,     18 active

```

Meaning The sample output shows summary statistics about the entries in the routing table (**show route summary** command) and the memory usage breakdown (**show task memory detail**

command) for the routing process (rpd). The two commands provide a comprehensive picture of the memory utilization of the routing protocol process.

The **show route summary** command shows the number of routes in the various routing tables. In the sample output, the routing tables represented are **inet.0**, **inet.2**, **inet.3**, **iso.0**, and **mpls.0**. Within each routing table, all of the active, hold-down, and hidden destinations and routes are summarized for all the protocols from which routes are learned. Routes are in the **hold-down** state prior to being declared inactive, and **hidden** routes are not used because of routing policy. Routes in the **hold-down** and **hidden** states are still using memory because they appear in the routing table.

In addition, routes are summarized in the following categories: those directly connected to the network (**Direct**), local routes (**Local**), and routes learned from configured routing protocols, such as BGP and IS-IS.

The **show task memory detail** command lists the data structures within the tasks run by the routing protocol process (rpd). Tasks are enabled depending on the router's configuration. For example, **isis_area_addr** is a data structure resulting from the IS-IS configuration. The **AllocBytes** field indicates the highest amount of memory used by the data structure. For example, the **isis_area_addr** data structure has 544 blocks of allocated memory, each block is allocated a value of 16 bytes, resulting in allocated bytes of 8704. The maximum allocated blocks and bytes are high-water marks for a data structure. For more information on displaying task-related information, see "Display Tasks" on page 1708.

The **Total bytes in use** field shows the total amount of memory used by the routing protocol process (rpd).

Display Tasks

Purpose You can display information about tasks to further your investigation of a memory problem on the router.

Action To display a list of tasks that are enabled on the router, enter the following Junos OS CLI operational mode commands:

```
user@host> show task
user@host> show task memory
user@host> show task task-name
```

Sample Output

```

```

Meaning The sample output shows a list of routing, routing protocol, and interface tasks that are currently running on the router (**show task**), a summary of memory utilization (**show task memory**), and the memory utilization of a particular task (**show task io**). Tasks can be baseline tasks performed regardless of the router configuration, and other tasks that depend on the router configuration. For example, the **BGP_Group_internal** task is the result of the configuration of BGP on the router, while the **INET6** task is a base task associated with the routing process (rpd).

Each task in the **show task** command output has a priority and a task name. For example, the current priority is 10 for **LMP Client** and 80 for **IF Delete**. A lower number indicates a higher priority.

Some tasks have flags attached to them. For example, the **BGP.0.0.0.0+179** task has two flags, **Accept** and **LowPrio.** The **Accept** flag indicates that the task is waiting for incoming connections, and the **LowPrio** flag indicates that the task will be dispatched to read its socket after other, higher priority tasks. Two additional flags are **Connect**, which indicates that a task is waiting for a connection to complete, and **Delete**, which indicates that a task has been deleted and is being cleaned up.

The **show task io** command shows the statistics gathered for each IO operation. The counters show the following:

- **Reads**—This counter increments when a datagram arrives on a connected socket of the task and the task's read callback is called.
- **Writes**—This counter increments when a connected socket of a task becomes writable and the tasks's callback is called.
- **Rcvd**—This counter increments when the task calls the Routing Engine to read a datagram from a socket which may or may not be connected.

- **Sent**—This counter increments when a task attempts to read or write a datagram on an existing or nonexisting socket.
- **Drops**—This counter increments when a task attempts to read or write a datagram through the Routing Engine on a prebuilt socket, but the request fails for any reason.

Run Snmpwalk from an NMS System to a Juniper Router

Purpose Snmpwalk is an SNMP application that you can use to query a MIB for information about the functioning of a router in your network. Snmpwalk uses **GetNext** requests to retrieve the specified information. Object identifiers (OIDs) are used to query the MIB. If the OID argument is not present, Snmpwalk searches MIB-2.

Action To run Snmpwalk for a specific OID, from a management station that has access to the router, and using a tool such as Snmpwalk, enter the following command:

```
user-nms# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```
user-nms %  snmpwalk -Os -M /volume/~/mibs -m all tp1 public .1.3.6.1.2.1.4
ipForwarding.0 = forwarding(1)
ipDefaultTTL.0 = 64
ipInReceives.0 = Counter32: 9262713
ipInHdrErrors.0 = Counter32: 0
ipInAddrErrors.0 = Counter32: 0
ipForwDatagrams.0 = Counter32: 614171
ipInUnknownProtos.0 = Counter32: 0
ipInDiscards.0 = Counter32: 0
ipInDelivers.0 = Counter32: 8648408
ipOutRequests.0 = Counter32: 1226483
ipOutDiscards.0 = Counter32: 0
ipOutNoRoutes.0 = Counter32: 0
ipReasmTimeout.0 = 60
ipReasmReqds.0 = Counter32: 0
ipReasmOKs.0 = Counter32: 0
ipReasmFails.0 = Counter32: 0
ipFragOKs.0 = Counter32: 0
ipFragFails.0 = Counter32: 0
ipFragCreates.0 = Counter32: 0
ipAdEntAddr.10.0.0.1 = IpAddress: 10.0.0.1
ipAdEntAddr.10.1.12.1 = IpAddress: 10.1.12.1
ipAdEntAddr.10.1.15.1 = IpAddress: 10.1.15.1
ipAdEntAddr.10.168.70.143 = IpAddress: 10.168.70.143
[...Output truncated...]
```

Meaning The sample output shows that the user is on a network management station (**user-nms %**) that has access to the router, **tp1**. In the command, the following options are used:

- **Os—**Deletes all but the last symbolic part of the OID **sysUpTime.0**. For example, Timeticks: (14096763) 1 day, 15:09:27.63.
- **-M—**Compiles the MIB and gives a path or location to the MIBs.

- **-m**—Uses the files in the directory pointed to by the **-M** option.
- **all**—Uses all the files in the directory pointed to by the **-M** option.

In addition, the command includes the hostname **tp1**, the community string **public**, and the OID **.1.3.6.1.2.1.4**.

The OID in this example is from RFC 2096, *IP Forwarding Table MIB*, which displays multipath IP routes that have the same network number but different network masks.

Before you can retrieve SNMP information from a router, you must have the minimum SNMP configuration for that router. Following is the minimum SNMP configuration required:

```
[edit]
snmp {
   community public {
     authorization read-only;
   }
 }
```

With this configuration, the system responds to SNMP **Get**, **GetNext**, and **GetBulk** commands that contain the community string **public**.

For more detailed information on configuring SNMP on a router, see the *Junos Network Management Configuration Guide*.

Configure Trace Operations for SNMP

Purpose Define tracing for SNMP to access more granular information about the packets sent and received through SNMP.

Action To configure SNMP tracing operations, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit snmp
```

2. Configure trace operations:

```
[edit snmp]
user@R1# set traceoptions flag pdu
```

3. Commit the configuration:

```
user@R1# commit and-quit
commit complete
Exiting configuration mode
```

Sample Output `user@R1>` **show configuration snmp**

```
view all {
    oid .1 include;
}
view system {
    oid system;
}
community public {
    view all;
    authorization read-only;
}
community private {
    view system;
    authorization read-write;
}
traceoptions {
    flag pdu;
}
```

Meaning The sample output shows a configuration for SNMP that includes traceoptions. The **pdu** flag is configured, which results in the generation of SNMP request and response packets. The output for the tracing operation is placed into various log files in the **/var/log** directory.

Protocol-specific tracing operations override any equivalent operations that you specify in the global **traceoptions** statement. If there are no equivalent operations, they supplement the global tracing options. If you do not specify any protocol-specific tracing, the routing protocol inherits all the global tracing operations.

Query a MIB With SNMPGet

Purpose Send an SNMP request to check that the SNMP configuration is correct.

Action To query a MIB with **SNMPGet**, enter the following command:

```
user@nms % snmpget hostname community oid
```

Sample Output

```
user-nms % snmpget tp1 public .1.3.6.1.2.1.1.1.0
system.sysDescr.0 = m7i internet router, kernel 6.0R1.5

user-nms % snmpget tp1 public sysDescr.0
system.sysDescr.0 = m7i internet router, kernel 6.0R1.5
```

Meaning The sample output shows a query from a network management station (**nms**) for the description of the system running on the router **tp1**. The OID is entered in numerical form in the command line, and a description (**sysDescr.0**) is obtained in the output. You can also use **sysDescr.0** in the command line to obtain the same output.

Check CPU Utilization

Purpose The enterprise-specific chassis MIB provides information about the router and its components. Within the chassis MIB, the **jnxMIBs** branch contains one main subbranch, **jnxBoxAnatomy**, which in turn contains a section, **jnxOperatingTable**. Within **jnxOperatingTable,** and under the **jnxOperatingEntry**, you can use the **jnxOperatingCPU** object to monitor the CPU on your router. (See Figure 139 on page 1714.)

```

After each object description is a value in parenthesis, such as (1). This value can be used to enter an OID for the specific object. For example, to gather information on the CPU, you can type the object description (**jnxOperatingCPU**) or the OID (**.1.3.6.1.4.1.2636.3.1.13.1.8**).

Action To check CPU utilization using the Juniper Networks enterprise chassis MIB, from a management station that has access to the router, and using a tool such as Snmpwalk, enter the following command:

```
user-bsd# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```
user-nms % snmpwalk -Os -M /volume/~/mibs -m all tp1 public jnxOperatingCPU
jnxOperatingCPU.1.1.1.0 = Gauge32: 0
```

```
jnxOperatingCPU.1.1.2.0 = Gauge32: 0
jnxOperatingCPU.1.1.3.0 = Gauge32: 0
jnxOperatingCPU.2.1.0.0 = Gauge32: 0
jnxOperatingCPU.4.1.1.0 = Gauge32: 0
jnxOperatingCPU.4.1.2.0 = Gauge32: 0
jnxOperatingCPU.4.1.3.0 = Gauge32: 0
jnxOperatingCPU.4.1.4.0 = Gauge32: 0
jnxOperatingCPU.6.1.1.0 = Gauge32: 224
jnxOperatingCPU.6.1.2.0 = Gauge32: 224
jnxOperatingCPU.7.1.0.0 = Gauge32: 2
jnxOperatingCPU.7.2.0.0 = Gauge32: 2
jnxOperatingCPU.8.1.1.0 = Gauge32: 0
jnxOperatingCPU.8.2.3.0 = Gauge32: 0
jnxOperatingCPU.8.2.4.0 = Gauge32: 0
jnxOperatingCPU.9.1.0.0 = Gauge32: 6
jnxOperatingCPU.9.1.1.0 = Gauge32: 0

user-nms % snmpwalk -Os -M /volume/~/mibs -m all tp1 public jnxOperatingDesc
jnxOperatingDescr.1.1.1.0 = midplane
jnxOperatingDescr.1.1.2.0 = midplane
jnxOperatingDescr.1.1.3.0 = midplane
jnxOperatingDescr.2.1.0.0 = Power Supply A
jnxOperatingDescr.4.1.1.0 = Left Tray front fan
jnxOperatingDescr.4.1.2.0 = Left Tray second fan
jnxOperatingDescr.4.1.3.0 = Left Tray third fan
jnxOperatingDescr.4.1.4.0 = Left Tray fourth fan
jnxOperatingDescr.6.1.1.0 = CFEB Internet Processor IIv1
jnxOperatingDescr.6.1.2.0 = CFEB Internet Processor IIv1
jnxOperatingDescr.7.1.0.0 = FPC @ 0/*/*
jnxOperatingDescr.7.2.0.0 = FPC @ 1/*/*
jnxOperatingDescr.8.1.1.0 = PIC: 4x OC-3 SONET, MM @ 0/0/*
jnxOperatingDescr.8.2.3.0 = PIC: 1x Tunnel @ 1/2/*
jnxOperatingDescr.8.2.4.0 = PIC: 1x G/E, 1000 BASE-SX @ 1/3/*
jnxOperatingDescr.9.1.0.0 = Routing Engine
jnxOperatingDescr.9.1.1.0 = Routing Engine PCMCIA Card
```

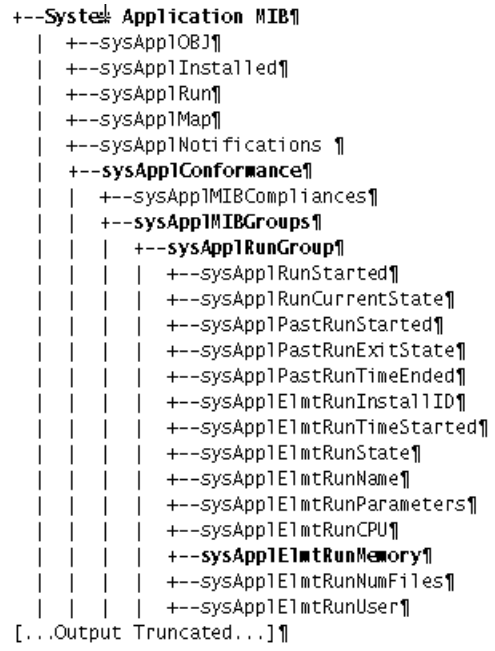
Meaning The sample output shows the percentage CPU utilization on router, **tp1**. The Routing Engine (**9.1.0.0**) has 6 percent CPU utilization, the two CFEB Internet Processors IIv1 (**6.1.1.0** and **6.1.2.0**) have 22 percent each, and the FPCs (**7.1.0.0** and **7.2.0.0**) have 2 percent each. Components with a value of zero indicate that the information is either unavailable or inapplicable.

The output for the **jnxOperatingDesc** object provides a description of the separate instances in the **jnxOperatingCPU** object. For example, **9.1.0.0** represents the Routing Engine.

Check CPU Utilization per Process

Purpose The standard system application MIB (RFC 2287, *Definitions of System-Level Managed Objects for Applications*), describes a set of managed objects that are restricted to information that can be determined from the system itself. The object **sysApplElmtRunCPU** provides information about applications and associated elements that have run or are currently running on the host system. (See Figure 140 on page 1716.)

Figure 140: System Application MIB Tree



Action To check CPU utilization per process, from a management station that has access to the router, and using a tool such as Snmpwalk, enter the following command:

```
user-bsd# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```

```

Meaning The sample output shows the number of centi-seconds of total system CPU resources consumed by a particular process. For example, the chassis process (**chassisd**, **3.2.2163**) has consumed 3 days, or 33,548,776 centi-seconds of total system CPU resources.

The **sysApplElmtRunName** object retrieves the name of the OID. For example, **sysApplElmtRunCPU.3.2.2163** represents the chassis process.

Retrieve Version Information about Router Software Components

Purpose RFC 2790, *Host Resources MIB,* describes a set of managed objects that are useful for managing host systems, including routers.

Action To retrieve version information about software components on the router, from a management station that has access to the router and using a tool, such as Snmpwalk, enter the following command:

```
user-bsd# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```
user-nms % snmpwalk -Os -M /volume/~/mibs -m all tp1 public
.1.3.6.1.2.1.25.6.3hrSWInstalledIndex.2 = 2
hrSWInstalledIndex.3 = 3
hrSWInstalledIndex.4 = 4
```

```
hrSWInstalledIndex.5 = 5
hrSWInstalledIndex.6 = 6
hrSWInstalledIndex.9 = 9
hrSWInstalledName.2 = "JUNOS Base OS Software Suite [6.0R1.5]"

hrSWInstalledDate.9 = 2003-11-22,4:8:47.0,-8:0a1
```

Meaning The sample output shows the version information for various software components on the router.

Checklist for Displaying Basic Chassis Information

Purpose Table 67 on page 1719 provides links and commands for displaying basic chassis information, including a list of all Flexible PIC Concentrators (FPCs) and Physical Interface Cards (PICs) installed in the router chassis, the hardware version level, and the serial number.

Action

Table 67: Checklist for Displaying Basic Chassis Information

Task	Command or Action
"Display Basic Chassis Information" on page 1719	**show chassis hardware <detail>**

Display Basic Chassis Information

Purpose Before you return a router component to Juniper Networks, you must contact the Juniper Networks Technical Assistance Center (JTAC) with the serial number of the failed component and failure information. JTAC will then grant a Return Materials Authorization (RMA).

Action To display a list of the serial numbers of components installed in the router chassis, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show chassis hardware <detail>
```

Sample Output

```
user@host> show chassis hardware
Hardware inventory:

```

Meaning The sample output is for an M20 and an M40 router. It shows a list of all FPCs and PICs installed in the router chassis, including the hardware version level and serial number.

The **detail** option displays detailed information about hardware, including memory, hardware version level, serial number, and additional information about memory.

If the Routing Engine is identified by a 10- and 16-digit serial number, both numbers are displayed in the output for the **detail** option, and are especially important when processing an RMA for such a Routing Engine. In addition, when you request an RMA for the M40 router, include the **maxicab** serial number.

Table 68 on page 1721 provides a description of all the output fields for the **show chassis hardware** command.

Table 68: Output fields for the show chassis hardware command

Output field	Description
Item	(For M-series routers) Chassis component. Information is displayed about the backplane; power supplies; Routing Engine; maxicab (the connection between the Routing Engine and the backplane, for the M40 router only); System Control Board (SCB), System and Switch Board (SSB), Switching and Forwarding Module (SFM), or Forwarding Engine Board (FEB); Miscellaneous Control Subsystem (MCS) and PFE clock generator (PCG) (for the M160 router only); and each FPC and PIC. (For T-series platforms) Chassis component. Information is displayed about the backplane, power supplies, midplane, Control Board (CB), Connector Interface Panel (CIP), FPC, Front Panel Module (FPM) (craft interface), Power Entry Module (PEM), PIC, SONET Clock Generator (SCG), Small Form-factor Pluggable (SFP) modules, Switch Interface Board (SIB), and Switch Processor Mezzanine Board (SPMB).
Version	Revision level of the chassis component.
Part number	Part number of the chassis component.

Table 68: Output fields for the show chassis hardware command (continued)

Output field	Description
Serial number	Serial number of the chassis component. For all RMAs, the chassis serial number must be provided to JTAC. If the RMA is for the chassis itself, you must obtain the backplane or midplane serial number as well.
Description	Brief description of the hardware item.

NOTE: When you request an RMA, you must also include output from the **show chassis environment** command, the **show version** command, and the troubleshooting output used to identify the failure.

Maintain a Single Configuration File for Both Routing Engines

Purpose For routers that support multiple Routing Engines, you can specify **re0** and **re1** as group names to ensure that the correct IP addresses are used for each Routing Engine and to maintain a single configuration file for both Routing Engines. It is important that the names of the Routing Engines correspond to a slot position because the names **re0** and **re1** are special group names that you must use for the Routing Engines to recognize which configuration statement to use. Routing Engine 0 must be in slot position 0 and must be named **re0**, and Routing Engine 1 must be in slot position 1 and must be named **re1.**

To maintain a single configuration file for both Routing Engines, follow these steps:

1. Configure the New Group on page 1722
2. Apply the New Group on page 1724

Configure the New Group

Purpose Each **re0** or **re1** group typically contains, at a minimum, the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Action To configure the **re0** and **re1** groups, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit groups
```

2. Configure the group:

```
[edit groups]
user@host# set group-name
```

For example:

```
[edit groups]
user@host#  set re0
```

3. To configure the management interface, go to the following hierarchy level:

```
[edit groups]
user@host# edit groups re0
```

4. Include the following statement:

```
[edit groups re0]
user@host#  set interfaces interface-name unit unit family inet address address
```

For example:

```
[edit groups re0]
user@host# set interfaces fxp0 unit 0 family inet address 1.1.1.1/24
```

5. To configure the hostname, go to the following hierarchy level:

```
[edit groups re0]
user@host# edit groups re0 system
```

6. Include the following statement:

```
[edit groups re0 system]
user@host#  set host-name hostname
```

For example:

```
[edit groups re0 system]
user@host# set host-name foo-re0
```

7. Verify the configuration:

```
[edit groups re0]
user@host# show
re0 {
   system {
      host-name foo-re0;
   }
   interfaces {
      fxp0 {
         unit 0 {
            family inet {
               address 1.1.1.1/24;
            }
         }
      }
   }
}
```

8. Commit the configuration:

```
user@host# commit
```

9. Repeat Step 1 through Step 8 for the **re1** group.

Meaning The sample output in Step 7 shows that the **re0** group contains the minimum configuration for a group, the hostname, and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Apply the New Group

Action To apply the **re0** group to maintain a single configuration file for both Routing Engines, follow these steps:

1. In configuration mode, go to the top hierarchy level and include the following statement:

```
user@host# [edit]
```

```
user@host# set apply-groups group-name
```

For example:

```
user@host# [edit]
```

```
user@host# set apply-groups re0
```

2. Verify the configuration:

```
user@host# show
```

```
groups {
    re0 {
        system {
            host-name foo-re0;
        }
        interfaces {
            fxp0 {
                unit 0 {
                    family inet {
                        address 1.1.1.1/24;
                    }
                }
            }
        }
    }
    re1 {
        system {
            host-name foo-re1;
```

```
    }
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address 1.1.1.2/24;
          }
        }
      }
    }
  }
}
apply-groups [ re0 re1 ];
```

3. Commit the configuration:

```
user@host# commit
```

Meaning The sample output shows that each group, **re0** and **re1**, has its own IP address that is used for each Routing Engine to maintain a single configuration file.

Configure the New Group

Purpose Each **re0** or **re1** group typically contains, at a minimum, the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Action To configure the **re0** and **re1** groups, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit groups
```

2. Configure the group:

```
[edit groups]
user@host# set group-name
```

For example:

```
[edit groups]
user@host#  set re0
```

3. To configure the management interface, go to the following hierarchy level:

```
[edit groups]
user@host# edit groups re0
```

4. Include the following statement:

```
[edit groups re0]
user@host#  set interfaces interface-name unit unit family inet address address
```

   For example:

```
[edit groups re0]
user@host# set interfaces fxp0 unit 0 family inet address 1.1.1.1/24
```

5. To configure the hostname, go to the following hierarchy level:

```
[edit groups re0]
user@host# edit groups re0 system
```

6. Include the following statement:

```
[edit groups re0 system]
user@host#  set host-name hostname
```

   For example:

```
[edit groups re0 system]
user@host# set host-name foo-re0
```

7. Verify the configuration:

```
[edit groups re0]
user@host# show
re0 {
  system {
    host-name foo-re0;
  }
  interfaces {
    fxp0 {
      unit 0 {
        family inet {
          address 1.1.1.1/24;
        }
      }
    }
  }
}
```

8. Commit the configuration:

```
user@host# commit
```

9. Repeat Step 1 through Step 8 for the **re1** group.

Meaning The sample output in Step 7 shows that the **re0** group contains the minimum configuration for a group, the hostname, and the management interface (**fxp0**). If each Routing Engine

uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Apply the New Group

Action To apply the **re0** group to maintain a single configuration file for both Routing Engines, follow these steps:

1. In configuration mode, go to the top hierarchy level and include the following statement:

```
user@host# [edit]
```

```
user@host# set apply-groups group-name
```

For example:

```
user@host# [edit]
```

```
user@host# set apply-groups re0
```

2. Verify the configuration:

```
user@host# show
```

```
groups {
    re0 {
        system {
            host-name foo-re0;
        }
        interfaces {
            fxp0 {
                unit 0 {
                    family inet {
                        address 1.1.1.1/24;
                    }
                }
            }
        }
    }
    re1 {
        system {
            host-name foo-re1;
        }
        interfaces {
            fxp0 {
                unit 0 {
                    family inet {
                        address 1.1.1.2/24;
                    }
                }
            }
```

```
    }
  }
}
apply-groups [ re0 re1 ];
```

3. Commit the configuration:

```
user@host# commit
```

Meaning The sample output shows that each group, **re0** and **re1**, has its own IP address that is used for each Routing Engine to maintain a single configuration file.

List Files and Directories on a Router

Problem **Description:** If a system board crashes, you must check that certain files are in specific directories.

Solution To display files in the **/var/tmp** and **var/crash** directories, use the following CLI operational mode command:

```
user@host> file list filename or directory
```

Sample Output

```
sampled.pkts
vi.recover/
user@host> file list /var/crash/
bounds
minfree
vmcore.0
```

Meaning The sample output shows the files in the **/var/tmp/** and **/var/crash/** directories. The Juniper Networks Technical Assistance Center (JTAC) can ask you to verify the existence of similar files.

Display File Contents

Purpose To display the contents of a file on the local router.

Action To display the contents of a file on the local router, use the following CLI operational mode command:

```
user@host> file show filename
```

Sample Output

```
user@host> file show /var/log/messages
Apr 13 21:00:08 romney /kernel: so-1/1/2: loopback suspected; going to standby.
Apr 13 21:00:40 romney /kernel: so-1/1/2: loopback suspected; going to standby.
Apr 13 21:02:48 romney last message repeated 4 times
Apr 13 21:07:04 romney last message repeated 8 times
Apr 13 21:07:13 romney /kernel: so-1/1/0: Clearing SONET alarm(s) RDI-P
Apr 13 21:07:29 romney /kernel: so-1/1/0: Asserting SONET alarm(s) RDI-P
Apr 13 21:07:36 romney /kernel: so-1/1/2: loopback suspected; going to standby.
Apr 13 21:08:08 romney /kernel: so-1/1/2: loopback suspected; going to standby.
...Output truncated...
```

Meaning The sample output shows the contents of the **/var/log/messages** file.

Rename a File on a Router

Action To rename a file on the local router, use the following CLI operational mode command:

```
user@host> file rename source destination
```

Sample Output

```
user@host> file list /var/tmp
dcd.core
rpd.core
snmpd.core

user@host> file rename /var/tmp/dcd.core /var/tmp/dcd.core.990413
user@host> file list /var/tmp
dcd.core.990413
rpd.core
snmpd.core
```

Meaning The sample output shows that the **dcd.core** file was renamed to **dcd.core.990413**. The original name of the file is the ***source*** and the new name for the file is the ***destination***.

Delete a File on a Router

Action To delete a file on the local router, use the following CLI operational mode command:

```
user@host> file delete filename
```

Sample Output

```
user@host> file list /var/tmp
dcd.core
rpd.core
snmpd.core

user@host> file delete /var/tmp/snmpd.core
user@host> file list /var/tmp
dcd.core
rpd.core
```

Meaning The sample output shows that the **snmpd.core** file was deleted.

Check the Time on a Router

Purpose Display the current time on a router and display information about how long the router, router software, and routing protocols have been running.

Action To check time on a router, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show system uptime
```

Sample Output

```
user@host> show system uptime
Current time:      1998-10-13 19:45:47 UTC
System booted:     1998-10-12 20:51:41 UTC (22:54:06 ago)
Protocols started: 1998-10-13 19:33:45 UTC (00:12:02 ago)
Last configured:   1998-10-13 19:33:45 UTC (00:12:02 ago) by abc
12:45PM  up 22:54, 2 users, load averages: 0.07, 0.02, 0.01
```

Meaning The sample output shows the current system time in UTC, the date and time when the router was last booted and how long it has been running, when the routing protocols were last started and how long they have been running, when a configuration was last committed, and the name of the user who issued the last **commit** command. If a different time zone is configured, the output shows that time zone. For information on configuring the time zone, see the *Junos System Basics Configuration Guide*.

The sample output shows that the current time is 12:45 PM, the router has been operational for 22:54 hours, and two users are logged in to the router. The output also shows that the load average is 0.07 seconds for the last minute, 0.02 seconds for the last 5 minutes, and 0.01 seconds for the last 15 minutes.

Check for Users in Configuration Mode

Purpose Before you change the configuration or commit a candidate configuration, it is a good idea to check for users in configuration mode.

Action To display users currently editing the configuration, follow these steps:

1. To enter configuration mode, type the following command:

```
user@host> edit
```

2. Enter the following configuration mode command:

```
[edit]
user@host# status
```

For example:

```
user@host> show system users
4:58PM PST up 5 days,  9:52, 5 users, load averages: 0.01, 0.01, 0.00
USER     TTY      FROM                              LOGIN@  IDLE WHAT
mwazna   p0       bigpunk.juniper.net              4:58PM      - -cli (cli)

jgchan   p1       bigpunk.juniper.net              2:25PM   2:32 -csh (csh)

jgchan   p2       bigpunk.juniper.net              2:35PM   2:18 cli

taffy    p3       bigpunk.juniper.net              3:28PM      5 -cli (cli)

tmauro   p4       bigpunk.juniper.net              4:16PM     37 cli
```

Sample Output

Meaning The sample output lists the users who are currently logged in to the router. Five users are logged in to the router, with one user logged in twice, **jgchan**. Each user is logged in through a different terminal (**TTY**—**p0**, **p1**, **p2**, **p3**, and **p4**) from the system **bigpunk.juniper.net**. A hyphen in the **FROM** field indicates that the user logged in through the console.

Additional information includes the time when the user logged in (**LOGIN**), the amount of time the user is not active on the router (**IDLE**), and the processes that the user is running (**WHAT**). In this example, the users are running the command-line interface (**cli**) and the UNIX-level shell (**csh**).

Check the Commands That Users Are Entering

Purpose A common set of operations you can check is when users log in to the router and the CLI commands they issue.

To check the commands that users are entering, follow these steps:

1. Configure the Log File for Tracking CLI Commands on page 1732
2. Display the Configured Log File on page 1733

Configure the Log File for Tracking CLI Commands

Action To configure the log file for tracking CLI commands, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit system syslog
```

2. Configure the log file:

```
[edit system syslog]
user@host# edit file filename
```

For example:

```
[edit system syslog]
user@host# edit file cli-commands
```

3. Configure the interactive-commands facility and severity level:

```
[edit system syslog  filename]
user@host# set interactive-commands info
```

4. Verify the configuration:

```
[edit system syslog]
user@host# show
file cli-commands {
   interactive-commands info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Meaning The configuration example shows that the log file **cli-commands** is configured with the **interactive-commands** facility at the **info** severity level. Table 69 on page 1732 lists and describes the severity levels.

Table 69: Severity Levels

Severity Level	Description
info	Log all top-level CLI commands, including the **configure** command, and all configuration mode commands.

Table 69: Severity Levels (continued)

Severity Level	Description
notice	Log the configuration mode commands **rollback** and **commit**.
warning	Log when any software process restarts.

Display the Configured Log File

Purpose To display the log file in configuration mode, enter the following command:

Action

```
[edit system syslog]
user@host# run show log filename
```

For example:

```
[edit system syslog]
user@host# run show log cli-commands
```

Sample Output

```
[edit system syslog]
user@host# run show log cli-commands
Sep 16 11:24:25  nut mgd[3442]: UI_COMMIT_PROGRESS: commit: signaling 'Syslog
daemon', pid 2457, signal 1, status 0
Sep 16 11:24:25  nut mgd[3442]: UI_COMMIT_PROGRESS: commit: signaling 'SNMP
daemon', pid 2592, signal 31, status 0
Sep 16 11:28:36  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'run
show log cli-commands '
Sep 16 11:30:39  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'run
show log security '
Sep 16 11:31:26  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'run
show log messages '
Sep 16 11:41:21  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'edit
 file cli-commands '
Sep 16 11:41:25  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'show
 '
Sep 16 11:44:57  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'set
interactive-commands info '
Sep 16 14:32:15  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'run
show log cli-commands '
```

Meaning The sample output shows the CLI commands that were entered since the log file was configured.

Configure the Log File for Tracking CLI Commands

Action To configure the log file for tracking CLI commands, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit system syslog
```

2. Configure the log file:

```
[edit system syslog]
user@host# edit file filename
```

   For example:

```
[edit system syslog]
user@host# edit file cli-commands
```

3. Configure the interactive-commands facility and severity level:

```
[edit system syslog  filename]
user@host# set interactive-commands info
```

4. Verify the configuration:

```
[edit system syslog]
user@host# show
file cli-commands {
   interactive-commands info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Meaning The configuration example shows that the log file **cli-commands** is configured with the **interactive-commands** facility at the **info** severity level. Table 69 on page 1732 lists and describes the severity levels.

Table 70: Severity Levels

Severity Level	Description
info	Log all top-level CLI commands, including the **configure** command, and all configuration mode commands.
notice	Log the configuration mode commands **rollback** and **commit**.
warning	Log when any software process restarts.

Check When the Last Configuration Change Occurred

Purpose When a problem occurs on a router, it is a good idea to check when the last configuration change was made because it may have had some influence on the problem.

To check when the last configuration change occurred, follow these steps:

1. Configure Configuration Change Tracking on page 1735
2. Display the Configured Log File on page 1735

Configure Configuration Change Tracking

Action To configure this type of logging, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit system syslog
```

2. Configure the log file:

```
[edit system syslog]
user@host# edit file filename
```

For example:

```
[edit system syslog]
user@host# edit file mw-configuration-changes
```

3. Configure the change-log facility and severity level:

```
[edit system syslog filename]
user@host# set change-log info
```

4. Verify the configuration:

```
[edit system syslog]
user@host# show
file mw-configuration-changes {
   change-log info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Display the Configured Log File

Purpose To display the log file in configuration mode.

Action To display the log file in configuration mode, enter the following command:

```
[edit system syslog]
user@host# run show log filename
```

For example:

```
[edit system syslog]
user@host# run show log mw-configuration-changes
```

Sample Output

```
[edit system syslog]
user@host# run show log mw-configuration-changes
Sep 17 07:03:22  nut mgd[7793]: UI_CFG_AUDIT_OTHER: User 'root' override:
/config/juniper.conf
Sep 17 07:07:21  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [interfaces
 lo0 unit 0 family inet address 127.0.0.1/32]
Sep 17 07:07:21  nut mgd[2751]: UI_CFG_AUDIT_SET: User 'root' set: [system
domain-name] "englab.company.net" -> "englab.company.net"
Sep 17 07:07:21  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [system
name-server 172.17.28.101]
Sep 17 07:07:22  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [system
domain-search] "englab.company.net"
Sep 17 07:07:22  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [system
domain-search] "company.net"
Sep 17 07:07:22  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [system
domain-search] "jnpr.net"
```

Meaning The sample output shows the contents of the log file and that the last configuration change was on September 17 at 07:07:22.

Configure Configuration Change Tracking

Action To configure this type of logging, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit system syslog
   ```

2. Configure the log file:

   ```
   [edit system syslog]
   user@host# edit file filename
   ```

   For example:

   ```
   [edit system syslog]
   user@host# edit file mw-configuration-changes
   ```

3. Configure the change-log facility and severity level:

   ```
   [edit system syslog filename]
   user@host# set change-log info
   ```

4. Verify the configuration:

```
[edit system syslog]
user@host# show
file mw-configuration-changes {
   change-log info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Display a Log File

Purpose To look at a log or trace file.

Action To look at a log or trace file, use the following Junos OS CLI operational mode command:

```
user@host> show log filename
```

Sample Output

```
user@host> show log messages
Sep 10 07:00:00 host newsyslog[7249]: logfile turned over
Sep 10 07:01:49 host rpd[6451]: bgp_listen_accept: Connection attempt from

Sep 10 07:21:33 host rpd[6451]: bgp_listen_accept: Connection attempt from
unconfigured neighbor:
```

Meaning The sample output shows the **rpd** log messages in the **messages** file for September 10 from 7:00 to 7:21 AM.

NOTE: Local log files are saved in the /var/log directory.

Configure IS-IS-Specific Options

Purpose When unexpected events or problems occur, or if you want to diagnose IS-IS adjacency establishment issues, you can view more detailed information by configuring options specific to IS-IS.

To configure IS-IS options, follow these steps:

1. Displaying Detailed IS-IS Protocol Information on page 1738
2. Displaying Sent or Received IS-IS Protocol Packets on page 1740
3. Analyzing IS-IS Link-State PDUs in Detail on page 1741

Displaying Detailed IS-IS Protocol Information

Action To trace IS-IS messages in detail, follow these steps:

1. Configure the flag to display detailed IS-IS protocol messages.

```
[edit protocols isis traceoptions]
user@host#  set flag hello detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 10k files 10;
flag hello detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
```

```
Nov 29 23:17:50 trace_on: Tracing to "/var/log/isislog" started
Nov 29 23:17:50 Sending PTP IIH on so-1/1/1.0
Nov 29 23:17:53 Sending PTP IIH on so-1/1/0.0
Nov 29 23:17:54 Received PTP IIH, source id abc-core-01 on so-1/1/0.0
Nov 29 23:17:54     from interface index 11
Nov 29 23:17:54     max area 0, circuit type l2, packet length 4469
Nov 29 23:17:54     hold time 30, circuit id 6
Nov 29 23:17:54     neighbor state up
```

```
Nov 29 23:17:54     speaks IP
Nov 29 23:17:54     area address 99.0008 (1)
Nov 29 23:17:54     IP address 10.10.10.29
Nov 29 23:17:54     4396 bytes of total padding
Nov 29 23:17:54     updating neighbor abc-core-01
Nov 29 23:17:55 Received PTP IIH, source id abc-core-02 on so-1/1/1.0
Nov 29 23:17:55     from interface index 12
Nov 29 23:17:55     max area 0, circuit type l2, packet length 4469
Nov 29 23:17:55     hold time 30, circuit id 6
Nov 29 23:17:55     neighbor state up
Nov 29 23:17:55     speaks IP
Nov 29 23:17:55     area address 99.0000 (1)
Nov 29 23:17:55     IP address 10.10.10.33
Nov 29 23:17:55     4396 bytes of total padding
Nov 29 23:17:55     updating neighbor abc-core-02
```

Meaning Table 71 on page 1739 lists tracing flags that can be configured specific to IS-IS and presents example output for some of the flags.

Table 71: IS-IS Protocol Tracing Flags

Tracing Flags	Description	Example Output
csn	Complete sequence number PDU (CSNP)	**Nov 28 20:02:48 Sending L2 CSN on interface so-1/1/0.0Nov 28 20:02:48 Sending L2 CSN on interface so-1/1/1.0** With the **detail** option. **Nov 28 20:06:08 Sending L2 CSN on interface so-1/1/1.0Nov 28 20:06:08 LSP abc-core-01.00-00 lifetime 1146Nov 28 20:06:08 sequence 0x1c4f8 checksum 0xa1e9Nov 28 20:06:08 LSP abc-core-02.00-00 lifetime 411Nov 28 20:06:08 sequence 0x7435 checksum 0x5424Nov 28 20:06:08 LSP abc-brdr-01.00-00 lifetime 465Nov 28 20:06:08 sequence 0xf73 checksum 0xab10Nov 28 20:06:08 LSP abc-edge-01.00-00 lifetime 1089Nov 28 20:06:08 sequence 0x1616 checksum 0xdb29Nov 28 20:06:08 LSP abc-edge-02.00-00 lifetime 1103Nov 28 20:06:08 sequence 0x45cc checksum 0x6883**
hello	Hello packet	**Nov 28 20:13:50 Sending PTP IIH on so-1/1/1.0Nov 28 20:13:50 Received PTP IIH, source id abc-core-01 on so-1/1/0.0Nov 28 20:13:53 Received PTP IIH, source id abc-core-02 on so-1/1/1.0Nov 28 20:13:57 Sending PTP IIH on so-1/1/0.0Nov 28 20:13:58 Received PTP IIH, source id abc-core-01 on so-1/1/0.0Nov 28 20:13:59 Sending PTP IIH on so-1/1/1.0**

Displaying Sent or Received IS-IS Protocol Packets

To configure the tracing for only sent or received IS-IS protocol packets, follow these steps:

1. Configure the flag to display sent, received, or both sent and received packets.

```
[edit protocols isis traceoptions]
user@host# set flag hello send
```

or

```
[edit protocols isis traceoptions]
user@host# set flag hello receive
```

or

```
[edit protocols isis traceoptions]
user@host# set flag hello
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 10k files 10;
flag hello send;
```

or

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 10k files 10;
flag hello receive;
```

or

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 10k files 10;
flag hello send receive;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
Sep 27 18:17:01 ISIS periodic xmit to 01:80:c2:00:00:15 (IFL 2)
Sep 27 18:17:01 ISIS periodic xmit to 01:80:c2:00:00:14 (IFL 2)
Sep 27 18:17:03 ISIS periodic xmit to 01:80:c2:00:00:15 (IFL 2)
Sep 27 18:17:04 ISIS periodic xmit to 01:80:c2:00:00:14 (IFL 2)
Sep 27 18:17:06 ISIS L2 hello from 0000.0000.0008 (IFL 2) absorbed
Sep 27 18:17:06 ISIS periodic xmit to 01:80:c2:00:00:15 (IFL 2)
Sep 27 18:17:06 ISIS L1 hello from 0000.0000.0008 (IFL 2) absorbed
```

Analyzing IS-IS Link-State PDUs in Detail

To analyze IS-IS link-state PDUs in detail, follow these steps:

1. Configure IS-IS open messages.

```
[edit protocols isis traceoptions]
user@host# set flag lsp detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 5m world-readable;
flag error;
flag lsp detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host#  run show log isislog
Nov 28 20:17:24 Received L2 LSP abc-core-01.00-00, interface so-1/1/0.0

Displaying Detailed IS-IS Protocol Information

Action To trace IS-IS messages in detail, follow these steps:

1. Configure the flag to display detailed IS-IS protocol messages.

```
[edit protocols isis traceoptions]
user@host#  set flag hello detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 10k files 10;
flag hello detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
```

```
Nov 29 23:17:50 trace_on: Tracing to "/var/log/isislog" started
Nov 29 23:17:50 Sending PTP IIH on so-1/1/1.0

Analyzing IS-IS Link-State PDUs in Detail

To analyze IS-IS link-state PDUs in detail, follow these steps:

1. Configure IS-IS open messages.

```
[edit protocols isis traceoptions]
user@host# set flag lsp detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 5m world-readable;
flag error;
flag lsp detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
Nov 28 20:17:24 Received L2 LSP abc-core-01.00-00, interface so-1/1/0.0

Configure OSPF-Specific Options

Purpose When unexpected events or problems occur, or if you want to diagnose OSPF neighbor establishment issues, you can view more detailed information by configuring options specific to OSPF.

To configure OSPF options, follow these steps:

1. Diagnose OSPF Session Establishment Problems on page 1748
2. Analyze OSPF Link-State Advertisement Packets in Detail on page 1752

Diagnose OSPF Session Establishment Problems

Action To trace OSPF messages in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols ospf traceoptions
   ```

2. Configure OSPF hello messages:

   ```
   [edit protocols ospf traceoptions]
   user@host# set flag hello detail
   ```

3. Verify the configuration:

   ```
   user@host# show
   ```

   For example:

   ```
   [edit protocols ospf traceoptions]
   user@host# show
   file ospf size 5m world-readable;
   flag hello detail;
   ```

4. Commit the configuration:

```
user@host# commit
```

5. View the contents of the file containing the detailed messages:

```
user@host# run show log filename
```

For example:

```
user@host# run show log ospf
```

```

Analyze OSPF Link-State Advertisement Packets in Detail

Action To analyze OSPF link-state advertisement packets in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols ospf traceoptions
   ```

2. Configure OSPF link-state packages:

   ```
   [edit protocols ospf traceoptions]
   user@host# set flag lsa-update detail
   ```

3. Verify the configuration:

   ```
   user@host# show
   ```

   For example:

   ```
   [edit protocols ospf traceoptions]
   user@host# show
   file ospf size 5m world-readable;
   flag hello detail;
   flag lsa-update detail;
   ```

4. Commit the configuration:

   ```
   user@host# commit
   ```

5. View the contents of the file containing the detailed messages:

   ```
   user@host# run show log filename
   ```

   For example:

```
user@host# run show log ospf
```

```
Dec 2 16:23:47 OSPF sent LSUpdate (4) -> 224.0.0.5 (so-1/1/0.0) ec 2 16:23:47
Version 2, length 196, ID 10.0.0.6, area 0.0.0.0
Dec 2 16:23:47 checksum 0xcc46, authtype 0
Dec 2 16:23:47 adv count 6 Dec 2 16:23:47 OSPF sent LSUpdate (4) -> 224.0.0.5
(so-1/1/1.0)
Dec 2 16:23:47 Version 2, length 196, ID 10.0.0.6, area 0.0.0.0 Dec 2 16:23:47
checksum 0xcc46, authtype 0
Dec 2 16:23:47 adv count 6
```

Diagnose OSPF Session Establishment Problems

Action To trace OSPF messages in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols ospf traceoptions
   ```

2. Configure OSPF hello messages:

   ```
   [edit protocols ospf traceoptions]
   user@host# set flag hello detail
   ```

3. Verify the configuration:

   ```
   user@host# show
   ```

   For example:

   ```
   [edit protocols ospf traceoptions]
   user@host# show
   file ospf size 5m world-readable;
   flag hello detail;
   ```

4. Commit the configuration:

   ```
   user@host# commit
   ```

5. View the contents of the file containing the detailed messages:

   ```
   user@host# run show log filename
   ```

   For example:

   ```
   user@host# run show log ospf
   ```

   ```
   Dec 2 16:14:24 Version 2, length 44, ID 10.0.0.6, area 1.0.0.0

Analyze OSPF Link-State Advertisement Packets in Detail

Action To analyze OSPF link-state advertisement packets in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   ```
   [edit]
   user@host# edit protocols ospf traceoptions
   ```

2. Configure OSPF link-state packages:

   ```
   [edit protocols ospf traceoptions]
   user@host# set flag lsa-update detail
   ```

3. Verify the configuration:

   ```
   user@host# show
   ```

   For example:

   ```
   [edit protocols ospf traceoptions]
   user@host# show
   file ospf size 5m world-readable;
   flag hello detail;
   flag lsa-update detail;
   ```

4. Commit the configuration:

   ```
   user@host# commit
   ```

5. View the contents of the file containing the detailed messages:

   ```
   user@host# run show log filename
   ```

For example:

```
user@host# run show log ospf
```

```
Dec 2 16:23:47 OSPF sent LSUpdate (4) -> 224.0.0.5 (so-1/1/0.0) ec 2 16:23:47
Version 2, length 196, ID 10.0.0.6, area 0.0.0.0

Dec 2 16:23:47 adv count 6
```

Chassis

Chassis dimensions are listed in the physical specifications table for each router. For more information about chassis dimensions, see the router platform-specific hardware guide.

Each Juniper Networks router features a rigid sheet metal chassis that houses all of the router components. The chassis are designed to install into a variety of racks, including standard 19-inch equipment racks, telco center-mount racks, and four-post racks and cabinets. See Table 75 on page 1758 for the maximum number of each router type that can be installed into a rack. Each chassis includes mounting ears or support posts to facilitate rack mounting, and one or more points for connecting an electrostatic discharge (ESD) wrist strap for use when servicing the router.

Table 75: Maximum Number of Routers per Rack

Router or Routing Node	Maximum in Standard Rack
T640	2
T320	3
M160	2
M40e	2
M40	2
M20	5
M5 and M10	14

Each chassis includes a midplane (called the backplane on an M40 router). The midplane transfers data packets to and from the FPCs, distributes power to router components, and provides signal connectivity to the router components for system monitoring and control.

Physical Interface Cards

Juniper Networks M-series routers and T-series platforms use PICs to connect to a wide variety of network media. PICs receive incoming packets from the network and transmit outgoing packets to the network, performing framing and line-speed signaling for their specific media type. Before transmitting outgoing data packets, the PICs encapsulate the packets received from the FPCs. Each PIC is equipped with an ASIC that performs control functions specific to the PIC's media type. For information about PICs, see the specific PIC guide.

Routing Engine

The Routing Engine consists of an Intel-based PCI platform running the Junos OS. The Routing Engine maintains the routing tables used by the router in which it is installed and controls the routing protocols on the router. The T640 routing node, and the T320, M160, M40e, and M20 routers support up to two Routing Engines, while the M40, M10, and M5 routers support a single Routing Engine.

Each Routing Engine consists of a CPU; SDRAM for storage of the routing and forwarding tables and other processes; a compact flash disk for primary storage of software images, configuration files, and microcode; a hard disk for secondary storage; a PC card slot (on some M40 routers, a floppy disk) for storage of software upgrades; and interfaces for out-of-band management access.

Compare Information Logged Before and After the Reinstall

Purpose Compare the operation of the system before and after the reinstall to ensure that everything is working as expected.

Action To obtain system information, use the following commands:

```
user@host> show version
user@host> show chassis hardware
user@host> show chassis environment
user@host> show system boot-messages
user@host> show configuration
user@host> show interface terse
user@host> show bgp summary
user@host> show isis adjacency brief
user@host> show ospf neighbor brief
user@host> show system storage
```

Compare the information from these commands with the information you obtained before the reinstall.

Back Up the New Software

Purpose After a week or so, when you are satisfied that the new software is running successfully, we recommend that you back up the reinstalled software.

Action To back up the reinstalled software, use the following Junos OS CLI operational mode command:

```
user@host> request system snapshot
```

The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Monitor Hardware Components

Purpose

NOTE: If the System Control Board (SCB), System and Switch Board (SSB), or Forwarding Engine Board (FEB) is not running, information about chassis components is not available through the command-line interface (CLI).

Action To use the CLI to monitor Juniper Networks routers, follow these steps:

1. Log in to the router. The CLI operational mode prompt (>) appears.

   If the operational mode prompt does not appear when you log in to the router, type **cli** to start the Junos OS and enter operational mode. The prompt changes to **>**, indicating that you are in operational mode.

2. Use one of the operational mode CLI commands listed in *Operational Mode CLI Commands for Router Monitoring* to monitor router hardware.

Log Software Version Information

Purpose To log the Junos OS version information.

Action To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output `user@host>` **show version**

```

Hardware Components

Each Juniper Networks router consists of a chassis and a set of components, including FPCs, PICs, Routing Engines, power supplies, cooling system, and cable management system. Many of the components are field-replaceable units. The following major components are discussed in this topic:

Chassis

Chassis dimensions are listed in the physical specifications table for each router. For more information about chassis dimensions, see the router platform-specific hardware guide.

Each Juniper Networks router features a rigid sheet metal chassis that houses all of the router components. The chassis are designed to install into a variety of racks, including standard 19-inch equipment racks, telco center-mount racks, and four-post racks and cabinets. See Table 75 on page 1758 for the maximum number of each router type that can be installed into a rack. Each chassis includes mounting ears or support posts to facilitate rack mounting, and one or more points for connecting an electrostatic discharge (ESD) wrist strap for use when servicing the router.

Table 76: Maximum Number of Routers per Rack

Router or Routing Node	Maximum in Standard Rack
T640	2
T320	3
M160	2
M40e	2
M40	2
M20	5
M5 and M10	14

Each chassis includes a midplane (called the backplane on an M40 router). The midplane transfers data packets to and from the FPCs, distributes power to router components, and provides signal connectivity to the router components for system monitoring and control.

Flexible PIC Concentrators

The FPCs house the PICs used in the router and connect them to other router components. FPCs install into the front of the router in either a vertical or horizontal orientation, depending on the router. A compatible FPC can be installed into any available FPC slot, regardless of the PICs it contains. If a slot is not occupied by an FPC, a blank FPC panel must be installed to shield the empty slot and allow cooling air to circulate properly through the FPC card cage. For information about FPCs, see the specific hardware guide.

Physical Interface Cards

Juniper Networks M-series routers and T-series platforms use PICs to connect to a wide variety of network media. PICs receive incoming packets from the network and transmit outgoing packets to the network, performing framing and line-speed signaling for their

specific media type. Before transmitting outgoing data packets, the PICs encapsulate the packets received from the FPCs. Each PIC is equipped with an ASIC that performs control functions specific to the PIC's media type. For information about PICs, see the specific PIC guide.

Routing Engine

The Routing Engine consists of an Intel-based PCI platform running the Junos OS. The Routing Engine maintains the routing tables used by the router in which it is installed and controls the routing protocols on the router. The T640 routing node, and the T320, M160, M40e, and M20 routers support up to two Routing Engines, while the M40, M10, and M5 routers support a single Routing Engine.

Each Routing Engine consists of a CPU; SDRAM for storage of the routing and forwarding tables and other processes; a compact flash disk for primary storage of software images, configuration files, and microcode; a hard disk for secondary storage; a PC card slot (on some M40 routers, a floppy disk) for storage of software upgrades; and interfaces for out-of-band management access.

Power Supplies

Each Juniper Networks M-series router, T-series platform, or MX-series router has one to four load-sharing power supplies depending on the platform. If a power supply in a redundant configuration is removed or fails, the other power supplies assume the electrical load. For more information about the power supplies in each router, see the router platform-specific hardware guide.

The power supplies are connected to the router midplane, which distributes the different output voltages throughout the router and its components. Some routers can operate using either AC or DC power; other routers operate with DC power only. For information about the type of power used by each router, see the platform-specific hardware guide.

Cooling System

Each Juniper Networks M-series router and T-series platform features a cooling system designed to keep all router components within recommended operating temperature limits. If one component of the cooling system fails or is removed, the system automatically adjusts the speed of the remaining components to keep the temperature within the acceptable range. The cooling system for each router is unique and can consist of fans, impellers, and air filters. For information about the cooling system components of each router, see the "Major Hardware Components" table in the router platform-specific hardware guide.

PART 10

Configuration Statements

CHAPTER 34

MPLS Configuration Statements

abstract-hop

Syntax

```
abstract-hop abstract-hop-name {
  constituent-list constituent-list-name (include-any-list | include-all-list | exclude-all-list
    | exclude-any-list);
  operators (AND | OR);
}
```

Hierarchy Level

```
[edit logical systems logical-systems-name protocols mpls]
[edit protocols mpls]
```

Release Information Statement introduced in Junos OS Release 17.1 for all platforms.

Description Define router clusters or groups, similar to the sequence of real-hop constraints (strict or loose), as a sequence of abstract hops for setting up a label-switched path (LSP).

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes. A path can use a combination of real and abstract hops as constraints.

Options

abstract-hop-name—Name of the abstract hop that is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops.

constituent-list *constituent-list-name*—Name of the predefined constituent list to be included in defining the abstract hop. A constituent list enables you to define a set of constituent attributes that is identified with a user-defined name.

include-any-list—Satisfy any one of the attributes specified in the constituent list.

include-all-list—Satisfy all of the attributes specified in the constituent list.

exclude-all-list—Satisfy none of the attributes specified in the constituent list.

exclude-any-list—Fail to satisfy any one of the attributes specified in the constituent list.

operators—Specify the operation between constituent lists when more than one constituent list is included in the abstract hop definition.

AND—Satisfy all the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

OR—Satisy at least one of the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

adaptive

Syntax
```
adaptive;
```

Hierarchy Level
[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* (primary | secondary) *path-name*],
[edit protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name* (primary | secondary) *path-name*]

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
During reroute, do not double-count bandwidth on links shared by the old and new paths. Including this statement causes RSVP to use shared explicit (SE) reservation styles and assists in smooth transition during rerouting.

Default
The configured object is disabled.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring Adaptive LSPs on page 457

adjust-interval

Syntax

```
adjust-interval seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify the bandwidth reallocation interval.

Options

seconds—Bandwidth reallocation interval, in seconds.

Range: 300 through 315,360,000 seconds

Default: 86,400 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Automatic Bandwidth Allocation Interval on page 445

adjust-threshold

Syntax

```
adjust-threshold percent;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify in percentage how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in bandwidth utilization.

To specify the changes in the automatic bandwidth adjustment for a LSP in absolute value, use the *adjust-threshold-absolute* statement instead.

Options

percent—Bandwidth demand for the current bandwidth adjustment interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the percentage specified by this statement, the LSP's bandwidth is adjusted to the current bandwidth demand.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Automatic Bandwidth Adjustment Threshold on page 447

adjust-threshold-activate-bandwidth

Syntax

```
adjust-threshold-activate-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information Statement introduced before Junos OS Release 14.1.

Description Specify an absolute value to prevent automatic adjustment of signaled bandwidth and aggressive re-signaling of a label-switched path (LSP) when the actual bandwidth over the LSP is below the configured threshold, although the adjust-threshold percentage condition is satisfied.

Options

bps—Amount of bandwidth that is compared with the maximum of all traffic samples during an adjustment interval. If the maximum average bandwidth is less than this configured value, automatic bandwidth adjustment or re-signaling does not happen, even if the adjust-threshold percentage condition is satisfied.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Automatic Bandwidth Adjustment Threshold on page 447

adjust-threshold-overflow-limit

Syntax

```
adjust-threshold-overflow-limit number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced in Junos OS Release 7.5.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify the number of consecutive bandwidth overflow samples before triggering a bandwidth adjustment.

Options

number—Number of consecutive bandwidth overflow samples.

Range: 1 through 65,535

Default: This feature is disabled by default.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring a Limit on Bandwidth Overflow and Underflow Samples on page 447

adjust-threshold-underflow-limit

Syntax
```
adjust-threshold-underflow-limit number;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information
Statement introduced in Junos OS Release 11.3.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description
Specify the number of consecutive bandwidth underflow samples before triggering a bandwidth adjustment.

Options
number—Number of consecutive bandwidth underflow samples.

Range: 1 through 65,535

Default: This feature is disabled by default.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring a Limit on Bandwidth Overflow and Underflow Samples on page 447

admin-down

Syntax
```
admin-down;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information
Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Set a nonpacket GMPLS LSP to the administrative down state. This statement does not affect control path setup or data forwarding for packet LSPs.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS on page 851

admin-group (for Interfaces)

Syntax

```
admin-group [ group-names ];
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls interface *interface-name*],
[edit protocols mpls interface *interface-name*]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Define administrative groups for an interface.

Options

group-names—One or more names of groups defined with the admin-groups statement at the **[edit protocols mpls]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Administrative Groups for LSPs on page 429
- admin-groups on page 1783

admin-group (for LSPs)

Syntax

```
admin-group {
  exclude [ group-names ];
  include-all [ group-names ];
  include-any [ group-names ];
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  (primary | secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Define the administrative groups to include or exclude an LSP and a path's primary and secondary paths.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Administrative Groups for LSPs on page 429

admin-group-extended

Syntax

```
admin-group-extended {

```

Release Information Statement introduced in Junos OS Release 11.1.

Description Specifies the group name and group identifier for an administrative group. The group identifier must be within the range of values specified by the **admin-groups-extended-range** statement. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

apply-groups—Apply the specified administrative groups for the LSP or for the primary and secondary paths.

apply-groups-except—Exclude the specified administrative groups from the LSP or from the primary and secondary paths.

exclude—Define the administrative groups to exclude from an LSP or from the primary and secondary paths.

include-all—Require the LSP to traverse links that include all of the defined administrative groups.

include-any—Define the administrative groups to include for an LSP for the primary and secondary paths.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

admin-groups

Syntax

```
admin-groups {
  group-name group-value;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure administrative groups to implement link coloring of resource classes.

Options

group-name—Name of the group. You can assign up to 32 names. The names and their corresponding values must be identical across all routers within a single domain.

group-value—Value assigned to the group. The names and their corresponding values must be identical across all routers within a single domain.

Range: 0 through 31

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 11.1.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Specifies the group name and group identifier for an administrative group. The group identifier must be within the range of values specified by the **admin-groups-extended-range** statement. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

group-name—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

group-value *group-identifier*—The group identifier must be within the range of configurable values, 32 and 4,294,967,295.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Enables you to configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in IGPs (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. By default, Juniper Networks routers interpret this 32-bit value as a bit mask with each bit representing a group. This normally limits each network to a total of 32 distinct administrative groups (value range 0 through 31).

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

maximum *maximum-number*—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

minimum *minimum-number*—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

advertise-mode (MPLS)

Syntax

```
advertise-mode (stub-alias | stub-proxy);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls egress-protection context-identifier
  context-id],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  egress-protection context-identifier context-id],
[edit protocols mpls egress-protection context-identifier context-id],
[edit protocols mpls label-switched-path lsp-name egress-protection context-identifier
  context-id]
```

Release Information Statement introduced in Junos OS Release 13.3.

Description Configure the method for the interior gateway protocol (IGP) to advertise egress protection availability.

Egress protection availability is advertised in the IGP. Label protocols along with CSPF use this information to do egress protection.

Options

stub-alias—Context identifier has an alias.

In the alias method, the LSP end-point address has an explicit backup egress node where the backup node can be learned or configured on the penultimate hop node (PHN) of a protected LSP. With this model, the PHN of a protected LSP sets up the bypass LSP tunnel to back up the egress node by avoiding the primary egress node. This model requires a Junos OS upgrade in core nodes, but is flexible enough to support all traffic engineering constraints.

stub-proxy—Context-identifier has a stub proxy node.

A stub node is one that only appears at the end of an AS path, which means it does not provide transit service. In this mode, known as the virtual or proxy mode, the LSP end-point address is represented as a node with bidirectional links, with the LSP's primary egress node and backup egress node. With this representation, the penultimate hop of the LSP primary egress point can behave like a PLR in setting up a bypass tunnel to back up the egress by avoiding the primary egress node. This model has the advantage that you do not need to upgrade Junos OS on core nodes and thereby helps operators to deploy this technology.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

allow-fragmentation

Syntax allow-fragmentation;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls path-mtu],
[edit protocols mpls path-mtu]

Release Information Statement introduced before Junos OS Release 7.4.

Description Allow IP packets to be fragmented before they are encapsulated in MPLS.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Enabling Packet Fragmentation*

always-mark-connection-protection-tlv

Syntax

```
always-mark-connection-protection-tlv;
```

Hierarchy Level

[edit logical-systems *logical-systems-name* protocols mpls interface *interface-name*],
[edit protocols mpls interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 10.2.

Description

(MX Series routers only) Enable you to switch an LSP away from a network node using a bypass LSP. This feature could be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.

This statement marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, you then need to configure the **switch-away-lsps** statement.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

associate-backup-pe-groups

Syntax

```
associate-backup-pe-groups;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced in Junos OS Release 9.0.

Description

Enable an LSP to monitor the status of its destination PE router. You can configure multiple backup PE router groups using the same router's address. Backup PE router groups provide ingress PE router redundancy when point-to-multipoint LSPs are configured for multicast distribution. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. This statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to the destination address.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling Point-to-Point LSPs to Monitor Egress PE Routers on page 557

associate-lsp

Syntax

```
associate-lsp lsp-name {
  from from-ip-address;
}
```

Hierarchy Level

[edit protocols mpls label-switched-path *lsp-name* oam]

Release Information

Statement introduced in Junos OS Release 12.1.

Description

Configure associated bidirectional label-switched paths (LSPs) on the two ends of an LSP for sending and receiving GAL and G-Ach OAM messages.

Options

from *from-ip-address*—(Optional) Source address for the associated LSP configuration.

If omitted, this is derived from the **to** address of the ingress LSP configuration.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

auto-bandwidth (MPLS Tunnel)

Syntax

```
auto-bandwidth {
  adjust-interval seconds;
  adjust-threshold percent;
  adjust-threshold-absolute adjust-threshold-absolute-value;
  adjust-threshold-activate-bandwidthbps
  adjust-threshold-overflow-limit number;
  adjust-threshold-underflow-limit number;
  maximum-bandwidth bps;
  minimum-bandwidth bps;
  minimum-bandwidth-adjust-interval
  minimum-bandwidth-adjust-threshold-change
  minimum-bandwidth-adjust-threshold-value
  monitor-bandwidth;
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for QFX Series switches.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Allow an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel.

NOTE: In calculating the value for Max AvgBW (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

Options

adjust-threshold-absolute *adjust-threshold-absolute-value*—Configure an absolute value based threshold along with the percentage based threshold that helps avoid the bandwidth getting triggered for LSPs of both small and large bandwidth reservations.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  class all (drop | loss-priority-high | loss-priority-low);
  class ct number (drop | loss-priority-high | loss-priority-low);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced for QFX10000 Series switches in release 15.1X53-D40.

Description

Enable the automatic policing of all the MPLS LSPs on the router or logical system.

Options

class all—Apply the same policer action to all the class types (**ct0**, **ct1**, **ct2**, and **ct3)**.

class ct*number*—Specific class type (**ct0**, **ct1**, **ct2**, or **ct3)** to which to apply a policer action.

Policer actions—You can specify the following policer actions:

Default: no action

- **drop**—Drop all packets.
- **loss-priority-high**—Set the packet loss priority (PLP) to high.
- **loss-priority-low**—Set the PLP to low.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

bandwidth (Fast Reroute, Signaled, and Multiclass LSPs)

Syntax

```
bandwidth bps {
  ct0 bps;
  ct1 bps;
  ct2 bps;
  ct3 bps;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  fast-reroute],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  (primary | secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name fast-reroute],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

When configuring an LSP, specify the traffic rate associated with the LSP.

When configuring fast reroute, allocate bandwidth for the reroute path. By default, no bandwidth is reserved for the rerouted path. The fast reroute bandwidth does not need to be identical to that allocated for the LSP itself.

When configuring a multiclass LSP, use the **ct*number bandwidth*** statements to specify the bandwidth to be allocated for each class type.

Options

bps—Bandwidth, in bits per second. You can specify this as an integer value. You can also use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

NOTE: On the ACX Series, *bps* is the only supported option.

ct*number bps*—Bandwidth for the specified class type, in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion [also called a thousand million]).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

bandwidth-model

Syntax

```
bandwidth-model {
  extended-mam;
  mam;
  rdm;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls diffserv-te],
[edit protocols mpls diffserv-te]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the bandwidth model for differentiated services. Note that you cannot configure both bandwidth models at the same time.

Options

extended-mam—The extended maximum allocation model (MAM) is a bandwidth model based on MAM.

mam—The MAM is defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

rdm—The Russian dolls bandwidth allocation model (RDM) is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*. RDM makes efficient use of bandwidth by allowing the class types to share bandwidth.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit protocols mpls oam]
```

Release Information

Statement introduced in Junos OS Release 7.6.
failure-action option added in Junos OS Release 8.5.
Statement introduced in Junos OS Release 12.2 for EX Series switches.

Description

Enable Bidirectional Forwarding Detection (BFD) for all of the MPLS LSPs or for just a specific LSP.

Options

minimum-interval—Minimum transmit and receive interval.

Range: 50 through 255,000 milliseconds

Default: 50

minimum-receive-interval—Minimum receive interval.

Range: 50 through 255,000 milliseconds

Default: 50

minimum-transmit-interval—Minimum transmit interval.

Range: 50 through 255,000 milliseconds

Default: 50

multiplier—Detection time multiplier.

Range: 1 through 255

Default: 3

The **failure-action** statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Class-of-service (CoS) value given to all packets in the LSP.

The CoS value might affect the scheduling or queuing algorithm of traffic traveling along an LSP.

Options

cos-value—CoS value. A higher value typically corresponds to a higher level of service.

Range: 0 through 7

Default: If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

```
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Configure a multi-label-switched path (LSP) tunnel between the ingress and the egress routers. The container LSP consists of several member LSPs to the same destination.

Options

disable—Disable MPLS container-label-switched path.

description *description*—Text describing the container LSP.

suffix *string*—Suffix to generate names of member LSPs of the container LSP.

to *ip-address*—IP address of the egress router.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

corouted-bidirectional

Syntax

```
corouted-bidirectional;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify that the label-switched path be established as a corouted bidirectional packet LSP. You cannot configure this statement at the same time as the **corouted-bidirectional-passive** statement.

Default

This statement is disabled by default.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Corouted Bidirectional LSPs on page 463
- corouted-bidirectional-passive on page 1805

corouted-bidirectional-passive

Syntax
```
corouted-bidirectional-passive;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information
Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Specify that the label-switched path be a passive LSP associated with a bidirectional LSP when it is signaled at the ingress router. This passive LSP enables the MPLS application to utilize the reverse LSP. You cannot configure this statement at the same time as the **corouted-bidirectional** statement.

Default
This statement is disabled by default.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

credibility

Syntax

```
credibility {
  direct;
  isis-level-1;
  isis-level-2;
  ospf;
  static;
  unknown;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls traffic-engineering database
  export],
[edit protocols mpls traffic-engineering database export]
```

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced in Junos OS Release 17.1R1 on QFX Series and QFX10000 switches.

Description

Configure preference values for entries from BGP-TE to the traffic engineering database. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value.

The credibility order for the BGP-TE protocols is as follows:

- **Unknown**—80
- **OSPF**—81
- **ISIS Level 1**—82
- **ISIS Level 2**—83
- **Static**—84
- **Direct**—85

Options

direct— Entries sourced from directly connected links.

isis-level-1—Entries sourced from IS-IS Level 1.

isis-level-2—Entries sourced from IS-IS Level 2.

ospf—Entries sourced from OSPF.

static—Entries sourced from static configuration.

unknown—Entries sourced from unknown entities.
Range: 0 through 512

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- traffic-engineering on page 1987

database

Syntax

```
database {
  export;
  import;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls traffic-engineering],
[edit protocols mpls traffic-engineering]

Release Information
Statement introduced in Junos OS Release 14.2.
Statement introduced in Junos OS Release 17.1R1 for QFX Series and QFX10000 switches.

Description
Include link and node entries from the traffic engineering database into the **lsdist.0** routing information base (RIB), so it gets picked up by the BGP export policy.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- traffic-engineering on page 1987

delay (querier)

Syntax

```
delay {
  traffic-class tc-value {
    average-sample-size sample size;
    padding-size size;
    query-interval milliseconds;
    rtt-delay-threshold rtt threshold value;
    twcd-delay-threshold twcd threshold value;
  }
}
```

Hierarchy Level

[edit protocols mpls oam performance-monitoring querier],
[edit protocols mpls label-switched-path *lsp-name* oam performance-monitoring querier],
[edit protocols mpls label-switched-path *lsp-name* primary *path-name* oam performance-monitoring querier],
[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam performance-monitoring querier]

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure delay measurement options.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

delay (responder)

Syntax

```
delay {
  min-query-interval milliseconds;
}
```

Hierarchy Level

[edit protocols mpls oam performance-monitoring responder],
[edit protocols mpls label-switched-path *lsp-name* oam performance-monitoring responder],
[edit protocols mpls label-switched-path *lsp-name* primary *path-name* oam performance-monitoring responder],
[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam performance-monitoring responder]

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure delay measurement options.

Options

min-query-interval *milliseconds*—(Optional) Specify the minimum query interval that the responder supports. If the minimum query interval of the responder is greater than the query interval configured at querier, the effective message query rate will be the minimum query interval configured for the responder.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

deselect-on-bandwidth-failure

Syntax

```
deselect-on-bandwidth-failure {
  tear-lsp;
}
```

Hierarchy Level

[edit protocols mpls],
[edit protocols mpls label-switched-path *path-name*]

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Deselect an active path if it does not meet the auto-bandwidth criteria required for path selection. The **deselect-on-bandwidth-failure** statement does not apply to static bandwidth.

Options

tear-lsp— Bring down an active path if none of the paths are able to reserve the required bandwidth.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

diffserv-te

Syntax

```
diffserv-te {
  bandwidth-model {
    extended-mam;
    mam;
    rdm;
  }
  te-class-matrix {
    tenumber {
      priority priority;
      traffic-class {

dual-transport

Syntax

```
dual-transport {
  inet-lsr-id inet-lsr-id;
  inet6-lsr-id inet6-lsr-id;
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information Statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description Configure to allow Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. **inet-lsr-id** and **inet6-lsr-id** are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Options

inet-lsr-id *inet-lsr-id*— Configure the LSR ID to establish an LDP session over IPv4 TCP transport.

inet6-lsr-id *inet6-lsr-id*— Configure the LSR ID to establish an LDP session over IPv6 TCP transport.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  routing-options],
[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Configure a dynamic tunnel between two PE routers.

NOTE: ACX Series routers do not support the gre statement.

Options

tunnel-name—Name of the dynamic tunnel.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

egress-protection (MPLS)

Syntax

```
egress-protection {
  context-identifier context-id {
    primary | protector;
    metric igp-metric-value;
    advertise-mode (stub-alias | stub-proxy);
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 10.4.
Options **primary**, **protector**, and **metric** introduced in Junos OS Release 11.4R3.
Option **advertise-mode** introduced in Junos OS Release 13.3.

Description

Enables an Edge Protection Virtual Circuit (EPVC) for the MPLS protocol.

Options

context-identifier *context-id-ip-address*—(Optional) The context identifier IPv4 address.

metric *igp-metric-value*—(Optional) The IGP metric value ranging from **2** through **16777215**.

(primary | protector)—On the primary PE router, configure as type **primary**. On the protector PE router, configure as type **protector**.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances routing-instance-name protocols vpls neighbor address]
```

Release Information

Statement introduced in Junos OS Release 9.2.
Statement introduced in Junos OS Release 11.1 for EX Series switches.

Description

Specify the type of Layer 2 traffic originating from the CE device. Only the **ethernet** and **ethernet-vlan** encapsulation types are supported for VPLS. Not all encapsulation types are supported on the switches. See the switch CLI.

Options

atm-aal5—ATM Adaptation Layer (AAL/5)

atm-cell—ATM cell relay

atm-cell-port-mode—ATM cell relay port promiscuous mode

atm-cell-vc-mode—ATM VC cell relay nonpromiscuous mode

atm-cell-vp-mode—ATM virtual path (VP) cell relay promiscuous mode

cesop—CESOP-based Layer 2 VPN

cisco-hdlc—Cisco Systems–compatible HDLC

ethernet—Ethernet

ethernet-vlan—Ethernet VLAN

frame-relay—Frame Relay

frame-relay-port-mode—Frame Relay port mode

interworking—Layer 2.5 interworking VPN

ppp—PPP

satsop-e1—SATSOP-E1–based Layer 2 VPN

satsop-e3—SATSOP-E3–based Layer 2 VPN

satsop-t1—SATSOP-T1–based Layer 2 VPN

satsop-t3—SATSOP-T3–based Layer 2 VPN

Default: For VPLS networks, the default encapsulation type is **ethernet**.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

encoding-type

Syntax

```
encoding-type (ethernet | packet | pdh | sonet-sdh);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  lsp-attributes],
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Specify the encoding type of payload carried by the LSP. It can be any of the following:

- **ethernet**—Ethernet
- **packet**—Packet
- **pdh**—Plesiochronous digital hierarchy (PDH)
- **sonet-sdh**—SONET/SDH

Default **packet**

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

entropy-label

Syntax

```
entropy-label {
  ingress-policy ingress-policy-name;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols ldp],

Release Information

Statement introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Assists the transit router in load-balancing MPLS traffic across ECMP paths or Link Aggregation groups by introducing the entropy label to the MPLS label stack. The entropy label allows routers to load balance MPLS traffic by using a hash-input without the need to perform deep packet inspection. Deep packet inspection requires more of the router's processing power and is not a capability shared by all routers.

Options

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

  labeled-unicast],
[edit logical-systems logical-system name protocols bgp group group-name neighbor address
  labeled-unicast],
[edit protocols bgp family inet labeled-unicast],
[edit protocols bgp group group-name family inet labeled-unicast],
[edit protocols bgp group group-name neighbor address labeled-unicast]
```

Release Information

Statement introduced in Junos OS Release 15.1.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Insert the entropy label into the BGP labeled unicast LSP packets, which assists the transit router in load-balancing BGP traffic across equal-cost multipaths or link aggregation groups. The ingress label edge router inspects the flow information of a packet and maps it to an entropy label, which is inserted into the BGP label stack. LSRs in the core use this entropy label as the key to hash the packet and direct it to the correct path.

Options

import *policy-name*— (Optional) Specify a policy that lists the routes that allow the use of entropy labels.

no-next-hop-validation—(Optional) Do not validate the next-hop field in the entropy label capability attribute against the route next hop.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

ethernet-vlan (Protocols Link Management)

Syntax

```
ethernet-label {
  vlan-id-range vlan-id-range;
}
```

Hierarchy Level

```
[edit protocols link-management te-link te-link-name]
```

Release Information Statement introduced in Junos OS Release 14.2.

Description Specify the TE-link to be used for Layer 2 VLAN label-switched path (LSP).

Options **vlan-id-range *vlan-id-range***—Pool of VALN IDs.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

ether-pseudowire

Syntax

```
ether-pseudowire {
  zero-control-word;
}
```

Hierarchy Level

```
[edit forwarding-options enhanced-hash-key family mpls]
```

Release Information Statement introduced in Junos OS Release 16.1 for the MX Series.

Description Load-balance IP over Ethernet pseudowire. Presence of zero-control-word in the payload indicates an Ethernet frame.

zero-control-word— Precedes Ethernet packet to indicate the start Ethernet farme in an MPLS ether-pseudowire payload.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name admin-group],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name
  admin-group]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Define the administrative groups to exclude for an LSP or for a path's primary and secondary paths.

Options *group-names*—Names of one or more groups defined with the admin-groups statement.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Administrative Groups for LSPs on page 429

exclude (for Fast Reroute)

Syntax

```
(exclude [ group-names ] | no-exclude);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  fast-reroute],
[edit protocols mpls label-switched-path lsp-name fast-reroute]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Control exclusion of administrative groups:

- **exclude**—Define the administrative groups to exclude for fast reroute.
- **no-exclude**—Disable administrative group exclusion.

Options

group-names—Names of one or more groups defined with the **admin-groups** statement.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

exclude-srlg;
```

Hierarchy Level

```
[edit protocols mpls],
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls label-switched-path path-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path path-name],
[edit protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit protocols rsvp interface interface-name link-protection bypass destination],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection bypass destination]
```

Release Information

Statement introduced in Junos OS Release 11.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Exclude Shared Risk Link Group (SRLG) links for the secondary path for critical links where it is imperative to keep the secondary and primary label-switched paths completely disjoint from any common SRLG.

When specified, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. When not specified and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Excluding SRLG Links Completely for the Secondary LSP on page 230

exp

Syntax

```
exp classifier-name {
  import (classifier-name | default);
  forwarding-class class-name {
    loss-priority level {
      code-points [aliases] [3–bit-patterns];
    }
  }
}
```

Hierarchy Level

```
[edit class-of-service classifiers],
  [edit class-of-service code-point-aliases],
  [edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules],
  [edit class-of-service rewrite-rules]
```

Release Information Statement introduced in Junos OS Release 10.1 for EX Series switches.

Description Define the experimental bits (EXP) code point mapping that is applied to MPLS packets. You can define an **exp** classifier only on EX3200 switches, EX4200 and EX8200 standalone switches, and EX8200 Virtual Chassis. You can bind an **exp** rewrite rule on EX8200 standalone switches and EX8200 Virtual Chassis.

EX Series switches support only one EXP code mapping on the switch (either default or custom). It is applied globally and implicitly to all the MPLS-enabled interfaces on the switch. You cannot bind it or disable it on individual interfaces.

Options ***classifier-name***—Name of the classifier.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Syntax

```
expand-loose-hop;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 7.6.
Point-to-multipoint LSP support introduced in Junos OS Release 11.2.

Description

Allow an LSP to traverse multiple OSPF areas within a service provider's network.

Allows a point-to-multipoint LSP to span multiple domains in a network. Effectively, this allows you to configure one or more sub-LSPs (branches) in separate network domains. Examples of such domains include OSPF areas and autonomous systems (ASs). A sub-LSP of an inter-domain point-to-multipoint LSP can be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source). Only OSPF areas are supported for inter-domain point-to-multipoint LSPs. IS-IS levels are not supported.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

explicit-null (Protocols MPLS)

Syntax

```
explicit-null;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Advertise label 0 to the egress router of an LSP.

Default

If you do not include the **explicit-null** statement in the MPLS configuration, label 3 (implicit null) is advertised.

NOTE: **Junos OS does not support explicit null routes with next hops to virtual tunnel (vt-) interfaces.**

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

failure-action (Protocols MPLS)

Syntax

```
failure-action {
  make-before-break teardown-timeout seconds;
  teardown;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls oam bfd-liveness-detection],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  oam bfd-liveness-detection],
[edit protocols mpls label-switched-path lsp-name oam bfd-liveness-detection],
[edit protocols mpls oam bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Configure route and next-hop properties in the event of a Bidirectional Forwarding Detection (BFD) protocol session failure event on an RSVP label-switched path (LSP). The failure event could be an existing BFD session that has gone down or a BFD session that never came up. RSVP adds back the route or next hop when the relevant BFD session comes back up.

Options

make-before-break—When a BFD session fails for an RSVP LSP, an attempt is made to signal a new LSP path before tearing down the old LSP path.

teardown—When a BFD session fails for an RSVP LSP, the associated LSP path is taken down and resignaled immediately.

teardown-timeout *seconds*—When you configure the **make-before-break** option, you can specify a time in seconds for the **teardown-timeout** option. At the end of the time specified, the associated RSVP LSP is automatically torn down and resignaled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

family mpls

Syntax

```
family mpls {
  all-labels;
  label-1;
  label-2;
  label-3;
  no-labels;
  no-label-1-exp;
  payload {
    ether-pseudowire {
      zero-control-word;
    }
    ip {
      disable;
      layer-3-only;
      port-data {
        source-msb;
        source-lsb;
        destination-msb;
        destination-lsb;
      }
    }
  }
}
```

Hierarchy Level

```
[edit forwarding-options hash-key]
```

Release Information

Statement introduced before Junos OS Release 7.4.
no-label-1-exp option introduced in Junos OS Release 8.0.
label-3 and **no-labels** options introduced in Junos OS Release 8.1.
ether-pseudowire statement introduced in Junos OS Release 9.1 (M320 and T Series routers only); support extended to M120 and MX Series routers in Junos OS Release 9.4.
all-labels and **payload ip disable** options introduced in Junos OS Release 12.1X48R2. (PTX Series Packet Transport Routers only).
zero-control-word option introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

Description

For aggregated Ethernet and SONET/SDH interfaces only, configure load balancing based on MPLS labels and payload. Only the IPv4 protocol is supported.

Options

family mpls—(Aggregated Ethernet interfaces, aggregated SONET/SDH interfaces, and multiple equal-cost MPLS next hops only) Incorporate MPLS label and payload information into the hash key for per-flow load balancing. Only the IPv4 protocol is supported.

- **all-labels**—(PTX Series Packet Transport Routers only) Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This is the default setting.
- **label-1**—(M120, M320, MX Series, and T Series routers only) Include the first MPLS label into the hash key. This is used for a one-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels.
- **label-2**—(M120, M320, MX Series, and T Series routers only) Include the second MPLS label into the hash key. This is used for a two-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels. To use the second MPLS label in the hash key, include both the **label-1** and **label-2** statements at the **[edit forwarding-options hash-key family mpls]** hierarchy level. By default, the router provides hashing on the first and second labels. If both labels are specified, the entire first label and the first 16 bits of the second label are hashed.
- **label-3**—(M120, M320, MX Series, and T Series routers only) Include the third MPLS label into the hash key. To use the third MPLS label, include the **label-1**, **label-2**, and **label-3** statements at the **[edit forwarding-options hash-key family mpls]** hierarchy level.
- **no-labels**—Include no MPLS labels into the hash key.
- **no-label-1-exp**—(M120, M320, MX Series, and T Series routers only) The EXP bit of the first label is not used in the hash calculation to avoid reordering complications.
- **payload**—Incorporate bits from the IP payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
  - **disable**—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
  - **ether-pseudowire**—(M120, M320, MX Series, and T Series routers only) Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
  - **zero-control-word**—(M Series, MX Series, and PTX Series) Precedes Ethernet packet to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.
  - **ip**—Include the IP address of the IPv4 or IPv6 payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels. For the PTX Series Packet Transport Routers, this is the default setting with both Layer 3 and Layer 4 IP information included in the hash key.
    - **disable**—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
    - **layer-3-only**—Include only Layer 3 IP information from the IP payload data into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
    - **port-data**—(M120, M320, MX Series, and T Series routers only) Include the source and destination port field information into the hash key. By default, the most significant byte and least significant byte of the source and destination port fields are hashed. To select specific bytes to be hashed, include one or more of the **source-msb**, **source-lsb**, **destination-msb**, and **destination-lsb** options at the **[edit forwarding-options hash-key family mpls payload ip port-data]** hierarchy level. To

prevent all four bytes from being hashed, include the **layer-3-only** statement at the **[edit forwarding-options hash-key family mpls payload ip]** hierarchy level.

- **destination-lsb**—Include the least-significant byte of the destination port.
- **destination-msb**—Include the most-significant byte of the destination port.
- **source-lsb**—Include the least-significant byte of the source port.
- **source-msb**—Include the most-significant byte of the source port.

Required Privilege Level

fate-sharing

Syntax

```
fate-sharing {
  group group-name {
    cost value;
    from address <to address>;
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options],
[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Specify a backup path in case the primary path becomes unusable.

You specify one or more objects with common characteristics within a group. All objects are treated as /32 host addresses. The objects can be a LAN interface, a router ID, or a point-to-point link. Sequence is insignificant.

Changing the fate-sharing database does not affect existing established LSPs until the next CSPF reoptimization. The fate-sharing database does affect fast-reroute detour path computations.

Options

cost *value*—Cost assigned to the group.

Range: 1 through 65,535

Default: 1

from *address*—Address of the router or address of the LAN/NBMA interface. For example, an Ethernet network with four hosts in the same fate-sharing group would require you to list all four of the separate **from** addresses in the group.

group *group-name*—Each fate-sharing group must have a name, which can have a maximum of 32 characters, including letters, numbers, periods (.), and hyphens (-). You can define up to 512 groups.

to *address*—(Optional) Address of egress router. For point-to-point link objects, you must specify both a **from** and a **to** address.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

gre (Routing Options)

Syntax

```
gre;
next-hop-based-tunnel;
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*],
[edit routing-options dynamic-tunnels *tunnel-name*]

Release Information

Statement introduced in Junos OS Release 10.1.
next-hop-based-tunnel option introduced in Junos OS Release 16.2.

Description

Enable generic routing encapsulation (GRE) type for IPv4 to automatically establish label-switched paths (LSPs) for any new provider edge (PE) router added to a full mesh of LSPs.

Options

next-hop-based-tunnel—Create a tunnel composite next hop for every dynamic GRE tunnel configured. The tunnel composite next hop includes the dynamic tunnel's encapsulation data and a VPN label (when chained composite next hop is not enabled). When this option is not configured, the default interface-based tunnel mode is enabled. By configuring this option, a device can scale up to 32,000 IP tunnels, which is otherwise restricted to the system limit on the number of interfaces supported.

At a given point in time, either the next-hop-based dynamic tunnel or the default interface-based dynamic GRE tunnel can exist on a device. A switchover from one tunnel mode to another deletes the existing tunnels and creates new tunnels in the new tunnel mode. As a result, a tunnel mode switchover can impact network performance.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

Range: 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)

Default: 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

import (MPLS Traffic Engineering Database)

Syntax

```
import {
  bgp-ls-identifier domain-identifier;
  identifier identifier;
  policy policy-name;
  igp-topology{
    bgp-link-state;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls traffic-engineering database],
[edit protocols mpls traffic-engineering database]

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Configure the traffic engineering database import parameters.

Options

bgp-ls-identifier *domain-identifier*—BGP-TE domain identifier.

identifier *identifier*—BGP-TE identifier.

Range: 2 through 18446744073709551615

policy *policy-name*—Name of the import policy.

igp-topology—Download IGP topology information into the traffic engineering database (TED). In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. The IGP routes are installed by the traffic engineering database on behalf of the corresponding IGP into a user-visible routing table called lsdist.0, subject to route policies.

bgp-link-state—Export IGP topology information into BGP-Link State (BGP-LS) from the lsdist.0 routing table. The lsdist.0 routing table stores the network topology information from the traffic engineering database. The BGP-LS reads IGP entries from lsdist.0 and advertises the information to BGP peers.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

ip-tunnel-rpf-check

Syntax

```
ip-tunnel-rpf-check {
   mode (strict | loose);
   fail-filter filter-name;
}
```

Hierarchy Level

[edit routing-instances *routing-instance-name* routing-options forwarding-table]

Release Information

Statement introduced in Junos OS Release 17.1 for MX Series Routers with MICs.

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (*strict* | *loose*)—(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

Default: If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*—(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  (primary | secondary) path-name admin-group],
[edit protocols mpls label-switched-path lsp-name admin-group],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name
  admin-group]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Define the administrative groups to include for an LSP or for a path's primary and secondary paths.

Options *group-names*—One or more names of groups defined with the **admin-groups** statement.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Administrative Groups for LSPs on page 429

include-any (for Fast Reroute)

Syntax

```
(include-any [ group-names ] | no-include-any);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  fast-reroute],
[edit protocols mpls label-switched-path lsp-name fast-reroute]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Control inclusion of administrative groups:

- **include-any**—Define the administrative groups to include for fast reroute.
- **no-include-any**—Disable administrative group inclusion.

Options

group-names—One or more names of groups defined with the **admin-groups** statement.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Fast Reroute on page 381

ingress (LSP)

Syntax

```
ingress {
  bandwidth bps;
  class-of-service cos-value;
  description string;
  entropy-label;
  install {
    destination-prefix <active>;
  }
  link-protection bypass-name name;
  metric metric;
  next-hop (address | interface-name | address/interface-name);
  node-protection bypass-name name next-next-label label;
  no-install-to-address;
  policing {
    filter filter-name;
    no-auto-policing;
  }
  preference preference;
  push out-label;
  to address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path
  lsp-name],
[edit protocols mpls static-label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 10.1.
entropy-label option introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure an ingress LSR for a static LSP.

The remaining statements are explained separately

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Static LSPs on page 491

install (Protocols MPLS)

Syntax

```
install {
  destination-prefix <active>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls static-label-switched-path
  lsp-name ingress],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Associate one or more prefixes with an LSP. When the LSP is up, all the prefixes are installed as entries into the inet.3 or inet6.3 routing table.

Options

active—(Optional) Install the route into the inet.0 or inet6.0 routing table. This allows you to issue a **ping** or **traceroute** command on this address.

NOTE: The **install** ***destination-prefix*** **active** statement is not supported on static LSPs. When the **install** ***destination-prefix*** **active** statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

destination-prefix—IPv4 or IPv6 address to associate with the LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table on page 384

ingress-policy

Syntax

```
ingress-policy [ ingress-policy-names ];
```

Hierarchy Level

[edit logical-system *logical-system-name* protocols ldp entropy-label],
[edit logical-system *logical-system-name* protocols ldp oam],
[edit protocols ldp entropy-label],
[edit protocols ldp oam]

Release Information

Statement introduced in Junos OS Release 9.4.
Statement introduced at the **[edit protocols ldp entropy-label]** hierarchy level in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Configure an LDP ingress policy for either the entropy label or Operation, Administration, and Management (OAM).

For OAM, configure the ingress policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

Options

ingress-policy-names—Specify the names of the ingress policies.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

interface (Protocols MPLS)

Syntax

```
interface (interface-name | all) {
  disable;
  admin-group [ group-names ];
  srlg srlg-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Enable MPLS on one or more interfaces.

Options

interface-name—Name of the interface on which to configure MPLS. To configure all interfaces, specify **all**. For details about specifying interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

srlg *srlg-name*—Name of the SRLG to associate with an interface.

The remaining options are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring SRLG on page 220

interface (MPLS)

Syntax interface (all | *interface-name*);

Hierarchy Level [edit protocols mpls]

Release Information Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description Enable MPLS on all interfaces on the switch or on the specified interface.

Default MPLS is disabled.

Options **all**—All interfaces on the switch.

interface-name—Name of an interface:

- Aggregated Ethernet—**ae*x***
- Gigabit Ethernet—**ge-*fpc/pic/port***

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

inter-domain

Syntax

```
inter-domain;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path
  label-switched-path-name],
[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information Statement introduced in Junos OS Release 10.2.

Description Allows the router to search for routes in the IGP database. You need to configure this statement on routers that might be unable to locate a path using intra-domain CSPF (by looking in the traffic engineering database (TED). When you configure inter-area or inter-AS LSPs, the **inter-domain** statement is required.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

ip-tunnel-rpf-check

Syntax

```
ip-tunnel-rpf-check {
  mode (strict | loose);
  fail-filter filter-name;
}
```

Hierarchy Level

[edit routing-instances *routing-instance-name* routing-options forwarding-table]

Release Information

Statement introduced in Junos OS Release 17.1 for MX Series Routers with MICs.

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (*strict* | *loose*)—(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

Default: If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*—(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

ipv6-tunneling

Syntax

```
ipv6-tunneling;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches.

Description

Allow IPv6 routes to be resolved over an MPLS network by converting LDP and RSVP routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks on page 281

[edit logical-systems *logical-system-name* protocols mpls],
[edit protocols mpls]

Release Information

Statement introduced before Junos OS Release 7.4.
cross-credibility-cspf option introduced in Junos OS Release 14.2.
self-ping-duration and **no-self-ping** options introduced in Junos OS Release 16.1.

Description

Configure an LSP to use in dynamic MPLS. When configuring an LSP, you must specify the address of the egress router in the **to** statement. All remaining statements are optional.

Options ***lsp-name***—Name that identifies the LSP. The name can be up to 64 characters and can contain letters, digits, periods, and hyphens. To include other characters, enclose the name in quotation marks. The name must be unique within the ingress router.

cross-credibility-cspf—Enable path computation across credibility levels. The constraint path computation is run across multi-protocol links and nodes, instead of a credibility-by-credibility basis.

link-protection—Enable protection for LSP from link faults only.

no-self-ping—Disable self-ping for the LSP.

NOTE: Starting in Junos OS 17.4, you can override the behavior of self-ping running by default using **no-self-ping** statement.

self-ping-duration ***seconds***—Specify the duration (in seconds) for which to run the self-ping mechanism unless the ping succeeds sooner.

LSP self-ping for an LSP starts at the ingress label edge router (LER), once a Resv message for that LSP has been received. The configured self-ping time indicates the duration for which the self-ping mechanism runs once the LSP instance is signaled to be **UP**.

By default, self-ping is enabled. The LSP types like CCC, P2MP, VLAN-based , and non-default instances do not support self-ping .

The self-ping mechanism runs until the self-ping probe is received back (at which point the traffic is immediately switched to it) , or until the configured self-ping duration for the LSP is over (at which point traffic is switched over).

When LSP self-ping-duration is enabled, the LSP behavior reverts back to a timer-based mechanism similar to the **optimize-switchover-delay**, where a specific amount of time is provided for all the downstream nodes to install the forwarding path before switchover. When LSP self-ping-duration is not enabled, the default behavior is to wait for an infinite amount of time for the self-ping to succeed before switching the traffic.

Range: 1 through 65535 seconds

NOTE: Starting in Junos OS 17.4R1, the default time-out duration for which the self-ping runs on an LSP instance is reduced from 65535 (runs until success) to 1800 seconds. You can also configure the self ping duration value between 1 to 65535 (runs until success) seconds.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

label-switched-path

Syntax
label-switched-path *lsp-name* to *remote-provider-edge-switch*;

Hierarchy Level
[edit protocols mpls]

Release Information
Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description
Define a label-switched path (LSP) to the remote provider edge switch to use for MPLS traffic. You must specify this statement on the provider edge switch.

Options
lsp-name —Name that identifies the LSP. The name can be up to 32 characters and can contain letters, digits, periods, and hyphens. To include other characters, enclose the name in quotation marks. The name must be unique on the ingress switch.

remote-provider-edge-switch —Either the loopback address or the switch address.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

label-switched-path-template (Container LSP)

Syntax

```
label-switched-path-template {
  (default-template | lsp-template-name);
}
```

Hierarchy Level

[edit protocols mpls container-label-switched-path *lsp-name*]
[edit routing-instances *instance-name* provider-tunnel]

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.
Statement introduced in Junos OS Release 18.2. under the heirarchy level [edit routing-instances *instance-name* provider-tunnel]

Description

Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs.

Options

default-template—Specify that the default LSP template be used for the dynamically generated LSPs.

lsp-template-name—Specify the name of an LSP to be used as a template for the dynamically generated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

link-protection (Dynamic LSPs)

Syntax

```
link-protection;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*], [edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable link protection on the specified LSP, which helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails. For point-to-multipoint LSPs, including this statement extends link protection to all of the paths used by the LSP.

To fully enable link protection, you must also include the **link-protection** statement at the **[edit protocols rsvp interface *interface-name*]** or **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]** hierarchy level.

Default

Link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

link-protection (Static LSPs)

Syntax

```
link-protection bypass-name name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls
   static-label-switched-path lsp-name ingress],
[edit logical-systems logical-system-name protocols mpls
   static-label-switched-path lsp-name transit incoming-label],
[edit protocols mpls static-label-switched-path lsp-name ingress],
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information Statement introduced in Junos OS Release 10.1.

Description Enable link protection on the specified static LSP. Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

Default Link protection is disabled.

Options **bypass-name *name***—Bypass LSP name.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP on page 531

load-balance-label-capability

Syntax load-balance-label-capability;

Hierarchy Level [edit forwarding-options]

Release Information Statement introduced in Junos OS Release 14.1.

Description Enables the router to push and pop the load balancing label and causes LDP and RSVP to advertise the entropy label TLV to neighboring routers.

The **load-balance-label-capability** and **no-load-balance-label-capability** statements at the **[edit forwarding-options]** hierarchy level are mutually exclusive, and at a given point in time, configuring one statement overrides the other.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

log-updown (Protocols MPLS)

Syntax

```
log-updown {
  no-trap {
    mpls-lsp-traps;
    rfc3812-traps;
  }
  (syslog | no-syslog);
  trap;
  trap-path-down;
  trap-path-up;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls],
[edit protocols mpls]

Release Information

Statement introduced before Junos OS Release 7.4.
The **mpls-lsp-traps** and **rfc-3812-traps** options added in Junos OS Release 9.0.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Log a message or send an SNMP trap whenever an LSP makes a transition from up to down, or vice versa, and whenever an LSP switches from one active path to another. Only the ingress router performs these operations.

NOTE: System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the **no-syslog** option under the **log-updown** statement.

Default

There is no default behavior for this statement. If you do not specify the options, the configuration cannot be committed.

Options

no-syslog—Do not log a message to the system log file.

no-trap—Do not send an SNMP trap.

syslog—Log a message to the system log file.

trap—Send an SNMP trap.

trap-path-down—Send an SNMP trap when an LSP path goes down.

trap-path-up—Send an SNMP trap when an LSP path comes up.

The **no-trap** statement is explained separately.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

longest-match

Syntax

```
longest-match {
  policy value |(expression) | [values ];
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information
Statement introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

Description
Enable longest match to allow LDP to learn the routes aggregated or summarized across OSPF areas or IS-IS levels in inter-domain.

Options
policy *value* |(*expression*) | [*values*]— Specify policy to provide per prefix granularity.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```
loss {
  min-query-interval milliseconds;
}
```

Hierarchy Level

[edit protocols mpls oam performance-monitoring responder],
[edit protocols mpls label-switched-path *lsp-name* oam performance-monitoring responder],
[edit protocols mpls label-switched-path *lsp-name* primary *path-name* oam performance-monitoring responder],
[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam performance-monitoring responder]

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure loss measurement options.

Options

min-query-interval *milliseconds*—(Optional) Specify the minimum query interval that the responder supports. If the minimum query interval of the responder is greater than the query interval configured at the querier, the effective message query rate is the minimum query interval configured for the responder.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

loss-delay (querier)

Syntax

```
loss-delay {
  traffic-class tc-value {
    average-sample-size sample size;
    loss-threshold loss threshold value;
    loss-threshold-window number of samples for loss threshold;
    measurement-quantity bytes|packets;
    padding-size size;
    query-interval milliseconds;
    rtt-delay-threshold rtt threshold value;
    twcd-delay-threshold twcd threshold value;
  }
}
```

Hierarchy Level

```
[edit protocols mpls oam performance-monitoring querier],
[edit protocols mpls label-switched-path lsp-name oam performance-monitoring querier],
[edit protocols mpls label-switched-path lsp-name primary path-name oam
  performance-monitoring querier],
[edit protocols mpls label-switched-path lsp-name secondary path-name oam
  performance-monitoring querier]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure combined loss-delay measurement options.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

lsp-attributes

Syntax

```
lsp-attributes {
  encoding-type (ethernet | packet | pdh | sonet-sdh);
  gpid (ethernet | hdlc | ipv4 | pos-scrambling-crc-16 | pos-no-scrambling-crc-16 |
    pos-scrambling-crc-32 | pos-no-scrambling-crc-32 | ppp);
  signal-bandwidth type;
  switching-type (fiber | lambda | psc-1 | tdm);
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
pos-scrambling-crc-16, **pos-no-scrambling-crc-16**, **pos-scrambling-crc-32**, and **pos-no-scrambling-crc-32** options added in Junos OS Release 8.0.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Define the parameters signaled during LSP setup. These usually determine the nature of the resource (label) allocated for the LSP.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

lsping-channel-type

Syntax

```
lsping-channle-type {
  ipv4;
  on-demand-cv;
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name oam mpls-tp-mode]
[edit protocols mpls oam mpls-tp-mode]
```

Release Information Statement introduced in Junos OS Release 16.1.

Description Specify the control-channel types for MPLS-TP mode. By default, LSPING (0x0008) is used, and the GACH-TLV is used along with this channel type.

As per RFC 7026, GACH-TLV is deprecated for ipv4 and on-demand-cv channel types.

Options

ipv4—Channel type 0x0021. This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

on-demand-cv—Channel type 0x0025. This is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

maximum-bandwidth (Protocols MPLS)

Syntax

```
maximum-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify the maximum amount of bandwidth in bits per second (bps).

Options

bps—Maximum amount of bandwidth.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446

maximum-helper-recovery-time

Syntax maximum-helper-recovery-time *seconds*;

Hierarchy Level [edit protocols rsvp graceful-restart],
[edit logical-systems *logical-system-name* protocols rsvp graceful-restart]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Specify the length of time the router or switch retains the state of its Resource Reservation Protocol (RSVP) neighbors while they undergo a graceful restart.

Options ***seconds***—Legnth of time that the router retains the state of its Resource Reservation Protocol (RSVP) neighbors while they undergo a graceful restart.

Range: 1 through 3600

Default: 180

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring Graceful Restart Options for RSVP, CCC, and TCC*
- maximum-helper-restart-time (RSVP) on page 1879

maximum-helper-restart-time (RSVP)

Syntax maximum-helper-restart-time *seconds*;

Hierarchy Level [edit protocols rsvp graceful-restart],
[edit logical-systems *logical-system-name* protocols rsvp graceful-restart]

Release Information Statement introduced in Junos OS Release 8.3.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Specify the length of time the router or switch waits after it discovers that a neighboring router has gone down before it declares the neighbor down. This value is applied to all RSVP neighbor routers and should be based on the time that the slowest RSVP neighbor requires for restart.

Options ***seconds***—The time the router or switch waits after it discovers that a neighboring router has gone down before it declares the neighbor down.

Range: 1 through 1800

Default: 60

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

maximum-labels

Syntax maximum-labels *maximum-labels*;

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family mpls],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family mpls]

Release Information Statement introduced in Junos OS Release 10.1.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 switches.

Description On the logical interface, specify the maximum number of MPLS labels upon which MPLS can operate.

You can configure this statement on the following devices:

- MX Series 5G Universal Routing Platform
- M120 Multiservice Edge Router
- M320 Multiservice Edge Router with Enhanced III FPCs
- M7i Multiservice Edge Router and M10i Multiservice Edge Router with Enhanced Compact Forwarding Engine Board (CFEB-E)
- T640, T1600, T4000, TX Matrix, and TX Matrix Plus routers with Enhanced Scaling FPC1, Enhanced Scaling FP2, Enhanced Scaling FPC3, and Enhanced Scaling FPC4
- QFX10000 switches.

Options ***maximum-labels***—Maximum number of labels.

Range: 3 through 5

Default: 3

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Maximum Number of MPLS Labels on page 370

minimum-bandwidth-adjust-interval

Syntax

```
minimum-bandwidth-adjust-interval seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify the duration (in seconds) for which minimum bandwidth is frozen.

Options

seconds—Minimum bandwidth reallocation interval, in seconds.

Range: 300 through 31,536,000 seconds.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446

minimum-bandwidth-adjust-threshold-change

Syntax

```
minimum-bandwidth-adjust-threshold-change percentage;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify the percentage change in maximum average bandwidth to freeze the minimum bandwidth.

Options

percentage—Percentage change in maximum average bandwidth.

Range: Range: 0 through 100 percent.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446

minimum-bandwidth-adjust-threshold-value

Syntax

```
minimum-bandwidth-adjust-threshold-value bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify the value in bits per second (bps) to freeze the minimum bandwidth if the maximum average bandwidth falls below this value.

Options

bps—Threshold value for minimum bandwidth if the maximum average bandwidth falls below the specified value.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446

metric (Protocols MPLS)

Syntax

```
metric metric;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls
  static-label-switched-path lsp-name ingress],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Compare against another LSP or against an IGP route. To disable dynamic metric tracking, assign a fixed metric value to an LSP. If no metric is assigned, the LSP metric is dynamic and automatically tracks underlying IGP metrics.

Options

metric—LSP metric value.

Default: No metric assigned (dynamic)

Range: 1 through 16,777,215

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Static LSP Metrics on page 424

minimum-bandwidth

Syntax

```
minimum-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Set the minimum bandwidth in bps for an LSP with automatic bandwidth allocation enabled.

NOTE: For a label-swtiched path (LSP) that has both **bandwidth** and **minimum-bandwidth** for autobandwidth configured under the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the maximum bandwidth.

Options

bps—Miniminum bandwidth for the LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446

monitor-bandwidth

Syntax monitor-bandwidth;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth],
[edit protocols mpls label-switched-path *lsp-name* auto-bandwidth]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description Do not automatically adjust bandwidth allocation. However, the maximum average bandwidth utilization is monitored on the LSP, and the information is recorded in the MPLS statistics file.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring Passive Bandwidth Utilization Monitoring on page 449

most-fill

See random

mpls (Protocols)

Syntax mpls { ... }

Hierarchy Level [edit logical-systems *logical-system-name* protocols],
[edit protocols]

Release Information Statement introduced before Junos OS Release 7.4.

Description Enable MPLS on the router.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols l2circuit],
[edit protocols l2circuit]

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Description Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router or switch to the local customer edge (CE) router or switch. All the Layer 2 circuits using a particular remote PE router or switch designated for remote CE routers or switches are listed under the **neighbor** statement (neighbor designates the PE router or switch). Each neighbor is identified by its IP address and is usually the end-point destination for the LSP tunnel (transporting the Layer 2 circuit).

Options ***address***—IP address of a neighboring router or switch.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Support for IPv6 addresses in static LSP configurations added in Junos OS Release 17.2R1.
Support for IPv4 or IPv6 lookup after poping the label added in Junos OS Release 17.4R1.

Description

Location of the next hop to the destination, specified as the IPv4 or IPv6 address of the next hop, the interface name (for point-to-point interfaces only), or the ***address/interface-name*** to specify an IP address on an operational interface.

Options

address—IPv4 or IPv6 address of the next-hop router.

NOTE: **IPv6 static LSPs are not supported at the [edit protocols mpls static-label-switched-path *lsp-name* ingress] hierarchy level.**

interface-name—IP address of the outgoing interface. It must be a point-to-point interface. The name can be a simple or fully qualified domain name.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

no-bfd-triggered-local-repair

Syntax

```
no-bfd-triggered-local-repair;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit routing-options]
```

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Disable Bidirectional Forwarding Detection (BFD) sessions to trigger fast reroute (FRR) using MPLS-FRR and loop-free alternates (LFAs). When this statement is configured, no BFD-triggered local repair is supported. However, logical interface down-based local repair is in force.

When using this statement to disable local repair, you also must restart routing to ensure proper behavior. To restart routing, include the **graceful-restart** command for the interior gateway protocol (IGP) used in your configuration. For example, if your IGP is OSPF, include the **graceful-restart** statement at the [edit protocols ospf] hierarchy level.

Default

BFD-triggered local repair is the default behavior. The loss of a neighbor results in BFD local repair for all next hops that derive themselves from the base next hop with which the BFD session is established.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable constrained-path LSP computation.

An explicit-path LSP is completely configured through operator action. Once configured, it is initiated only along the explicitly specified path.

A constrained-path LSP relies on an ingress router to compute the complete path. The ingress router takes into account the following information during the computation:

- Interior gateway protocol (IGP) topology database
- Link utilization information from extensions in the IGP link-state database
- Administrative group information from extensions in the IGP link-state database
- LSP requirements, including bandwidth, hop count, and administrative group

Constrained-path LSPs can generally avoid link failures and congested links. They also permit recomputation (therefore, a new path) during topology changes or unsuccessful setup.

Default

Constrained-path LSP computation enabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable normal time-to-live (TTL) decrementing, which decrements the TTL field in the IP header by 1. This statement decrements the IP TTL by 1 before encapsulating the IP packet within an MPLS packet. When the penultimate router pops off the top label, it does not use the standard write-back procedure of writing the MPLS TTL into the IP TTL field. Therefore, the IP packet is decremented by 1. The ultimate router then decrements the packet by one more for a total cloud appearance of 2, thus hiding the network topology.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- no-propagate-ttl on page 1902

graceful-restart (Enabling Globally)

Syntax

```
graceful-restart {
  disable;
  helper-disable;
  maximum-helper-recovery-time seconds;
  maximum-helper-restart-time seconds;
  notify-duration seconds;
  recovery-time seconds;
  restart-duration seconds;
  stale-routes-time seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options],
[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

You configure the graceful restart routing option globally to enable the feature, but not to enable graceful restart for all routing protocols in a routing instance. Because all routing protocols are not usually run on every routing instance, you must also configure graceful restart for individual routing protocols running on a routing instance, including the main routing instance. You can, optionally, modify the global settings at the individual protocol level.

NOTE:

- For VPNs, the graceful-restart statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.
- For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.
- LDP sessions flap when graceful-restart configurations change.

Default

Graceful restart is disabled by default.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

helper-disable (Multiple Protocols)

Syntax
```
helper-disable;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols (isis | ldp | ospf | ospf3 | rsvp)
  graceful-restart],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  (ldp | ospf | ospf3) graceful-restart],
[edit protocols (isis | ldp | ospf | ospf3 | rsvp) graceful-restart],
[edit routing-instances routing-instance-name protocols (ldp | ospf | ospf3) graceful-restart]
```

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Disable helper mode for graceful restart. When helper mode is disabled, a router or switch cannot help a neighboring router that is attempting to restart.

Default
Helper mode is enabled by default for these supported protocols: IS-IS, LDP, OSPF/OSPFv3, and RSVP.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

no-mcast-replication

Syntax

```
no-mcast-replication;
```

Hierarchy Level

[edit chassis fpc *slot-number* pic *pic-number*],
[edit chassis lcc *number* fpc *slot-number* pic *pic-number*]

Release Information

Statement introduced in Junos OS Release 11.3.

Description

For point-to-multipoint LSPs configured on T Series routers, protect the Packet Forwarding Engine (PFE) from bandwidth saturation. When a PFE does not need to replicate traffic, the PFE's bandwidth is less likely to become saturated. When you include the **no-mcast-replication** statement, the PFE is forced to be a leaf node in the binary tree. Leaf nodes, unlike branch nodes, do not replicate traffic in the process of forwarding traffic. Because leaf nodes have no children, they do not need to replicate traffic, and thus are less likely to become saturated with traffic.

Default

If you omit the **no-mcast-replication** statement, the PFE can become a branch node or a leaf node. When the PFE becomes a branch node, the PFE must replicate traffic.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Point-to-Multipoint LSPs Overview on page 527

no-propagate-ttl

Syntax no-propagate-ttl;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls],
[edit protocols mpls]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Disable normal time-to-live (TTL) decrementing. You configure this statement once per router, and it affects all RSVP-signaled or LDP-signaled LSPs. When this router acts as an ingress router for an LSP, it pushes an MPLS header with a TTL value of 255, regardless of the IP packet TTL. When the router acts as the penultimate router, it pops the MPLS header without writing the MPLS TTL into the IP packet.

When you add the **no-propagate-ttl** statement to the configuration or delete it from the configuration, the effect takes place immediately. There is no need to clear existing RSVP LSPs or LDP sessions.

Default Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

node-protection (Static LSP)

Syntax

```
node-protection bypass-name name next-next-label label;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls
   static-label-switched-path lsp-name ingress],
[edit logical-systems logical-system-name protocols mpls
   static-label-switched-path lsp-name transit incoming-label],
[edit protocols mpls static-label-switched-path lsp-name ingress],
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information Statement introduced in JUNOS Release 10.1.

Description Enable node protection on the specified static bypass LSP. Node protection ensures that traffic from an LSP traversing a neighboring router can continue to reach its destination even if the neighboring router fails.

Default Node protection is disabled.

Options **bypass-name *name***—Bypass LSP name.

next-next-label *label*—Bypass LSP name.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

normalization

Syntax

```
normalization {
  failover-normalization;
  no-incremental-normalize;
  normalization-retry-duration seconds;
  normalization-retry-limits number;
  normalize-interval seconds;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced in Junos OS Release 17.2R1 for QFX Series switches.

Description

Perform normailzation.

Options

failover-normalization—Enable the ingress router to pro-actively normalize or re-distribute traffic when a link or node failure happens on a member LSP. A member LSP can go down between two scheduled normalization events because of a link-failure or pre-emption.

Default: Disabled

no-incremental-normalize—Disables automatic switchover by the ingress router to a new instance of the container LSP until the desired demand is satisfied, although the given number of LSPs can be successfully signaled such that the new aggregate bandwidth value exceeds the old aggregate bandwidth value.

Default: False (disabled)

normalization-retry-duration *seconds*—Specifies the duration before which the ingress router performs a normalization reattempt when the previous normalization has not been successful. Normalization is done until a sufficient number of LSPs come up with an aggregate bandwidth that is more than the current aggregate or desired bandwidth.

Default: 30 seconds

normalization-retry-limits *number*—Specifies the maximum number of times the ingress router performs normalization reattempts until a sufficient number of LSPs come up successfully with new bandwidth values.

Default: 1

normalize-interval *seconds*—Specifies the duration between two normalization events.

Range: 21600 seconds through 6 hours

Default: 21600 seconds

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

optimize-adaptive-teardown

Syntax

```
optimize-adaptive-teardown {
  p2p:
}
```

Hierarchy Level

```
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 15.1R1.

Description

Make use of a new feedback mechanism from TAG library which relies on RPD infrastructure to decide when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover. When this statement is configured, the **optimize-hold-dead-delay** statement, which delays the teardown of the old LSP instance after MBB switchover, is ignored.

Options

p2p—This is the only option. Only point-to-point LSPs configured in the system will be affected.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

optimize-aggressive

Syntax
```
optimize-aggressive;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
If enabled, the LSP reoptimization is based solely on the IGP metric. The reoptimization process ignores the available bandwidth ratio calculations, the least-fill 10 percent congestion improvement rule, and the hop-counts rule. This statement makes reoptimization more aggressive than the default.

Default
Aggressive optimization is disabled.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

optimize-hold-dead-delay

Syntax

optimized-hold-dead-delay *seconds*;

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls],
[edit logical-systems *logical-system-name* protocols mpls label-switch-path *lsp-name*],
[edit protocols mpls],
[edit protocols mpls label-switch-path *lsp-name*]

Description

Allows you to specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths. This delay timer starts when the timer specified by the **optimize-switchover-delay** statement has elapsed, which is typically 30 seconds, and at the start of the next retry sequence (in other words, the delay is not an absolute countdown of the seconds configured here).

You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The specified delay helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths.

Options

seconds—Configure the time in seconds to wait before tearing down the old paths that were in use prior to the last LSP optimization.

Default: 60 to 90 seconds

Range: 0 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
  (primary | secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Enable periodic reoptimization of an LSP that is already set up. If topology changes occur, an existing path might become suboptimal, and a subsequent recomputation might be able to determine a better path. This feature is useful only on LSPs for which constrained-path computation is enabled; that is, for which the **no-cspf** statement is not configured. Also, you only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers).

To avoid extensive resource consumption that might result because of frequent path recomputations, or to avoid destabilizing the network as a result of constantly changing LSPs, we recommend that you either leave the timer value sufficiently large or disable the timer value.

Default

The optimize timer is disabled.

Options

seconds—Length of the optimize timer, in seconds.

Range: 0 through 65,535 seconds

Default: 0 seconds (the optimize timer is disabled)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Specify a point-to-multipoint LSP as the next hop for a static route, and configure an independent metric or preference on that next-hop LSP.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.
abstract-hop-name option introduced in Junos OS Release 17.1 for all platforms.

Description

Create a named path and optionally specify the sequence of explicit routers that form the path.

You must include this statement when configuring explicit LSPs.

Options

abstract-hop-name—Name of the predefined abstract hop. The abstract hop can be used in combination with real IP next hops. An abstract hop is traversed by traversing the member nodes. This traversal can be done by either links that satisfy the logical combination of defined constituent attributes, or by any kind of link. This choice is controlled by the use of abstract hop qualifiers – abstract, loose, loose-link, and strict.

abstract—Indicate that the next hop configured in the **path** statement is an abstract hop..

loose-link—Indicate that the next hop in the **path** statement is a loose-link abstract hop. This means that the LSP cannot traverse other routers before reaching this router. In other words, the abstract hop of type loose-link is processed only if any of the viable routers is reached in constraint through a link of associated abstract hop membership.

loose—Indicate that the next hop in the **path** statement is a loose abstract hop. The path can traverse any real nodes that do not have abstract hop membership, before reaching a node with abstract hop membership, which is a feasible starting point for processing the next abstract hop.

strict—Indicate that the next hop in the **path** statement is a strict abstract hop. After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership, before reaching a node with abstract hop membership, which is a feasible starting point for processing the next abstract hop.

address—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router

if its type is **loose**. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.

hostname—See ***address***.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.

loose—(Optional) Indicate that the next address in the **path** statement is a loose link. This means that the LSP can traverse through other routers before reaching this router.

Default: **strict**

path-name—Name that identifies the sequence of nodes that form an LSP. The name can contain up to 32 characters and can include letters, digits, periods, and hyphens. To include other characters or use a longer name, enclose the name in quotation marks. The name must be unique within the ingress router.

strict—(Optional) Indicate that the LSP must go to the next address specified in the **path** statement without traversing other nodes. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

path

Syntax

```
path destination {
  <address | hostname> <strict | loose>
}
```

Hierarchy Level

```
[edit protocols mpls]
```

Release Information Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description Configure path protection on your MPLS network.

Options

destination —Name of a label switched path (LSP). In addition to specifying the name of the configured LSP, you can include some other designation such as **primary-path**.

address —(Optional) IP address of each transit switch (or the IP address of the loopback interface on the switch) in the LSP. If you want to control exactly which switches are selected for the LSP, specify the address or hostname of each transit switch. Specify the addresses in order, starting with the first provider (transit) switch, and continuing sequentially along the path until reaching the egress provider edge switch.

Default: If you do not specify the addresses or hostnames of any switches, the LSP is calculated by the switch.

hostname —(Optional) See ***address*** .

Default: If you do not specify the addresses or hostnames of any switches, the LSP is calculated by the switch.

loose—(Optional) Indicates that the next address in the **path** statement is a loose link. This means that the LSP can traverse through other switches before reaching this switch.

Default: **strict**

strict—(Optional) Indicates that the LSP must go to the next address specified in the **path** statement without traversing other switches. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 12.1x48 for PTX Series Packet Transport Routers.
Statement introduced in Junos OS Release 12.3 for M Series, T Series, and MX Series routers.

Description

Allocate a unique label for each prefix. The **per-prefix-label** statement helps minimize packet loss in most deployments.

Although allocating a label for each prefix is not generally ideal for scaling, it is assumed that a small number of labels are used for BGP labeled-unicast. When labeled BGP is used to set up transport label-switched paths (LSPs), the common case is that each prefix has a unique next hop. Thus, the use of per-prefix labels does not have an adverse scaling impact. On the contrary, the use of per-prefix labels reduces churn in the network when multipath load balancing is enabled for IPv4 labeled-unicast, and a subset of the paths are withdrawn for some reason.

The advantage of per-prefix labeling is that the advertised upstream label is more stable during network changes. That is, if the downstream label changes, the advertised upstream label remains the same under most scenarios. This way, the upstream router is isolated from the downstream network change, and the overall network is more stable. The greater stability of the advertised upstream label helps to reduce traffic loss during many different network change scenarios.

Default

By default, label allocation is per next-hop router.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

aggregate-bandwidth and **limit-bandwidth *limit-bandwidth*** options introduced in Junos OS Release 17.4R1 for MX Series, PTX Series, and QFX Series.

Description Define a routing policy, including subroutine policies.

A *term* is a named structure in which match conditions and actions are defined. Routing policies are made up of one or more terms. Each routing policy term is identified by a term name. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in double quotation marks.

Each term contains a set of match conditions and a set of actions:

- Match conditions are criteria that a route must match before the actions can be applied. If a route matches all criteria, one or more actions are applied to the route.
- Actions specify whether to accept or reject the route, control how a series of policies are evaluated, and manipulate the characteristics associated with a route.

Generally, a router compares a route against the match conditions of each term in a routing policy, starting with the first and moving through the terms in the order in which they are defined, until a match is made and an explicitly configured or default action of **accept** or **reject** is taken. If none of the terms in the policy match the route, the router compares the route against the next policy, and so on, until either an action is taken or the default policy is evaluated.

If none of the match conditions of each term evaluates to true, the final action is executed. The final action is defined in an unnamed term. Additionally, you can define a default action (either **accept** or **reject**) that overrides any action intrinsic to the protocol.

The order of match conditions in a term is not relevant, because a route must match all match conditions in a term for an action to be taken.

To list the routing policies under the **[edit policy-options]** hierarchy level by **policy-statement *policy-name*** in alphabetical order, enter the **show policy-options** configuration command.

The statements are explained separately.

Options

actions—(Optional) One or more actions to take if the conditions match. The actions are described in *Configuring Flow Control Actions*.

family *family-name*—(Optional) Specify an address family protocol. Specify **inet** for IPv4. Specify **inet6** for 128-bit IPv6, and to enable interpretation of IPv6 router filter addresses. For IS-IS traffic, specify **iso**. For IPv4 multicast VPN traffic, specify **inet-mvpn**. For IPv6 multicast VPN traffic, specify **inet6-mvpn**. For multicast-distribution-tree (MDT) IPv4 traffic, specify **inet-mdt**. For BGP route target VPN traffic, specify **route-target**. For traffic engineering, specify **traffic-engineering**.

NOTE: When **family** is not specified, the routing device or routing instance uses the address family or families carried by BGP. If multiprotocol BGP (MP-BGP) is enabled, the policy defaults to the protocol family or families carried in the network layer reachability information (NLRI) as configured in the *family* statement for BGP. If MP-BGP is not enabled, the policy uses the default BGP address family unicast IPv4.

from—(Optional) Match a route based on its source address.

as-path-unique-count *count* (equal | orhigher | orlower)—(Optional) Specify a number from 0 through 1024 to filter routes based on the number of unique autonomous systems (ASs) in the AS path. Specify the match condition for the unique AS path count.

aggregate-bandwidth—(Optional) Enable BGP to advertise aggregate outbound link bandwidth for load balancing.

dynamic-tunnel-attributes *dynamic-tunnel-attributes*—(Optional) Choose a set of defined dynamic tunnel attributes for forwarding traffic over V4oV6 tunnels.

match-conditions—(Optional in **from** statement; required in **to** statement) One or more conditions to use to make a match. The qualifiers are described in *Routing Policy Match Conditions*.

multipath-resolve *multipath-resolve*—(Optional) Enable the use of all paths for resolution over the specified prefix.

limit-bandwidth *limit-bandwidth*—(Optional) Specify the limit for advertised aggregate outbound link bandwidth for load balancing.

Range: 0 through 4,294,967,295 bytes

no-entropy-label-capability—(Optional) Disable the entropy label capability advertisement at egress or transit routes specified in the policy.

priority (high | medium | low)—(Optional) Configure the priority for an IS-IS route to change the default order in which the routes are installed in the routing table, in the event of a network topology change.

policy ***subroutine-policy-name***—Use another policy as a match condition within this policy. The name identifying the subroutine policy can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (“ ”). Policy names cannot take the form **__.*-internal__**, as this form is reserved. For information about how to configure subroutines, see *Understanding Policy Subroutines in Routing Policy Match Conditions*.

policy-name—Name that identifies the policy. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (“ ”).

prefix-list ***prefix-list-name***—Name of a list of IPv4 or IPv6 prefixes.

prefix-list-filter ***prefix-list-name***—Name of a prefix list to evaluate using qualifiers; ***match-type*** is the type of match, and ***actions*** is the action to take if the prefixes match.

protocol ***protocol-name***—Name of the protocol used to control traffic engineering database import at the originating point.

route-filter ***destination-prefix match-type <actions>***—(Optional) List of routes on which to perform an immediate match; ***destination-prefix*** is the IPv4 or IPv6 route prefix to match, ***match-type*** is the type of match (see *Configuring Route Lists*), and ***actions*** is the action to take if the ***destination-prefix*** matches.

source-address-filter ***source-prefix match-type <actions>***—(Optional) Unicast source addresses in multiprotocol BGP (MBGP) and Multicast Source Discovery Protocol (MSDP) environments on which to perform an immediate match. ***source-prefix*** is the IPv4 or IPv6 route prefix to match, ***match-type*** is the type of match (see *Configuring Route Lists*), and ***actions*** is the action to take if the ***source-prefix*** matches.

tag ***value***—(Optional) A numeric value that identifies a route. You can tag certain routes to prioritize them over other routes. In the event of a network topology change, Junos OS updates these routes in the routing table before updating other routes with lower priority. You can also tag some routes to identify and reject them based on your requirement.

term ***term-name***—Name that identifies the term. The term name must be unique in the policy. It can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (“ ”). A policy statement can include multiple terms. We recommend that you name all terms. However, you do have the option to include an unnamed term which must be the final term in the policy. To configure an unnamed term, omit the **term** statement when defining match conditions and actions.

to—(Optional) Match a route based on its destination address or the protocols into which the route is being advertised.

then—(Optional) Actions to take on matching routes. The actions are described in *Configuring Flow Control Actions* and *Configuring Actions That Manipulate Route Characteristics*.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Preference for the route.

You can optionally configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for LSPs is lower (more preferred) than all learned routes except direct interface routes.

Options

preference—Preference to assign to the route. A route with a lower preference value is preferred.

Range: 1 through 255

Default: 5 for static MPLS LSPs, 7 for RSVP MPLS LSPs, 9 for LDP MPLS LSPs

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Statement introduced before Junos OS Release 7.4.

Description

Configure the setup priority and reservation priority for an LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. Sessions with lower hold priorities are preempted.

Options

reservation-priority—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 0 (Once the session is set up, no other session can preempt it.)

setup-priority—Setup priority.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 7 (The session cannot preempt any existing sessions.)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

protection-revert-time

Syntax protection-revert-time *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls interface *interface-name* static], [edit protocols mpls interface *interface-name* static]

Release Information Statement introduced in Junos OS Release 10.1.

Description Specify the amount of time (in seconds) that a static LSP must wait before traffic reverts from the bypass path to the original path.

If you have configured a value of 0 seconds for the **protection-revert-time** statement and traffic is switched to the bypass path, the traffic remains on that path indefinitely. It is never switched back to the original path unless the bypass path is down or you intervene.

Options ***seconds***—Time in seconds.

Range: 0 through 65,535 seconds

Default: 5 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Static LSPs on page 491

push

Syntax

```
push out-label;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls
   static-label-switched-path lsp-name bypass],
[edit logical-systems logical-system-name protocols mpls
   static-label-switched-path lsp-name ingress],
[edit protocols mpls static-label-switched-path lsp-name bypass],
[edit protocols mpls static-label-switched-path lsp-name ingress]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Add a new label to the top of the label stack. This statement is used to configure static LSPs at ingress routers and to configure bypass LSPs for static LSPs.

Options

out-label—Manually assigned outgoing label value.

Range: 0 through 1,048,575.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

random

Syntax

```
(random | least-fill | most-fill);
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the preferred path when several equal-cost candidate paths to a destination exist, and prefer the path with the highest available bandwidth (with the largest minimum available bandwidth ratio). The available bandwidth ratio of a link is the available bandwidth on a link divided by the maximum reservable bandwidth on the link.

- **least-fill**—Prefer the path with the most available bandwidth (with the largest available bandwidth ratio).
- **most-fill**—Prefer the path with the least available bandwidth (with the minimum available bandwidth ratio). The minimum available bandwidth ratio of a path is the smallest available bandwidth ratio belonging to any of the links in the path.
- **random**—Choose the path at random.

Default

random

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring CSPF Tie Breaking on page 389

record

Syntax

```
(record | no-record);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path  (primary |
  secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify whether an LSP should actively record the routes in the path. Recording routes requires that all transit routers support the RSVP Record Route object. Recording routes can be useful for diagnostics and loop detection.

Default

Record routes.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Disabling Path Route Recording by LSPs on page 434

remote-interface-switch

Syntax

```
remote-interface-switch connection-name {
  interface interface-name.unit-number;
  receive-lsp label-switched-path;
  transmit-lsp label-switched-path;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols connections],
[edit protocols connections (MPLS)]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Configure MPLS LSP tunnel cross-connects. This makes an association between a CCC interface and two LSPs, one for transmitting MPLS packets from the local provider edge switch to the remote provider edge switch and the other for receiving MPLS packets on the local provider edge switch from the remote provider edge switch.

Options

connection-name—Connection name.

interface *interface-name.unit-number*—Interface name. Include the logical portion of the name, which corresponds to the logical unit number of the CCC interface.

receive-lsp *label-switched-path*—Name of the LSP from the connection's source. This LSP name was specified by the **label-switched-path** statement on the remote provider edge switch in the **protocols mpls** stanza.

transmit-lsp *label-switched-path*—Name of the LSP to the connection's destination. This LSP name was specified by the **label-switched-path** statement on the local provider edge switch in the **protocols mpls** stanza.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

remote-site-id

Syntax

```
remote-site-id remote-site-ID;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  l2vpn site site-name interface interface-name],
[edit routing-instances routing-instance-name protocols l2vpn site site-name interface
  interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for EX Series switches.

Description

Control the remote interface to which the interface should connect. If you do not explicitly configure the remote site ID, the order of the interfaces configured for the site determines the default value. This statement is optional.

Options

remote-site-ID—Identifier specifying the interface on the remote PE router the Layer 2 VPN routing instance connects to.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring the Remote Site ID*

retry-limit

Syntax retry-limit *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*], [edit protocols mpls label-switched-path *lsp-name*],

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Maximum number of times the ingress router tries to establish the primary path. This counter is reset each time a primary path is created successfully. When the limit is exceeded, no more connection attempts are made. Intervention is then required to restart the connection.

Options *number*—Maximum number of tries to establish the primary path.

Range: 0 through 10,000

Default: 0 (The ingress node never stops trying to establish the primary path.)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

retry-timer

Syntax retry-timer *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*], [edit protocols mpls label-switched-path *lsp-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Amount of time the ingress router waits between attempts to establish the primary path.

Options ***seconds***—Amount of time between attempts to connect to the primary path.

Range: 1 through 600 seconds

Default: 30 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Connection Between Ingress and Egress Routers on page 419

revert-timer

Syntax

```
revert-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
BFD behavior modified in Junos OS Release 9.0.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the amount of time (in seconds) that an LSP must wait before traffic reverts to a primary path. If during this time the primary path experiences any connectivity problem or stability problem, the timer is restarted.

If you have configured BFD on the LSP, the Junos OS waits until the BFD session is restored before starting the revert timer counter.

If you have configured a value of 0 seconds for the **revert-timer** statement and traffic is switched to the secondary path, the traffic remains on that path indefinitely. It is never switched back to the primary path unless you intervene.

Options

seconds—Time in seconds.

Range: 0 through 65,535 seconds

Default: 60 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

rpf-check-policy (Routing Options)

Syntax

```
rpf-check-policy policy;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options multicast],
[edit routing-options multicast]
```

Release Information

Statement introduced in Junos OS Release 8.0.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Enable you to control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to Protocol Independent Multicast (PIM) islands situated downstream from the egress routers of the point-to-multipoint LSPs.

Options

policy—Name of the RPF check routing policy.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs on page 556

rsvp-error-hold-time

Syntax rsvp-error-hold-time *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls],
[edit protocols mpls]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations. The more time you configure, the more time a source node (ingress of an RSVP LSP) can have to learn about the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes.

Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the database and the network.

Options ***seconds***—Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations.

Range: 0 through 240 seconds

Default: 25 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

sampling (Protocols MPLS)

Syntax

```
sampling {
  cut-off-threshold percentile;
  use-average-aggregate;
  use-percentile percentile;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced in Junos OS Release 17.2R1 for the QFX Series switches.

Description

Configure traffic sampling.

Options

cut-off-threshold *percentile*—Specify the percentile value to be used as a cut-off threshold in removing outlier bandwidth samples. All the aggregate bandwidth samples determined as outliers are used for computing aggregate bandwidth used at the time of normalization.

Default: 0 percentile (the ingress considers all aggregate bandwidth samples for normlaization.)

Range: 0 through 100

use-average-aggregate—Specify the ingress router to take average of the aggregate samples for normalization.

This option is mutually exclusive with the **use-percentile** configuration option.

use-percentile *percentile*—Specify the ingress router to compute and use the **pth** percentile from all the bandwidth samples, and use that for normalization.

This option is mutually exclusive with the **use-average-aggregate** configuration option.

Range: 0 through 100

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- splitting-merging on page 1963

secondary (Protocols MPLS)

Syntax

```
secondary path-name {
  adaptive;
  admin-group {
    exclude [ group-names ];
    include-all [ group-names ];
    include-any [ group-names ];
  }
  bandwidth bps;
  class-of-service cos-value;
  hop-limit number;
  no-cspf;
  no-decrement-ttl;
  optimize-timer seconds;
  preference preference;
  priority setup-priority reservation-priority;
  (record | no-record);
  retry-limit number;
  retry-timer seconds;
  select (manual | unconditional);
  standby;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify one or more secondary paths to use for the LSP. You can configure more than one secondary path. All secondary paths are equal, and the first one that is available is chosen.

You can specify secondary paths even if you have not specified any primary paths.

Optionally, you can specify preference, CoS, and bandwidth values for the secondary path, which override any equivalent values that you configure for the LSP (at the **[edit mpls label-switched-path]** hierarchy level).

Options

path-name—Name of a path that you created with the **path** statement.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

segment

Syntax

```
segment {
  (pop | swap swap);
  description description;
  next-hop next-hop;
  sid-label;
}
```

Hierarchy Level

```
[edit logical-systems name protocols mpls static-label-switched-path],
[edit logical-systems name routing-instances name protocols mpls
  static-label-switched-path],
[edit protocols mpls static-label-switched-path],
[edit routing-instances name protocols mpls static-label-switched-path]
```

Release Information

Statement introduced in Junos OS Release OS 18.1R1 for MX Series, PTX Series, and QFX Series.

Description

Static segment for segment routing. A static segment is identified by a unique name. This segment type is assigned a segment identifier (SID) which falls under a default range of 100000 through 1048575. The segment has label operation such as pop-and-forward for adjacency segment and swap-and-forward for prefix or node segment. For both types of label operation, the segment is assigned a next hop that specifies the remote IP address if the outgoing interface is a multi-access interface, or the name of the outgoing interface if the interface is a point-to-point interface. Static segment configuration is used to statically configure or provision the adjacency SIDs, node SIDs, and prefix SIDs on transit routers.

Options

pop—Pop the SID label

swap—Swap the SID label to this label

description—Text description of label-switched path

next-hop—IPv4 address or interface of next-hop router

sid-label—Segment identifier (SID) label

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing

segment-list

Syntax

```
segment-list name {
  hop-name name {
    ip_address ip address;
    label label;
  }
}
```

Hierarchy Level

```
[edit logical-systems name protocols source-packet-routing],
[edit protocols source-packet-routing]
```

Release Information

Statement introduced in Junos OS Release 17.4R1 for MX Series and PTX Series with FPC-PTX-P1-A.
ip-address statement introduced in Junos OS Release 18.1R1 for MX Series.

Description

Specify an explicit path for source routing label switched path (LSPs) to traverse through traffic engineering segments. The segment list is essentially a stack of segment identifiers. that

NOTE: The segment list enables BGP and static segment routing LSP to steer traffic based on segment routing policies. When a segment list is used by the protocol BGP, the BGP protocol validates these segment identifiers and selects valid segments for traffic engineering.

Options

name—Specify a name to identify the segment routing list, which is used in traffic engineering policy.

hop-name—Specify the name of a hop from the segment list in the segment routing traffic engineering policy.

ip-address—Specify the IP address of the hop. For a segment-list to be used by a non-colored segment routing LSP, the first hop must specify an IP address..

label—Specify the SID label of the hop in a segment routing traffic engineering segment list. In static segment routing LSPs, the source routing path uses the segment list only if the second to Nth hop specifies segment identifiers (SID) labels.

Range: **0** through **1,048,576**

NOTE: The range is applicable for protocol BGP and static segment routing LSPs.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

select

Syntax
```
select (manual | unconditional);
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name
    (primary | secondary) path-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Specify the conditions under which the path is selected to carry traffic. The **manual** and **unconditional** options are mutually exclusive.

Options
manual—The path is selected for carrying traffic if it is up and stable for at least the revert timer window (potentially before the revert timer has elapsed). Traffic is sent to other working paths if the current path is down or degraded (receiving errors).

unconditional—The path is always selected for carrying traffic, even if it is currently down or degraded (receiving errors).

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

smart-optimize-timer

Syntax smart-optimize-timer *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mpls],
[edit protocols mpls]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Enable the smart optimization timer. When you enable the smart optimization timer on a router, the Junos OS operates on the assumption that the original LSP path is preferable to any alternate or secondary path. When you enable the smart optimization timer and an LSP fails and its traffic is switched to an alternate path, the smart optimization timer starts and waits 3 minutes (this time is configurable). After 3 minutes have passed, the LSP is switched back to the original path. If the original path fails again and the LSP is switched to an alternate path again, the router waits 1 hour before attempting to switch the LSP back to its original path.

If you want to disable the smart optimizer, you can set it to zero. The **smart-optimize-timer** value in seconds indicates the time before which the LSP is switched back to its primary path in case the primary path becomes available. Otherwise, the time to wait is controlled by the optimize-timer, which is usually set to a high value. Some ISPs have the **optimize-timer** set to once a day. Sometimes after the smart optimizer causes the LSP to be placed back on its primary path, the primary path goes down again within 60 minutes. When this happens, the **smart-optimize-timer** is disabled automatically, and the **optimize-timer** (regular path optimization) goes into effect. This is to protect against a flapping link being used.

Default The smart optimization timer is enabled by default.

Options ***seconds***—(Optional) Specify the number of seconds to wait before switching an LSP back to its original path. If you do not specify the number of seconds, the default value is used.

Range: 0 through 65,535 seconds

Default: 180 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

source-routing-path

Syntax

```
source-routing-path name {
  binding-sid binding-sid;
  color color;
  metric value;
  no-ingress;
  preference preference;
  primary name {
    weight weight;
  }
  secondary name {
    weight weight;
  }
  sr-preference sr-preference;
  to to;
}
```

Hierarchy Level

```
[edit logical-systems name protocols source-packet-routing],
[edit protocols source-packet-routing]
```

Release Information

Statement introduced in Junos OS Release 17.4R1 for MX Series and PTX Series with FPC-PTX-P1-A.
The **metric**, **no-ingress**, and **secondary** statements are introduced in Junos OS Release 18.1R1 for MX Series.

Description

Configure a source routing label switched path (LSP) for steering traffic at an ingress router. Specify a binding segment identifier from the static label range. Configure other parameters such as color, weight, preference, and segment routing SR) preference for traffic engineering.

Starting with Junos OS Release 18.1R1, static non-colored SR label switched paths (LSPs) for protocol SPRING-TE in an MPLS network. Configure parameters such as destination address, binding SIDs, primary segment, secondary segment, metric, and preference. These SR LSPs do not have a color associated with them. If an ingress route is not required for a non-colored SR LSP then the ingress route installation in inet.3 table can be disabled.

Options

name—Specify a name to identify a source routing path.

binding-sid—Specify the binding label to enable transit functionality for this tunnel. For a non-colored static SR LSP, the binding SID label of protocol SPRING-TE have , by default, a preference of 8 and a metric of 1.

NOTE: This is optional for MPLS networks.

Range: 16 through 1,048,576

color—Specify a color identifier for the tunnel end point.

NOTE: This is only for colored SR LSPs. For non-colored SR LSPs, you do not have to configure the color parameter.

metric—Specify metric for routes downloaded for the non-colored static SR tunnel.

Default:

NOTE: This is the default label range for static LSPs in MPLS networks. You can configure the label range at **[edit protocols mpls label-range static label-range]** hierarchy level.

1000000 through 1048575

Range:

NOTE: This range is for protocol BGP.

1 through 16777215

no-ingress—Disable ingress route that is not required for the non-colored static SR tunnel

preference—Specify the preference for routes downloaded for this tunnel.

primary—Specify a primary segment list for the configured source routing path.

The non-colored static SR LSP can have a maximum of 8 primary paths. incase of multiple operational primary paths, the PFE distributes the traffic over the paths based on the weight configured on the paths. If none of the paths have weights configured then the weights default to 1 making it an ECMP path. the paths become weighted ECMP if the at least one of the paths have a non-zero weight. In both cases , when one or some of the paths fail, the PFE automatically re-balances the traffic over the remaining paths resulting in path protection.

weight *weight_value*—Specify a percentage of the bandwidth with respect to the sum of weights of all paths for the primary segment list. If forwarding interfaces are also configured with weighted ECMP, then Junos OS applies hierarchical weighted ECMP. If the weight percentage is not configured, then only IGP weights are applied on the forwarding interfaces.

secondary—Specify a secondary segment list for the configured non-colored static SR LSP.

sr-preference—Configure a preference for segment routing routes for traffic engineering. BGP chooses a higher preference over a lower preference value.

Range: **0** through **4,294,967,295**

to—Specify the IP address of the tunnel end-point

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details..

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

splitting-merging

Syntax

```
splitting-merging {
  maximum-member-lsps number;
  maximum-signaling-bandwidth bps;
  merging-bandwidth bps;
  minimum-member-lsps number;
  minimum-signaling-bandwidth bps;
  normalization;
  sampling;
  splitting-bandwidth bps;
  splitting-merging-threshold percent;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced for QFX Series switches in Junos OS Release 15.1X53-D30.

Description

Perform splitting and merging.

Options

maximum-member-lsps *number*—Number of label-switched paths (LSPs) that a container LSP can have as member LSPs at maximum.

Default: 1

maximum-signaling-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at maximum after normalization. When **maximum-signaling-bandwidth** is not configured, the value is derived from the **splitting-bandwidth**.

When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the **splitting-bandwidth**.

Default: 1 bps

merging-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that is used for merging during normalization.

Default: 1 bps

minimum-member-lsps *number*—Number of LSPd that a container LSP can have as member LSPs at minimum.

Default: 64

minimum-signaling-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at minimum after normalization. When **minimum-signaling-bandwidth** is not configured, the value is derived from the **merging-bandwidth**.

When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the **merging-bandwidth**.

Default: 1 bps

splitting-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be used for splitting during normalization.

Default: 1 bps

splitting-merging-threshold *percent*—Percentage changes in aggregate bandwidth relevant for splitting and merging.

Default: 0%

The remaining statements are explained separately. See CLI Explorer.

statistics (Protocols MPLS)

Syntax

```
statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
  traffic-class-statistics;
  transit-statistics-polling;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
traffic-class-statistics option introduced in Junos OS Release 14.2.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Enable MPLS statistics collection and reporting.

Options

file *filename*—(Optional) Name of the file to receive the output. We recommend that you place MPLS tracing output in the file mpls-stat in the /var/log directory.

files *number*—(Optional) Maximum number of trace files. When a trace file named *file* reaches its maximum size, it is renamed *file*.0, then *file*.1, and so on, until the maximum number of files is reached. Then, the oldest file is overwritten.

Range: 2 or more

Default: 2 files

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option.

interval *seconds*—Interval at which to periodically collect statistics.

Range: 1 through 65,535

Default: 300 seconds

no-world-readable—(Optional) Prevent users from reading the log file.

size *size*—(Optional) Maximum size of each file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a file named *file* reaches this size, it is renamed *file*.0. When the *file* again reaches its maximum size, *file*.0 is renamed *file*.1 and *file* is renamed *file*.0. This renaming scheme continues until the maximum number of files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of files with the **files** option.

world-readable—(Optional) Enable users to read the log file.

Syntax: Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

traffic-class-statistics—(Optional) Create counters that maintain data traffic statistics per traffic class at the ingress of all types of LSPs and egress of ultimate hop popping (UHP) point-to-point LSPs. These counters are not created by default and are required to be configured to perform traffic-class-scoped loss measurement.

transit-statistics-polling—(Optional) Enable the polling and display of MPLS statistics for LSPs transiting the router. By default, RSVP does not periodically poll for transit LSP statistics. You cannot configure this statement and the **no-transit-statistics** statement at the same time.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

swap

Syntax

```
swap out-label;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path
  lsp-name transit incoming-label],
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Remove the label at the top of the label stack and replace it with the specified label. Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. This statement is used to configure static LSPs at transit routers.

Options

out-label—Manually assigned outgoing label value.

Range: 0 through 1,048,575

Default: If you do not define the ***out-label*** option, the original label value remains unchanged.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

switch-away-lsps

Syntax

```
switch-away-lsps;
```

Hierarchy Level

[edit logical-systems *logical-systems-name* protocols mpls interface *interface-name*],
[edit protocols mpls interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 10.2.

Description

(MX Series routers only) Enable you to switch an LSP away from a network node using a bypass LSP. This feature could be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic. Configure this statement only after you have configured and committed the **always-mark-connection-protection-tlv** statement.

The **always-mark-connection-protection-tlv** statement marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. When you configure the **switch-away-lsps** statement, traffic is switched to the bypass LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name auto-bandwidth (MPLS Tunnel)],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced in Junos OS Release 13.2.

Description

When you have a primary and a secondary path configuration, specify that a path needs to be signaled with the active-path bandwidth when the auto-bandwidth adjustment happens and that the secondary path synchronizes the bandwidth reservations to that of the primary path.

When a primary path fails, bandwidth reservations are made by the secondary path on the links that it uses. If you include the **sync-active-path-bandwidth** statement, the secondary path releases the bandwidth it has reserved and adjusts its bandwidth after the primary path begins carrying traffic.

For example, suppose the active path is a secondary path with a reserved bandwidth of 10 GB as a result of the automatic bandwidth adjustment. Then suppose there is a switchover from the secondary path to the primary path. After some time the primary path reserves 5 GB as a result of a new automatic adjustment. Without the **sync-active-path-bandwidth** statement, the secondary path does not release the 10 GB after a switchover occurs. That bandwidth is wasted. If the **sync-active-path-bandwidth** is included in the configuration, the secondary path adjusts its bandwidth to 5 GB along with the primary path.

Default

When you have a primary and a secondary path configuration, and the primary path fails, bandwidth reservations are made by the secondary path on the links that it uses. When the primary path comes back and the traffic switches over, the secondary path does not release its bandwidth reservations.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

te-class-matrix

Syntax

```
te-class-matrix {
  tenumber {
    priority priority;
    traffic-class {
      ctnumber priority priority;
    }
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls diffserv-te],
[edit protocols mpls diffserv-te]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the traffic engineering class matrix for a multiclass LSP or a DiffServ-aware traffic engineering LSP.

Default

The default traffic engineering class matrix is:

```
te-class-matrix {
   te0 traffic-class ct0 priority 7;
   te1 traffic-class ct1 priority 7;
   te2 traffic-class ct2 priority 7;
   te3 traffic-class ct3 priority 7;
   te4 traffic-class ct0 priority 0;
   te5 traffic-class ct1 priority 0;
   te6 traffic-class ct2 priority 0;
   te7 traffic-class ct3 priority 0;
}
```

If you define any of the traffic engineering classes, all the default values are dropped.

Options

ct*number*—Specify the number of the class type. It can be one of four values: **ct0**, **ct1**, **ct2**, or **ct3**.

priority ***priority***—Specify the priority of the class type. It can be one of eight values from 0 through 7.

te*number*—Specify the number of the traffic engineering class. It can be one of eight values: **te0**, **te1**, **te2**, **te3**, **te4**, **te5**, **te6**, or **te7**. You must configure the traffic engineering classes in order, starting with **te0**.

traffic-class—Specify the traffic class for the traffic engineering class.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols MPLS)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
ted-export option introduced in Junos OS Release 14.2.
ted-import option introduced in Junos OS Release 14.2.
lsp-history option added in Junos OS Release 15.1.

Description

Configure MPLS tracing options at the protocol level or for a label-switched path.

To specify more than one tracing operation, include multiple **flag** statements.

Default

The default MPLS protocol-level tracing options are inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MPLS Tracing Flags

- **all**—Trace all operations
- **autobw-state**—Automatic bandwidth events.

- **connection**—All circuit cross-connect (CCC) activity
- **connection-detail**—Detailed CCC activity
- **cspf**—CSPF computations
- **cspf-link**—Links visited during CSPF computations
- **cspf-node**—Nodes visited during CSPF computations
- **error**—MPLS error packets
- **graceful-restart**—Trace MPLS graceful restart events
- **lsp-history**—Trace LSP history events
- **lsping**—Trace lsping packets and return codes
- **nsr-synchronization**—Trace NSR synchronization events
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail
- **state**—All LSP state transitions
- **static**—Trace static label-switched path
- **ted-export**—Trace leaking of entries from **lsdist.0** table into the traffic engineering database
- **ted-import**—Trace leaking traffic engineering database entries into the **lsdist.0** table
- **timer**—Timer usage

no-world-readable—(Optional) Allow only certain users to read the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When the ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

traffic-class (delay)

Syntax

```
traffic-class tc-value {
  average-sample-size sample size;
  padding-size size;
  query-interval milliseconds;
  rtt-delay-threshold rtt threshold value;
  twcd-delay-threshold twcd threshold value;
}
```

Hierarchy Level

[edit protocols mpls oam performance-monitoring querier delay],
[edit protocols mpls label-switched-path *lsp-name* oam performance-monitoring querier delay],
[edit protocols mpls label-switched-path *lsp-name* primary *path-name* oam performance-monitoring querier delay],
[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam performance-monitoring querier delay]

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure traffic class specific options.

Specify the traffic classes for which loss measurement has to be performed. This parameter takes one of the *tc-all|tc-0|tc-1|tc-2|tc-3|tc-4|tc-5|tc-6|tc-7|tc-none* traffic-class values. For each traffic class, you can configure the respective parameters.

To enable traffic-class parameters, configure the **traffic-class-statistics** configuration statement under the **[edit protocol mpls statistic]** hierarchy level.

Options

average-sample-size *sample size*—(Optional) Specify the number of samples used for calculating the average of various metrics.

Default: 5

Range: 1 through 30

padding-size *size*—(Optional) Specify the delay-measurement message length, which is used to calculate the delay experienced by messages of different sizes.

Default: 0

Range: 1 through 1500

query-interval *milliseconds*—Specify the minimum transmit interval, which signifies how often the loss measurement message is generated from the querier.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

rtt-delay-threshold *rtt threshold value*—Specify the round-trip delay threshold value.

Range: 1 through 4294967295 microseconds

twcd-delay-threshold *twcd threshold value*—Specify the two-way channel delay threshold value.

Range: 1 through 4294967295 microseconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traffic-engineering (Protocols MPLS)

Syntax

```
traffic-engineering (bgp | bgp-igp | bgp-igp-both-ribs | mpls-forwarding);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Select whether MPLS performs traffic engineering on BGP destinations only or on both BGP and IGP destinations. Affects only LSPs originating from this routing device, not transit or egress LSPs.

Default

bgp

Options

bgp—On BGP destinations only. Ingress routes are installed in the inet.3 routing table.

bgp-igp—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 routing table. If IGP shortcuts are enabled, the shortcut routes are automatically installed in the inet.0 routing table.

bgp-igp-both-ribs—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 and inet.3 routing tables. This option is used to support VPNs.

mpls-forwarding—On both BGP and IGP destinations. Use ingress routes for forwarding only, not for routing.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traffic-engineering

Syntax

```
traffic-engineering {
  disable;
}
```

Hierarchy Level

[edit protocols ospf | isis]

Release Information

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Enable the traffic engineering features of the specified routing protocol.

Default

Traffic engineering is disabled.

Starting in Junos OS release 15.1, traffic engineering is enabled by default whenever the IS-IS protocol is enabled. You can disable it by including the **disable** statement at the **[edit protocols isis traffic-engineering]** hierarchy level. For the EX3300, EX4200, EX4500, EX4550, EX8200 and XRE200, you can disable traffic engineering starting in Junos OS release 15.1R7.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols bgp family],
[edit routing-instances *routing-instance-name* protocols bgp group *group-name* family],
[edit routing-instances *routing-instance-name* protocols bgp group *group-name* neighbor *address* family]

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced on QFX5100 switches in Junos OS Release 15.1
Statement introduced on QFX10000 switches in Junos OS Release 17.1.

Description

Enable traffic engineering address family. This generates a multiprotocol address family indicator (AFI) and a subsequent address family identifier (SAFI) to be negotiated with the BGP peers.

The BGP network layer reachability information (NLRI) information is exchanged between the peers only when the traffic engineering AFI and SAFI are shared between them. If the peers do not agree on the use of the AFI and SAFI, the connection between the peers is terminated.

Options

unicast—Include BGP-TE NLRI.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Link State Distribution Using BGP on page 662

transit-lsp-association

Syntax

```
transit-lsp-association transit-association-lsp-group-name {
  from-1 address-of-associated-lsp-1;
  from-2 address-of-associated-lsp-2;
  lsp-name-1 name-of-associated-lsp-1;
  lsp-name-2 name-of-associated-lsp-2;
}
```

Hierarchy Level

```
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 12.1.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Associate two label-swiched paths (LSPs) at a transit node to configure a path for sending and receiving GAL and G-Ach messages for MPLS-TP OAM.

Options

transit-association-lsp-group-name—Name of the transit association LSP group.

from-1 ***address-of-associated-lsp-1***—Address of the first associated LSP.

from-2 ***address-of-associated-lsp-2***—Address of the second associated LSP.

lsp-name-1 ***name-of-associated-lsp-1***—Name of the first associated LSP.

lsp-name-2 ***name-of-associated-lsp-1***—Name of the second associated LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

- Example: Configuring the MPLS Transport Profile for OAM on page 714

ultimate-hop-popping

Syntax

```
ultimate-hop-popping;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path
  label-switched-path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information

Statement introduced in Junos OS Release 12.3.
Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

Description

Enable ultimate-hop popping on LSPs. Configure this statement on the device at the LSP ingress. In ultimate-hop popping, the MPLS label is popped from the IP packet at the PE router. The IP address is checked in a second address lookup (also at the PE router), and then the packet is forwarded to its destination.

Be aware of the following platform requirements and restrictions:

- UHP LSPs using VT interfaces—Supported on all M Series, MX Series, T Series, and TX Matrix routers.
- UHP LSPs using LSI interfaces—Supported on MX 3D Series routers only.
- UHP LSP requirements for the egress PE device—For M Series and T Series routers, a VT interface is needed.
- UHP LSPs and Layer 3 VPNs—UHP LSPs are supported for Layer 3 VPNs configured on MX 3D Series routers only.
- UHP LSPs and VPLS—UHP LSPs are supported for VPLS configured on MX 3D Series routers only. You must configure the *no-tunnel-services* statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

Default

Ultimate-hop popping is disabled by default on LSPs. Penultimate-hop popping is the default behavior. In penultimate-hop popping, the final MPLS label is popped from the IP packet at the last provider router in the network before being forwarded to the PE router. The PE router receives the packet and checks the IP address, and then the packet is forwarded to its destination.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

vrf-table-label

Syntax

```
vrf-table-label {
  source-class-usage;
  static;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*],
[edit routing-instances *routing-instance-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Support for the **source-class-usage** statement added in Junos OS Release 9.3.
Statement introduced in Junos OS Release 11.1 for EX Series switches.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.
Statement introduced in Junos OS Release 15.1F5 and 16.1R2 for PTX5000 routers with third-generation FPCs installed.
Statement introduced in Junos OS Release 15.1F6 and 16.1R2 for PTX3000 routers with third-generation FPCs.
Statement introduced in Junos OS Release 16.1X65 and 17.2R1 for PTX1000 routers.
Support for the **static** statement added in Junos OS Release 17.2.

Description

Map the inner label of a packet to a specific VPN routing and forwarding (VRF) instance. This allows the examination of the encapsulated IP header. The first lookup is done on the VPN label to determine which VRF instance to refer to, and the second lookup is done on the IP header to determine how to forward packets to the correct end hosts.

When you include the **vrf-table-label** statement in the configuration of a VRF routing instance, a label-switched interface (LSI) logical interface label is created and mapped to the VRF routing table. Any routes in the VRF routing table are advertised with the LSI logical interface label allocated for the VRF routing table. When packets destined for the VRF routing instance arrive on a core-facing interface, they are treated as if the enclosed IP packet arrived on the LSI interface and are then forwarded and filtered based on the correct table.

All routes in a VRF routing instance configured with this option are advertised with one label allocated per VRF.

NOTE:

- The **vrf-table-label** statement is supported on PTX5000 and PTX3000 routers only when third-generation FPCs are installed on the router and **enhanced-ip** command is configured on the chassis.
- Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides

more flexibility and scalability. The vrf-table-label space is increased to at least 16,000, if the platform can support the scale.

Options The remaining statements are explained separately.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

CHAPTER 35

RSVP Configuration Statements

admin-group

Syntax

```
admin-group {
  exclude [ group-names ];
  include-all [ group-names ];
  include-any [ group-names ];
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information Statement introduced in Junos OS Release 9.2.

Description Enable you to configure administrative groups for bypass label-switched paths (LSPs). You can configure administrative groups either globally for all bypass LSPs traversing an interface or for just a specific bypass LSP.

Options

exclude *group-names*—Specify the administrative groups to exclude for a bypass LSP.

include-all *group-names*—Specify the administrative groups whose links the bypass LSP must traverse.

include-any *group-names*—Specify the administrative groups whose links the bypass LSP can traverse.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring Administrative Groups for Bypass LSPs*

aggregate (Protocols RSVP)

Syntax

```
(aggregate | no-aggregate);
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp peer-interface *peer-interface-name*],
[edit protocols rsvp peer-interface *peer-interface-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the use of RSVP aggregate messages on an interface or peer interface, as described below.

Note that starting in Junos OS Release 15.2, this statement has been deprecated at the **[edit protocols rsvp interface *interface-name*]** and **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]** hierarchy levels for MX Series and PTX Series routers.

- **aggregate**—Use RSVP aggregate messages.
- **no-aggregate**—Do not use RSVP aggregate messages.

  Aggregate messages can pack multiple RSVP messages into a single transmission, thereby reducing network overhead and enhancing efficiency. The number of supportable sessions and processing overhead are significantly improved when aggregation is enabled.

  Not all routers connected to a subnet need to support aggregation simultaneously. Each RSVP router negotiates its intention to use aggregate messages on a per-neighbor basis. Only when both routers agree are aggregate messages sent.

To have refresh reduction and reliable delivery, you must include the **aggregate** and **reliable** statements.

Default

Aggregation is disabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

authentication-key (Protocols RSVP)

Syntax

```
authentication-key key;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],
[edit logical-systems logical-system-name protocols rsvp peer-interface peer-interface-name],
[edit protocols rsvp],
[edit protocols rsvp interface interface-name],
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Authentication key (password). Neighboring routers use the password to verify the authenticity of packets sent from this interface or peer interface. To authenticate node hellos or remote messages between the Point of Local Repair (PLR) to the Merge Point (MP), enable **authentication-key** at the **[edit protocols rsvp]** hierarchy level.

RSVP uses HMAC-MD5 authentication, which is defined in RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*.

All routers that are connected to the same IP subnet must use the same authentication scheme and password.

Options

key—Authentication password. It can be 1 through 16 contiguous digits or letters. Separate decimal digits with periods. Separate hexadecimal digits with periods and precede the string with 0x. If you include spaces in the password, enclose the entire password in quotation marks (" ").

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring RSVP Authentication*

bandwidth (Protocols RSVP)

Syntax

```
bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

For certain logical interfaces (such as Asynchronous Transfer Mode [ATM], Permanent Virtual Circuit [PVC], or Frame Relay), you cannot determine the correct bandwidth from the hardware. This statement enables you to specify the actual available bandwidth.

This statement also enables you to specify the bandwidth for a bypass label switched path (LSP). If you have configured multiple bypasses, this statement is mandatory and is applied to all of the bypass LSPs.

Default

The hardware raw bandwidth is used.

Options

bps—Bandwidth in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion [also called a thousand million]).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring the Bandwidth for Bypass LSPs*
- *Configuring Link Protection on Interfaces Used by LSPs*
- *Configuring Bypass LSPs*

bypass (Signaled LSP)

Syntax

```
bypass bypass-name {
  bandwidth bps;
  description text;
  hop-limit number;
  no-cspf;
  path address <strict | loose>;
  priority setup-priority reservation-priority;
  to address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.
The **description** option was added in Junos OS Release 10.4.

Description

Enables you to configure specific bandwidth and path constraints for a bypass LSP. It is possible to individually configure multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.

If you specify the **bandwidth**, **hop-limit**, and **path** statements for the bypass LSP, these values take precedence over the values configured at the **[edit protocols rsvp interface *interface-name* link-protection]** hierarchy level. The other attributes (**subscription**, **no-node-protection**, and **optimize-timer**) are inherited from the general constraints.

Options

bypass-name—(Required) Specify a name for the bypass LSP. The name can be up to 64 characters.

description—Provides a textual description of the bypass LSP. Enclose any descriptive text that includes spaces in quotation marks (" "). Any descriptive text you include is displayed in the output of the **show mpls lsp bypass detail** command and has no effect on the operation of the bypass LSP. The description text can be no more than 80 characters in length.

to *address*—(Required) Specify the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

bypass (Static LSP)

Syntax

```
bypass bypass-name {
  bandwidth bps;
  description string;
  next-hop (address | interface-name | address/interface-name);
  push out-label;
  to address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path
  lsp-name],
[edit protocols mpls static-label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 10.1.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure specific bandwidth and path constraints for a bypass ingress LSP. It is possible to configure multiple bypass LSPs individually. If you do not, they all share the same path and bandwidth constraints.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

chained-composite-next-hop

Syntax

```
chained-composite-next-hop {
  ingress;
  transit;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table],
[edit routing-options forwarding-table]
```

NOTE: The **[edit logical-systems]** hierarchy level is not supported on the QFX10000 switches.

Release Information

Statement introduced in Junos OS Release 12.1.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.
Statement introduced in Junos OS Release 15.1 for QFX10000 Series switches.

Description

Allows you to configure the chained composite next hops for devices handling ingress or transit traffic in the network.

Chained composite next hops help to facilitate the handling of large volumes of transit traffic in the core of large networks by allowing the router to process much larger volumes of routes. A chained composite next hop allows the router to direct sets of routes sharing the same destination to a common forwarding next hop, rather than having each route also include the destination. In the event that a network destination is changed, rather than having to update all of the routes sharing that destination with the new information, just the shared forwarding next hop is updated with the new information. The chained composite next hops continue to point to this forwarding next hop which now contains the new destination.

On platforms containing only MPCs, such as PTX Series Packet Transport Routers, the MX80 router, the MX2020 router, and the QFX10000 switches, chained composite next hops are enabled by default. On MX Series 5G Universal Routing Platforms containing both DPC and MPC FPCs and on T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default and need to be explicitly configured.

NOTE:

- Starting with Junos OS Release 13.3, for chained composite next hop feature to take effect for directly connected PE devices, the chassis must be configured to use the **enhanced-ip** option (in the case of MX Series 5G Universal Routing Platforms containing both DPC and MPC FPCs) or the **enhanced-mode** option (in the case of T4000 Core Routers containing MPC

and FPCs) in the network service mode, in addition to the l3vpn configuration.

For more information about configuring chassis network services, see the *Junos OS Administration Library*.

- On MX Series routers, removing the chained-composite-next-hop statement from a PE device configuration causes all IBGP sessions to be torn down and triggers the BGP session to flap as well. A similar change on a router configured as a route reflector does not have any effect, however.

  The following is a sample system log message that is generated to record such an event:

```
Nov  6 15:16:21.670 host PE1: rpd[6947]: bgp_peer_mgmt_clear:5995:
NOTIFICATION sent to 10.0.100.2 (External AS 100): code 6 (Cease)
subcode 4 (Administratively Reset), Reason: Management session cleared
 BGP neighbor
```

NOTE: Starting in Junos OS Release 14.1, the transit l3vpn statement is enabled by default on PTX Series Packet Transport Routers only.

The remaining statements are explained separately. See CLI Explorer.

Default This statement is disabled by default.

Options **ingress**—Enable or disable composite chained next hop for ingress traffic.

transit—Enable or disable composite chained next hop for transit traffic.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

class-of-service (Protocols RSVP)

Syntax

```
class-of-service cos-value;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Class-of-service (CoS) value given to all packets in the bypass LSP. You can specify a single CoS value for all the bypass LSPs traversing an interface. You can also configure CoS values for specific bypass LSPs traversing an interface.

The CoS value might affect the scheduling or queuing algorithm of traffic traveling along an LSP.

Options ***cos-value***—CoS value. A higher value typically corresponds to a higher level of service.

Range: 0 through 7

Default: If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  rsvp-te entry],
[edit routing-options dynamic-tunnels tunnel-name],
[edit routing-options dynamic-tunnels tunnel-name rsvp-te entry]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Specify the IPv4 prefix range for the destination network. Only tunnels within the specified IPv4 prefix range can be created.

Options

prefix—Destination prefix of the network.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

devices

Syntax devices *device-names*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information Statement introduced in Junos OS Release 8.1.

Description Specifies one of the virtual tunnel (VT) interfaces to de-encapsulate the egress traffic for ultimate-hop popping on point-to-multipoint LSPs. If no device is specified, the selection process is performed automatically.

Default The device selection process is performed automatically if no device is configured. Junos OS selects one of the available VT interfaces to de-encapsulate the egress traffic.

Options ***device-names***—Specify which VT interfaces are used to handle the RSVP traffic.

Range: 0 to 8 devices

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

disable (Protocols RSVP)

Syntax

```
disable;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit logical-systems logical-system-name protocols rsvp graceful-restart],
[edit logical-systems logical-system-name protocols rsvp interface interface-name],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit logical-systems logical-system-name protocols rsvp peer-interface peer-interface-name],
[edit protocols rsvp],
[edit protocols rsvp graceful-restart],
[edit protocols rsvp interface interface-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable RSVP or RSVP graceful restart. Explicitly disable link protection on the specified interface.

Default

RSVP is enabled on interfaces and peer interfaces configured with the RSVP **interface** statement. RSVP graceful restart is enabled on the router. Link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

dynamic-bidirectional-transport

Syntax

```
dynamic-bidirectional-transport {
  template template;
}
```

Hierarchy Level

[edit protocols rsvp peer-interface *peer-interface-name*]

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Enable the dynamic setup of associated bidirectional packet LSP for transporting non-packet Generalized Multiprotocol Label Switching (GMPLS) label-switched path (LSP).

Options

template *template*—Name of the template for the dynamic bidirectional packet LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

fast-reroute (Protocols RSVP)

Syntax

```
fast-reroute optimize-timer seconds;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information

Statement added in Junos OS Release 7.5.
Statement introduced in Junos OS Release 14.1 for the QFX Series.

Description

Configure the optimize timer for fast reroute. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

Options

seconds—Specify the number of seconds between fast reroute detour LSP optimizations.

Range: 0 through 65,535 seconds

Default: 0 (disabled)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Optimization Interval for Fast Reroute Paths on page 384

graceful-deletion-timeout

Syntax graceful-deletion-timeout *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Specify the time, in seconds, before completing graceful deletion of signaling.

Options ***seconds***—Time before completing graceful deletion of signaling.

Range: 1 through 300 seconds

Default: 30 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Graceful Deletion Timeout Interval on page 853

graceful-restart (Protocols RSVP)

Syntax

```
graceful-restart {
  disable;
  helper-disable;
  maximum-helper-recovery-time seconds;
  maximum-helper-restart-time seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit protocols rsvp],
[edit routing-options]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure graceful restart on the router. You must configure the **graceful-restart** statement at the **[edit routing-options]** hierarchy level to enable graceful restart on the router.

Options

disable—Disable graceful restart on the router or for RSVP.

helper-disable—Disable RSVP graceful restart helper mode (this option is only available at the **[edit protocols rsvp]** hierarchy level).

Default: Helper mode is enabled by default.

maximum-helper-recovery-time *seconds*—The maximum length of time the router stores the state of neighboring routers when they undergo a graceful restart. The value applies to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

Default: 180 seconds

Range: 1 through 3600 seconds

maximum-helper-restart-time *seconds*—The maximum length of time the router waits between when it discovers that a neighboring router has gone down and when it declares the neighbor down. This value is applied to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

Default: 20 seconds

Range: 1 through 1800 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring RSVP Graceful Restart*

hello-acknowledgements

Syntax hello-acknowledgements;

Hierarchy Level [edit logical-systems *logical-systems-name* protocols rsvp],
[edit protocols rsvp]

Release Information Statement introduced in Junos OS Release 10.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Enable hello messages from nonsession neighbors to be acknowledged with a hello acknowledgment message. Once hello acknowledgments are enabled, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or the configuration is changed by an administrator.

Default Hello acknowledgments are disabled.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring Hello Acknowledgments for Nonsession RSVP Neighbors*

hello-interval (Protocols RSVP)

Syntax

```
hello-interval seconds;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*],
[edit logical-systems *logical-system-name* protocols rsvp peer-interface *peer-interface-name*],
[edit protocols rsvp interface *interface-name*],
[edit protocols rsvp peer-interface *peer-interface-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable the sending of hello packets on the interface.

Options

seconds—Length of time between hello packets. A value of 0 disables the sending of hello packets on the interface.

Range: 1 through 60 seconds

Default: 9 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

  link-protection bypass bypass-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name fast-reroute],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

Range: 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)

Default: 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
```

[edit protocols rsvp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Enable RSVP on one or more router interfaces.

Default RSVP is disabled on all interfaces.

Options ***interface-name***—Name of an interface. To configure all interfaces, specify **all**. For details about specifying interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Minimum RSVP Configuration*

keep-multiplier

Syntax keep-multiplier *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Specify a value used by RSVP to calculate timer values for network outages, and declare that a reservation or a neighbor is down. It indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

Starting in Junos OS Release 16.1, for MX Series routers and PTX Series routers, the default RSVP message refresh time, to which this multiplier is applied, has increased from 30 seconds to 20 minutes. The higher message refresh time provides support for RSVP Refresh Reduction Extensions, and improved scaling for MPLS traffic-engineered LSPs, as defined in RFC 2961. The changes are backward compatible so if any nodes in the two-hop neighborhood do not support the higher refresh time, the updated node will automatically fall back to the previous default refresh time to prevent error or tear down messages.

Options ***number***—Multiplier value.

Range: 1 through 255

Default: 3

NOTE: For MX Series routers and PTX Series routers (running Junos OS release 16.1 or later), this multiplier is applied to a default refresh time of 20 minutes. In earlier Junos OS releases, and for other platforms, the default refresh time remains 30 seconds.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 8.5.
Statement introduced in Junos OS Release 18.2. under the heirarchy level [edit routing-instances *instance-name* provider-tunnel]

Description

Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs. This feature can be used for a number of applications, including point-to-multipoint LSPs, flooding VPLS traffic, configuring ingress replication for IP multicast using MBGP MVPNs, and to enable RSVP automatic mesh. There is no default setting for the **label-switched-path-template** statement, so you must configure either the default-template using the **default-template** option, or you must specify the name of your preconfigured LSP template.

Options

default-template—Specify that the default LSP template be used for the dynamically generated LSPs.

lsp-template-name—Specify the name of an LSP to be used as a template for the dynamically generated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  subscription percentage;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*],
[edit protocols rsvp interface *interface-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable link protection on the specified interface. Using link protection, you can configure a network to reroute traffic quickly around broken links. To fully enable link protection, you also need to configure the **link-protection** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level. You can configure single or multiple bypasses for protected interface.

Default Link protection is disabled.

Options **no-node-protection**—Disable node-link protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- link-protection (Dynamic LSPs) on page 1865

load-balance (Protocols RSVP)

Syntax

```
load-balance {
  bandwidth;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Load-balance traffic between RSVP LSPs.

Options **bandwidth**—Load-balance traffic between RSVP LSPs based on the bandwidth configured for each LSP.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- *Configuring Load Balancing Across RSVP LSPs*

max-bypasses

Syntax max-bypasses *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*], [edit protocols rsvp interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Range modified in Junos OS Release 9.3.

Description Specify the maximum number of dynamic bypass LSPs permitted for protecting this interface. When this option is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled. The limit on bypasses configured applies only to dynamically generated bypass LSPs. By default, this option is disabled and only one dynamic bypass LSP is enabled for each interface. If you configure **max-bypasses**, you must also configure the **bandwidth** statement.

Options ***number***—Configure the maximum number of bypass LSPs. If you configure a value of 0, no dynamic bypass LSPs are allowed to be established for the interface. Only static bypass LSPs can be configured.

Range: 0 through 99

Default: 1

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring the Maximum Number of Bypass LSPs*

no-local-reversion

Syntax

```
local-reversion;
no-local-reversion;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information Statement introduced in Junos OS Release 10.4.

Description Disable RSVP local revertive mode as specified in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, **no-local-reversion** is enabled by default, that is, local reversion is not running, and the statement has been deprecated. To enable local reversion, use the **local-reversion** statement.

RSVP local revertive mode is supported on all Juniper Networks routers running Junos OS. It is the default behavior. If you include this statement, the Juniper Networks router uses global revertive mode instead. You might need to disable RSVP local revertive mode on Juniper Networks routers if your network includes equipment that does not support this mode.

The following information can also be found in RFC 4090. Refer to the RFC for additional information. When an LSP fails, the connection can be repaired locally using a traffic protection mechanism such as fast reroute. To restore the LSP to a full working path, RFC 4090 specifies the following strategies:

- Local revertive mode—Upon detecting that the path is restored, the point of local repair (PLR) resignals each of the LSPs that were formerly routed over the restored path. Every LSP successfully resignaled along the restored path is switched back.
- Global revertive mode—The ingress router of each tunnel is responsible for reoptimizing the LSPs that used the failed path. There are several potential reoptimization triggers: RSVP error messages, inspection of OSPF LSAs or IS-IS LSPs, and timers. This re-optimization process can proceed as soon as the failure is detected. It is not tied to the restoration of the failed path.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

node-hello

Syntax

```
(node-hello | no-node-hello);
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information

Statement introduced in Junos OS Release 10.0.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable node-ID based RSVP hellos globally on all of the RSVP interfaces on the router to allow Juniper Networks routers to interoperate with the equipment of other vendors. By default, the Junos OS uses interface-based RSVP hellos;node-ID based RSVP hellos are disabled. If you have not enabled RSVP node IDs on the router, Junos OS does not accept any node-ID hello packets.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, when using enhanced FRR, node-ID based hellos are enabled by default. Disabling the enhanced fast reroute (FRR) profile by using the no-enhanced-frr-bypass command also disables the node-hello command. To re-enable node hellos after the enhanced FRR profile has been disabled, use the node-hello command.

NOTE: If link-protection is enabled, remote node hellos that are initiated by the Point of Local Repair (PLR) to Node Protecting Merge Point (NP-MP) are enabled automatically. Similarly, if no-enhanced-frr-profile is enabled (that is, enhanced FRR is off), remote node hellos are automatically disabled. There is no command to explicitly enable or disable remote-node hellos.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

no-adjacency-down-notification (Protocols IS-IS)

Syntax

```
no-adjacency-down-notification;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols isis interface *interface-name*],
[edit protocols isis interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 8.0.

Description

Disable adjacency down notification for IS-IS to allow for migration from IS-IS to OSPF without disruption of the RSVP neighbors and associated RSVP-signaled label-switched paths (LSPs).

Whenever IS-IS is deactivated, the IS-IS adjacencies are brought down. IS-IS signals to RSVP to bring down any RSVP neighbors associated with the IS-IS adjacencies, and this further causes the associated LSPs signaled by RSVP to go down as well.

A similar process occurs whenever OSPF is deactivated. The OSPF neighbors are brought down. OSPF signals to RSVP to bring down any of the RSVP neighbors associated with the OSPF neighbors, and this further causes the associated LSPs signaled by RSVP to go down as well.

If you need to migrate from IS-IS to OSPF or from OSPF to IS-IS, the internal gateway protocol (IGP) notification to RSVP for an adjacency or neighbor down event needs to be ignored. Using the **no-adjacency-down-notification** or no-neighbor-down-notification statements, you can disable IS-IS adjacency down notification or OSPF neighbor down notification, respectively, until the migration is complete. The network administrator is responsible for configuring the statements before the migration, and then removing them from the configuration afterward, so that IGP notification can function normally.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- no-neighbor-down-notification on page 2029

no-cspf (Protocols RSVP)

Syntax

```
no-cspf;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information Statement introduced in Junos OS Release 7.5.

Description Disable CSPF computation on all bypass LSPs or on a specific bypass LSP. You need to disable CSPF for link protection to function properly on interarea paths.

Default CSPF is enabled.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Disabling CSPF for Bypass LSPs*

no-interface-hello

Syntax no-interface-hello;

Hierarchy Level [edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information Statement introduced in Junos OS Release 10.0.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Explicitly disable RSVP interface hellos globally on the router.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, the behavior of this statement has changed. On these platforms, rather than disabling RSVP interface hellos globally, the no-interface-hello command triggers a switch back to the previous profile for all label-switched paths (LSPs.)

This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the hello-interval statement. This configuration disables RSVP interface hellos globally but enables RSVP interface hellos on the specified interface. This configuration might be necessary in a heterogeneous network where some devices support RSVP node-ID hellos and other devices support RSVP interface hellos.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- hello-interval (Protocols RSVP) on page 2013

no-neighbor-down-notification

Syntax
```
no-neighbor-down-notification;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols ospf area area-id interface
  interface-name],
[edit protocols ospf area area-id interface interface-name]
```

Release Information Statement introduced in Junos OS Release 8.0.

Description Disable neighbor down notification for OSPF to allow for migration from OSPF to IS-IS without disruption of the RSVP neighbors and associated RSVP-signaled LSPs.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

no-node-id-subobject

Syntax

```
no-node-id-subobject;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information

Statement introduced in Junos OS Release 9.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable the record route object (RRO) node-ID subobject for compatibility with earlier versions of Junos OS.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, the behavior of this statement has changed. On these platforms, rather than disabling the record route object (RRO) node ID sub-object, the **no-node-id-subobject** command triggers a switch back to the previous profile for all label-switched paths (LSPs).

To interoperate with other vendors' equipment, Junos OS supports the RRO node-ID subobject for use in inter-AS link and node protection configurations.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring Inter-AS Node and Link Protection*

no-p2mp-sublsp

Syntax
```
no-p2mp-sublsp;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information
Statement introduced in Junos OS Release 9.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Reject Resv messages that include the S2L_SUB_LSP object. By default, Resv messages that include the S2L_SUB_LSP object are accepted. However, in a network which includes Juniper Networks devices running both Junos OS Release 9.2 and later and Junos OS Release 9.1 and earlier, it is necessary to configure the **no-p2mp-sublsp** statement on devices running Junos OS Release 9.2 and later to ensure that point-to-multipoint LSPs function properly.

Default
Resv messages that include the S2L_SUB_LSP object are accepted.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases on page 558

no-enhanced-frr-bypass (Protocols RSVP)

Syntax

```
no-enhanced-frr-bypass;
```

Hierarchy Level

```
[edit protocols rsvp ]
```

Release Information

Statement introduced in Junos OS Release 15.2R1.

Description

Enable **no-enhanced-frr-bypass** to turn off all Fast reroute (FRR) facility protection enhancements, which includes improved LSP scaling and enhanced RSVP message handling, and reduce the default refresh time to 30 seconds.

FRR is enabled by default for MX Series and PTX Series routers starting in Junos OS Release 15.2R1.

Default

This feature, **no-enhanced-frr-bypass**, is disabled by default. That is, enhanced FRR is enabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *RSVP Refresh Reduction*

node-link-protection (Protocols MPLS)

Syntax

```
node-link-protection;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*],
[edit protocols mpls label-switched-path *lsp-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable node and link protection on the specified LSP. To fully enable node and link protection, you also need to include the **link-protection** statement at the **[edit protocols rsvp interface *interface-name*]** hierarchy level.

Default

Node and link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

optimize-timer (Protocols RSVP)

Syntax

```
optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit protocols rsvp interface interface-name link-protection]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure an optimize timer for a bypass LSP. The optimize timer initiates a periodic optimization process that reshuffles data LSPs among bypass LSPs to achieve the most efficient use of network resources. The optimization process attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all bypasses, or both.

Options ***seconds***—Specify the number of seconds between optimizations.

Range: 0 through 65,535 seconds

Default: 0 (disabled)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring the Optimization Interval for Bypass LSPs*

path (Protocols RSVP)

Syntax

```
path address <strict | loose>;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name
  link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure an explicit path (a sequence of strict or loose routes) to control where and how a bypass LSP is established. If multiple bypasses are configured, they all will use the same explicit path.

Default No path is configured. CSPF automatically calculates the path the bypass LSP takes.

Options

address—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the bypass LSP.

loose—(Optional) The next address in the **path** statement is loose. The LSP can traverse other routers before reaching this router.

Default: **strict**

strict—(Optional) The LSP must go to the next address specified in the **path** statement without traversing other nodes. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

peer-interface (Protocols RSVP)

Syntax

```
peer-interface peer-interface-name {
  disable;
  (aggregate | no-aggregate);
  authentication-key key;
  dynamic-bidirectional-transport template template;
  hello-interval seconds;
  (reliable | no-reliable);
}
```

Hierarchy Level

```
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
dynamic-bidirectional-transport template *template* option introduced in Junos OS Release 14.2.

Description

Configure the name of the LMP peer device.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

pop-and-forward (Protocols RSVP)

Syntax

```
pop-and-forward {
  application-label depth depth;
}
```

Hierarchy Level

```
[edit logical-systems name protocols rsvp],
[edit logical-systems name routing-instances name protocols rsvp],
[edit protocols rsvp],
[edit routing-instances name protocols rsvp]
```

Release Information Statement introduced in Junos OS Release 18.1R1 on MX Series routers, PTX Series routers, and vMX.

Description Specify RSVP pop-and-forward LSP tunnel-specific global parameters. The application label depth (AppLD) value must be configured uniformly across the RSVP-TE network.

Options **application-label depth *depth***—Specify the maximum number of service labels.

Range: 0 through 3

Default: 1

Required Privilege Level routing

preemption

Syntax

```
preemption {
  (aggressive | disabled | normal);
  soft-preemption {
    cleanup-timer seconds;
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control RSVP session preemption.

Default

normal

Options

aggressive—Preempt RSVP sessions whenever bandwidth is insufficient to handle all sessions. A session is preempted whenever bandwidth is lowered or a new higher-priority session is established.

disabled—Do not preempt RSVP sessions.

normal—Preempt RSVP sessions to accommodate new higher-priority sessions when bandwidth is insufficient to handle all sessions.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Preempting RSVP Sessions*

priority (Protocols RSVP)

Syntax

priority *setup-priority reservation-priority*;

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection],
[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*],
[edit protocols rsvp interface *interface-name* link-protection],
[edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*],

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the setup priority and reservation priority for a bypass LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. The session with the lower-hold priority is preempted.

Options

reservation-priority—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 0 (Once the session is set up, no other session can preempt it.)

setup-priority—Setup priority.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 7 (The session cannot preempt any existing sessions.)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

reliable

Syntax

```
(reliable | no-reliable);
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*],
[edit logical-systems *logical-system-name* protocols rsvp peer-interface *peer-interface-name*],
[edit protocols rsvp interface *interface-name*],
[edit protocols rsvp peer-interface *peer-interface-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable reliable message delivery on the interface.

To have both refresh reduction and reliable delivery, enable both the **aggregate** and **reliable** statements.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, setting **no-reliable** on an interface automatically disables the fast reroute (FRR) scalability enhancements, including refresh reduction, for all label-switched paths (LSPs) traversing the interface.

Default

This option, **reliable**, is disabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

rsvp

Syntax

```
rsvp;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols],
[edit protocols]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Enable Resource Reservation Protocol (RSVP) signaling.

You must include the **rsvp** statement in the configuration to enable RSVP on the router.

The primary purpose of RSVP in Junos OS for EX Series switches is to support dynamic signaling within label switched paths (LSPs).

Default

RSVP is disabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

rsvp-te (Routing Options)

Syntax

```
rsvp-te entry-name {
  destination-networks network-prefix;
  label-switched-path-template (Multicast) {
    default-template;
    template-name;
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*],
[edit routing-options dynamic-tunnels *tunnel-name*]

Release Information

Statement introduced in Junos OS Release 10.1.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Enable RSVP to automatically establish LSPs for any new PE router added to a full mesh of LSPs. To enable this feature, you must configure the **rsvp-te** statement on all of the PE routers in the full mesh.

Options

entry-name—Specify the entry for the RSVP tunnel.

The other options are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

setup-protection

Syntax

```
setup-protection;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Description

The facility-backup fast reroute mechanism can provide setup protection for LSPs which are in the process of being signaled. Both point-to-point LSPs and point-to-multipoint LSPs are supported. You should configure the **setup-protection** statement on each of the routers along the LSP path on which you want to enable LSP setup protection. You should also configure IGP traffic engineering on all of the routers on the LSP path.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring RSVP Setup Protection*

soft-preemption (Protocols RSVP)

Syntax

```
soft-preemption {
  cleanup-timer seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp preemption],
[edit protocols rsvp preemption]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable soft preemption to attempt to establish a new path for a preempted LSP before tearing it down.

Options

cleanup-timer—A value of 0 disables soft preemption.

Range: 0 through 180 seconds

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the amount of bandwidth subscribed to a class type (when you have enabled Differentiated Services) or bypass LSP (when you have enabled link protection). **subscription** is the percentage of the link bandwidth that can be used for the RSVP reservation process.

Options

ct*number percentage*—Percentage of the class-type bandwidth allowed for reservations. If you specify a value greater than 100, you are oversubscribing the class type. You can specify bandwidth subscriptions for class types 0 through 3. This option is not available for bypass LSPs.

Range: 0 through 65,000

Default: 100 percent

percentage—Percentage of the class-type or bypass LSP bandwidth allowed for reservations. If you specify a value greater than 100, you are oversubscribing the class type or bypass LSP.

Range: 0 through 65,000

Default: 100 percent

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols RSVP)

Syntax

```
traceoptions {
  enhanced-frr ;
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols rsvp],
[edit protocols rsvp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable RSVP-level trace options.

Default

The default RSVP-level trace options are those inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

enhanced-frr —(Optional) Enable this option to trace internal events and state changes related to the FRR facility protection enhancements associated with the increased RSVP scaling introduced in Junos OS Release 16.1.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **all**—All tracing operations
- **error**—All detected error conditions

- **event**—RSVP-related events
- **io-event [detail] [disable]** —Enable tracing of events that occur within the RSVP I/O task; can only be configured for the master routing instance. The trace output is generally independent of routing instance.
- **io-packets [detail] [disable] [receive] [send]** —Enable tracing of messages as they are received from the network or as they are sent out. This flag can be configured independently for each routing instance. Both bundled and individual messages are identified. Use *detail* to show all objects contained in the message. Use *send* and *receive* to limit tracing to outgoing or incoming packets.
- **lmp**—RSVP-LMP interactions
- **packets**—All RSVP packets
- **path**—All path messages
- **pathtear**—PathTear messages
- **resv**—Resv messages
- **resvtear**—ResvTear messages
- **route**—Routing information
- **state**—Session state transitions, including when RSVP-signaled LSPs come up and go down.

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-world-readable—(Optional) Enable only certain users to read the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When the ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

    bandwidth bps;
    description string;
    link-protection bypass-name name;
    next-hop (address | interface-name | address/interface-name);
    node-protection bypass-name name next-next-label label;
  }
  swap out-label;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path
  lsp-name],
[edit protocols mpls static-label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 10.1.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
Statement updated to include switch option in Junos OS Release 14.1X53-D25

Description

Configure a transit static LSP.

NOTE: When configuring transit static LSPs with label operation as stitch, the configured next-hop can only be a valid IP address and not an interface name.

The remaining statements are explained separately. See CLI Explorer.

Options

incoming-label—Incoming label value.

Range: 1000000 through 1048575

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

tunnel-services (RSVP)

Syntax

```
tunnel-services {
  devices device-names;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 8.1.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable ultimate-hop popping on point-to-multipoint LSPs. The Junos OS selects one of the available virtual tunnel (VT) interfaces to de-encapsulate the egress traffic. By default, the selection process is performed automatically.

Default

Ultimate-hop popping is disabled.

Options

devices *device-names*—Specify which VT interfaces are used to handle the RSVP traffic.

Range: 0 to 8 devices

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information

Statement introduced in Junos OS Release 12.3.
Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

Description

Enable ultimate-hop popping on LSPs. Configure this statement on the device at the LSP ingress. In ultimate-hop popping, the MPLS label is popped from the IP packet at the PE router. The IP address is checked in a second address lookup (also at the PE router), and then the packet is forwarded to its destination.

Be aware of the following platform requirements and restrictions:

- UHP LSPs using VT interfaces—Supported on all M Series, MX Series, T Series, and TX Matrix routers.
- UHP LSPs using LSI interfaces—Supported on MX 3D Series routers only.
- UHP LSP requirements for the egress PE device—For M Series and T Series routers, a VT interface is needed.
- UHP LSPs and Layer 3 VPNs—UHP LSPs are supported for Layer 3 VPNs configured on MX 3D Series routers only.
- UHP LSPs and VPLS—UHP LSPs are supported for VPLS configured on MX 3D Series routers only. You must configure the *no-tunnel-services* statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

Default

Ultimate-hop popping is disabled by default on LSPs. Penultimate-hop popping is the default behavior. In penultimate-hop popping, the final MPLS label is popped from the IP packet at the last provider router in the network before being forwarded to the PE router. The PE router receives the packet and checks the IP address, and then the packet is forwarded to its destination.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Statement introduced for BMP in Junos OS Release 13.3.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Configure an authentication algorithm type.

NOTE: Keep the following points in mind when you configure the authentication algorithm in an IPsec proposal:

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, an error occurs and the tunnel is not established in this scenario. For example, if one end of the tunnel contains router 1 configured with the authentication algorithm as hmac-sha-256-128 and the other end of the tunnel contains router 2 configured with the

authentication algorithm as hmac-md5-96, the VPN tunnel is not established.

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, and when one end of the tunnel contains two IPsec proposals to check whether a less secure algorithm is selected or not, an error occurs and the tunnel is not established. For example, if you configure two authentication algorithms for an IPsec proposal as hmac-sha-256-128 and hmac-md5-96 on one end of the tunnel, router 1, and if you configure the algorithm for an IPsec proposal as hmac-md5-96 on the other end of the tunnel, router 2, the tunnel is not established and the number of proposals mismatch.
- When you configure two IPsec proposals at both ends of a tunnel, such as the **authentication-algorithm hmac-sha-256-128** and **authentication- algorithm hmac-md5-96** statements at the **[edit services ipsec-vpn ipsec proposal** *proposal-name*] hierarchy level on one of the tunnel, router 1 (with the algorithms in two successive statements to specify the order), and the **authentication-algorithm hmac-md5-96** and **authentication- algorithm hmac-sha-256-128** statements at the **[edit services ipsec-vpn ipsec proposal** *proposal-name*] hierarchy level on one of the tunnel, router 2 (with the algorithms in two successive statements to specify the order, which is the reverse order of router 1), the tunnel is established in this combination as expected because the number of proposals is the same on both ends and they contain the same set of algorithms. However, the authentication algorithm selected is hmac-md5-96 and not the stronger algorithm of hmac-sha-256-128. This method of selection of the algorithm occurs because the first matching proposal is selected. Also, for a default proposal, regardless of whether the router supports the Advanced Encryption Standard (AES) encryption algorithm, the 3des-cbc algorithm is chosen and not the aes-cfb algorithm, which is because of the first algorithm in the default proposal being selected. In the sample scenario described here, on router 2, if you reverse the order of the algorithm configuration in the proposal so that it is the same order as the one specified on router 1, hmac-sha-256-128 is selected as the authentication method.
- You must be aware of the order of proposals in an IPsec policy at the time of configuration if you want the matching of proposals to happen in a certain order of preference, such as the strongest algorithm to be considered first when a match is made when both policies from the two peers have a proposal.

Options ***algorithm***—Specify one of the following types of authentication algorithms:

- **aes-128-cmac-96**—Cipher-based message authentication code (AES128, 96 bits).
- **hmac-sha-1-96**—Hash-based message authentication code (SHA1, 96 bits).
- **md5**—Message digest 5.

Default: hmac-sha-1-96

NOTE: **The default is not displayed in the output of the show bgp bmp command unless a key or key-chain is also configured.**

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

authentication-key-chain (Protocols LDP)

Syntax

```
authentication-key-chain key-chain;
```

Hierarchy Level

```
[edit logical-systems name protocols ldp session address],
[edit logical-systems name routing-instances instance-name protocols ldp session address],
[edit protocols ldp session address],
[edit routing-instances instance-name protocols ldp session address]
```

Release Information

Statement introduced in Junos OS Release 8.0.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Apply and enable an authentication keychain to the routing device. Note that the referenced key chain must be defined. When configuring the authentication key update mechanism for LDP, you cannot commit the **0.0.0.0/allow** statement with authentication keys or key chains. The CLI issues a warning and fails to commit such configurations.

NOTE: You must also configure an authentication algorithm using the **authentication-algorithm** statement.

Options

key-chain—Authentication keychain name. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (“ ”).

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

auto-targeted-session

Syntax

```
auto-targeted-session {
  maximum-sessions seconds;
  teardown-delay seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit protocols ldp]
```

Release Information Statement introduced in Junos OS Release 14.2.

Description Configure session parameters for LDP sessions established with the remote LFA node that are automatically targeted using the loopback addresses. Configure parameters of automatically targeted sessions for remote LFA only.

Options

maximum-sessions *seconds* —Specify the maximum number of auto-targeted LDP sessions allowed. Include this statement to optimize the use of router memory.

Default: 100

Range: 1 through 1000

teardown-delay *seconds* —Specify the minimum time period for which the auto-targeted session must be alive before tearing down the auto-targeted LDP sessions to the remote LFA node. Include this statement to prevent rapid route-resolution in case of temporary change in IGP topology.

Default: 90 seconds

Range: 1 through 300 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```
[edit logical-systems logical-system-name protocols ldp oam],
[edit logical-systems logical-system-name protocols ldp oam fec address],
[edit protocols ldp oam],
[edit protocols ldp oam fec address]
```

Release Information

Statement introduced in Junos OS Release 7.6.
Support for the **bfd-liveness-detection** statement at the **[edit protocols ldp oam fec *address*]** hierarchy level and the **ecmp** option added in Junos OS Release 9.0.
Support for the **failure-action** statement with the **remove-nexthop** and **remove-route** options and the **holddown-interval** statement added in Junos OS Release 9.4.

Description

Enable Bidirectional Forwarding Detection (BFD) for all MPLS LSPs or for just a specific LSP.

Options

minimum-interval—Minimum transmit and receive interval.

Range: 50 through 255,000 milliseconds

Default: 50

minimum-receive-interval—Minimum receive interval.

Range: 50 through 255,000 milliseconds

Default: 50

minimum-transmit-interval—Minimum transmit interval.

Range: 50 through 255,000 milliseconds

Default: 50

multiplier—Detection time multiplier.

Range: 50 through 255

Default: 3

The other options are explained separately.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

deaggregate

Syntax

```
deaggregate | no-deaggregate;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Control forwarding equivalence class (FEC) deaggregation on the router. The use of the **deaggregate** statement in LDP is a standard practice that we recommend for LDP deployments.

Default
Deaggregation is disabled on the router.

Options
deaggregate—Deaggregate FECs.

no-deaggregate—Aggregate FECs.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

dod-request-policy

Syntax

```
dod-request-policy dod-request-policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the name of the LDP downstream on demand request policy. LDP sends label request messages only for those FECs matching in the downstream on demand request policy.

Options

dod-request-polcy-name—Specify the name of the downstream on demand request policy.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Example: Configuring LDP Downstream on Demand*

downstream-on-demand

Syntax

```
downstream-on-demand;
```

Hierarchy Level

[edit logical systems *logical-system-name* protocols ldp session *session-address*],
[edit protocols ldp session *session-address*]

Release Information

Statement introduced in Junos OS Release 12.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable LDP downstream on demand on the LDP session. LDP is widely deployed in downstream unsolicited advertisement mode. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between access and aggregation networks to minimize the workload for the access node (AN) control plane and to avoid the storage of tens of thousands of label bindings from upstream aggregation nodes.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Example: Configuring LDP Downstream on Demand*

ecmp

Syntax

```
ecmp;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-liveness-detection],
[edit logical-systems logical-system-name protocols ldp oam fec address
  bfd-liveness-detection],
[edit protocols ldp oam bfd-liveness-detection],
[edit protocols ldp oam fec address bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 8.5.
Statement introduced in Junos OS Release 15.1X53-D30 for QFX Series switches.

Description

Allows LDP to establish BFD sessions for all ECMP paths configured for the specified FEC. If you configure the **ecmp** statement, you must also configure the **periodic-traceroute** statement for the specified FEC. If you do not do so, the commit operation fails. You can configure the **periodic-traceroute** statement at the global hierarchy level (**[edit protocols ldp oam]**) while only configuring the **ecmp** statement for a specific FEC (**[edit protocols ldp oam fec *address* bfd-liveness-detection]**).

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  bfd-livenesss-detection],
[edit protocols ldp oam bfd-livenesss-detection],
[edit protocols ldp oam fec address bfd-livenesss-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Configure route and next-hop properties in the event of a BFD session failure event on an LDP LSP. The failure event could be an existing BFD session that has gone down or could be a BFD session that never came up. LDP adds back the route or next hop when the relevant BFD session comes back up.

Options

remove-nexthop—Remove a route corresponding to a next hop of the LSP's route at the ingress node when a BFD session failure event is detected.

remove-route—Remove the route corresponding to an LSP from the appropriate routing tables when a BFD session failure event is detected. If the LSP is configured with ECMP and a BFD session corresponding to any path goes down, the route is removed.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

graceful-restart (Protocols LDP)

Syntax

```
graceful-restart {
  disable;
  helper-disable;
  maximum-neighbor-recovery-time value;
  reconnect-time seconds;
  recovery-time value;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Configure LDP graceful restart on the LDP master protocol instance or for a specific routing instance.

NOTE: When you alter the graceful restart configuration at either the **[edit routing-options graceful-restart]** or **[edit protocols ldp graceful-restart]** hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

hello-interval (Protocols LDP)

Syntax

```
hello-interval seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp interface interface-name],
[edit logical-systems logical-system-name protocols ldp targeted-hello],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp interface interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp targeted-hello],
[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Support for LDP targeted hellos added in Junos OS Release 9.5.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the LDP timer that regulates how often hello messages are sent. You can control the rate both link hello messages and targeted hello messages are sent depending on the hierarchy level at which you configure the **hello-interval** statement.

Options

seconds—Length of time between transmission of hello packets.

Range: 1 through 65,535 seconds

Default: 5 seconds for link hello messages, 15 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring the LDP Timer for Hello Messages*

helper-disable (LDP)

Syntax

```
helper-disable;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp graceful-restart],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
    ldp graceful-restart],
[edit protocols ldp graceful-restart],
[edit routing-instances routing-instance-name protocols ldp graceful-restart]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable helper mode for LDP graceful restart. When helper mode is disabled, a router cannot help a neighboring router that is attempting to restart LDP.

Default

Helper mode is enabled by default on all routing protocols (including LDP) that support graceful restart.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring LDP Graceful Restart*

holddown-interval

Syntax

```
holddown-interval holddown-interval;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-livenesss-detection],
[edit logical-systems logical-system-name protocols ldp oam fec address
  bfd-livenesss-detection],
[edit protocols ldp oam bfd-livenesss-detection],
[edit protocols ldp oam fec address bfd-livenesss-detection]
```

Release Information Statement introduced in Junos OS Release 9.4.

Description Specify how long the BFD session should be up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

Options ***holddown-interval***—Number of seconds the BFD session should remain up before adding the route or next hop.

Default: 0 seconds

Range: 0 through 65,535 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring the Holddown Interval for the BFD Session*

hold-time (Protocols LDP)

Syntax

```
hold-time seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp interface interface-name],
[edit logical-systems logical-system-name protocols ldp targeted-hello],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp interface interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp targeted-hello],
[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Support for LDP targeted hellos added in Junos OS Release 9.5.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. You can specify times for both link hello messages and targeted hello messages depending on the hierarchy level at which you configure the **hold-time** statement.

Options

seconds—Hold-time value.

Range: 1 through 65,535 seconds

Default: 15 seconds for link hello messages, 45 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

ignore-lsp-metrics

Syntax

```
ignore-lsp-metrics;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts],
[edit protocols ospf traffic-engineering shortcuts]

Release Information

Statement introduced in Junos OS Release 7.5.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Cause OSPF to ignore the RSVP LSP metric.

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This can cause interoperability problems when you configure LDP tunneling over RSVP LSPs in heterogeneous networks.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks*

igp-synchronization

Syntax

```
igp-synchronization holddown-interval seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 9.5.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

Options

holddown-interval *seconds*—Time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational.

Default: 10 seconds

Range: 10 through 60 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Configuring LDP Synchronization with the IGP on the Router*

import (Protocols LDP)

Syntax

```
import [ policy-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
    ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Apply policy filters to received LDP label bindings. Filters are applied to all label bindings from all neighbors.

Options

policy-names—Name of one or more routing policies.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Filtering Inbound LDP Label Bindings*

ingress-policy

Syntax

```
ingress-policy [ ingress-policy-names ];
```

Hierarchy Level

[edit logical-system *logical-system-name* protocols ldp entropy-label],
[edit logical-system *logical-system-name* protocols ldp oam],
[edit protocols ldp entropy-label],
[edit protocols ldp oam]

Release Information

Statement introduced in Junos OS Release 9.4.
Statement introduced at the **[edit protocols ldp entropy-label]** hierarchy level in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Configure an LDP ingress policy for either the entropy label or Operation, Administration, and Management (OAM).

For OAM, configure the ingress policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

Options

ingress-policy-names—Specify the names of the ingress policies.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

interface (Protocols LDP)

Syntax

```
interface interface-name {
  disable;
  hello-interval seconds;
  hold-time seconds;
  transport-address (interface | loopback);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable LDP on one or more router interfaces.

Default

LDP is disabled on all interfaces.

Options

interface-name—Name of an interface. To configure all interfaces, specify **all**.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

keepalive-timeout

Syntax

```
keepalive-timeout seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Set the keepalive timeout value. The keepalive timeout defines the amount of time that the neighbor LDP node waits before determining that the session has failed.

Options

seconds—Keepalive timeout value.

Range: 1 through 65,535

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for EX Series switches.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
dual-transport statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.
family statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.
transport-preference option introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description

Enable LDP routing on the router or switch.

You must include the **ldp** statement in the configuration to enable LDP on the router or switch.

Default

LDP is disabled on the router.

Options

transport-preference ipv4 | ipv6— Select the preferred transport for TCP connection when both IPv4 and IPv6 are enabled. If **transport-preference ipv4** is configured, LDP will attempt to establish the TCP connection using IPv4. If **transport-preference ipv6** is configured, LDP will attempt to establish the TCP connection using IPv6.

Default: ipv6

The other statements are explained separately.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

make-before-break (LDP)

Syntax

```
make-before-break {
  timeout seconds;
  switchover-delay seconds;
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Description

Configures make before break (MBB) for multicast LDP (MLDP) link protection to ensure minimum packet loss when attempting to signal a new label-switched path (LSP) before tearing down the old LSP path.

Options

timeout *seconds*—Specify a value to change a make -before-break timeout for point-to-multipoint LSPs. Even if an MBB acknowledgment is not received for a point-to-multipoint LSP before the specified timeout period expires, the label-switching router (LSR) performs an MBB switchover from the old LSR to the new upstream LSR.

Range: 1 through 300 seconds

Default: 30 seconds

switchover-delay *seconds*—Specify a value to change switchover delay for a point-to-multipoint LSP from the old LSR to the new upstream LSR. If an MBB acknowledgment is received on a point of local repair (PLR) router, the PLR waits for the specified seconds to switch its upstream LSR from the old LSR to the new LSR.

Range: 1 through 300 seconds

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

mapping-server-entry mapping-server-name {
  prefix-segment prefix;
  prefix-segment-range prefix-segment-range-name;
}
```

Hierarchy Level

```
[edit logical-systems name routing-instances name routing-options source-packet-routing],
[edit logical-systems name routing-options source-packet-routing],
[edit routing-instances name routing-options source-packet-routing],
[edit routing-options source-packet-routing]
```

Release Information

Statement introduced in Junos OS Release 18.2R1.

Description

Configure an LDP mapping server to enable interoperability between islands of devices supporting only segment routing and only LDP in an LDP network domain.

The mapping server configuration can be included an on any device in the segment routing network.

Options

mapping-server-entry-name—Name of the LDP mapping server.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing

mldp-inband-signalling (Protocols Multipoint LDP)

Syntax

```
mldp-inband-signalling {
  policy policy-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim],
[edit protocols pim],
```

Release Information

Statement introduced in Junos OS Release 13.2.
Support added in Junos OS Release 18.2R1 for using this command in conjunction with distributed MLD or distributed IGMP.

Description

Multipoint LDP (mLDP) in-band signalling lets you carry multicast traffic across an existing IP/MPLS backbone, while avoiding the use of PIM in the provider core.

On the label-edge router (LER), enable PIM to use mLDP in-band signaling for the upstream neighbors when the LER does not detect a PIM upstream neighbor. On the egress nodes, configure the MPLS LSP root in the PIM configuration, using the **policy** statement.

When used in conjunction with distributed MLD or distributed IGMP, mLDP inband signalling supports interconnecting separate PIM domains via a MPLS-based core. To enable the inter-working, **chassis network-services enhanced-ip** must be enabled and you need to set the **dynamic-profiles profile-name protocols *igmp|mld* interface *interface-name*** to **distributed**. Enabling this command, **mldp-inband-signalling**, has PIM act as a multipoint LDP inband edge router.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- *Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs*

mofrr-asm-starg (Multicast-Only Fast Reroute in a PIM Domain)

Syntax

```
mofrr-asm-starg;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options multicast stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

Enable **mofrr-asm-starg** to include any-source multicast (ASM) for (*,G) joins in the Multicast-only fast reroute (MoFRR).

NOTE: **mofrr-asm-starg** applies to IP-PIM only. When enabled for group G, *,G will undergo MoFRR as long as there is no S#,G for Group G. In other words, *,G MoFRR will cease and any old states will be torn down when S#,G is created. Note too, that **mofrr-asm-starg** is not supported for mLDP (since mLDP itself does not support *,G).

In a PIM domain with MoFRR enabled, the default for **stream-protection** is S,G routes only.

Context: Multicast-only fast reroute (MoFRR) can be used to reduce traffic loss in a multicast distribution tree in the event of link down. To employ MoFRR, a downstream router is configured with an alternative path back towards the source, over which it receives a backup live stream of the same multicast traffic. That router propagates the same (S,G) join toward both upstream neighbors in order to create duplicate multicast trees. If a failure is detected on the primary tree, the router switches to the backup tree to prevent packet loss.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

mofrr-disjoint-upstream-only (Multicast-Only Fast Reroute in a PIM Domain)

Syntax

```
mofrr-disjoint-upstream-only;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options multicast stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

When you configure multicast-only fast reroute (MoFRR) in a PIM domain, allow only a disjoint RPF (an RPF on a separate plane) to be selected as the backup RPF path.

In a multipoint LDP MoFRR domain, the same label is shared between parallel links to the same upstream neighbor. This is not the case in a PIM domain, where each link forms a neighbor. The **mofrr-disjoint-upstream-only** statement does not allow a backup RPF path to be selected if the path goes to the same upstream neighbor as that of the primary RPF path. This ensures that MoFRR is triggered only on a topology that has multiple RPF upstream neighbors.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

mofrr-primary-path-selection-by-routing (Multicast-Only Fast Reroute)

Syntax

```
mofrr-primary-path-selection-by-routing;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options multicast stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

MoFRR is supported on both equal-cost multipath (ECMP) paths and non-ECMP paths. Unicast loop-free alternate (LFA) routes need to be enabled to support MoFRR on non-ECMP paths. LFA routes are enabled with the link-protection statement in the interior gateway protocol (IGP) configuration. When you enable link protection on an OSPF or IS-IS interface, Junos OS creates a backup LFA path to the primary next hop for all destination routes that traverse the protected interface.

In the context of load balancing, MoFRR prioritizes the disjoint backup in favor of load balancing the available paths.

For Junos OS releases before 15.1R7, for both ECMP and Non-ECMP scenarios, the default MoFRR behavior was *sticky* , that is, if the Active link went down, the Active Path selection would give preference to Backup Path for the transition. The Active Path would not follow the unicast selected gateway

Starting in Junos OS Release 15.1R7 however, the default behavior for non-EMCP scenarios is to be *non*sticky, that is, the selection of Active Path strictly follows unicast selected gateway. MoFRR no longer chooses a unicast LFA path to become the MoFRR Active path; only a unicast LFA path can be selected to become MoFRR Backup.

Default

By default, the backup path gets promoted to be the primary path when MoFRR is configured in a PIM domain.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Do not add ingress routes to the inet.0 routing table even if traffic-engineering **bgp-igp** (configured at the **[edit protocols mpls]** hierarchy level) is enabled.

Default

The **no-forwarding** statement is disabled. Ingress routes are added to the inet.0 routing table instead of the inet.3 routing table when traffic-engineering **bgp-igp** is enabled.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

    ttl ttl-value;
    wait seconds;
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp]
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 7.6.
lsp-ping-interval option introduced in Junos OS Release 9.4.

Description

Configure Operation, Administration, and Maintenance (OAM) and Bidirectional Forwarding Detection (BFD) protocol for LDP.

Options

fec *fec-address*—Specify the forwarding equivalence class (FEC) address. You must either specify a FEC address or configure an OAM ingress policy to ensure that the BFD session comes up.

lsp-ping-interval *seconds*—Specify the duration of the LSP ping interval in seconds. To issue a ping on an LDP-signaled LSP, use the **ping mpls ldp** command.

Default: 60 seconds

Range: 30 through 3,600 seconds

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

p2mp (Protocols LDP)

Syntax

```
p2mp {
  no-rsvp-tunneling;
  recursive;
  root-address root-address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 11.2.
no-rsvp-tunneling option added in Junos OS Release 16.1R5.

Description

Enable point-to-multipoint MPLS LSPs in an LDP-signaled LSP.

Options

no-rsvp-tunneling—(Optional) Disable LDP point-to-multipoint LSPs from using RSVP-TE LSPs for tunneling, and use LDP paths instead.

NOTE: The **no-rsvp-tunneling** option is introduced in Junos OS Release 16.1R5, 17.3R1, 17.2R2, 16.2R3, and later releases.

Starting in Junos OS Release 12.3R1, Junos OS provides support for Multipoint LDP (M-LDP) for Targeted LDP (T-LDP) sessions with unicast replication, in addition to link sessions. As a result, the default behavior of M-LDP over RSVP tunneling is similar to unicast LDP. However, because T-LDP is chosen over LDP and link sessions to signal point-to-multipoint LSPs, the **no-rsvp-tunelling** option enables LDP natively throughout the network.

recursive—(Optional) Configure point-to-multipoint recursive parameters, including **route**.

root-address ***root-address***—(Optional) Specify the root address of the point-to-multipoint LSP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

p2mp-ldp-next-hop

Syntax

```
p2mp-ldp-next-hop {
root-address root-address{
  lsp-id id;
    }
  }
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options static route destination-prefix],
[edit logical-systems logical-system-name routing-options static route destination-prefix],
[edit routing-instances routing-instance-name routing-options static route destination-prefix].
[edit routing-options static route destination-prefix]
```

Release Information Statement introduced in Junos OS Release 13.3.

Description Specify a point-to-multipoint LDP label-switched path (LSP) as the next hop for a static route, and configure a root and provide an lsp-id on that LDP-signalled label-switched path.

Options **root-address *root address*** — Specify the root address of the point-to-multipoint LSP.

lsp-id *id* — Specify the generic LSP identifier. The range is 1 through 65535.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 8.4.
Support added at the **[edit protocols ldp oam]** and **[edit logical-systems *logical-system-name* protocols ldp oam]** hierarchy levels in Junos OS Release 9.0.
Statement introduced in Junos OS Release 12.2 for EX Series switches.

Description

Enable tracing of forwarding equivalence classes (FECs) for LDP LSPs.

Options

disable—(Optional) Disable tracing for a specific FEC. This option is available at the **[edit protocols ldp oam fec *fec-address* periodic-traceroute]** and **[edit logical-systems *logical-system-name* protocols ldp oam fec *fec-address* periodic-traceroute]** hierarchy levels only.

exp *exp-value*—(Optional) Specify the class of service to use when sending probes.

Default: 7

Range: 0 through 7

fanout *fanout-value*—(Optional) Specify the maximum number of next hops to search per node.

Default: 16

Range: 1 though 16

frequency *minutes*—(Optional) Specify the interval between traceroute attempts.

Default: 60 minutes

Range: 15 through 120 minutes

paths *number-of-paths*—(Optional) Specify the maximum number of paths to search.

Default: 3

Range: 1 through 255

retries ***retry-attempts***—(Optional) Specify the number of attempts to send a probe to a specific node before giving up.

Default: 3

Range: 1 through 9

source ***address***—(Optional) Specify the IPv4 source address to use when sending probes.

ttl ***value***—(Optional) Specify the maximum time-to-live value. Nodes that are beyond this value are not traced.

Default: 64

Range: 1 through 255

wait ***seconds***—(Optional) Specify the wait interval before resending a probe packet.

Default: 10 seconds

Range: 5 though 15 seconds

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

policy (Multicast-Only Fast Reroute)

Syntax

```
policy policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name
  routing-options multicast stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

When you configure multicast-only fast reroute (MoFRR), apply a routing policy that filters for a restricted set of multicast streams to be affected by your MoFRR configuration. You can apply filters that are based on source or group addresses.

For example:

```
routing-options {
   multicast {
      stream-protection {
         policy mofrr-select;
      }
   }
}
policy-statement mofrr-select {
   term A {
      from {
         source-address-filter 225.1.1.1/32 exact;
      }
      then {
         accept;
      }
   }
   term B {
      from {
         source-address-filter 226.0.0.0/8 orlonger;
      }
      then {
         accept;
      }
   }
   term C {
      from {
         source-address-filter 227.1.1.0/24 orlonger;
         source-address-filter 227.4.1.0/24 orlonger;
         source-address-filter 227.16.1.0/24 orlonger;
      }
      then {
```

```
        accept;
      }
    }
    term D {
      from {
        source-address-filter 227.1.1.1/32 exact;
      }
      then {
        reject; #MoFRR disabled
      }
    }
    term E {
      from {
        route-filter 227.1.1.0/24 orlonger;
      }
      then accept;
    }
    ...
}
```

Required Privilege Level

policy (Protocols Multipoint LDP)

Syntax

```
policy policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim mldp-inband-signalling],
[edit protocols pim mldp-inband-signalling]
```

Release Information

Statement introduced in Junos OS Release 13.2.

Description

Multipoint LDP (M-LDP) in-band signaling enables you to carry multicast traffic across an existing IP/MPLS backbone, while avoiding the use of PIM in the provider core.

On the egress nodes of the point-to-multipoint LSP, specify an M-LDP join translation filter policy where PIM messages are translated into M-LDP FEC bindings. The policy statement is needed when internal BGP (IBGP) is not available in the core site or to override IBGP-based LSP root detection.

The filter policy is configured at the **[edit policy-options]** hierarchy level. The policy generally specifies one or more source-address filters and the point-to-multipoint LDP root IP address using the **p2mp-lsp-root** policy action.

Options

policy-name—Name of a policy configured at the **[edit policy-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Description Configure when an LDP session is torn down and resignaled after the router stops receiving hello messages from a neighboring router. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished. The LDP session remains up for the duration specified as long as the routers maintain IP network connectivity.

Options **timeout *seconds***—Time in seconds before the LDP session is torn down and resignaled.

Range: 1 through 65,535 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-options multicast]
```

Release Information

Statement introduced in Junos OS Release 14.1.
Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

Enable multicast-only fast reroute (MoFRR) on a routing or switching device. MoFRR minimizes packet loss in a network when there is a link failure.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols LDP)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
match-on address option for the **filter** flag modifier added in Junos OS Release 10.4.
nsr-synchronization and **p2mp-nsr-synchronization** operations for **flag** statement introduced in Junos OS Release 13.3.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify LDP protocol-level trace options.

Default

The default LDP protocol-level trace options are inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **ldp-log**. We recommend that you place LDP tracing output in the file **ldp-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **address**—Operation of address and address withdrawal messages

- **binding**—Label-binding operations
- **error**—Error conditions
- **event**—Protocol events
- **initialization**—Operation of initialization messages
- **label**—Operation of label request, label map, label withdrawal, and label release messages
- **notification**—Operation of notification messages
- **nsr-synchronization**— Nonstop active routing synchronization events
- **p2mp-nsr-synchronization**—Point-to-multipoint nonstop active routing synchronization events
- **packets**—Equivalent to setting **address**, **initialization**, **label**, **notification**, and **periodic** flags (see also the **filter** flag modifier)
- **path**—Label-switched path operations
- **periodic**—Operation of hello and keepalive messages
- **route**—Operation of route messages
- **state**—Protocol state transitions

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information.
- **disable**—Disable this trace flag.
- **filter**—Filter to apply to this flag. The **filter** flag modifier can be applied only to the **route**, **path**, and **binding** flags. This flag modifier has the following options:
  - **match-on**—Match on argument specified. The **match-on** option has the following suboptions:
    - **address**—Filter based on the source and destination addresses of packets. Available for the **packets** flag option only.
    - **fec**—Filter based on the FEC associated with the traced object.
  - **policy** *policy-name*—Specify the filter policy.
- **receive**—Packets being received.
- **send**—Packets being transmitted.

no-world-readable—(Optional) Prevent all users from reading the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When the ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable any user to read the log file.

Required Privilege Level
routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

- *Network Management and Monitoring Guide*

track-igp-metric

Syntax

```
track-igp-metric;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description
Cause the IGP route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1).

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

traffic-statistics (Protocols LDP)

Syntax

```
traffic-statistics {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-penultimate-hop;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

LDP traffic statistics display the amount of traffic passed through a router for a particular FEC.

Options

file *filename*—Name of the file to receive the output of the LDP statistics operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.

files *number*—(Optional) Maximum number of LDP statistics files. When a statistics file named ***ldp-stat*** reaches its maximum size, it is renamed ***ldp-stat*.0**, then ***ldp-stat*.1**, and so on, until the maximum number of LDP statistics files is reached. Then the oldest file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you also must include the **size** statement to specify the maximum file size.

interval *seconds*—(Optional) Specify the interval at which the statistics are polled and written to the file.

Default: 300 seconds (5 minutes)

no-penultimate-hop—(Optional) Do not collect traffic statistics on the penultimate hop router.

no-world-readable—(Optional) Prevent all users from reading the log file.

size *size*—(Optional) Maximum size of each statistics file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a statistics file named ***ldp-stat*** reaches this size, it is renamed ***ldp-stat*.0**. When ***ldp-stat*** again reaches this size, ***ldp-stat*.0** is renamed ***ldp-stat*.1** and ***ldp-stat*** is renamed ***ldp-stat*.0**. This renaming scheme continues until

the maximum number of statistics files is reached. Then the oldest statistics file is overwritten.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you also must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable log file access for all users.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

transport-address

Syntax

```
transport-address (interface | router-id);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name protocols ldp interface interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
  ldp],
[edit protocols ldp],
[edit protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enables you to configure the IP address used to specify the TCP session for the LDP session. Routers must first establish a TCP session between one another before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

Default

router-id

Options

interface—The first IP address on the interface is used as the transport address for any LDP sessions to neighbors that can be reached over that interface. You cannot specify the **interface** option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the **router-id** option.

router-id—The router identifier is used as the transport address. Unless otherwise configured, the router identifier is the loopback address.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- *Specifying the Transport Address Used by LDP*

version (BFD)

Syntax

```
version (0 | 1 | automatic);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-liveness-detection],
[edit logical-systems logical-system-name protocols ldp oam fec address

  bfd],
[edit protocols ldp oam bfd-liveness-detection],
[edit protocols ldp oam fec address bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 12.1.
Statement introduced in Junos OS Release 12.3R2 for EX Series switches.

Description

Configure the BFD protocol version to detect.

Options

0—Use BFD protocol version 0.

1—Use BFD protocol version 1.

automatic—Autodetect the BFD protocol version.

Default: automatic

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit interfaces rlsq *number* unit *logical-unit-number*]
[edit protocols evpn]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (**ethernet**,**vlan-ccc**, and **vlan-tcc** options only).
Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Metro Routers. Only the **atm-ccc-cell-relay** and **atm-ccc-vc-mux** options are supported on ACX Series routers.
Statement introduced in Junos OS Release 17.3R1 for QFX10000 Series switches (**ethernet-ccc** and **vlan-ccc** options only).

Description

Configure a logical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.

Options

atm-ccc-cell-relay—Use ATM cell-relay encapsulation.

atm-ccc-vc-mux—Use ATM virtual circuit (VC) multiplex encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

atm-cisco-nlpid—Use Cisco ATM network layer protocol identifier (NLPID) encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-mlppp-llc—For ATM2 IQ interfaces only, use Multilink Point-to-Point (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a Link Services or Voice Services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.

atm-nlpid—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-ppp-llc—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over AAL5 LLC encapsulation.

atm-ppp-vc-mux—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over ATM AAL5 multiplex encapsulation.

atm-snap—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM subnetwork attachment point (SNAP) encapsulation.

atm-tcc-snap—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.

atm-tcc-vc-mux—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

atm-vc-mux—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

ether-over-atm-llc—(All IP interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) For interfaces that carry IP traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.

ether-vpls-over-atm-llc—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

ether-vpls-over-fr—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, per RFC 2427, *Multiprotocol Interconnect over Frame Relay*.

NOTE: **The SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, and the DS3/E3 MIC do not support Ethernet over Frame Relay encapsulation.**

ether-vpls-over-ppp—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Point-to-Point Protocol (PPP) encapsulation to support Bridged Ethernet over PPP-encapsulated TDM interfaces for VPLS applications.

ethernet—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

ethernet-ccc—Use Ethernet CCC encapsulation on Ethernet interfaces.

ethernet-vpls—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

ethernet-vpls-fr—Use in a VPLS setup when a CE device is connected to a PE router over a time-division multiplexing (TDM) link. This encapsulation type enables the PE router to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

frame-relay-ether-type—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ether-type-tcc—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ppp—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only.

frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

gre-fragmentation—For adaptive services interfaces only, use GRE fragmentation encapsulation to enable fragmentation of IPv4 packets in GRE tunnels. This encapsulation clears the do not fragment (DF) bit in the packet header. If the packet' s size exceeds the tunnel' s maximum transmission unit (MTU) value, the packet is fragmented before encapsulation.

multilink-frame-relay-end-to-end—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

multilink-ppp—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

ppp-over-ether—Use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

ppp-over-ether-over-atm-llc—(MX Series routers with MPCs using the ATM MIC with SFP only) For underlying ATM interfaces, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

vlan-bridge—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible-ethernet-services, and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

vlan-ccc—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-vci-ccc—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-tcc—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

vlan-vpls—Use Ethernet VLAN encapsulation on VPLS circuits.

vxlan—Use VXLAN data plane encapsulation for EVPN.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Statement introduced in Junos OS Release 11.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (**flexible-ethernet-services**, **ethernet-ccc**, and **ethernet-tcc** options only).

Description

For M Series, MX Series, QFX Series, T Series, PTX Series, specify the physical link-layer encapsulation type.

For SRX Series, specify logical link layer encapsulation.

NOTE: Not all encapsulation types are supported on the switches. See the switch CLI.

Default

ppp—Use serial PPP encapsulation.

Physical Interface Options and Logical Interface Options

[Warning: element unresolved in stylesheets: <title> (in <config-options>). This is probably a new element that is not yet supported in the stylesheets.]
Physical Interface Options and Logical Interface Options

For physical interfaces:

NOTE: **Frame Relay, ATM, PPP, SONET, and SATSOP options are not supported on EX Series switches.**

- **atm-ccc-cell-relay**—Use ATM cell-relay encapsulation.
- **atm-pvc**—Defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. When you configure physical ATM interfaces with ATM PVC encapsulation, an RFC 2684-compliant ATM Adaptation Layer 5 (AAL5) tunnel is set up to route the ATM cells over a Multiprotocol Label Switching (MPLS) path that is typically established between two MPLS-capable routers using the Label Distribution Protocol (LDP).
- **cisco-hdlc**—Use Cisco-compatible High-Level Data Link Control (HDLC) framing. E1, E3, SONET/SDH, T1, and T3 interfaces can use Cisco HDLC encapsulation. Two related versions are supported:
  - CCC version (**cisco-hdlc-ccc**)—The logical interface does not require an encapsulation statement. When you use this encapsulation type, you can configure the **ccc** family only.
  - TCC version (**cisco-hdlc-tcc**)—Similar to CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **cisco-hdlc-ccc**—Use Cisco-compatible HDLC framing on CCC circuits.
- **cisco-hdlc-tcc**—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.
- **ethernet-bridge**—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.
- **ethernet-over-atm**—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.
- **ethernet-tcc**—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.
- **ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.
- **ethernet-vpls-ppp**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.
- **ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.
- **extended-frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC. When you use this encapsulation type, you can configure the **ccc** family only.
- **extended-frame-relay-ether-type-tcc**—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.
- **extended-frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.
- **extended-vlan-bridge**—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.
- **extended-vlan-ccc**—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. Extended VLAN CCC encapsulation supports TPIDs 0x8100, 0x9100, and 0x9901. When you use this encapsulation type, you can configure the **ccc** family only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.
- **extended-vlan-tcc**—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

- **extended-vlan-vpls**—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

  NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

- **flexible-ethernet-services**—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and for Gigabit Ethernet interfaces, use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.
- **flexible-frame-relay**—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.
- **frame-relay**—Use Frame Relay encapsulation is defined in RFC 1490, *Multiprotocol Interconnect over Frame Relay*. E1, E3, link services, SONET/SDH, T1, T3, and voice services interfaces can use Frame Relay encapsulation.
- **frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation is same as standard Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to CCC. The logical interface must also have **frame-relay-ccc** encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay. IETF frame relay encapsulation identifies the payload format using NLPID and SNAP formats. Cisco-compatible Frame Relay encapsulation uses the Ethernet type to identify the type of payload.

  NOTE: When the encapsulation type is set to Cisco-compatible Frame Relay encapsulation, ensure that the LMI type is set to ANSI or Q933-A.

- **frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. This encapsulation is Cisco-compatible Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to TCC.

- **frame-relay-port-ccc**—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. The connection between the two CE routers can be either user-to-network interface (UNI) or network-to-network interface (NNI); this is completely transparent to the PE routers. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-tcc**—This encapsulation is similar to Frame Relay CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **generic-services**—Use generic services encapsulation for services with a hierarchical scheduler.
- **multilink-frame-relay-uni-nni**—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.
-
- **ppp**—Use serial PPP encapsulation. This encapsulation is defined in RFC 1661, *The Point-to-Point Protocol (PPP) for the Transmission of Multiprotocol Datagrams over Point-to-Point Links*. PPP is the default encapsulation type for physical interfaces. E1, E3, SONET/SDH, T1, and T3 interfaces can use PPP encapsulation.
- **ppp-ccc**—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.
- **ppp-tcc**—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.
- **vlan-ccc**—Use Ethernet VLAN encapsulation on CCC circuits. VLAN CCC encapsulation supports TPID 0x8100 only. When you use this encapsulation type, you can configure the **ccc** family only.

- **vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE:

- Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.
- Starting with Junos OS release 13.3, a commit error occurs when you configure **vlan-vpls** encapsulation on a physical interface and configure **family inet** on one of the logical units. Previously, it was possible to commit this invalid configuration.

For logical interfaces:

- **frame-relay**—Configure a Frame Relay encapsulation when the physical interface has multiple logical units, and the units are either point to point or multipoint.
- **multilink-frame-relay-uni-nni**—Link services interfaces functioning as FRF.16 bundles can use Multilink Frame Relay UNI NNI encapsulation.
- **ppp**—For normal mode (when the device is using only one ISDN B-channel per call). Point-to-Point Protocol is for communication between two computers using a serial interface.
- **ppp-over-ether**—This encapsulation is used for underlying interfaces of pp0 interfaces.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

interface-switch

Syntax

```
interface-switch connection-name {
  interface interface-name.unit-number;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],
[edit protocols connections]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure Layer 2 switching cross-connects. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

For Layer 2 switching cross-connects to work, you must also configure MPLS.

Options ***connection-name***—Connection name (up to 128 characters in Junos 12.3 and later).

interface *interface-name.unit-number*—Interface name. Include the logical portion of the name, which corresponds to the logical unit number.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration

l2circuit-control-passthrough

Syntax l2circuit-control-passthrough;

Hierarchy Level [edit forwarding-options]

Release Information Statement introduced in Junos OS Release 17.4R1.

Description Configure the device to allow LACP, LLDP, OAM LFM, and OAM CFM packets to cross the Layer 2 circuit. If the **l2circuit-control-passthrough** statement is not configured, LACP, LLDP, OAM LFM, and OAM CFM packets are classified as control packets and are not transmitted across the Layer 2 circuit.

Default By default, this statement is not configured.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- *forwarding-options*

lsp-switch

Syntax

```
lsp-switch connection-name {
   transmit-lsp label-switched-path;
   receive-lsp label-switched-path;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],
[edit protocols connections]
```

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure Layer 2 switching cross-connects.

Options ***connection-name***—Connection name.

receive-lsp *label-switched-path*—Name of the LSP from the connection's source.

transmit-lsp *label-switched-path*—Name of the LSP to the connection's destination.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Connection for Layer 2 Switching TCCs on page 1099

output-interface (CCC)

Syntax

```
output-interface [interface-name 1 interface-name n];
```

Hierarchy Level

```
[edit protocols connections p2mp-transmit-switch p2mp-transmit-switch-name]
```

Release Information Statement introduced in Junos OS Release 12.3.

Description Specify one or more output interfaces to switch traffic on an incoming CCC interface to one or more outgoing CCC interfaces.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring CCC Switching for Point-to-Multipoint LSPs on page 1104

p2mp-receive-switch

Syntax

```
p2mp-receive-switch point-to-multipoint-switch-name {
  output-interface [ interface-name.unit-number ];
  receive-p2mp-lsp receiving-point-to-multipoint-lsp;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols connections],
[edit protocols connections]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the CCC switch for a point-to-multipoint LSP on the egress PE router.

Options

point-to-multipoint-switch-name—Point-to-multipoint CCC receive switch name.

output-interface *interface-name.unit-number*—Name of the egress interfaces for the point-to-multipoint LSP traffic. You can configure multiple output interfaces.

receive-p2mp-lsp *receiving-point-to-multipoint-lsp*—Name of the point-to-multipoint LSP that is switched to the output interface.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers on page 1105

p2mp-transmit-switch

Syntax

```
p2mp-transmit-switch point-to-multipoint-transmit-switch-name {
  input-interface interface-name.unit-number;
  transmit-p2mp-lsp transmitting-point-to-multipoint-lsp;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols connections],
[edit protocols connections]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the CCC switch for the point-to-multipoint LSP on the ingress PE router.

Options

point-to-multipoint-transmit-switch-name—Point-to-multipoint CCC transmit switch name.

input-interface *input-interface-name.unit-number*—Specify the name of the interface carrying incoming traffic to be switched to the point-to-multipoint LSP.

transmit-p2mp-lsp *transmitting-point-to-multipoint-lsp*—Specify the name of the point-to-multipoint LSP carrying traffic to the CCC switch on the egress PE router.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers on page 1104

remote-interface-switch

Syntax

```
remote-interface-switch connection-name {
  interface interface-name.unit-number;
  transmit-lsp label-switched-path;
  receive-lsp label-switched-path;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols connections],
[edit protocols connections]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure MPLS LSP tunnel cross-connects.

Options

connection-name—Connection name.

interface *interface-name.unit-number*—Interface name. Include the logical portion of the name, which corresponds to the logical unit number.

receive-lsp *label-switched-path*—Name of the LSP from the connection's source.

transmit-lsp *label-switched-path*—Name of the LSP to the connection's destination.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the **realm** statement introduced in Junos OS Release 9.2.
Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Specify how long OSPF waits before declaring that a neighboring routing device is unavailable. This is an interval during which the routing device receives no hello packets from the neighbor.

Options

seconds—Interval to wait.

Range: 1 through 65,535 seconds

Default: Four times the hello interval—40 seconds (broadcast and point-to-point networks); 120 seconds (nonbroadcast multiple access (NBMA) networks)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the **realm** statement introduced in Junos OS Release 9.2.
Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Disable OSPF, an OSPF interface, or an OSPF virtual link.

By default, control packets sent to the remote end of a virtual link must be forwarded using the default topology. In addition, the transit area path consists only of links that are in the default topology. You can disable a virtual link for a configured topology, but not for a default topology. Include the **disable** statement at the **[edit protocols ospf area *area-id* virtual-link neighbor-id *router-id* transit-area *area-id* topology *name*]** hierarchy level.

NOTE: If you disable the virtual link by including the **disable** statement at the **[edit protocols ospf area *area-id* virtual-link neighbor-id *router-id* transit-area *area-id*]** hierarchy level, you disable the virtual link for all topologies, including the default topology. You cannot disable the virtual link only in the default topology.

Default The configured object is enabled (operational) unless explicitly disabled.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Apply one or more policies to routes being exported from the routing table into BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no routes match the filters, the routing table exports into BGP only the routes that it learned from BGP. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of **metric 500** defined in the next policy.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

hello-dead-interval

Syntax

```
hello-dead-interval milliseconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols link-management peer peer-name
  lmp-protocol],
[edit protocols link-management peer peer-name lmp-protocol]
```

Release Information Statement introduced in Junos OS Release 8.0.

Description Specify how long the Link Management Protocol (LMP) waits before declaring the control channel to be dead. This is an interval during which the router receives no LMP hello packets from the neighbor on a control that is active or up.

Options ***milliseconds***—Interval to wait before declaring the control channel to be dead.

Range: 500 through 300,000

Default: 500 milliseconds (three times the hello interval)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the **realm** statement introduced in Junos OS Release 9.2.
Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Specify how often the routing device sends hello packets out the interface. The hello interval must be the same for all routing devices on a shared logical IP network.

Options

seconds—Time between hello packets, in seconds.

Range: 1 through 255 seconds

Default: 10 seconds (broadcast and point-to-point networks); 30 seconds (nonbroadcast multiple access [NBMA] networks)

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Apply one or more routing policies to routes being imported into the Junos OS routing table from BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no match is found, BGP places into the routing table only those routes that were learned from BGP routing devices. The policy framework software evaluates the routing policies in a chain sequentially. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of **metric 500** defined in the next policy.

It is also important to understand that in Junos OS, although an import policy (inbound route filter) might reject a route, not use it for traffic forwarding, and not include it in an advertisement to other peers, the router retains these routes as hidden routes. These hidden routes are not available for policy or routing purposes. However, they do occupy memory space on the router. A service provider filtering routes to control the amount of information being kept in memory and processed by a router might want the router to entirely drop the routes being rejected by the import policy.

Hidden routes can be viewed by using the **show route receive-protocol bgp** *neighbor-address* **hidden** command. The hidden routes can then be retained or dropped from the routing

table by configuring the **keep all | none** statement at the **[edit protocols bgp]** or **[edit protocols bgp group *group-name*]** hierarchy level.

The rules of BGP route retention are as follows:

- By default, all routes learned from BGP are retained, except those where the AS path is looped. (The AS path includes the local AS.)
- By configuring the **keep all** statement, all routes learned from BGP are retained, even those with the local AS in the AS path.
- By configuring the **keep none** statement, all routes received are discarded. When this statement is configured and the inbound policy changes, Junos OS re-advertises all the routes advertised by the peer.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information Statement introduced before Junos OS Release 7.4.
virtual-switch and **layer2-control** options introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 9.2 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.
mpls-internet-multicast option introduced in Junos OS Release 11.1 for the EX Series, M Series, MX Series, and T Series.
evpn option introduced in Junos OS Release 13.2 for MX 3D Series routers.
evpn option introduced in Junos OS Release 17.3 for the QFX Series.
forwarding option introduced in Junos OS Release 14.2 for the PTX Series.
mpls-forwarding option introduced in Junos OS Release 16.1 for the MX Series.
evpn-vpws option introduced in Junos OS Release 17.1 for MX Series routers.
Support for logical systems on MX Series routers added in Junos OS Release 17.4R1.

Description Define the type of routing instance.

Options

NOTE: On ACX Series routers, you can configure only the forwarding, virtual router, and VRF routing instances.

type—Can be one of the following:

- **evpn**—(MX 3D Series routers, QFX switches and EX9200 switches)—Enable an Ethernet VPN (EVPN) on the routing instance.
  hierarchy level.
- **evpn-vpws**—Enable an Ethernet VPN (EVPN) Virtual Private Wire Service (VPWS) on the routing instance.
- **forwarding**—Provide support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance. Other instances are used for populating RPD learned routes. For this instance type, there is no one-to-one mapping between an interface and a routing instance. All interfaces belong to the default instance inet.0.
- **l2backhaul-vpn**—Provide support for Layer 2 wholesale VLAN packets with no existing corresponding logical interface. When using this instance, the router learns both the outer tag and inner tag of the incoming packets, when the **instance-role** statement is

defined as **access**, or the outer VLAN tag only, when the **instance-role** statement is defined as **nni**.

- **l2vpn**—Enable a Layer 2 VPN on the routing instance. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **layer2-control**—(MX Series routers only) Provide support for RSTP or MSTP in customer edge interfaces of a VPLS routing instance. This instance type cannot be used if the customer edge interface is multihomed to two provider edge interfaces. If the customer edge interface is multihomed to two provider edge interfaces, use the default BPDU tunneling.
- **mpls-forwarding**—(MX Series routers only) Allow filtering and translation of route distinguisher (RD) values in IPv4 and IPv6 VPN address families on both routes received and routes sent for selected BGP sessions. In particular, for Inter-AS VPN Option-B networks, this option can prevent the malicious injection of VPN labels from one peer AS boundary router to another.
- **mpls-internet-multicast**—(EX Series, M Series, MX Series, and T Series routers only) Provide support for ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, using MBGP or next-generation MVPN.
- **no-forwarding**—This is the default routing instance. Do not create a corresponding forwarding instance. Use this routing instance type when a separation of routing table information is required. There is no corresponding forwarding table. All routes are installed into the default forwarding table. IS-IS instances are strictly nonforwarding instance types.
- **virtual-router**—Enable a virtual router routing instance. This instance type is similar to a VPN routing and forwarding instance type, but used for non-VPN-related applications. You must configure the **interface** statement for this type of routing instance. You do not need to configure the **route-distinguisher**, **vrf-import**, and **vrf-export** statements.
- **virtual-switch**—(MX Series routers, EX9200 switches, and QFX switches only) Provide support for Layer 2 bridging. Use this routing instance type to isolate a LAN segment with its Spanning Tree Protocol (STP) instance and to separate its VLAN identifier space.
- **vpls**—Enable VPLS on the routing instance. Use this routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **vrf**—VPN routing and forwarding (VRF) instance. Provides support for Layer 3 VPNs, where interface routes for each instance go into the corresponding forwarding table only. Required to create a Layer 3 VPN. Create a VRF table (***instance-name*.inet.0**) that contains the routes originating from and destined for a particular Layer 3 VPN. For this instance type, there is a one-to-one mapping between an interface and a routing instance. Each VRF instance corresponds with a forwarding table. Routes on an interface go into the corresponding forwarding table. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the **realm** statement introduced in Junos OS Release 9.2.
Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description Specify how long the routing device waits to receive a link-state acknowledgment packet before retransmitting link-state advertisements (LSAs) to an interface's neighbors.

Options ***seconds***—Interval to wait.

Range: 1 through 65,535 seconds

Default: 5 seconds

NOTE: You must configure LSA retransmit intervals to be equal to or greater than 3 seconds to avoid triggering a retransmit trap, because Junos OS delays LSA acknowledgments by up to 2 seconds.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

retry-limit (Protocols Link Management)

Syntax
```
retry-limit number;
```

Hierarchy Level
```
[edit logical-systems logical-system-name protocols link-management peer peer-name
  lmp-protocol],
[edit protocols link-management peer peer-name lmp-protocol]
```

Release Information
Statement introduced in Junos OS Release 8.1.

Description
Specify how many times the Link Management Protocol (LMP) sends Config and LinkSummary messages on the LMP control channel without receiving an appropriate acknowledgment before it logs a message and restarts the LMP control channel configuration process.

Options
number—Maximum number of times messages are sent without receiving an acknowledgment.

Range: 3 through 1000

Default: 3

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

route-distinguisher

Syntax route-distinguisher (*as-number:id* | *ip-address:id*);

Hierarchy Level
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn mesh-group *mesh-group-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*],
[edit routing-instances *routing-instance-name*],
[edit routing-instances *routing-instance-name* protocols l2vpn mesh-group *mesh-group-name*],
[edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for EX Series switches.
Support at **[edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]** hierarchy level introduced in Junos OS Release 11.2.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.
Support at **[edit routing-instances *routing-instance-name* protocols l2vpn mesh-group *mesh-group-name*]** hierarchy level introduced in Junos OS Release 13.2.
Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches.

Description
Specify an identifier attached to a route, enabling you to distinguish to which VPN or virtual private LAN service (VPLS) the route belongs. Each routing instance must have a unique route distinguisher (RD) associated with it. The RD is used to place bounds around a VPN so that the same IP address prefixes can be used in different VPNs without having them overlap. If the instance type is **vrf**, the **route-distinguisher** statement is required.

For Layer 2 VPNs and VPLS, if you configure the **l2vpn-use-bgp-rules** statement, you must configure a unique RD for each PE router participating in the routing instance.

For other types of VPNs, we recommend that you use a unique RD for each provider edge (PE) router participating in specific routing instance. Although you can use the same RD on all PE routers for the same VPN routing instance, if you use a unique RD, you can determine the customer edge (CE) router from which a route originated within the VPN.

For Layer 2 VPNs and VPLSs, if you configure mesh groups, the RD in each mesh group must be unique.

CAUTION: We strongly recommend that if you change an RD that has already been configured, make the change during a maintenance window, as follows:

1. Deactivate the routing instance.
2. Change the RD.

3. Activate the routing instance.

This is not required if you are configuring the RD for the first time.

Options

as-number:number*—*as-number is an assigned AS number, and ***number*** is any 2-byte or 4-byte value. The AS number can be from 1 through 4,294,967,295. If the AS number is a 2-byte value, the administrative number is a 4-byte value. If the AS number is 4-byte value, the administrative number is a 2-byte value. An RD consisting of a 4-byte AS number and a 2-byte administrative number is defined as a type 2 RD in RFC 4364 *BGP/MPLS IP VPNs*.

NOTE: In Junos OS Release 9.1 and later, the numeric range for AS numbers is extended to provide BGP support for 4-byte AS numbers, as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*. All releases of Junos OS support 2-byte AS numbers. To configure an RD that includes a 4-byte AS number, append the letter "L" to the end of the AS number. For example, an RD with the 4-byte AS number 7,765,000 and an administrative number of 1,000 is represented as 77765000L:1000.

In Junos OS Release 9.2 and later, you can also configure a 4-byte AS number using the AS dot notation format of two integer values joined by a period: *<16-bit high-order value in decimal>.<16-bit low-order value in decimal>*. For example, the 4-byte AS number of 65,546 in the plain-number format is represented as 1.10 in AS dot notation format.

ip-address*:*id—IP address (***ip-address*** is a 4-byte value) within your assigned prefix range and a 2-byte value for the ***id***. The IP address can be any globally unique unicast address.

Range: 0 through 4,294,967,295 ($2^{32} - 1$). If the router you are configuring is a BGP peer of a router that does not support 4-byte AS numbers, you need to configure a local AS number. For more information, see *Using 4-Byte Autonomous System Numbers in BGP Networks Technology Overview*.

NOTE: For Ethernet VPN (EVPN), an RD that includes zero as the *id* value is reserved for the default EVPN routing instance by default. Because the same RD cannot be assigned for two routing instances, using a *ip-address*:*id* RD for another routing instance (default-switch), where the *id* value is zero, throws a commit error.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

te-link

Syntax

```
te-link te-link-name {
  disable;
  ethernet-vlan;
  interface interface-name {
    disable;
    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
  }
  local-address ip-address;
  remote-address ip-address;
  remote-id id-number;
}
```

Hierarchy Level

```
[edit protocols link-management],
[edit protocols link-management peer peer-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.
ethernet-vlan option introduced in Junos OS Release 14.2.

Description

Represent a collection of physical ports or time slots. Assign a traffic engineering link to the specified network peer.

Options

te-link-name—Name of the collection of physical ports or the name of the time slots.

disable—Disable the traffic engineering link or an interface to a traffic engineering link.

The remaining statements are explained separately..

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols Link Management)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols link-management],
[edit protocols link-management]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Support for **hello-packets**, **packets**, and **state** flags added in Junos OS Release 8.1.

Description

Trace options for the LMP protocol.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel
- **init**—Output from the initialization messages
- **packets**—Trace all packets other than hello packets on any LMP control channel
- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols

- **server**—Server processing operations
- **show**—**show** command servicing operations
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-world-readable—(Optional) Prevent all users from reading the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When the ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable log file access for all users.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols ospf3 realm (ipv4-unicast | ipv4-multicast | ipv6-multicast) area *area-id* interface *interface-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for the **realm** statement introduced in Junos OS Release 9.2.
Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Set the estimated time required to transmit a link-state update on the interface. When calculating this time, make sure to account for transmission and propagation delays.

You should never have to modify the transit delay time.

Options

seconds—Estimated time, in seconds.

Range: 1 through 65,535 seconds

Default: 1 second

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

upstream-label

Syntax

```
upstream-label {
  vlan-id vlan-id;
}
```

Hierarchy Level

[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Specify the upstream label for the bidirectional label-switched path (LSP).

Options

vlan-id *vlan-id*—VLAN ID to be used for the Generalized MPLS (GMPLS) VLAN LSP at the ingress provider edge (PE) to customer edge (CE) link.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  vpls mesh-group mesh-group-name],
[edit routing-instances routing-instance-name protocols evpn vni-options],
[edit routing-instances routing-instance-name protocols l2vpn mesh-group
  mesh-group-name],
[edit routing-instances routing-instance-name protocols vpls mesh-group mesh-group-name],
[edit switch-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for EX Series switches.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.
Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches. **auto option** was also added at this time.

Description

Specify a virtual routing and forwarding (VRF) target community. If you configure the ***community*** option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. The purpose of the **vrf-target** statement is to simplify the configuration by allowing you to configure most statements at the **[edit routing-instances]** hierarchy level. In effect, this statement configures a single policy for import and a single policy for export to replace the per-VRF policies for every community.

You can still create more complex policies by explicitly configuring VRF import and export policies using the **import** and **export** options.

Options

community—Community name.

auto—Automatically derives the route target (RT) for QFX5100 switches.

import *community-name*—Allowed communities accepted from neighbors.

export *community-name*—Allowed communities sent to neighbors.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

delegation-cleanup-timeout

Syntax delegation-cleanup-timeout *seconds*;

Hierarchy Level [edit protocols pcep pce *pce-id*]

Release Information Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description Specify the amount of time (in seconds) that a Path Computation Client (PCC) must wait before returning control of all LSPs to the routing protocol process after a PCEP session with the main active stateful Path Computation Element (PCE) is disconnected.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

Options ***seconds***—Time (in seconds) that a PCC must wait before returning control of all LSPs to the routing protocol process after a PCEP session with the main active stateful PCE is disconnected.

Range: 0 through 600 seconds

Default: 30 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pce on page 2208

delegation-priority

Syntax delegation-priority *priority-number*;

Hierarchy Level [edit protocols pcep pce *pce-id*]

Release Information Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description Specify the priority number of the active stateful Path Computation Element (PCE). This value is used by the Path Computation Client (PCC) to elect a PCE to delegate LSPs. No two PCEs can have the same delegation-priority value. The PCC elects the PCE with a lower priority as the main active stateful PCE to delegate LSPs.

Options *priority-number*—Priority number of the active stateful PCE.

Range: 1 through 65535

Default: 0 (no priority is set)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pce on page 2208

destination-ipv4-address

Syntax destination-ipv4-address *ipv4-address*;

Hierarchy Level [edit protocols pcep pce *pce-id*]

Release Information Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description Specify the IPv4 address of the Path Computation Element (PCE) to which the Path Computation Client (PCC) should connect.

Options ***ipv4-address***—IPv4 address of the PCE.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- pce on page 2208

destination-port

Syntax destination-port *port-number*;

Hierarchy Level [edit protocols pcep pce *pce-id*]

Release Information Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFXswitches added in Junos OS Release 16.1R3.

Description Specify the TCP port number of the Path Computation Element (PCE) to which the Path Computation Client (PCC) should connect.

Options *port-number*—Destination TCP port number.

Range: 1 through 65535

Default: 4189

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pce on page 2208

label-switched-path-template

Syntax

```
label-switched-path-template {
  (default-template | lsp-template-name);
}
```

Hierarchy Level

[edit protocols mpls lsp-external-controller *lsp-external-controller*]

Release Information

Statement introduced in Junos OS Release 13.3.

Description

Specify the LSP template with parameters for setting up the PCE-initiated LSPs when the PCE initiating the LSP does not provide the PCE-initiated parameters. When **label-switched-path-template** is not configured, the default LSP parameters are used.

Options

default-template—Specify that the default LSP template be used for the dynamically generated PCE-initiated LSPs.

lsp-template-name—Specify the name of the LSP template to be used for setting up PCE-initated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pcep on page 2196

lsp-cleanup-timer

Syntax lsp-cleanup-timer *seconds*;

Hierarchy Level [edit protocols pcep pce *pce-id*]
[edit protocols pcep pce-group *group-id*]

Release Information Statement introduced in Junos OS Release 13.3.

Description Specify the amount of time (in seconds) that the Path Computation Client (PCC) must wait before deleting any non-delegated Path Computation Element (PCE)-initiated LSPs from the failed PCE after a PCEP session terminates.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

Options ***seconds***—Time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates.

Range: 0 through 4294967294 seconds

Default: 0 (Non-delegated PCE-initiated LSPs are deleted immediately)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pcep on page 2196

lsp-external-controller

Syntax

```
lsp-external-controller controller-name;
```

Hierarchy Level

```
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
[edit protocols spring-traffic-engineering]
```

Release Information

Statement introduced in Junos OS Release 12.3.
Statement introduced in Junos OS Release 16.1R3 for QFX Series switches.
Support for ACX Series added in Junos OS Release 17.1.
Support at the **[edit protocols spring-traffic-engineering]** hierarchy level introduced in Junos OS Release 17.2.

Description

Enable external path computing capability for the device.

Options

controller-name—Name of the external path computing entity. By default, *pccd* is the only allowed LSP external controller.

Values: *pccd*

Required Privilege Level

max-unknown-messages

Syntax max-unknown-messages *messages-per-minute*;

Hierarchy Level [edit protocols pcep pce *pce-id*]

Release Information Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description Specify the number of unknown messages per minute that the Path Computation Client (PCC) can receive at maximum after which the PCEP session is closed.

Options ***messages-per-minute***—Number of unknown messages per minute that the PCC can receive at maximum after which the PCEP session is closed. Recommended value is **5**. If the number of unknown messages received by the PCC is greater than or equal to the maximum number, the PCEP session is closed.

Range: 1 through 16384

Default: 0 (disabled or no limit)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

max-unknown-requests

Syntax max-unknown-requests *requests-per-minute*;

Hierarchy Level [edit protocols pcep pce *pce-id*]
[edit protocols pcep pce-group *group-id*]

Release Information Statement introduced in Junos OS Release 13.3.

Description Specifies the number of unknown requests per minute that the Path Computation Client (PCC) can receive at maximum after which the PCEP session is terminated.

Options ***requests-per-minute***—Number of unknown requests per minute that the PCC can receive at maximum after which the PCEP session is terminated.

Range: 0 through 16384 (0 disables this statement)

Default: 5

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

Release Information

Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.
lsp-cleanup-timer, **lsp-provisioning**, **max-unknown-requests**, **request-timer**, and **request-priority** options introduced in Junos OS Release 13.3.
authentication-key *key*, **authentication-key-chain** *key-chain*, and **p2mp-lsp-report-capability** options introduced in Junos OS Release 16.1.
max-sid-depth and **spring-capability** options introduced in Junos OS Release 17.2.
p2mp-lsp-init-capability and **p2mp-lsp-update-capability** options introduced in Junos OS Release 18.3R1 on all platforms.

Description

Configure per-Path Computation Element (PCE) parameters.

Options

pce-id—IP address of the PCE.

authentication-key ***key***—(Optional) Authentication password. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (“ ”).

It is recommended to define and bind an authentication key for securing a PCEP session, as opposed to binding an authentication keychain.

authentication-key-chain *key-chain*—(Optional) Authentication keychain password. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

local-address *ip-address*—(Optional) IP address of the local end of the PCEP session, the PCC.

lsp-retry-delegation—(Optional) Enable retry LSP delegation process.

lsp-retry-delegation-timer—(Optional) Specify the amount of time (in seconds) that the Path Computation Client (PCC) must wait before retrying delegation of Path Computation Element (PCE)-initiated LSPs in case of delegation failure or re-delegation.

Default: 3600 seconds

Range: 0 through 4294967294 seconds

max-sid-depth—(Optional) Specify the maximum value for service identifier (SID) depth.

Default: 5

Range: 1 through 5

p2mp-lsp-init-capability—(Optional) Capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable PCE-initated point-to-multipoint LSPs.

p2mp-lsp-report-capability—(Optional) Capability to report point-to-multipoint RSVP-TE LSPs to a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable reporting of point-to-multipoint LSPs to a PCE.

p2mp-lsp-update-capability—(Optional) Capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable updating of PCE-initated point-to-multipoint LSPs.

spring-capability—(Optional) Enable SPRING-based provisioning for the PCE.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

pce-group (PCE)

Syntax pce-group *pce-group-name*;

Hierarchy Level [edit protocols pcep pce *pce-id*]

Release Information Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description Specify the Path Computation Element (PCE) group to which the configured PCE belongs.

Options ***pce-group-name***—Name of the PCE group.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pce on page 2208

pce-group (Protocols PCEP)

Syntax

```
pce-group pce-group-id {
  delegation-cleanup-timeout seconds;
  max-unknown-messages messages-per-minute;
  pce-type {
    active stateful;
  }
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag (all | pcep);
    no-remote-trace;
  }
}
```

Hierarchy Level

```
[edit protocols pcep]
```

Release Information

Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description

Configure the Path Computation Element (PCE) group parameters. A maximum of 10 PCE groups can be configured at any given point in time.
The remaining statements are explained separately.

NOTE: A PCE group can include PCEs that are either only stateful or only active stateful. A combination of stateful PCEs and active stateful PCEs in one PCE group is not supported.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- pcep on page 2196

pce-type

Syntax

```
pce-type {
  active stateful;
}
```

Hierarchy Level

[edit protocols pcep pce *pce-id*]

Release Information

Statement introduced in Junos OS Release 12.3.
Support for PTX Series added in Junos OS Release 14.2.
Support for QFX Series switches added in Junos OS Release 16.1R3.
Support for ACX Series added in Junos OS Release 17.1R1.

Description

Configure the path computation element (PCE) type:

- active—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegated control over their LSPs to the PCE.
- stateful—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update the LSP state. A PCC maintains synchronization with the PCE.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (PCE)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag (all | pcep);
  no-remote-trace;
}
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Description Configure the Path Computation Element Protocol (PCEP) tracing options.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory **/var/log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000 files

Default: 2 files. If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Area of path computation client process (pccd) to enable debugging output.

- all—Trace all areas of PCD code.
- pcep—Trace Path Computation Element Protocol (PCEP) operations.

no-remote-trace—(Optional) Disable remote tracing options.

no-world-readable—(Optional) Allow only certain users to read the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches this size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB.

Range: 10 KB through the maximum file size supported on your system.

Default: 1 MB. If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level
routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

traceoptions (Protocols PCEP)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
  no-remote-trace;
}
```

Hierarchy Level

```
[edit protocols pcep]
```

Description Configure the Path Computation Element Protocol (PCEP) tracing options.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory **/var/log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000 files

Default: 2 files. If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Area of path computation client process (pccd) to enable debugging output.

PCEP Tracing Flags

- ***all***—Trace all areas of PCCD code
- ***pccd-config***—All configuration parsing operations
- ***pccd-core***—PCCD core operations
- ***pccd-functions***—PCCD function entries and outs
- ***pccd-main***—PCCD main module
- ***pccd-rpd***—PCCD communication with RPD
- ***pccd-ui***—PCCD user interface handling

no-remote-trace—(Optional) Disable remote tracing options.

no-world-readable—(Optional) Allow only certain users to read the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches this size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues

until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB.

Range: 10 KB through the maximum file size supported on your system.

Default: 1 MB. If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

```

Syntax (EX and QFX Series Switches)

```
clear mpls lsp
<all>
<autobandwidth>
<name name>
<optimize | optimize-aggressive>
<path regular-expression>
<statistics>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Release the routes and states associated with MPLS label-switched paths (LSPs), and start new LSPs.

CAUTION: This command disconnects existing Resource Reservation Protocol (RSVP) sessions on the ingress routing device. If there is a time lag between the old path being torn down and the new path being set up, this command might impact traffic traveling along the LSPs.

Options

all—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

autobandwidth—(Optional) Clear LSP autobandwidth counters.

counters—(Optional) Reset the flap and the MBB counters to zero.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *name*—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

optimize | optimize-aggressive—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

path *regular-expression*—(Optional) Clear the specific LSP path matching the specified regular expression.

statistics—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

Required Privilege Level clear

<member>
<name name>
<optimize | optimize-aggressive>
<statistics>
```

Release Information

Statement introduced in Junos OS Release 14.2.
Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Release the routes and states associated with MPLS container label-switched paths (LSPs), and start new LSPs.

Options

none—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

autobandwidth—(Optional) Clear LSP autobandwidth counters.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *name*—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

optimize | optimize-aggressive—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

statistics—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

Required Privilege Level

```

monitor mpls delay rsvp

Syntax

```
monitor mpls delay rsvp lsp-name
<detail>
<count count>
<interval seconds>
<padding-size padding-size>
<traffic-class traffic-class>
```

Release Information Command introduced in Junos OS Release 14.2.

Description Perform an on-demand delay measurement and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the delay measurement is performed.

detail—(Optional) Display detailed output of the LSP delay measurement.

count *count*—(Optional) Specify the number of delay measurements to be carried out for the MPLS UHP LSP. For LSP delay measurement, the number of queries sent is the specified count number plus one additional query, because the LSP delay is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval *seconds*—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

padding-size *padding-size*— (Optional) Specify the length of padding TLV to be included in the query message.

Range: 0 through 1500

traffic-class *traffic-class*—(Optional) Specify the traffic class for the LSP delay measurement. When the traffic-class value is not specified, the default traffic-class code-point of 111 is used.

Range: 0 though 7

Required Privilege Level view

monitor mpls lsp delay rsvp count detail on page 2230

Output Fields Table 77 on page 2229 describes the output fields for the **monitor mpls delay rsvp** command. Output fields are listed in the approximate order in which they appear.

Table 77: monitor mpls delay rsvp Output Fields

Field Name	Field Description	Level of Output
Current two-way channel delay	Sum of packet delays, excluding the processing time of the remote provider edge (PE) router.	All Levels
Current round-trip-time	Total time taken for completing round-trip of packet.	All Levels
Best two-way channel delay	Best available two-way channel delay count.	All Levels
Worst two-way channel delay	Worst available two-way channel delay count.	All Levels
Average two-way channel delay	Average of the available two-way channel delay counts.	All Levels
Best round-trip-time	Best available round-trip-time count.	All Levels
Worst round-trip-time	Worst available round-trip-time count.	All Levels
Average round-trip-time	Average of the available round-trip-time counts.	All Levels
Average forward delay variation	Average of the variation in forward delay.	All Levels
Average reverse delay variation	Average of the variation in reverse delay.	All Levels
DM queries sent	Number of queries sent for delay measurement.	All Levels
DM responses received	Number of responses received for delay measurement queries.	All Levels
DM queries timedout	Number of timed out queries sent for delay measurement.	All Levels
DM responses dropped due to errors	Number of loss measurement responses dropped due to errors.	All Levels
Response code	Status of the messages used for delay measurement. Response code can be one of the following: • **Success**—Successful response code. • **Failed**—Failed response code.	**detail**
Querier transmit timestamp	Timestamp on the query message when the message is sent out the ingress PE router (querier). This is done in the hardware before packet is sent out of an interface.	**detail**

Table 77: monitor mpls delay rsvp Output Fields (continued)

Field Name	Field Description	Level of Output
Responder receive timestamp	Timestamp on the response message when the message is received by the egress PE router (responder). This is done in the hardware before packet is received by an interface.	**detail**
Responder transmit timestamp	Timestamp on the query message when the message is sent out the egress PE router (responder). This is done in the hardware before packet is sent out of an interface.	**detail**
Querier receive timestamp	Timestamp on the response message when the message is received by the ingress PE router (querier). This is done in the hardware before packet is received by an interface.	**detail**

Sample Output

monitor mpls lsp delay rsvp count

```
user@host> monitor mpls lsp delay rsvp LSP-A count 2

(1)

```

monitor mpls loss rsvp

Syntax

```
monitor mpls loss rsvp lsp-name
<detail>
<bytes>
<count count>
<interval seconds>
<traffic-class traffic-class>
```

Release Information Command introduced in Junos OS Release 14.2.

Description Perform an on-demand loss measurement and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the loss measurement is performed.

detail—(Optional) Display detailed output of the LSP loss measurement.

bytes—(Optional) Specify the measurement quantity for the LSP loss measurement as bytes. By default, LSP loss is measured in packets.

NOTE: The byte count of a packet sent or received over a channel counts only the payload, including the total length of that packet and excluding the headers, labels, and framing of the channel itself.

count *count*—(Optional) Specify the number of loss measurements to be carried out for the MPLS UHP LSP. For LSP loss measurement, the number of queries sent is the specified count number plus one additional query, because the LSP loss is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval *seconds*—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

traffic-class *traffic-class*—(Optional) Specify the traffic class and enable traffic-class-statistics for the LSP loss measurement.

Range: 0 though 7

Output Fields

Table 77 on page 2229 describes the output fields for the **monitor mpls loss rsvp** command. Output fields are listed in the approximate order in which they appear.

Table 78: monitor mpls loss rsvp Output Fields

Field Name	Field Description	Level of Output
Current forward loss	Difference between the current forward transmit count and the current forward receive count.	All Levels
Current forward loss ratio	Total packet loss (current forward loss divided by current forward transmit count).	All Levels
Current forward throughput	Current forward transmit count divided by 1000.	All Levels
Current reverse loss	Difference between the current reverse transmit count and the current reverse receive count.	All Levels
Current reverse loss ratio	Total packet loss (current reverse loss divided by current reverse transmit count).	All Levels
Current reverse throughput	Current reverse transmit count divided by 1000.	All Levels
Cumulative forward transmit count	Cumulative forward transmit counter value at the time the loss measurement message was originated.	All Levels
Cumulative forward loss	Cumulative forward loss counter value at the time the loss measurement message was originated.	All Levels
Average forward loss ratio	Average packet loss (current forward loss divided by current forward transmit count).	All Levels
Average forward throughput	Average forward transmit count divided by 1000.	All Levels
Cumulative reverse transmit count	Cumulative reverse transmit counter value at the time the loss measurement message was originated.	All Levels
Cumulative reverse loss	Difference between the cumulative reverse transmit count and the cumulative reverse receive count.	All Levels
Average reverse loss ratio	Average packet loss (average reverse loss divided by average reverse transmit count).	All Levels
Average reverse throughput	Average reverse transmit count divided by 1000.	All Levels

Table 78: monitor mpls loss rsvp Output Fields (continued)

Field Name	Field Description	Level of Output
LM queries sent	Number of queries sent for loss measurement.	All Levels
LM responses received	Number of responses received for loss measurement queries.	All Levels
LM queries timedout	Number of timed out queries sent for loss measurement.	All Levels
LM responses dropped due to errors	Number of loss measurement responses dropped due to errors.	All Levels
Response code	Status of the messages used for loss measurement. Response code can be one of the following: • **Success**—Successful response code. • **Failed**—Failed response code.	**detail**
Origin timestamp	Time and date the loss measurement message is originated without any specific format (NTP and PTP).	**detail**
Forward transmit count	Forward transmit counter value at the time the loss measurement message was originated.	**detail**
Forward receive count	Forward receive counter value at the time the loss measurement message was originated.	**detail**
Reverse transmit count	Reverse transmit counter value at the time the loss measurement message was originated.	**detail**
Reverse receive count	Reverse receive counter value at the time the loss measurement message was originated.	**detail**
Current forward transmit count	Difference between the current forward transit count and the previous forward transit count.	**detail**
Current forward receive count	Difference between the current forward receive count and the previous forward receive count.	**detail**
Current reverse transmit count	Difference between the current reverse transit count and the previous reverse transit count.	**detail**
Current reverse receive count	Difference between the current reverse receive count and the previous reverse receive count.	**detail**

monitor mpls loss-delay rsvp

Syntax

```
monitor mpls loss-delay rsvp lsp-name
<detail>
<bytes>
<count count>
<interval seconds>
<padding-size padding-size>
<traffic-class traffic-class>
```

Release Information Command introduced in Junos OS Release 14.2.

Description Perform a simultaneous on-demand loss and delay measurement using combined loss and delay messages, and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options ***lsp-name***—Name of the associated bidirectional MPLS UHP LSP for which the delay measurement is performed.

detail—(Optional) Display detailed output of the LSP delay measurement.

bytes—(Optional) Specify the measurement quantity for the LSP loss measurement as bytes. By default, LSP loss is measured in packets.

NOTE: The byte count of a packet sent or received over a channel counts only the payload, including the total length of that packet and excluding the headers, labels, and framing of the channel itself.

count *count*—(Optional) Specify the number of delay measurements to be carried out for the MPLS UHP LSP. For LSP delay measurement, the number of queries sent is the specified count number plus one additional query, because the LSP delay is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval *seconds*—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

padding-size *padding-size*—(Optional) Specify the length of padding TLV to be included in the query message.

Range: 0 through 1500

traffic-class *traffic-class*—(Optional) Specify the traffic class for the LSP delay measurement. When the traffic-class value is not specified, the default traffic-class code-point of 111 is used.

Range: 0 though 7

```

ping mpls bgp

Syntax

```
ping mpls bgp fec
<bottom-label-ttl>
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<size bytes>
<source source-address>
<sweep>
```

Release Information Command introduced in Junos OS Release 11.1.

Description Check the operability of MPLS BGP-signaled label-switched path (LSP) connections. Press Ctrl+c to interrupt a **ping mpls bgp** command.

NOTE: The **ping mpls bgp *fec*** command only supports single paths.

Options

bottom-label-ttl—(Optional) Time-to-live (TTL) value for the bottom label in the label stack. The range of values is 1 through 255. The default value is **255**.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

destination *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping a BGP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

size *bytes*—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the

router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only BGP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

ping mpls bgp fec count on page 2244

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (**!**) indicates that an echo reply was received. A period (**.**) indicates that an echo reply was not received within the timeout period. An **x** indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately. To display the error codes, use the **detail** option (for example, **ping mpls bgp 10.255.245.222 detail**).

Sample Output

ping mpls bgp fec count

```
user@host> ping mpls bgp 10.255.245.222 count 10
!!!xxx...x--- lsping statistics ---10 packets transmitted, 3 packets received,
70% packet loss 4 packets received with error status, not counted as received.
```

ping mpls lsp-end-point

Syntax

```
ping mpls lsp-end-point prefix-name
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
The **size** and **sweep** options were introduced in Junos OS Release 9.6.
The **instance** option was introduced in Junos OS Release 10.0.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS label-switched path (LSP) endpoint connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

instance *routing-instance-name*—(Optional) Ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP connection.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

prefix-name—LDP forwarding equivalence class (FEC) prefix or RSVP LSP endpoint address.

size *bytes*—(Optional) Size of the LSP ping request packet. If the endpoint is LDP-based, the minimum size of the packet is **88** bytes. If the endpoint is RSVP-based, the minimum size of the packet is **100** bytes. The maximum size in either case is **65468** bytes.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
The **size** and **sweep** options were introduced in Junos OS Release 9.6.
The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

Description

Check the operability of the MPLS Layer 2 circuit connections. Type Ctrl+c to interrupt a **ping mpls l2circuit** command.

NOTE: This command is not supported on EX4500 and EX4550 switches.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

interface *interface-name*—Ping an interface configured for the Layer 2 circuit on the egress provider edge (PE) router.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

reply-mode—(Optional) Reply mode for the ping request. This option has the following suboptions:

application-level-control-channel—Reply using an application level control channel.

ip-udp—Reply using an IPv4 or IPv6 UDP packet.

no-reply—Do not reply to the ping request.

NOTE: The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

v1—(Optional) Use the type 9 Layer 2 circuit type, length, and value (TLV).

virtual-circuit *virtual-circuit-id* neighbor *address*—Ping the virtual circuit identifier on the egress PE router or switch and the specified neighbor, testing the integrity of the Layer 2 circuit between the ingress and egress PE routers or switches.

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
The **size** and **sweep** options were introduced in Junos OS Release 9.6.
The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

Description

Check the operability of MPLS Layer 2 virtual private network (VPN) connections. Type Ctrl+c to interrupt a **ping mpls l2vpn** command.

Options

bottom-label-ttl—(Optional) Display the time-to-live value for the bottom label in the label stack.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through 1,000,000. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

instance *instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number*—Ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, testing the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the ingress and egress provider edge (PE) routers or switches.

interface *interface-name*—Ping an interface configured for the Layer 2 VPN on the egress PE router or switch.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

reply-mode—(Optional) Reply mode for the ping request. This option has the following suboptions:

application-level-control-channel—Reply using an application level control channel.

ip-udp—Reply using an IPv4 or IPv6 UDP packet.

no-reply—Do not reply to the ping request.

The **reply-mode** option and its suboptions **application-level-control-channel, ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
The **size** and **sweep** options were introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Check the operability of a MPLS Layer 3 virtual private network (VPN) connection. Type Ctrl+c to interrupt a **ping mpls l3vpn** command.

Options

bottom-label-ttl—(Optional) Display the time-to-live value for the bottom label in the label stack.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

l3vpn-name—(Optional) Layer 3 VPN name.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

prefix *prefix-name*—Ping to test whether a prefix is present in a provider edge (PE) router's or switch's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix. This option does not test the connection between a PE router or switch and a customer edge (CE) router or switch.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

If the Layer 3 VPN traffic transits a route reflector within the network, the **ping mpls l3vpn** command does not work.

Required Privilege Level

network

List of Sample Output

ping mpls l3vpn on page 2255
ping mpls l3vpn detail on page 2255

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (**!**) indicates that an echo reply was received. A period (**.**) indicates that an echo reply was not received within the timeout period. An **x** indicates that an echo reply was received with an error code these packets are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls l3vpn

```
user@host> ping mpls l3vpn vpn1 prefix 10.255.245.122/32
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

ping mpls l3vpn detail

```
user@host> ping mpls l3vpn vpn1 prefix 10.255.245.122/32 detail
```

```
Request for seq 1, to interface 68, labels <100128, 100112>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 68, labels <100128, 100112>
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 68, labels <100128, 100112>
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 68, labels <100128, 100112>
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 68, labels <100128, 100112>
Reply for seq 5, return code: Egress-ok
--- lsping statistics ---

```

request mpls container-lsp

Syntax

```
request mpls container-lsp
<logical-system (all | logical-system-name)>
<name lsp-name>
<adjust-autobandwidth>
<normalization>
```

Release Information

Command introduced in Junos OS Release 14.2.
Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Manually trigger a bandwidth allocation adjustment for the container label-switched path (LSP).

Options

none—Manually trigger a bandwidth allocation adjustment for all active member LSP paths.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Manually trigger a bandwidth allocation adjustment on the specified member LSP only.

adjust-autobandwidth—(Optional) Request LSP autobandwidth adjustment.

normalization—(Optional) Request container LSP normalization.

Required Privilege Level

clear, maintenance

<logical-system (all | logical-system-name)>
<name lsp-name>
```

Syntax (EX and QFX Series Switches)

```
request mpls lsp adjust-autobandwidth
<name lsp-name>
```

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.5 for EX Series switches.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Manually trigger a bandwidth allocation adjustment for active label-switched paths (LSPs).

Without running this command, the bandwidth adjustment is recomputed at a configurable interval. The default interval is 5 minutes. If you do not want to wait for the periodic adjustment (for example, during a software demonstration), this command is useful.

During bandwidth allocation adjustment, the LSP stays up to enable the bandwidth to be changed without dropping any traffic. This functionality is often referred to as *make-before-break*.

Options

none—Manually trigger a bandwidth allocation adjustment for all active LSP paths.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Manually trigger a bandwidth allocation adjustment on the specified LSP only.

Additional Information

For this command to work properly, the following conditions must exist:

- Automatic bandwidth allocation must be enabled on the LSP. The parameters for adjustment interval and maximum average bandwidth are not reset after you issue the **request mpls lsp adjust-autobandwidth** command.
- The difference between the adjusted bandwidth and the current LSP path bandwidth must be greater than the threshold limit.

Required Privilege Level clear, maintenance

```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about the configured circuit cross-connect (CCC) connections.

Options

none—Display the standard level of output for all configured CCC connections.

all—(Optional) Display all connections.

brief | extensive—(Optional) Display the specified level of output. Use history to display information about connection history. Use labels to display labels used for transmit and receive LSPs. Use status to display information about the connection and interface status.

interface-switch—(Optional) Display interface switch connections only.

lsp-switch—(Optional) Display LSP switch connections only.

p2mp-receive-switch—(Optional) Display point-to-multipoint LSP to local interfaces switch connections only.

p2mp-transmit-switch—(Optional) Display local interface to point-to-multipoint LSP switch connections only.

remote-interface-switch—(Optional) Display remote interface switch connections only.

down | up | up-down—(Optional) Display nonoperational, operational, or both kinds of connections.

history—(Optional) Display information about connection history.

labels—(Optional) Display labels used for transmit and receive.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name—(Optional) Display information about the specified connection only.

status—(Optional) Display information about the connection and interface status.

Required Privilege Level view

Output Fields Table 79 on page 2261 describes the output fields for the **show connections** command. Output fields are listed in the approximate order in which they appear.

Table 79: show connections Output Fields

Field Name	Field Description
CCC and TCC connections [Link Monitoring On I Off]	Whether link monitoring is enabled: **On** or **Off**.
Legend for Status (St)	Connection or circuit status. See the output's legend for an explanation of the status field values.
Legend for connection types	Type of connection: • **if-sw**—Layer 2 switching cross-connect. • **rmt-if**—Remote interface switch. While graceful restart is in progress, **rmt-if** will display a state **(St)** of **Restart**. • **lsp-sw**—LSP stitching cross-connect. While graceful restart is in progress, **lsp-sw** will display a state **(St)** of **Restart**.
Legend for circuit types	Type of circuits: • **intf**—Interface circuit. • **tlsp**—Transmit LSP circuit. • **rlsp**—Receive LSP circuit.
Connection/Circuit	Name of the configured CCC connection.
Type	Type of connection.
St	State of the connection.

Table 79: show connections Output Fields (continued)

Field Name	Field Description
Time last up	Time that the connection or circuit last transitioned to the **Up** (operational) state.
# Up trans	Number of times that the connection or circuit has transitioned to the **Up** (operational) state.

Sample Output

List of Sample Output show link-management on page 2266

Output Fields Table 80 on page 2263 describes the output fields for the **show link-management** command. Output fields are listed in the approximate order in which they appear.

Table 80: show link-management Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is **0** through **64,000**.
State	State of the peer: **Up** or **Down**.
Control address	Address to which a control channel is established.
CC local ID	Identifier assigned to the control channel by the local peer. The range of values is **1** through **4,294,967,296**.
CC remote ID	Identifier assigned to the control channel by the remote peer. The range of values is **1** through **4,294,967,296**.
State	State of the control channel: **Up** or **Down**.

Table 80: show link-management Output Fields (continued)

Field Name	Field Description
TxSeqNum	Sequence number of the hello message being sent to the peer. The range of values is 1 through **4,294,967,295**.
RcvSeqNum	Sequence number of the last hello message received from the peer. The range of values is **0** through **4,294,967,295.**
Flags	Code that provides information about the control channel. Currently supports only code value **R**, which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts.
TE links	Traffic-engineered links that are managed by their peer.
TE link name	Name of the traffic-engineered link.
State	State of the traffic-engineered link: **Up**, **Down**, or **Init**.
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include **SDH/SONET, Ethernet**, **Packet**, and **PDH**.
Switching	Type of switching that can be performed on the traffic-engineered link. Supported values are **PSC-1** and **Packet**.
Minimum bandwidth	Smallest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link (in bps).
Maximum bandwidth	Largest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).
Total bandwidth	Sum of the bandwidth, in bits per second (bps) and megabits per second (Mbps), of all interfaces that are members of the link.
Available bandwidth	Sum of the bandwidths of all interfaces that are members of the link and that are not yet allocated (in bps).
Name	Name of the interface.
State	State of the interface: **Up** or **Down**.
Local ID	Identifier of the local side of the interface.

Table 80: show link-management Output Fields (continued)

Field Name	Field Description
Remote ID	Identifier of the remote side of the interface.
Bandwidth	Bandwidth, in bps or Mbps, of the member interface.
Used	Whether the resource is allocated to an LSP: **Yes** or **No**.
LSP-name	LSP name.

Sample Output

show link-management peer on page 2268

Output Fields

Table 81 on page 2267 describes the output fields for the **show link-management peer** command. Output fields are listed in the approximate order in which they appear.

Table 81: show link-management peer Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is **0** through **64,000**.
State	State of the peer: **Up** or **Down**.
Control address	Address to which a control channel is established.
Hello interval	How often the routing device sends Link Management Protocol (LMP) hello packets.
Hello dead interval	How long LMP waits before declaring the control channel to be dead. This is an interval during which the routing device receives no LMP hello packets from the neighbor on a control that is active or up.
CC local ID	Identifier assigned to the control channel by the local peer. The range of values is **1** through **4,294,967,296**.

Table 81: show link-management peer Output Fields (continued)

Field Name	Field Description
CC remote ID	Identifier assigned to the control channel by the remote peer. The range of values is **1** through **4,294,967,296**.
State	State of the control channel: **Up** or **Down**.
TxSeqNum	Sequence number of the hello message being sent to the peer. The range of values is **1** through **4,294,967,295**.
RcvSeqNum	Sequence number of the last hello message received from the peer. The range of values is **0** through **4,294,967,295.**
Flags	Code that provides information about the control channel. Currently supports only code value **R**, which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts.

Output Fields

Table 82 on page 2269 describes the output fields for the **show link-management routing** command. Output fields are listed in the approximate order in which they appear.

Table 82: show link-management routing Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is **0** through **64,000**.
State	State of the peer: **Up** or **Down**.

Table 82: show link-management routing Output Fields (continued)

Field Name	Field Description
Control address	Address to which a control channel is established.
Control channel	Interface over which control packets are sent.
State	State of the control channel.
TE link name	Traffic-engineered link name.
State	State of the traffic-engineered link: **Up** or **Down**.
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include **SDH/SONET**, **Ethernet**, and **Packet**.
Minimum bandwidth	Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link.
Maximum bandwidth	Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).
Total bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link.
Available bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.
Resource	Forwarding adjacency LSP information.
Type	Type of resource. The type is always a forwarding adjacency LSP.
State	State of the LSP: **Up** or **Down**.
System Identifier	Internal identifier for the peer. The range of values is **0** through **64,000**.
Total bandwidth	Bandwidth resource, in bps or Mbps, on the TE-link learned from the routing process.

Table 82: show link-management routing Output Fields (continued)

Field Name	Field Description
Traffic parameters	• **Encoding**—Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include **SDH/SONET**, **Ethernet**, and **Packet**. • **Switching**—Type of switching that can be performed on the traffic-engineered link: **PSC-1** and **Packet**. • **Granularity**—Layer 2 data for switching Layer 2 LSPs for this resource. Not supported. This value is always **unknown**.

show link-management statistics on page 2274

Output Fields

Table 83 on page 2273 describes the output fields for the **show link-management statistics** command. Output fields are listed in the approximate order in which they appear.

Table 83: show link-management statistics Output Fields

Field Name	Field Description
Received packets	Number of received packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Received bad packets	Number of received bad packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Small packets	Number of packets that are too small.
Wrong protocol version	Number of packets specifying the wrong LMP version.
Messages for unknown peer	Number of packets destined for an unknown peer.
Messages for bad state	Number of packets indicating a state that does not match the recipient.

Table 83: show link-management statistics Output Fields (continued)

Field Name	Field Description
Stale acknowledgments	Number of **configAck** and **LinkSummaryAck** packets received that have a stale message ID.
Stale negative acknowledgments	Number of **configNack** and **LinkSummaryNack** packets received that have a stale message ID.
Sent packets	Number of sent packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Retransmitted packets	Number of retransmitted packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Dropped packets	Number of packets sent, by message type, that have been dropped by the receiver after the LMP retransmission interval has been exceeded. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.

Sample Output

show link-management statistics

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display the resources used to set up Multiprotocol Label Switching (MPLS) traffic-engineered forwarding paths.

Options

none—Display information for all traffic-engineered links.

brief | detail—(Optional) Display the specified level of output.

name *name*—(Optional) Display information for the specified traffic-engineered link only.

Required Privilege Level

Output Fields

Table 84 on page 2275 describes the output fields for the **show link-management te-link** command. Output fields are listed in the approximate order in which they appear.

Table 84: show link-management te-link Output Fields

Field Name	Field Description
TE link name	Traffic-engineered link name.
State	State of the traffic-engineered link: **Up** or **Down.**
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.

Table 84: show link-management te-link Output Fields (continued)

Field Name	Field Description
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include **SDH/SONET**, **Ethernet**, **Packet**, and **PDH**.
Switching	Type of switching that can be performed on the traffic-engineered link. Supported values are **PSC-1** and **Packet**.
Minimum bandwidth	Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link.
Maximum bandwidth	Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link.
Total bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link (in bps).
Available Bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.
Name	Name of the interface.
State	State of the interface: **Up** or **Down**.
Local ID	Identifier of the local side of the interface.
Remote ID	Identifier of the remote side of the interface.
Bandwidth	Bandwidth, in bps or Mbps, of the member interface.
Used	Whether the resource is allocated to an LSP: **Yes** or **No**.
LSP-name	LSP name.

Sample Output

show link-management te-link

show mpls abstract-hop-membership

Syntax

```
show mpls abstract-hop-membership
<abstract-hop-name>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information Command introduced in Junos OS Release 17.1 for all platforms.

Description Display MPLS abstract hop membership tables for each abstract hop configured on the device.

Options

none—(Optional) Display the MPLS abstract hop membership table for all the configured abstract hops on the router.

abstract-hop-name—(Optional) Display the MPLS abstract hop membership table for the specified abstract hop.

instance *instance-name*—(Optional) Display the MPLS abstract hop membership table for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Display the MPLS abstract hop membership table for all logical systems or on a particular logical system.

Table 86: show mpls admin-groups Output Fields

Field Name	Field Description
Group	Name of the administrative group.
Bit index	Value assigned to the administrative group.

Sample Output

show mpls admin-groups

```
user@host> show mpls admin-groups
```

```
Group        Bit index
black         3
blue          2
gold          1
green         0
```

show mpls association

Syntax

```
show mpls association (iif incoming-interface | oif outgoing-interface)
<logical-system (all | logical-system-name)>
```

Release Information Command introduced in Junos OS Release 16.1 for the M Series, MX Series, and T Series.

Description Display the Multiprotocol Label Switching (MPLS) label-switched paths (LSPs) based on the association with an incoming or outgoing LSP interface. The command output displays the list of RSVP-TE LSPs carrying traffic in and out of the same interface.

Options

iif *incoming-interface-name*—Display list of RSVP-TE LSPs that share the specified incoming interface to bring in traffic. This option works on transit label-switching routers (LSRs) and egress label edge routers (LERs).

oif *outgoing-interface-name*—Display list of RSVP-TE LSPs that share the specified outgoing interface to carry out traffic. This option works on ingress LERs and transit LSRs.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Release Information
Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance *instance-name* option added in Junos OS Release 15.1.

Description
Display Multiprotocol Label Switching (MPLS) label-switched path (LSP) call admission control (CAC) information.

Options
none—Display CAC information for all LSPs.

instance *instance-name*—(Optional) Display MPLS LSP CAC information for the specified instance. If ***instance-name*** is omitted, MPLS LSP CAC information for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-name—(Optional) Display CAC information for the specified LSP only.

Additional Information
The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by any Layer 2 connection at that class type.

Required Privilege Level
view

List of Sample Output
show mpls call-admission-control on page 2285

Output Fields
Table 88 on page 2285 describes the output fields for the **show mpls call-admission-control** command. Output fields are listed in the approximate order in which they appear.

Table 88: show mpls call-admission-control Output Fields

Field Name	Field Description
Available bandwidth	Current available bandwidth on each LSP path. Depending on whether the LSP is an E-LSP or a regular LSP, either per-class bandwidth or a single bandwidth value (corresponding to best-effort bandwidth at **ct0**) is displayed. The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by some Layer 2 connections at that class type.
Layer2 connections	Different Layer 2 connections that had some bandwidth requirement and were admitted into an LSP path.
LSP name	LSP pathname.
Neighbor address	Neighbor address from which CAC and bandwidth booking are configured for Layer 2 circuits.
Circuit	Interface name and circuit information.
Primary	LSP's primary standby path.
Standby	LSP's secondary standby path.
VC bandwidth	Bandwidth constraints associated with a Layer 2 circuit route.

```

Release Information Command introduced in Junos OS Release 14.2.
Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description Display information about configured and active Multiprotocol Label Switching (MPLS) container label-switched paths (LSPs).

Options

none—Display standard information about all configured and active member LSPs of the container LSP.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

count-active-routes—(Optional) Show active routes for the container LSP.

defaults—(Optional) Display the default settings of the container LSP.

descriptions—(Optional) Display the container LSP descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls container-lsp]** hierarchy level. Only the LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

egress—(Optional) Display the LSPs ending at this device.

NOTE: The egress option displays all the LSPs including regular LSPs, members of container LSPs, and transit LSPs. This is an expected behavior for all platforms.

ingress—(Optional) Display the member LSPs originating from this device.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *name*—(Optional) Display information about the specified LSP or group of LSPs.

statistics—(Optional) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

transit—(Optional) Display LSPs transiting this routing device.

unidirectional—(Optional) Display unidirectional LSP information.

Output Fields Table 89 on page 2288 describes the output fields for the **show mpls container-lsp** command. Output fields are listed in the approximate order in which they appear.

Table 89: show mpls container-lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSP	Information about the member LSPs on the ingress routing device. Each LSP has one line of output.	All levels
Container LSP name	Name of the container LSP.	All levels
Member LSP count	Number of member LSPs in the container LSP.	All levels
To	Destination (egress routing device) of the session.	brief
From	Source (ingress routing device) of the session.	brief detail
State	State of the LSP handled by this RSVP session: • **Up** • **Dn** (down) • **Restart**	brief detail

Table 89: show mpls container-lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Rt	Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
P	Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.	brief
ActivePath	(Ingress LSP) Name of the active path: Primary or Secondary.	detail extensive
LSPname	Name of the member LSP.	brief detail
Egress LSP	Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output.	All levels
Transit LSP	Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
Min LSPs	Minimum number of member LSPs. Default: 1	extensive
Max LSPs	Number of member LSPs that the container LSP can have at maximum. Default: 64 (due to ECMP limit)	extensive
Aggregate bandwidth	Sum of the bandwidths of all member LSPs.	extensive
NormalizeTimer	Duration between two normalization events. When not configured, 21600 seconds (6 hours) is set as the default value.	extensive
NormalizeThreshold	Change in aggregate LSP utilization to trigger splitting or merging expressed in percentage.	extensive
Max Signaling BW	Maximum bandwidth used to signal LSPs after a normalization event. Default value is 0 bps. When not configured, the value is inherited from the splitting bandwidth configuration. NOTE: Between two normalization events, when auto-bandwidth adjustment happens, the per-LSP auto-bandwidth configuration and thresholds are used, instead of the maximum signaling bandwidth threshold.	extensive

Table 89: show mpls container-lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Min Signaling BW	Minimum bandwidth used to signal LSPs after a normalization event. Default value is 0 bps. When not configured, the value is inherited from the merging bandwidth configuration. NOTE: Between two normalization events, when auto-bandwidth adjustment happens, the per-LSP auto-bandwidth configuration and thresholds are used, instead of the minimum signaling bandwidth threshold.	extensive
Splitting BW	Bandwidth used for LSP splitting and merging. Default value is 0 bps. When not configured, the value is inherited from the auto-bandwidth maximum bandwidth configuration.	extensive
Merging BW	Bandwidth used for LSP splitting and merging. Default value is 0 bps. When not configured, the value is inherited from the auto-bandwidth minimum bandwidth configuration.	extensive
LSPtype		extensive
LoadBalance		extensive
MinBW	Minimum LSP bandwidth in bps related to auto-bandwidth.	extensive
AdjustTimer	Total amount of time in seconds allowed before LSP bandwidth adjustment take place. Range: 300 through 315360000 seconds	extensive
Max AvgBW util	Current value of the actual maximum average bandwidth utilization in bps.	extensive
Overflow limit	Threshold overflow limit.	extensive
Underflow limit	Threshold underflow limit.	extensive
Encoding type		extensive
Switching type		extensive
GPID		extensive
Priorities	Setup priority and hold priority values. For setup priority, 0 and 7 is the highest and lowest priority, respectively. When not explicitly configured, 7 and 0 are set as the default values for the setup priority and hold priority, respectively.	extensive
Bandwidth		extensive

Table 89: show mpls container-lsp Output Fields (continued)

Field Name	Field Description	Level of Output
SmartOptimizeTimer	Time in seconds allowed before path reoptimization.	extensive
Computed ERO	Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	extensive
Received RRO	Received record route. RRO is a series of hops, each with an address followed by a flag. In most cases, the received RRO is the same as the computed ERO. If the received RRO is different from the computed ERO, there is a topology change in the network, and the route is taking a detour. The following flags identify the protection capability and status of the downstream node: • **0x01**—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding path message. • **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously). • **0x03**—Combination of **0x01** and **0x02**. • **0x04**—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section. • **0x08**—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the local protection available bit is set but the node protection bit is cleared. • 0x09—Detour is established. Combination of **0x01** and **0x08**. • **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted. • **0x20**—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently. • **0xb**—Detour is in use. Combination of **0x01**, **0x02**, and **0x08**.	extensive
Make-before-break		extensive
Record Route		extensive
Automatic Autobw adjustment succeeded		extensive
CSPF		extensive
Created	Date and time the LSP was created.	extensive

show mpls context-identifer

Syntax

```
show mpls context-identifer
<brief | detail>
<logical-system (all | logical-system-name)>
<primary>;
<protector>;
```

Release Information Command introduced in Junos OS Release 11.4R3.

Description Display information about configured egress protection context identifiers.

Options

none—Display standard information about egress protection.

brief | detail—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

primary—(Optional) Perform this operation on the primary node.

protector—(Optional) Perform this operation on the protector node.

Required Privilege Level view

List of Sample Output

show mpls context-identifier detail (Protector) on page 2295
show mpls context-identifier detail (Primary) on page 2295

Output Fields Table 90 on page 2294 describes the output fields for the **show mpls egress-protection detail** command. Output fields are listed in the approximate order in which they appear.

Table 90: show mpls lsp Output Fields

Field Name	Field Description	Level of Output
ID	Context identifier.	All levels
Type	Indicates node type: protector or primary	All levels
Metric	MPLS cost value of the context identifier route. This route appears in inet.0 on the protector and primary nodes. On the protector node, the metric is a larger number.	All levels
Mode	Indicates advertise-mode: proxy or alias	**detail**

Table 90: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Context table	Name of the MPLS routing table created for egress protection.	All levels
Context LSPs	Names of the LSPs that have egress protection configured. Loopback interface addresses of the devices from which the LSPs are originated.	**detail**
Total	Total number of primary and protector nodes.	All levels
Primary	Number of primary nodes.	All levels
Protector	Number of protector nodes.	All levels

Sample Output

show mpls context-identifier detail (Protector)

```
user@host> show mpls context-identifier detail

ID: 166.1.3.1
  Type: protector, Metric: 16777215, Mode: alias
  Context table: __166.1.3.1__.mpls.0, Label out: 299968
```

Sample Output

show mpls context-identifier detail (Primary)

```
user@host> show mpls context-identifier detail

ID: 166.1.3.1
  Type: primary, Metric: 1, Mode: alias

Total 1, Primary 1, Protector 0
```

show mpls correlation label

Syntax

```
show mpls correlation label label-value
<brief | detail | extensive | terse>
<descriptions>
<logical-system (all | logical-system-name)>
```

Release Information Command introduced in Junos OS Release 15.2 for the M Series, MX Series, and T Series.

Description Display the correlation information for the Multiprotocol Label Switching (MPLS) label-switched path (LSP) with the owner of the label.

Options

label-value—Display information about the specified label.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

descriptions—(Optional) Display the LSP descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls lsp]** hierarchy level. Only the LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level view

Output Fields

Table 92 on page 2298 describes the output fields for the **show mpls cspf** command. Output fields are listed in the approximate order in which they appear.

Table 92: show mpls cspf Output Fields

Field Name	Field Description
Queue length	Number of LSPs queued for automatic path computation.
current	Current queue length.
maximum	Maximum queue length (high-water mark).
dequeued	Number of aborted computation attempts.

Table 92: show mpls cspf Output Fields (continued)

Field Name	Field Description
Paths	Counters for label-switched path computations.
total	Sum of the next four fields.
successful	Number of path computations that were successfully completed.
no route	Number of path computations that failed because the destination is unreachable.
Sys Error	Number of path computations that failed because of lack of memory.
CSPFs	Total number of CSPF computations. A single path might require multiple CSPF computations.
Time	Time, in seconds, required to perform the label-switched path computation.
Total	Total amount of time consumed by the CSPF path computation algorithm.
CSPFs	Total number of CSPF computations.
Avg per CSPF	Average amount of time required for each CSPF computation.
% of rpd	Percentage of routing process CPU used in the CSPF computation.

Sample Output

show mpls cspf

```
user@host> show mpls cspf
CSPF statistics
Queue length   current       maximum      dequeued
                     0             0             0

List of Sample Output

show mpls diffserv-te on page 2301

Output Fields

Table 93 on page 2300 describes the output fields for the **show mpls diffserv-te** command. Output fields are listed in the approximate order in which they appear.

Table 93: show mpls diffserv-te Output Fields

Field Name	Field Description
Bandwidth model	Bandwidth constraint model supported. The maximum allocation model (MAM) for EXP-inferred LSPs (E-LSPs) is currently supported.
TE class	DiffServ traffic engineering class.

Table 93: show mpls diffserv-te Output Fields (continued)

Field Name	Field Description
Traffic class	MPLS class type that corresponds to the DiffServ traffic engineering class: • **ct0**—Best effort • **ct1**—Assured forwarding • **ct2**—Expedited forwarding • **ct3**—Network control
Priority	MPLS preemption priority for this class type, a value from **0** through **7**. Interior gateway protocols (IGPs) distribute information about the available bandwidth for each traffic engineering class.

Sample Output

show mpls diffserv-te

```
user@host> show mpls diffserv-te
Bandwidth model: Maximum Allocation Model with support for E-LSPs.
TE class     Traffic class       Priority
te0          ct0                 3
te1          ct1                 2
```

show mpls interface

Syntax show mpls interface

Release Information Command introduced in Junos OS Release 9.5 for EX Series switches.

Description Display information about MPLS-enabled interfaces. MPLS is enabled on an interface when the interface is configured with both the **set protocols mpls interface** *interface-name* and **set interfaces** *interface-name* **unit 0 family mpls** commands.

Required Privilege Level view

Output Fields Table 94 on page 2302 describes the output fields for the **show mpls interface** command. Output fields are listed in the approximate order in which they appear.

Table 94: show mpls interface Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: **Up** or **Dn** (down).
Administrative groups	Administratively assigned colors of the link.

Sample Output

show mpls interface

```
user@switch> show mpls interface
Interface   State       Administrative groups
so-1/0/0.0  Up          Blue Yellow Red
```

show mpls egress-protection

Syntax

```
show mpls egress-protection
<brief | detail>
<logical-system (all | logical-system-name)>
```

Release Information Command introduced in Junos OS Release 11.4R3.

Description Display information about egress protection.

NOTE: Use this command on the device configured as the protector PE router to display information about egress protection. If you use this command on the device configured as the primary PE router, no output is displayed.

Options

none—Display standard information about egress protection.

brief | detail—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

```
show mpls interface
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance *instance-name* option added in Junos OS Release 15.1.

Description

Display information about Multiprotocol Label Switching (MPLS)-enabled interfaces.

Options

none—Display information about MPLS-enabled interfaces.

instance *instance-name*—(Optional) Display information about MPLS-enabled interfaces for the specified routing instance. If ***instance-name*** is omitted, information about MPLS-enabled interfaces is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

MPLS is enabled on an interface when the interface is configured with both the **set protocol mpls interface *interface-name*** and **set interface *interface-name* unit 0 family mpls** statements.

Required Privilege Level

view

List of Sample Output

show mpls interface on page 2306

Output Fields

Table 96 on page 2305 describes the output fields for the **show mpls interface** command. Output fields are listed in the approximate order in which they appear.

Table 96: show mpls interface Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: **Up** or **Dn** (down).

Table 96: show mpls interface Output Fields (continued)

Field Name	Field Description
Administrative groups	Administratively assigned colors of the link.
Maximum labels	Maximum number of MPLS labels upon which MPLS can operate on a logical interface. This is configured using the **maximum-labels** statement at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family mpls]** or the **[edit interfaces *interface-name* unit *logical-unit-number* family mpls]** hierarchy levels.
Static protection revert time	Time (in seconds) that a static LSP must wait before traffic reverts from the bypass path to the original path. This is configured using the **protection-revert-time** statement at the **[edit logical-systems *logical-system-name* protocols mpls interface *interface-name* static]** or the **[edit protocols mpls interface *interface-name* static]** hierarchy levels.
Always mark connection protection tlv	**Enabled** or **Disabled**: **Enabled** indicates that the **always-mark-connection-protection-tlv** statement is configured at the **[edit logical-systems *logical-system-name* protocols mpls interface *interface-name* static]** or the **[edit protocols mpls interface *interface-name* static]** hierarchy levels. When this statement is configured, it marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, the **switch-away-lsps** statement must be configured.
Switch away lsps	**Enabled** or **Disabled**: **Enabled** indicates that the **switch-away-lsps** statement is configured at the **[edit logical-systems *logical-system-name* protocols mpls interface *interface-name* static]** or the **[edit protocols mpls interface *interface-name* static]** hierarchy levels. This enables you to switch an LSP away from a network node using a bypass LSP. This feature can be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.

Sample Output

show mpls interface

```
user@host> show mpls interface

Interface: ge-0/2/1.57
  State: Up
  Administrative group: <none>
  Maximum labels: 5
  Static protection revert time: 5 seconds
  Always mark connection protection tlv: Disabled
  Switch away lsps : Disabled
```

show mpls label usage

Syntax

```
show mpls label usage
<label label value>
<label-range range-start range-end>
<logical-system (all | logical-sytem-name)>
```

Release Information

Command introduced in Junos OS Release 15.1.
Support for the **label** statement added in Junos OS Release 17.2.
Support for the **label-range** statement added in Junos OS Release 17.2.

Description

Show the available label space resource in RPD and also the applications that use the label space in RPD. There are four different label spaces currently used in MPLS—namely LSI, dynamic, block, and static. Each label space has a fixed number and cannot grow beyond the fixed value. Using this command, the administrator can monitor the available labels in each label space and the applications that are using the labels. Based on the availability of labels, the administrator can decide to stop any service and free some labels or use other service where the labels are available.

Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability.

When you set each member router's network services to **enhanced-ip**, only MPC or Modular Interface Cards (MICs) modules and Multiservices Dense Port Concentrator (MS-DPC) modules are powered on in the chassis. Non-service DPCs do not work with enhanced IP network services.

Options

none— Display the available labels in each label space and the applications using the labels.

label *label value*—(Optional) Display the information about which *label value* is used by which protocol, if any.

label-range *range-start range-end* —(Optional) Display the complete information about the **label-range** specified. WIth the **enhanced-ip** command enabled on the supported device, effective ranges and configured ranges along with details of different label spaces such as LSI, dynamic, block, and static types are displayed.

logical-system (all |*logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

Once the label space crosses the threshold, a new syslog message is added.

<label-space-name> label space usage crossed threshold limit of 90%.

For instance, LSI label space usage crossed threshold limit of 90%.

Required Privilege Level view

List of Sample Output show mpls label usage on page 2308

Output Fields Table 97 on page 2308 describes the output fields for the **show mpls label usage** command. Output fields are listed in the order in which they appear.

Table 97: show mpls label usage Fields

Field Name	Field Description
Label Space	Indicates the different types of labels currently used in MPLS.
Total	Indicates the total label space available.
Available	Indicates the number of freely available labels and also the percentage of the label space available.
Applications	Indicates the applications that use the MPLS label spaces.
Effective Ranges	Indicates actual ranges in use, which can be different from configured ranges, if conflicting with label already allocated.
Configured Ranges	Indicates the currently configured range assigned to different label spaces on the device.

Sample Output

show mpls label usage

```
user@host> show mpls label usage
Label space Total   Available        Applications
LSI         999984  999971 (100.00%) BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label
Block       999984  999971 (100.00%) BGP/LDP VPLS with tunnel-services, BGP L2VPN
Dynamic     999984  999971 (100.00%) RSVP, LDP, PW, L3VPN, RSVP-P2MP, LDP-P2MP,
MVPN, EVPN, BGP
Static      48576   48576  (100.00%) Static LSP, Static PW
```

With **enhanced-ip** enabled on the supported device, you get the following additional output.

```
user@host> show mpls label usage
Label space Total   Available        Applications
LSI         101     99     (98.02% ) BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label
Block       101     101    (100.00%) BGP/LDP VPLS with tunnel-services, BGP L2VPN
Dynamic     101     98     (97.03% ) RSVP, LDP, PW, L3VPN, RSVP-P2MP, LDP-P2MP,
MVPN, EVPN, BGP
Static      48576   48576  (100.00%) Static LSP, Static PW
Effective Ranges
Range name  Shared with Start   End
```

```

show mpls label usage label-range

Syntax

```
show mpls label usage label-range
<block-label-range range-start range-end>
<dynamic-label-range range-start range-end>
<label-limit label-limit value>
<lsi-label-range range-start range-end>
<static-label-range range-start range-end>
```

Release Information Command introduced in Junos OS Release 17.2.

Description There are four different label spaces currently used in MPLS—namely LSI, dynamic, block, and static. Each label space has a fixed number and cannot grow beyond the fixed value. Using **show mpls label usage label-range** command, the administrator can monitor the available labels in each label space and the applications that are using the labels. Based on the availability of labels, the administrator can decide to stop any service and free some labels or use other service where the labels are available.

Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability.

When you set each member router's network services to **enhanced-ip**, only MPC or Modular Interface Cards (MICs) modules and Multiservices Dense Port Concentrator (MS-DPC) modules are powered on in the chassis. Non-service DPCs do not work with enhanced IP network services.

Options

block-label-range *range-start range-end*—Display the details of block label type.

dynamic-label-range *range-start range-end* —Display the details of dynamic label type.

label-limit *label-limit value*—Limit for the number of concurrent active labels.

lsi-label-range *range-start range-end*—Display the details of LSI label type.

static-label-range *range-start range-end*—Display the details of static label type.

Output Fields Table 98 on page 2311 describes the output fields for the **show mpls label usage label-range** command. Output fields are listed in the order in which they appear.

Table 98: show mpls label usage label-range Fields

Field Name	Field Description
Label Space	Indicates the different types of labels currently used in MPLS.
Total	Indicates the total label space available.
Available	Indicates the number of freely available labels and also the percentage of the label space available.
Applications	Indicates the applications that use the MPLS label spaces.
Effective Ranges	Indicates actual ranges in use, which can be different from configured ranges, if conflicting with label already allocated.
Configured Ranges	Indicates the currently configured range assigned to different label spaces on the device.
Total	Indicates the currently used labels with label type and application type details.

Sample Output

With the **enhanced-ip** command enabled on the supported device, you get the following output.

```
user@host> show mpls label usage label-range 16 600
Label space Total   Available        Applications
LSI         101     99     (98.02% ) BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label
Block       101     101    (100.00%) BGP/LDP VPLS with tunnel-services, BGP L2VPN
Dynamic     101     98     (97.03% ) RSVP, LDP, PW, L3VPN, RSVP-P2MP, LDP-P2MP,
MVPN, EVPN, BGP
Static      48576   48576  (100.00%) Static LSP, Static PW
Effective Ranges
Range name  Shared with Start   End
LSI         300     400
Block       500     600

Release Information

Command introduced before Junos OS Release 7.4.
defaults option added in Junos OS Release 8.5.
Command introduced in Junos OS Release 9.5 for EX Series switches.
autobandwidth option added in Junos OS Release 11.4.
externally-controlled option added in Junos OS Release 12.3.
externally-provisioned option added in Junos OS Release 13.3.
Command introduced in Junos OS Release 13.2X51-D15 for QFX Series.
instance *instance-name* option added in Junos OS Release 15.1.

Description Display information about configured and active dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options **none**—Display standard information about all configured and active dynamic MPLS LSPs.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

In the extensive command output, the duplicate back-to-back messages are recorded as aggregated messages. An additional timestamp is included for these aggregated messages, where if the aggregated messages are five or less, timestamp deltas are recorded for each message, and if the aggregated messages are greater than five, the first and last timestamp is recorded.

For example:

- All timestamps

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route
 [3 times - 13:21:00, 13:22:01, 13:23:10]
```

- Timestamp deltas

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route
 [3 times - 13:21:00, +1:01, +2:10]
```

- First and last timestamp

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route
 [6 times - 13:21:00, 13:23:10]
```

abstract-computation—(Optional) Display abstract computation preprocessing for LSPs.

See show mpls lsp abstract-computation for more details.

autobandwidth—(Optional) Display automatic bandwidth information. This option is explained separately (see show mpls lsp autobandwidth).

bidirectional | unidirectional—(Optional) Display bidirectional or unidirectional LSP information, respectively.

bypass—(Optional) Display LSPs used for protecting other LSPs.

count-active-routes—(Optional) Display active routes for LSPs.

defaults—(Optional) Display the MPLS LSP default settings.

descriptions—(Optional) Display the MPLS label-switched path (LSP) descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls lsp]** hierarchy level. Only LSPs with a description are displayed. This

command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

externally-controlled—(Optional) Display the LSPs that are under the control of an external Path Computation Element (PCE).

externally-provisioned—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

instance *instance-name*—(Optional) Display MPLS LSP information for the specified instance. If ***instance-name*** is omitted, MPLS LSP information is displayed for the master instance.

locally-provisioned—(Optional) Display LSPs that have been provisioned locally by the Path Computation Client (PCC).

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **egress**—Sessions that terminate on this routing device.
- **ingress**—Sessions that originate from this routing device.
- **pop-and-forward**—Sessions that originate from RSVP-TE pop-and-forward LSP tunnels.
- **transit**—Sessions that pass through this routing device.

name *name*—(Optional) Display information about the specified LSP or group of LSPs.

p2mp—(Optional) Display information about point-to-multipoint LSPs.

reverse-statistics—(Optional) Display packet statistics for reverse direction of LSPs.

segment—(Optional) Display segment identifier (SID) labels.

statistics—(Optional) (Ingress and transit routers only) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

NOTE: If a bypass LSP is configured for the primary static LSP, display cumulative statistics of packets traversing through the protected LSP and bypass LSP when traffic is re-optimized when the protected LSP link is restored. (Bypass LSPs are not supported on QFX Series switches.)

When used with the **bypass** option (**show mpls lsp bypass statistics**), display statistics for the traffic that flows only through the bypass LSP.

transit—(Optional) Display LSPs transiting this routing device.

Output Fields

Table 99 on page 2316 describes the output fields for the **show mpls lsp** command. Output fields are listed in the approximate order in which they appear.

Table 99: show mpls lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSP	Information about LSPs on the ingress routing device. Each session has one line of output.	All levels
Egress LSP	Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output.	All levels

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Transit LSP	Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
P2MP name	Name of the point-to-multipoint LSP. Dynamically generated P2MP LSPs used for VPLS flooding use dynamically generated P2MP LSP names. The name uses the format ***identifier*:vpls:*router-id*:*routing-instance-name***. The ***identifier*** is automatically generated by Junos OS.	All levels
P2MP branch count	Number of destination LSPs the point-to-multipoint LSP is transmitting to.	All levels
P	An asterisk (*) under this heading indicates that the LSP is a primary path.	All levels
address	(**detail** and **extensive**) Destination (egress routing device) of the LSP.	**detail extensive**
To	Destination (egress routing device) of the session.	**brief**
From	Source (ingress routing device) of the session.	**brief detail**
State	State of the LSP handled by this RSVP session: **Up**, **Dn** (down), or **Restart**.	**brief detail**
Active Route	Number of active routes (prefixes) installed in the forwarding table. For ingress LSPs, the forwarding table is the primary IPv4 table (**inet.0**). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (**mpls.0**).	**detail extensive**
Rt	Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (**inet.0**). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	**brief**
P	Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.	**brief**
ActivePath	(Ingress LSP) Name of the active path: **Primary** or **Secondary**.	**detail extensive**
LSPname	Name of the LSP.	**brief detail**
Statistics	Displays the number of packets and the number of bytes transmitted over the LSP. These counters are reset to zero whenever the LSP path is optimized (for example, during an automatic bandwidth allocation).	**extensive**
Aggregate statistics	Displays the number of packets and the number of bytes transmitted over the LSP. These counters continue to iterate even if the LSP path is optimized. You can reset these counters to zero using the **clear mpls lsp statistics** command.	**extensive**
Packets	Displays the number of packets transmitted over the LSP.	**brief extensive**
Bytes	Displays the number of bytes transmitted over the LSP.	**brief extensive**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
DiffServeInfo	Type of LSP: multiclass LSP **(multiclass diffServ-TE LSP)** or Differentiated-Services-aware traffic engineering LSP **(diffServ-TE LSP)**.	**detail**
LSPtype	Type of LSP: • **Static configured**—Static • **Dynamic configured**—Dynamic • **Externally controlled**—External path computing entity Also indicates if the LSP is a **Penultimate hop popping** LSP or an **Ultimate hop popping** LSP.	**detail extensive**
Bypass	(Bypass LSP) Destination address (egress routing device) for the bypass LSP.	All levels
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. **LSPpath** can be either **primary** or **secondary** and can be displayed on the ingress, egress, and transit routing devices.	**detail**
Bidir	(GMPLS) The LSP allows data to travel in both directions between GMPLS devices.	All levels
Bidirectional	(GMPLS) The LSP allows data to travel both ways between GMPLS devices.	All levels
FastReroute desired	Fast reroute has been requested by the ingress routing device.	**detail**
Link protection desired	Link protection has been requested by the ingress routing device.	**detail**
Node/Link protection desired	Link protection has been requested by the ingress routing device.	**detail**
LSP Control Status	(Ingress LSP) LSP control mode: • External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP. • Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control. A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.	**extensive**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
External Path CSPF status	(PCE-controlled LSPs) Status of the PCE-controlled LSP with per path attributes: • Local • External	**extensive**
Externally Computed ERO	(PCE-controlled LSPs) Externally computed explicit route when the route object is not null or empty. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (**S**) or loose (**L**).	**extensive**
EXTCTRL_LSP	(PCE-controlled LSPs) Display path history including the bandwidth, priority, and metric values received from the external controller.	**extensive**
flap counter	Counts the number of times a LSP flaps down or up.	extensive
LoadBalance	(Ingress LSP) CSPF load-balancing rule that was configured to select the LSP's path among equal-cost paths: **Most-fill**, **Least-fill**, or **Random**.	**detail extensive**
Signal type	Signal type for GMPLS LSPs. The signal type determines the peak data rate for the LSP: **DS0**, **DS3**, **STS-1**, **STM-1**, or **STM-4**.	All levels
Encoding type	LSP encoding type: **Packet**, **Ethernet**, **PDH**, **SDH/SONET**, **Lambda**, or **Fiber**.	All levels
Switching type	Type of switching on the links needed for the LSP: **Fiber**, **Lamda**, **Packet**, **TDM**, or **PSC-1**.	All levels
GPID	Generalized Payload Identifier (identifier of the payload carried by an LSP): **HDLC**, **Ethernet**, **IPv4**, **PPP**, or **Unknown**.	All levels
Protection	Configured protection capability desired for the LSP: **Extra**, **Enhanced**, **none**, **One plus one**, **One to one**, or **Shared**.	All levels
Upstream label in	(Bidirectional LSPs) Incoming label for reverse direction traffic for this LSP.	All levels
Upstream label out	(Bidirectional LSPs) Outgoing label for reverse direction traffic for this LSP.	All levels
Suggested label received	(Bidirectional LSPs) Label the upstream interface suggests to use in the Resv message that is sent.	All levels
Suggested label sent	(Bidirectional LSPs) Label the downstream node suggests to use in the Resv message that is returned.	All levels
Autobandwidth	(Ingress LSP) The LSP is performing autobandwidth allocation.	**detail extensive**
Mbb counter	Counts the number of times a LSP incurs MBB.	extensive
MinBW	(Ingress LSP) Configured minimum value of the LSP, in bps.	**detail extensive**
MaxBW	(Ingress LSP) Configured maximum value of the LSP, in bps.	**detail extensive**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Dynamic MinBW	(Ingress LSP) Displays the current dynamically specified minimum bandwidth allocation for the LSP, in bps.	**detail extensive**
Dynamic MinBW	(Ingress LSP) Displays the current dynamically specified minimum bandwidth allocation for the LSP, in bps.	**detail extensive**
AdjustTimer	(Ingress LSP) Configured value for the **adjust-timer** statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.	**detail extensive**
Adjustment Threshold	(Ingress LSP) Configured value for the **adjust-threshold** statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization.	**detail extensive**
Time for Next Adjustment	(Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.	**detail extensive**
Time of Last Adjustment	(Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.	**detail extensive**
MaxAvgBW util	(Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps.	**detail extensive**
Overflow limit	(Ingress LSP) Configured value of the threshold overflow limit.	**detail extensive**
Overflow sample count	(Ingress LSP) Current value for the overflow sample count.	**detail extensive**
Bandwidth Adjustment in *nnn* second(s)	(Ingress LSP) Current value of the bandwidth adjustment timer, indicating the amount of time remaining until the bandwidth adjustment will take place, in seconds.	**detail extensive**
Underflow limit	(Ingress LSP) Configured value of the threshold underflow limit.	**detail extensive**
Underflow sample count	(Ingress LSP) Current value for the underflow sample count.	**detail extensive**
Underflow Max AvgBW	(Ingress LSP) The highest sample bandwidth among the underflow samples recorded currently. This is the signaling bandwidth if an adjustment occurs because of an underflow.	**detail extensive**
Active path indicator	(Ingress LSP) A value of * indicates that the path is active. The absence of * indicates that the path is not active. In the following example, “long” is the active path. ***Primary long** **Standby short**	**detail extensive**
Primary	(Ingress LSP) Name of the primary path.	**detail extensive**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Secondary	(Ingress LSP) Name of the secondary path.	**detail extensive**
Standby	(Ingress LSP) Name of the path in standby mode.	**detail extensive**
State	(Ingress LSP) State of the path: **Up** or **Dn** (down).	**detail extensive**
COS	(Ingress LSP) Class-of-service value.	**detail extensive**
Bandwidth per class	(Ingress LSP) Active bandwidth for the LSP path for each MPLS class type, in bps.	**detail extensive**
Priorities	(Ingress LSP) Configured value of the setup priority and the hold priority respecitively (the setup priority is displayed first), where 0 is the highest priority and 7 is the lowest priority. If you have not explicitly configured these values, the default values are displayed (7 for the setup priority and 0 for the hold priority).	**detail extensive**
OptimizeTimer	(Ingress LSP) Configured value of the optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.	**detail extensive**
SmartOptimizeTimer	(Ingress LSP) Configured value of the smart optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.	**detail extensive**
Reoptimization in xxx seconds	(Ingress LSP) Current value of the optimize timer, indicating the amount of time remaining until the path will be reoptimized, in seconds.	**detail extensive**
Computed ERO (S [L] denotes strict [loose] hops)	(Ingress LSP) Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (**S**) or loose (**L**).	**detail extensive**
CSPF metric	(Ingress LSP) Constrained Shortest Path First metric for this path.	**detail extensive**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Received RRO	(Ingress LSP) Received record route. A series of hops, each with an address followed by a flag. (In most cases, the received record route is the same as the computed explicit route. If **Received RRO** is different from **Computed ERO**, there is a topology change in the network, and the route is taking a detour.) The following flags identify the protection capability and status of the downstream node: • **0x01**—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the Local protection flag was set in the **SESSION_ATTRIBUTE** object of the corresponding Path message. • **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously). • **0x03**—Combination of **0x01** and **0x02**. • **0x04**—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section. • **0x08**—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the **Local protection available** bit is set but the **Node protection** bit is cleared. • **0x09**—Detour is established. Combination of **0x01** and **0x08**. • **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted. • **0x20**—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently. • **0xb**—Detour is in use. Combination of **0x01**, **0x02**, and **0x08**.	**detail extensive**
Labels	Labels of pop-and-forward LSP tunnel: • P—Pop labels. • D—Delegation labels.	**extensive**
Index number	(Ingress LSP) Log entry number of each LSP path event. The numbers are in chronological descending order, with a maximum of 50 index numbers displayed.	**extensive**
Date	(Ingress LSP) Date of the LSP event.	**extensive**
Time	(Ingress LSP) Time of the LSP event.	**extensive**
Event	(Ingress LSP) Description of the LSP event.	**extensive**
Created	(Ingress LSP) Date and time the LSP was created.	**extensive**
Resv style	(Bypass) RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be **FF** (fixed filter), **SE** (shared explicit), or **WF** (wildcard filter).	**brief detail extensive**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Labelin	Incoming label for this LSP.	**brief detail**
Labelout	Outgoing label for this LSP.	**brief detail**
LSPname	Name of the LSP.	**brief detail**
Time left	Number of seconds remaining in the lifetime of the reservation.	**detail**
Since	Date and time when the RSVP session was initiated.	**detail**
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	**detail**
Port number	Protocol ID and sender or receiver port used in this RSVP session.	**detail**
PATH rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this router, and number of packets received from the upstream neighbor.	**detail**
PATH sentto	Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor, and number of packets sent to the downstream routing device.	**detail**
RESV rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor. The output in this field, which is consistent with that in the **PATH rcvfrom** field, indicates that the RSVP negotiation is complete.	**detail**
Record route	Recorded route for the session, taken from the record route object.	**detail**
Pop-and-forward	Attributes of the pop-and-forward LSP tunnel.	**extensive**
ETLD In	Number of transport labels that the LSP-Hop can potentially receive from its upstream hop. It is recorded as Effective Transport Label Depth (ETLD) at the transit and egress devices.	**extensive**
ETLD Out	Number of transport labels the LSP-Hop can potentially send to its downstream hop. It is recorded as ETLD at the transit and ingress devices.	**extensive**
Delegation hop	Specifies if the transit hop is selected as a delegation label: • Yes • No	**extensive**
Soft preempt	Number of soft preemptions that occurred on a path and when the last soft preemption occurred. Only successful soft preemptions are counted (those that actually resulted in a new path being used).	**detail**
Soft preemption pending	Path is in the process of being soft preempted. This display is removed once the ingress router has calculated a new path.	**detail**

Table 99: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
MPLS-TE LSP Defaults	Default settings for MPLS traffic engineered LSPs: • **LSP Holding Priority**—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. • **LSP Setup Priority**—Determines whether a new LSP that preempts an existing LSP can be established. • **Hop Limit**—Specifies the maximum number of routers the LSP can traverse (including the ingress and egress). • **Bandwidth**—Specifies the bandwidth in bits per second for the LSP. • **LSP Retry Timer**—Length of time in seconds that the ingress router waits between attempts to establish the primary path.	**defaults**

The XML tag name of the **bandwidth** tag under the **auto-bandwidth** tag has been updated to **maximum-average-bandwidth** . You can see the new tag when you issue the **show mpls lsp extensive** command with the **| display xml** pipe option. If you have any scripts that use the **bandwidth** tag, ensure that they are updated to **maximum-average-bandwidth**.

Sample Output

show mpls lsp defaults

```
user@host> show mpls lsp defaults
   MPLS-TE LSP Defaults
      LSP Holding Priority      0
      LSP Setup Priority        7
      Hop Limit                 255
      Bandwidth                 0
      LSP Retry Timer           30 seconds
```

show mpls lsp abstract-computation

Syntax

```
show mpls lsp abstract-computation
<brief | detail | extensive>;
<logical-system (all | logical-system-name)>;
<name lsp-name>;
```

Release Information Command introduced in Junos OS Release 17.1 for all platforms.

Description Display the ingress to egress abstract hop computation used by the constrained shortest path in the preprocessing for LSPs. The command output displays the various computation passes involved per LSP, and the qualifying exit devices for each pass. It also displays the affinity per pass, and the current start device chosen for the pass.

Options

brief | detail | extensive—(Optional) Display the desired level of output.

logical-system (all | *logical-system-name*)—(Optional) Display the abstract computation for abstract hop constraints on all logical systems or on a particular logical system.

lsp-name—(Optional) Name of the LSP for which the abstract hop computation is displayed.

Required Privilege Level view

Output Fields Table 100 on page 2333 describes the output fields for the **show mpls lsp abstract-computation** command. Output fields are listed in the approximate order in which they appear.

Table 100: show mpls lsp abstract-computation Output Fields

Field Name	Field Description
Path computation using abstract hops for LSP	Name of the LSP for which the abstract hop computation is performed.
Path type	The type of the path can be primary or secondary.
Path name	Name of the path.

Table 100: show mpls lsp abstract-computation Output Fields (continued)

Field Name	Field Description
Credibility	Credibility value associated with the interior gateway protocol in use.
Total no of CSPF passes	Number of constrained shortest path passes for the abstract hop.
CSPF pass no	Constrained shortest path pass number for the abstract hop computation.
Start address of the pass	IP address where the pass starts.
Affinity	Name of the abstract hop.
Destination	Destination IP address for a node in the pass.
State	State of the backtracking: • Valid • Disqualified

Sample Output

show mpls lsp abstract-computation

```
user@R0> show mpls lsp abstract-computation

<name lsp-name>
```

Release Information

Statement introduced in Junos OS Release 11.4.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 15.1X54–D60 for the ACX5000 Series.
Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.
name*lsp-name* option introduced in Junos OS Release 18.1R1 for all platforms.

Description

Display automatic bandwidth information for the LSP(s).

After a Routing Engine switchover, the output of the **show mpls autobandwidth** command might not be up-to-date, as the automatic bandwidth information for the LSP(s) is gathered by the new master Routing Engine during the first adjustment interval.

Options

brief | detail | extensive—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Specify name of the LSP for which the automatic bandwidth information should be displayed.

Output Fields

Table 101 on page 2335 describes the output fields for the **show mpls lsp autobandwidth** command. Output fields are listed in the approximate order in which they appear.

Table 101: show mpls lsp autobandwidth Output Fields

Field Name	Field Description	Level of Output
To	Destination (egress routing device) of the session.	All Levels
From	Source (ingress routing device) of the session.	All Levels

Table 101: show mpls lsp autobandwidth Output Fields (continued)

Field Name	Field Description	Level of Output
LSPname	Name of the LSP.	All Levels
Min BW	(Ingress LSP) Configured minimum value of the LSP, in bps.	**detail extensive**
Max BW	(Ingress LSP) Configured maximum value of the LSP, in bps.	**detail extensive**
Max AvgBW util	(Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps. NOTE: In calculating this value, the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.	**detail extensive**
Overflow limit	(Ingress LSP) Configured value of the threshold overflow limit.	**detail extensive**
Overflow sample count	(Ingress LSP) Current value for the overflow sample count.	**detail extensive**
Underflow limit	(Ingress LSP) Configured value of the threshold underflow limit.	**detail extensive**
Underflow sample count	(Ingress LSP) Current value for the underflow sample count.	**detail extensive**
Adjustment Timer	(Ingress LSP) Configured value for the adjust-timer statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.	**detail extensive**
Adjustment Threshold	(Ingress LSP) Configured value for the adjust-threshold statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization.	**detail extensive**
Time for Next Adjustment	(Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.	**detail extensive**
Time of Last Adjustment	(Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.	**detail extensive**
Last BW	Previous active bandwidth of the LSP.	**detail extensive**
Last Requested BW	Bandwidth requested in the previous automatic bandwidth adjustment.	**detail extensive**
Last Signaled BW	Bandwidth signaled in the previous automatic bandwidth adjustment.	**detail extensive**
Highest Watermark BW	Maximum bandwidth used by the LSP.	**detail extensive**
Total AutoBw Adjustments	Total number of attempts to adjust automatic bandwidth including failed and successful adjustments.	**detail extensive**

Table 101: show mpls lsp autobandwidth Output Fields (continued)

Field Name	Field Description	Level of Output
Successful Adjustments	Number of successful automatic bandwidth adjustments.	**detail extensive**
Failed Adjustments	Number of failed automatic bandwidth adjustments.	**detail extensive**

Sample Output

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance *instance-name* option added in Junos OS Release 15.1.

Description

Display dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all MPLS LSPs.

instance *instance-name*—(Optional) Display the dynamic MPLS LSP for the specified instance. If ***instance-name*** is omitted, dynamic MPLS LSP for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

path-name—(Optional) Display information about the specified LSP only.

Output Fields

Table 102 on page 2338 describes the output fields for the **show mpls path** command. Output fields are listed in the approximate order in which they appear.

Table 102: show mpls path Output Fields

Field Name	Field Description
Path name	Information about ingress LSPs. Each path has one line of output.
Address	Addresses of the routing devices that form the LSP.
Strict/loose address	Whether the address is a configured as a strict or loose address.

Sample Output

show mpls path

```
user@host> show mpls path

Path name        Address          Strict/loose address
p1               123.456.55.6     Strict
                 123.456.1.6      Loose
p2               191.456.1.4      Strict
```

show mpls srlg

Syntax

```
show mpls srlg
<logical-systems (all | logical-system-name)>
```

Release Information Command introduced before Junos OS Release 11.4.

Description Display Shared Risk Link Group (SRLG) cost and value configuration information.

NOTE: If an SRLG is associated with a link that is used by an ingress LSP in the router, then on deleting the SRLG configuration from that router, the SRLG gets removed from the SRLG table only on the next reoptimization of the LSP. Until then, the output of the **run show mpls srlg** command displays **Unknown-XXX** instead of the SRLG name and a non zero srlg-cost for that SRLG.

Options **logical-system (all | *logical-system-name*)**—(Optional) View SRLG configuration information for all logical systems or a particular logical system.

Required Privilege Level view

Related Documentation

- Example: Configuring SRLG on page 220

Output Fields Table 103 on page 2340 lists the output fields for the **show mpls srlg** command. Output fields are listed in the approximate order in which they appear.

Table 103: show mpls srlg Output Fields

Field Name	Field Description
SRLG	Name of the SRLG.
Value	A group ID for the SRLG ranging from **1** through **4294967295**.
Cost	A cost for the Shared Risk Link Group (SRLG) ranging from **1** through **65535**.

Sample Output

```
user@host> show mpls srlg
```

```
SRLG              Value      Cost
srlg-a              101        10

Release Information

Command introduced in Junos OS Release 10.1.
Command updated in Junos OS Release 14.1X53-D25 to accommodate the stitching feature of MPLS.
Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Display information about configured and active static Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all configured and active static MPLS LSPs.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The **extensive** option displays the same information as the **detail** option, but covers the most recent 50 events.

bypass—(Optional) Display LSPs used for protecting other static LSPs.

descriptions—(Optional) Display the MPLS static LSP descriptions. To view this information, you must configure the description statement at the **[edit protocols mpls static-label-switched-path *path-name* bypass]**, **[edit protocols mpls static-label-switched-path *path-name* ingress]**, or **[edit protocols mpls static-label-switched-path *path-name* transit *incoming-label*]** hierarchy levels. Only static LSPs with a description are displayed.

down | up—(Optional) Display only static LSPs that are inactive or active, respectively.

instance *instance-name*—(Optional) Display information about all configured and active static MPLS LSPs for the specified routing instance. If ***instance-name*** is omitted, information about all configured and active static MPLS LSPs for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that pass through this routing device.

name *name*—(Optional) Display information about the specified static LSP or group of LSPs.

statistics—(Optional) Display accounting information about static LSPs.

transit—(Optional) Display static LSPs transiting this routing device.

Required Privilege Level view

Output Fields Table 89 on page 2288 describes the output fields for the **show mpls static-lsp** command. Output fields are listed in the approximate order in which they appear.

Table 104: show mpls static-lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSPs	Information about the static LSPs on the ingress routing device. Each session has one line of output.	All levels
Transit LSPs	Number of static LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
Bypass LSPs	Information about the bypass LSPs configured on the routing device. Each session has one line of output.	All levels
LSPname	Name of the static LSP.	All levels
To	Destination (egress routing device) of the session.	All levels
State	State of the static LSP handled by this RSVP session: **Up**, **Dn** (down), or **Restart**.	All levels
Packets	Number of packet transiting the static LSP (**statistics** option only).	All levels
Bytes	Number of bytes transiting the static LSP (**statistics** option only).	All levels
Nexthop	IP address for the next-hop router for the static LSP.	**detail**, **extensive**
Bypass	(Bypass LSP) Destination address (egress routing device) for the bypass LSP.	All levels

Table 104: show mpls static-lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Link protection desired	Link protection has been requested by the ingress routing device.	**detail**, **extensive**
LabelOperation	Label operation to perform: **Push**, **Pop**, **Swap**.	**detail**, **extensive**
Outgoing-label	Outgoing label to use for the MPLS packet in either push or swap label operations.	**detail**, **extensive**
Created	(Ingress LSP) Date and time the static LSP was created.	**extensive**
Bandwidth	Bandwidth configured for the static LSP.	**detail**, **extensive**
Resv style	(Bypass) RSVP reservation style. This field consists of two parts: the number of active reservations and the reservation style, which can be **FF** (fixed filter), **SE** (shared explicit), or **WF** (wildcard filter).	All levels

show route forwarding-table

Syntax

```
show route forwarding-table
<detail | extensive | summary>
<ccc ccc-interface-name>
<destination>
<family family-name>
<label label>
<matching ip_prefix>
<multicast>
<vpn vpn>
```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.
Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.
Command introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

Options

none—Display the routes in the forwarding table.

detail | extensive | summary—(Optional) Display the specified level of output.

ccc—(Optional) Display the specified circuit cross-connect interface name for entries to match.

destination—(Optional) Display the destination prefix.

family *family-name*—(Optional) Display routing table entries for the specified family: **ethernet-switching**, **inet**, **inet6**, **iso**, **mpls**, **vlan classification**.

label *label*—(Optional) Display route entries for the specified label name.

matching *ip_prefix*—(Optional) Display route entries for the specified IP prefix.

multicast—(Optional) Display route entries for multicast routes.

vpn *vpn*—(Optional) Display route entries for the specified VPN.

Required Privilege Level

Output Fields

Table 106 on page 2353 lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified or when the **detail** keyword is used instead of the **extensive** keyword.

Table 106: show route forwarding-table Output Fields

Field Name	Field Description	Level of Output
Routing table	Name of the routing table (for example, **inet**, **inet6**, **mpls**).	All levels
Address family	Address family (for example, **IP**, **IPv6**, **ISO**, **MPLS**).	All levels
Destination	Destination of the route.	**detail, extensive**
Route Type (Type)	How the route was placed into the forwarding table. When the **detail** keyword is used, the route type might be abbreviated (as shown in parentheses): • **cloned** (**clon**)—(TCP or multicast only) Cloned route. • **destination** (**dest**)—Remote addresses directly reachable through an interface. • **destination down** (**iddn**)—Destination route for which the interface is unreachable. • **interface cloned** (**ifcl**)—Cloned route for which the interface is unreachable. • **route down** (**ifdn**)—Interface route for which the interface is unreachable. • **ignore** (**ignr**)—Ignore this route. • **interface** (**intf**)—Installed as a result of configuring an interface. • **permanent** (**perm**)—Routes installed by the kernel when the routing table is initialized. • **user**—Routes installed by the routing protocol process or as a result of the configuration.	All levels
Route reference (RtRef)	Number of routes to reference.	**detail, extensive**

Table 106: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Flags	Route type flags: • **none**—No flags are enabled. • **accounting**—Route has accounting enabled. • **cached**—Cache route. • **incoming-iface *interface-number*** —Check against incoming interface. • **prefix load balance**—Load balancing is enabled for this prefix. • **sent to PFE**—Route has been sent to the Packet Forwarding Engine. • **static**—Static route.	**extensive**
Nexthop	IP address of the next hop to the destination.	**detail, extensive**
Next hop type (Type)	Next-hop type. When the **detail** keyword is used, the next-hop type might be abbreviated (as indicated in parentheses): • **broadcast (bcst)**—Broadcast. • **deny**—Deny. • **hold**—Next hop is waiting to be resolved into a unicast or multicast type. • **indexed (idxd)**—Indexed next hop. • **indirect (indr)**—Indirect next hop. • **local (locl)**—Local address on an interface. • **routed multicast (mcrt)**—Regular multicast next hop • **multicast (mcst)**—Wire multicast next hop (limited to the LAN). • **multicast discard (mdsc)**—Multicast discard. • **multicast group (mgrp)** —Multicast group member. • **receive (recv)**—Receive. • **reject (rjct)**—Discard. An ICMP unreachable message was sent. • **resolve (rslv)**—Resolving the next hop. • **unicast (ucst)**—Unicast. • **unilist (ulst)**—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.	**detail, extensive**
Index	Software index of the next hop that is used to route the traffic for a given prefix.	**detail, extensive** none
Route interface-index	Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.	**extensive**
Reference (NhRef)	Number of routes that refer to this next hop.	none **detail, extensive**
Next-hop interface (Netif)	Interface used to reach the next hop.	none **detail, extensive**
Alternate forward nh index	Index number of the alternate next hop interface. Seen with **multicast** option only.	**extensive**

Table 106: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Next-hop L3 Interface	The next hop layer 3 interface. This option can be expressed as a VLAN name and is only seen with the **multicast** option.	**extensive**
Next-hop L2 Interfaces	The next hop layer 2 interfaces. Seen with **multicast** option only.	**extensive**

```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 14.1X53-D15 for QFX Series switches.
Show route table evpn statement introduced in Junos OS Release 15.1X53-D30 for QFX Series switches.

Description

Display the route entries in a particular routing table.

Options

brief | detail | extensive | terse—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

routing-table-name—Display route entries for all routing tables whose names begin with this string (for example, inet.0 and inet6.0 are both displayed when you run the **show route table inet** command).

Required Privilege Level

Output Fields Table 107 on page 2361 describes the output fields for the **show route table** command. Output fields are listed in the approximate order in which they appear.

Table 107: show route table Output Fields

Field Name	Field Description
routing-table-name	Name of the routing table (for example, inet.0).

Restart complete	All protocols have restarted for this routing table.
	
	Restart state:
	
	• **Pending:*protocol-name***—List of protocols that have not yet completed graceful restart for this routing table.
	• **Complete**—All protocols have restarted for this routing table.
	
	For example, if the output shows-
	
	• `LDP.inet.0 : 5 routes (4 active, 1 holddown, 0 hidden)`
	`Restart Pending: OSPF LDP VPN`
	
	This indicates that **OSPF**, **LDP**, and **VPN** protocols did not restart for the **LDP.inet.0** routing table.
	
	• `vpls_1.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)`
	`Restart Complete`
	
	This indicates that all protocols have restarted for the **vpls_1.l2vpn.0** routing table.

Table 107: show route table Output Fields (continued)

Field Name	Field Description
number destinations	Number of destinations for which there are routes in the routing table.
number routes	Number of routes in the routing table and total number of routes in the following states: • **active** (routes that are active) • **holddown** (routes that are in the pending state before being declared inactive) • **hidden** (routes that are not used because of a routing policy)

route-destination (entry, announced)	Route destination (for example:10.0.0.1/24). The **entry** value is the number of routes for this destination, and the **announced** value is the number of routes being announced for this destination. Sometimes the route destination is presented in another format, such as:
	• ***MPLS-label*** (for example, 80001).
	• ***interface-name*** (for example, ge-1/0/2).
	• ***neighbor-address*:*control-word-status*:*encapsulation type*:*vc-id*:*source*** (Layer 2 circuit only; for example, 10.1.1.195:NoCtrlWord:1:1:Local/96).
	  • ***neighbor-address***—Address of the neighbor.
	  • ***control-word-status***—Whether the use of the control word has been negotiated for this virtual circuit: **NoCtrlWord** or **CtrlWord**.
	  • ***encapsulation type***—Type of encapsulation, represented by a number: (1) Frame Relay DLCI, (2) ATM AAL5 VCC transport, (3) ATM transparent cell transport, (4) Ethernet, (5) VLAN Ethernet, (6) HDLC, (7) PPP, (8) ATM VCC cell transport, (10) ATM VPC cell transport.
	  • ***vc-id***—Virtual circuit identifier.
	  • ***source***—Source of the advertisement: **Local** or **Remote**.
	• ***inclusive multicast Ethernet tag route***—Type of route destination represented by (for example, 3:100.100.100.10:100::0::10::100.100.100.10/384):
	  • *route distinguisher*—(8 octets) Route distinguisher (RD) must be the RD of the EVPN instance (EVI) that is advertising the NLRI.
	  • *Ethernet tag ID*—(4 octets) Identifier of the Ethernet tag. Can set to 0 or to a valid Ethernet tag value.
	  • *IP address length*—(1 octet) Length of IP address in bits.
	  • *originating router's IP address*—(4 or 16 octets) Must set to the provider edge (PE) device's IP address. This address should be common for all EVIs on the PE device, and may be the PE device's loopback address.

label stacking	**(**Next-to-the-last-hop routing device for MPLS only) Depth of the MPLS label stack, where the label-popping operation is needed to remove one or more labels from the top of the stack. A pair of routes is displayed, because the pop operation is performed only when the stack depth is two or more labels. • **S=0 route** indicates that a packet with an incoming label stack depth of 2 or more exits this routing device with one fewer label (the label-popping operation is performed). • If there is no **S=** information, the route is a normal MPLS route, which has a stack depth of 1 (the label-popping operation is not performed).

Table 107: show route table Output Fields (continued)

Field Name	Field Description
[*protocol*, *preference*]	Protocol from which the route was learned and the preference value for the route. • **+**—A plus sign indicates the active route, which is the route installed from the routing table into the forwarding table. • **-** —A hyphen indicates the last active route. • *****—An asterisk indicates that the route is both the active and the last active route. An asterisk before a **to** line indicates the best subpath to the route. In every routing metric except for the BGP **LocalPref** attribute, a lesser value is preferred. In order to use common comparison routines, Junos OS stores the 1's complement of the **LocalPref** value in the **Preference2** field. For example, if the **LocalPref** value for Route 1 is 100, the **Preference2** value is -101. If the **LocalPref** value for Route 2 is 155, the **Preference2** value is -156. Route 2 is preferred because it has a higher **LocalPref** value and a lower **Preference2** value.
Level	(IS-IS only). In IS-IS, a single AS can be divided into smaller groups called areas. Routing between areas is organized hierarchically, allowing a domain to be administratively divided into smaller areas. This organization is accomplished by configuring Level 1 and Level 2 intermediate systems. Level 1 systems route within an area. When the destination is outside an area, they route toward a Level 2 system. Level 2 intermediate systems route between areas and toward other ASs.
Route Distinguisher	IP subnet augmented with a 64-bit prefix.
PMSI	Provider multicast service interface (MVPN routing table).
Next-hop type	Type of next hop. For a description of possible values for this field, see Table 108 on page 2367.
Next-hop reference count	Number of references made to the next hop.
Flood nexthop branches exceed maximum message	Indicates that the number of flood next-hop branches exceeded the system limit of 32 branches, and only a subset of the flood next-hop branches were installed in the kernel.
Source	IP address of the route source.
Next hop	Network layer address of the directly reachable neighboring system.
via	Interface used to reach the next hop. If there is more than one interface available to the next hop, the name of the interface that is actually used is followed by the word **Selected**. This field can also contain the following information: • Weight—Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible. • Balance—Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a routing device is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.
Label-switched-path *lsp-path-name*	Name of the LSP used to reach the next hop.

Table 107: show route table Output Fields (continued)

Field Name	Field Description
Label operation	MPLS label and operation occurring at this routing device. The operation can be **pop** (where a label is removed from the top of the stack), **push** (where another label is added to the label stack), or **swap** (where a label is replaced by another label).
Interface	(Local only) Local interface name.
Protocol next hop	Network layer address of the remote routing device that advertised the prefix. This address is used to derive a forwarding next hop.
Indirect next hop	Index designation used to specify the mapping between protocol next hops, tags, kernel export policy, and the forwarding next hops.
State	State of the route (a route can be in more than one state). See Table 109 on page 2368.
Local AS	AS number of the local routing devices.
Age	How long the route has been known.
AIGP	Accumulated interior gateway protocol (AIGP) BGP attribute.
Metric*n*	Cost value of the indicated route. For routes within an AS, the cost is determined by IGP and the individual protocol metrics. For external routes, destinations, or routing domains, the cost is determined by a preference value.
MED-plus-IGP	Metric value for BGP path selection to which the IGP cost to the next-hop destination has been added.
TTL-Action	For MPLS LSPs, state of the TTL propagation attribute. Can be enabled or disabled for all RSVP-signaled and LDP-signaled LSPs or for specific VRF routing instances.
Task	Name of the protocol that has added the route.
Announcement bits	The number of BGP peers or protocols to which Junos OS has announced this route, followed by the list of the recipients of the announcement. Junos OS can also announce the route to the kernel routing table (KRT) for installing the route into the Packet Forwarding Engine, to a resolve tree, a Layer 2 VC, or even a VPN. For example, ***n*-Resolve inet** indicates that the specified route is used for route resolution for next hops found in the routing table. • ***n***—An index used by Juniper Networks customer support only.

Table 107: show route table Output Fields (continued)

Field Name	Field Description
AS path	AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated: • **I**—IGP. • **E**—EGP. • **Recorded**—The AS path is recorded by the sample process (sampled). • **?**—Incomplete; typically, the AS path was aggregated. When AS path numbers are included in the route, the format is as follows: • **[ ]**—Brackets enclose the number that precedes the AS path. This number represents the number of ASs present in the AS path, when calculated as defined in RFC 4271. This value is used in the AS-path merge process, as defined in RFC 4893. • **[ ]**—If more than one AS number is configured on the routing device, or if AS path prepending is configured, brackets enclose the local AS number associated with the AS path. • **{ }**—Braces enclose AS sets, which are groups of AS numbers in which the order does not matter. A set commonly results from route aggregation. The numbers in each AS set are displayed in ascending order. • **( )**—Parentheses enclose a confederation. • **([ ])**—Parentheses and brackets enclose a confederation set. NOTE: In Junos OS Release 10.3 and later, the AS path field displays an unrecognized attribute and associated hexadecimal value if BGP receives attribute 128 (attribute set) and you have not configured an independent domain in any routing instance.
validation-state	(BGP-learned routes) Validation status of the route: • **Invalid**—Indicates that the prefix is found, but either the corresponding AS received from the EBGP peer is not the AS that appears in the database, or the prefix length in the BGP update message is longer than the maximum length permitted in the database. • **Unknown**—Indicates that the prefix is not among the prefixes or prefix ranges in the database. • **Unverified**—Indicates that the origin of the prefix is not verified against the database. This is because the database got populated and the validation is not called for in the BGP import policy, although origin validation is enabled, or the origin validation is not enabled for the BGP peers. • **Valid**—Indicates that the prefix and autonomous system pair are found in the database.
FECs bound to route	Indicates point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.
Primary Upstream	When multipoint LDP with multicast-only fast reroute (MoFRR) is configured, indicates the primary upstream path. MoFRR transmits a multicast join message from a receiver toward a source on a primary path, while also transmitting a secondary multicast join message from the receiver toward the source on a backup path.
RPF Nexthops	When multipoint LDP with MoFRR is configured, indicates the reverse-path forwarding (RPF) next-hop information. Data packets are received from both the primary path and the secondary paths. The redundant packets are discarded at topology merge points due to the RPF checks.
Label	Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.

Table 107: show route table Output Fields (continued)

Field Name	Field Description
weight	Value used to distinguish MoFRR primary and backup routes. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.
VC Label	MPLS label assigned to the Layer 2 circuit virtual connection.
MTU	Maximum transmission unit (MTU) of the Layer 2 circuit.
VLAN ID	VLAN identifier of the Layer 2 circuit.
Prefixes bound to route	Forwarding equivalent class (FEC) bound to this route. Applicable only to routes installed by LDP.
Communities	Community path attribute for the route. See Table 110 on page 2370 for all possible values for this field.
Layer2-info: encaps	Layer 2 encapsulation (for example, VPLS).
control flags	Control flags: **none** or **Site Down**.
mtu	Maximum transmission unit (MTU) information.
Label-Base, range	First label in a block of labels and label block size. A remote PE routing device uses this first label when sending traffic toward the advertising PE routing device.
status vector	Layer 2 VPN and VPLS network layer reachability information (NLRI).
Accepted Multipath	Current active path when BGP multipath is configured.
Accepted LongLivedStale	The LongLivedStale flag indicates that the route was marked LLGR-stale by this router, as part of the operation of LLGR receiver mode. Either this flag or the LongLivedStaleImport flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.
Accepted LongLivedStaleImport	The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy. Either this flag or the LongLivedStale flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag. Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and import into the inet.0 routing table
ImportAccepted LongLivedStaleImport	Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and imported into the inet.0 routing table The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy.
Accepted MultipathContrib	Path currently contributing to BGP multipath.
Localpref	Local preference value included in the route.
Router ID	BGP router ID as advertised by the neighbor in the open message.

Table 107: show route table Output Fields (continued)

Field Name	Field Description
Primary Routing Table	In a routing table group, the name of the primary routing table in which the route resides.
Secondary Tables	In a routing table group, the name of one or more secondary tables in which the route resides.

Table 108 on page 2367 describes all possible values for the Next-hop Types output field.

Table 108: Next-hop Types Output Field Values

Next-Hop Type	Description
Broadcast (bcast)	Broadcast next hop.
Deny	Deny next hop.
Discard	Discard next hop.
Flood	Flood next hop. Consists of components called branches, up to a maximum of 32 branches. Each flood next-hop branch sends a copy of the traffic to the forwarding interface. Used by point-to-multipoint RSVP, point-to-multipoint LDP, point-to-multipoint CCC, and multicast.
Hold	Next hop is waiting to be resolved into a unicast or multicast type.
Indexed (idxd)	Indexed next hop.
Indirect (indr)	Used with applications that have a protocol next hop address that is remote. You are likely to see this next-hop type for internal BGP (IBGP) routes when the BGP next hop is a BGP neighbor that is not directly connected.
Interface	Used for a network address assigned to an interface. Unlike the router next hop, the interface next hop does not reference any specific node on the network.
Local (locl)	Local address on an interface. This next-hop type causes packets with this destination address to be received locally.
Multicast (mcst)	Wire multicast next hop (limited to the LAN).
Multicast discard (mdsc)	Multicast discard.
Multicast group (mgrp)	Multicast group member.
Receive (recv)	Receive.
Reject (rjct)	Discard. An ICMP unreachable message was sent.

Table 108: Next-hop Types Output Field Values (continued)

Next-Hop Type	Description
Resolve (rslv)	Resolving next hop.
Routed multicast (mcrt)	Regular multicast next hop.
Router	A specific node or set of nodes to which the routing device forwards packets that match the route prefix. To qualify as a next-hop type router, the route must meet the following criteria: • Must not be a direct or local subnet for the routing device. • Must have a next hop that is directly connected to the routing device.
Table	Routing table next hop.
Unicast (ucst)	Unicast.
Unilist (ulst)	List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.

Table 109 on page 2368 describes all possible values for the State output field. A route can be in more than one state (for example, **<Active NoReadvrt Int Ext>**).

Table 109: State Output Field Values

Value	Description
Accounting	Route needs accounting.
Active	Route is active.
Always Compare MED	Path with a lower multiple exit discriminator (MED) is available.
AS path	Shorter AS path is available.
Cisco Non-deterministic MED selection	Cisco nondeterministic MED is enabled, and a path with a lower MED is available.
Clone	Route is a clone.
Cluster list length	Length of cluster list sent by the route reflector.
Delete	Route has been deleted.
Ex	Exterior route.

Table 109: State Output Field Values (continued)

Value	Description
Ext	BGP route received from an external BGP neighbor.
FlashAll	Forces all protocols to be notified of a change to any route, active or inactive, for a prefix. When not set, protocols are informed of a prefix only when the active route changes.
Hidden	Route not used because of routing policy.
IfCheck	Route needs forwarding RPF check.
IGP metric	Path through next hop with lower IGP metric is available.
Inactive reason	Flags for this route, which was not selected as best for a particular destination.
Initial	Route being added.
Int	Interior route.
Int Ext	BGP route received from an internal BGP peer or a BGP confederation peer.
Interior > Exterior > Exterior via Interior	Direct, static, IGP, or EBGP path is available.
Local Preference	Path with a higher local preference value is available.
Martian	Route is a martian (ignored because it is obviously invalid).
MartianOK	Route exempt from martian filtering.
Next hop address	Path with lower metric next hop is available.
No difference	Path from neighbor with lower IP address is available.
NoReadvrt	Route not to be advertised.
NotBest	Route not chosen because it does not have the lowest MED.
Not Best in its group	Incoming BGP AS is not the best of a group (only one AS can be the best).
NotInstall	Route not to be installed in the forwarding table.
Number of gateways	Path with a greater number of next hops is available.
Origin	Path with a lower origin code is available.

Table 109: State Output Field Values (continued)

Value	Description
Pending	Route pending because of a hold-down configured on another route.
Release	Route scheduled for release.
RIB preference	Route from a higher-numbered routing table is available.
Route Distinguisher	64-bit prefix added to IP subnets to make them unique.
Route Metric or MED comparison	Route with a lower metric or MED is available.
Route Preference	Route with lower preference value is available.
Router ID	Path through a neighbor with lower ID is available.
Secondary	Route not a primary route.
Unusable path	Path is not usable because of one of the following conditions: • The route is damped. • The route is rejected by an import policy. • The route is unresolved.
Update source	Last tiebreaker is the lowest IP address value.

Table 110 on page 2370 describes the possible values for the Communities output field.

Table 110: Communities Output Field Values

Value	Description
area-number	4 bytes, encoding a 32-bit area number. For AS-external routes, the value is **0**. A nonzero value identifies the route as internal to the OSPF domain, and as within the identified area. Area numbers are relative to a particular OSPF domain.
bandwidth: ***local AS number:link-bandwidth-number***	Link-bandwidth community value used for unequal-cost load balancing. When BGP has several candidate paths available for multipath purposes, it does not perform unequal-cost load balancing according to the link-bandwidth community unless all candidate paths have this attribute.
domain-id	Unique configurable number that identifies the OSPF domain.
domain-id-vendor	Unique configurable number that further identifies the OSPF domain.
link-bandwidth-number	Link-bandwidth number: from **0** through **4,294,967,295** (bytes per second).
local AS number	Local AS number: from **1** through **65,535**.

Table 110: Communities Output Field Values (continued)

Value	Description
options	1 byte. Currently this is only used if the route type is **5** or **7**. Setting the least significant bit in the field indicates that the route carries a type 2 metric.
origin	(Used with VPNs) Identifies where the route came from.
ospf-route-type	1 byte, encoded as **1** or **2** for intra-area routes (depending on whether the route came from a type 1 or a type 2 LSA); **3** for summary routes; **5** for external routes (area number must be**0**); **7** for NSSA routes; or **129** for sham link endpoint addresses.
route-type-vendor	Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute **0x8000**. The format is ***area-number:ospf-route-type:options***.
rte-type	Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute **0x0306**. The format is ***area-number:ospf-route-type:options***.
target	Defines which VPN the route participates in; **target** has the format ***32-bit IP address:16-bit number***. For example, 10.19.0.0:100.
unknown IANA	Incoming IANA codes with a value between **0x1** and **0x7fff**. This code of the BGP extended community attribute is accepted, but it is not recognized.
unknown OSPF vendor community	Incoming IANA codes with a value above **0x8000**. This code of the BGP extended community attribute is accepted, but it is not recognized.

Sample Output

<system-name>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance *instance-name* option added in Junos OS Release 15.1.
topology-id *topology* option added in Junos OS Release 17.4R1 for MX Series and PTX Series.

Description

Display the entries in the Multiprotocol Label Switching (MPLS) traffic engineering database.

Options

none—Display standard information about all entries in the traffic engineering database.

brief | detail | extensive—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If ***instance-name*** is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

system-name—(Optional) Display traffic engineering database information for a particular system.

topology-id *topology*— Display the topology information. By default, traffic engineering topology information is displayed.

Required Privilege Level

Output Fields Table 111 on page 2400 describes the output fields for the **show ted database** command. Output fields are listed in the approximate order in which they appear.

Table 111: show ted database Output Fields

Field Name	Field Description	Level of Output
TED database	Number of nodes and pseudonodes participating in IS-IS and OSPF domain routing.	All levels
ID	Hostname and address of the node that the link is coming from. An address of **.00** indicates that the node is the routing device itself. An address in the range **0.01** through **0.FF** indicates that the node is a pseudonode. If the node contains a router ID, it is displayed in parentheses.	**brief**
NodeID	Hostname and address of the node that the link is coming from. An address of **.00** indicates that the node is the routing device itself. An address in the range **0.01** through **0.FF** indicates that the node is a pseudonode.	**extensive**
Type	Type of node. It can be either **Rtr** (router) or **Net** (pseudonode).	All levels
Age(s)	How long since the node was last refreshed, in seconds.	All levels
LnkIn	Number of nodes pointing toward this node.	All levels
LnkOut	Number of nodes to which this node points.	All levels
Protocol	Protocol that reported the node information: • **IS-IS(1)**—IS-IS Level 1. • **IS-IS(2)**—IS-IS Level 2. • **OSPF (area-number)**—OSPF from the specified area.	All levels
To	Address on the far end of a link.	**detail extensive**
Local	Address of the local interface being used to reach the remote node.	**detail extensive**
Remote	Address of the interface on the remote node.	**detail extensive**
Local interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	**detail extensive**
Remote interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	**detail extensive**
Metric	Configured traffic engineering metric.	**extensive**
IGP metric	Configured interior gateway protocol metric.	**extensive**
Static BW	Total interface bandwidth in bps.	**extensive**

Table 111: show ted database Output Fields (continued)

Field Name	Field Description	Level of Output
Reservable bandwidth	Subscription factor for the interface, which is the percentage of the link bandwidth that can be used for the RSVP reservation process. You configure this by including the **subscription** statement when configuring RSVP.	**extensive**
Available BW [priority]	(Must include **diffserv-te** statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each priority level. The bandwidth shown is for the entire interface, not for each individual LSP.	**extensive**
Diffserv-TE BW Model	Bandwidth constraint model used by the LSPs.	**extensive**
Available BW [TE-class]	(Must include the **diffserv-te** statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each traffic engineering class.	**extensive**
Static BW [CT-class]	Total interface bandwidth used by an MPLS traffic class, in bps.	**extensive**

Table 111: show ted database Output Fields (continued)

Field Name	Field Description	Level of Output

Interface Switching Capability Descriptor (*n*)	Information about the interface switching capability descriptor, which is a subtype length value (TLV) of the link TLV. ***n*** is the index number.
	• **Switching type**—Type of switching to be performed on a particular link:
	  • **PSC-1**—Packet switch-capable 1
	  • **PSC-2**—Packet switch-capable 2
	  • **PSC-3**—Packet switch-capable 3
	  • **PSC-4**—Packet switch-capable 4
	  • **L2SC**—Layer-2-switch-capable
	  • **TDM**—Time-division-multiplexing-capable
	  • **LSC**—Lambda switch-capable
	  • **FSC**—Fiber switch-capable
	• **Encoding type**—Encoding of the LSP being requested:
	  • **Packet**
	  • **Ethernet**
	  • **ANSI/ETSI PDH**
	  • **Reserved**
	  • **SDH /SONET**
	  • **Digital Wrapper**
	  • **Lambda (photonic)**
	  • **Fiber**
	  • **FiberSDH/SONET**
	• **Maximum LSP BW [priority] bps**—Maximum LSP bandwidth information. Amount of bandwidth actually reserved for each priority level. The bandwidth shown is for the entire interface.
	  • **[*n*]**—Priority level. The range is from **0** (high) through **7** (low).
	  • ***n* Mbps**—Amount of the maximum bandwidth.
	• **Minimum LSP BW**—Minimum LSP bandwidth in Mbps. Amount of bandwidth actually reserved for each priority level. The bandwidth shown is for the entire interface. **Minimum LSP BW** is displayed only when **switching type** is **PSC-1** or **TDM**.
	• **Interface MTU**—Displayed only when **switching type** is **TDM**.
	• **Interface supports standard SONET/SDH**—Displayed only when **switching type** is **TDM**.
		extensive

Syntax on page 2408
Syntax (EX Series Switches) on page 2408

Syntax

```
show ted link
<brief | detail>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switches)

```
show ted link
<brief | detail>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance *instance-name* option added in Junos OS Release 15.1.

Description

Display Multiprotocol Label Switching (MPLS) traffic engineering database link information.

Options

none—Display standard information about traffic engineering database link information.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If ***instance-name*** is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

view

List of Sample Output

show ted link brief on page 2409
show ted link detail on page 2410

Output Fields

Table 112 on page 2408 describes the output fields for the **show ted link** command. Output fields are listed in the approximate order in which they appear.

Table 112: show ted link Output Fields

Field Name	Field Description	Level of Output
ID	Hostname and address of the node that the link is coming from. An address of **.00** indicates that the node is the routing device itself. An address in the range **0.01** through **0.FF** indicates that the node is a pseudonode.	**brief**

Table 112: show ted link Output Fields (continued)

Field Name	Field Description	Level of Output
-->ID	Hostname and address of the node that the link is going to. An address of **.00** indicates that the node is the routing device itself. An address in the range **0.01** through **0.FF** indicates that the node is a pseudonode.	**brief**
hostname	Hostname and address of the node that the link is coming from. An address of **.00** indicates that the node is the routing device itself. An address in the range **0.01** through **0.FF** indicates that the node is a pseudonode.	**detail**
hostname	Hostname and address of the node that the link is going to. An address of **.00** indicates that the node is the routing device itself. An address in the range **0.01** through **0.FF** indicates that the node is a pseudonode.	**detail**
Local Path	Number of paths CSPF on the local routing device has placed on the link.	All levels
Metric	Configured traffic engineering metric.	**extensive**
IGP metric	Configured interior gateway protocol metric.	**detail**
Local BW	Amount of bandwidth the local routing device has placed on the link.	All levels
Local	Address of the local interface being used to reach the remote node.	**detail extensive**
Remote	Address of the interface on the remote node.	**detail extensive**
Local interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	**detail**
Remote interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	**detail**

Syntax (EX Series Switches)

```
show ted protocol
<brief | detail>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance *instance-name* option added in Junos OS Release 15.1.

Description

Display information about the protocols from which the Multiprotocol Label Switching (MPLS) traffic engineering database learned about its nodes.

Options

none—Display standard information about the protocols from which the traffic engineering database learned about its nodes.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If ***instance-name*** is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

List of Sample Output

show ted protocol on page 2413

Output Fields

Table 113 on page 2413 describes the output fields for the **show ted protocol** command. Output fields are listed in the approximate order in which they appear.

Table 113: show ted protocol Output Fields

Field Name	Field Description
Protocol name	Protocol that reported the node information: • **IS-IS(1)**—IS-IS Level 1. • **IS-IS(2)**—IS-IS Level 2. • **OSPF** (***area-number***)—OSPF from the specified area.
Credibility	If the protocols provide conflicting information about a node, the protocol with the highest credibility value is the one that the traffic engineering database uses.
Self node	Address the protocol uses as the local address.

Sample Output

show ted protocol

```
user@host> show ted protocol
Protocol name        Credibility  Self node
IS-IS(2)             2  (highest) corriedale.00(123.456.1.11)
IS-IS(1)             1            corriedale.00(123.456.1.11)
```

traceroute mpls bgp

Syntax

```
traceroute mpls bgp fec
<destination destination-address>
<detail>
<exp exp>
<fanout fanout-number>
<logical-system logical system-name>
<no-resolve>
<paths paths-number>
<pipe-mode>
<retries retries-number>
<routing-instance routing-instance-name>
<source source-address>
<ttl value>
<wait seconds>
```

Release Information Command introduced in Junos OS Release 14.2.

Description Trace route to a remote host for an MPLS label-switched path (LSP) signaled by the Border Gateway Protocol (BGP). Use **traceroute mpls bgp** as a debugging tool to locate MPLS BGP forwarding issues in a network. (Currently supported for IPv4 packets only.)

NOTE: The **traceroute mpls bgp** *fec* command only supports single paths.

Options

fec—Specify the IP address and optional prefix of the forwarding equivalence class (FEC). Suppose you are at PE1, use would want to use the IP address of PE2 to trace the BGP path to that router.

destination ***destination-address***—(Optional) Specify the destination address to use when sending probes.

detail—(Optional) Display detailed output.

exp ***exp***—(Optional) Specify the class of service to use when sending probes.

Range: 0 through 7

Default: 7

fanout ***fanout-number***—(Optional) Specify the maximum number of next hops to search per node.

Range: 1 through 16

Default: 16

logical-system ***logical-system-name***—(Optional) Specify the name of the logical system for the traceroute attempt.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

paths ***paths-number***—(Optional) Specify the number of paths to search.

Range: 1 through 255

Default: 16

pipe-mode—(Optional) Specify to trace only the outermost FEC.

retries ***retries-number***—(Optional) Specify the number of times to resend probe values.

Range: 1 through 9

Default: 3

routing-instance ***routing-instance-name***—(Optional) Specify the name of the routing instance for the trace route attempt.

source ***source-address***—(Optional) Specify the source address of the outgoing traceroute packets.

ttl ***value***—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds.

Range: 1 through 125

Default: 64

wait ***seconds***—(Optional) Specify the number of seconds to wait before resending a probe.

Range: 5 though 15

Default: 10

Required Privilege Level

Output Fields

Table 114 on page 2415 describes the output fields for the **traceroute mpls bgp** ***fec*** command and the **traceroute mpls bgp** ***fec*** **detail** command. Output fields are listed in the approximate order in which they appear.

Table 114: traceroute mpls bgp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the **traceroute mpls bgp** ***fec*** command.	All levels

Table 114: traceroute mpls bgp Output Fields (continued)

Field Name	Field Description	Level of Output
ttl	Time to live value of the labeled packet.	None
Label	Outgoing label used for forwarding the packet along the label-switched paths.	None
Protocol	Signaling protocol used. For this command, it is BGP.	None
Address	Address of the next hop.	None
Previous Hop	Address of the previous hop. Previous hop address of the first hop is **null**.	None
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).	None
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	**detail**
Parent	Address of the previous hop. Parent value for the first hop is **null**.	**detail**
Return Code	Return code for reporting the result of processing the echo request by the receiver.	**detail**
Response time	Time for the echo request to reach the receiver.	**detail**
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is **none**.	**detail**
Label Stack	Label stack used to forward the packet.	**detail**

Sample Output

traceroute mpls bgp

transit (Chained Composite Next Hops)

Syntax

```
transit {
  (all | no-all);
  (l2vpn | no-l2vpn);
  (l3vpn | no-l3vpn);
  (labeled-bgp | no-labeled-bgp);
  (ldp | no-ldp);
  (ldp-p2mp | no-ldp-p2mp);
  lsp-statistics-from-route;
  (rsvp | no-rsvp);
  (rsvp-p2mp | no-rsvp-p2mp);
  (static | no-static);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table
  chained-composite-next-hop],
[edit routing-options forwarding-table chained-composite-next-hop]
```

NOTE: The **[edit logical-systems]** hierarchy level is not supported on the QFX10000 switches.

Release Information

Statement introduced in Junos OS Release 12.1.
Statement introduced in Junos OS Release 15.1 for QFX10000 Series switches.

Description

Allows you to configure the chained composite next hops transit configuration options for devices handling transit traffic in the network. This statement and the associated functionality is available on PTX Packet Transport Routers and QFX10000 switches.

Default

All of the **transit** statement options are enabled on PTX transport routers and QFX10000 switches. However, you can disable any of the statements with a **no** option.

Options

all | no-all—Enable or disable chained composite next-hops for all of the possible packet transit protocols and applications. The **all | no-all** statements do not apply to the **lsp-statistics-from-route** statement.

l2vpn | no-l2vpn—Enable or disable chained composite next-hops for Layer 2 VPNs.

l3vpn | no-l3vpn—Enable or disable chained composite next-hops for Layer 3 VPNs.

labeled-bgp | no-labeled-bgp—Enable or disable chained composite next-hops for labeled BGP.

ldp | no-ldp—Enable or disable chained composite next-hops for LDP.

ldp-p2mp | no-ldp-p2mp—Enable or disable chained composite next-hops for LDP-signaled P2MP LSPs.

NOTE: On an MX series router with redundant Routing Engines and enhanced-ip mode configuration, enabling the **rsvp-p2mp** and **ldp-p2mp** statements under the **[edit routing-options forwarding-table chained-composite-next-hop transit]** hieracrhy level causes ping from the current master logical system to fail at the time of a Routing Engine switchover.

lsp-statistics-from-route—Enable LSP statistics collection from the route.

rsvp | no-rsvp—Enable or disable chained composite next-hops for RSVP.

rsvp-p2mp | no-rsvp-p2mp—Enable or disable chained composite next-hops for RSVP-signaled P2MP LSPs.

NOTE: On an MX series router with redundant Routing Engines and enhanced-ip mode configuration, enabling the **rsvp-p2mp** and **ldp-p2mp** statements under the **[edit routing-options forwarding-table chained-composite-next-hop transit]** hieracrhy level causes ping from the current master logical system to fail at the time of a Routing Engine switchover.

static | no-static—Chained composite next hops are enabled for transit static LSPs by default. You can also disable this functionality for transit static LSPs.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

clear rsvp session
<connection-destination address>
<connection-source address>
<gracefully>
<lsp-id identifier>
<name name>
<optimize-fast-reroute>
<tunnel-id identifier>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Reset and restart Resource Reservation Protocol (RSVP) sessions.

Options

all—Clear all RSVP sessions for which this routing device is the ingress, transit, or egress routing device.

connection-source *address*—(Optional) Source address for GMPLS and MPLS LSPs from the RSVP sender template.

connection-destination *address*—(Optional) Destination address for GMPLS and MPLS LSPs from the RSVP sender template.

gracefully—(Optional) Gracefully reset an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin-Status object is signaled along the path to the other endpoint of the RSVP session. In the second pass, the path used by the RSVP session is torn down. This option can only be used on the ingress or egress routing device of the RSVP session and is only valid for nonpacket LSPs.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-id *identifier*—(Optional) LSP identifier (source port) for the RSVP sender template.

name *name*—(Optional) Reset and restart the specified RSVP session.

optimize-fast-reroute—(Optional) Begin fast reroute optimization.

tunnel-id *identifier*—(Optional) Tunnel identifier (destination port) for the RSVP session.

monitor label-switched-path

Syntax

monitor label-switched-path *lsp-name*
<logical-system (*logical-system-name*)>

Release Information

Command introduced before Junos OS Release 7.4.
Logical system support introduced in Junos OS Release 9.4.
Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Display the real-time status of the specified RSVP label-switched path (LSP). You can also use this command to monitor LSPs configured within logical systems.

Options

logical-system (*logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-name—Name of the LSP.

Additional Information

You can track the amount of traffic traversing an RSVP LSP and observe its essential parameters, such as uptime, ingress and egress addresses, labels, routes, and ports. Values are typically sampled every second. The display also allows you to scroll to other currently running LSPs. You cannot use this command to display information about static LSPs or LDP-signaled LSPs.

The output of this command shows how much each field has changed since you started the command or since you cleared the counters by using the c key. To control the output of the **monitor label-switched-path** command while it is running, use the keys listed in Table 115 on page 2425. The keys are not case-sensitive.

Table 115: Output Control Keys for the monitor label-switched-path Command

Key	Action
c	Clears the screen and refreshes the display for this LSP.
f	Freezes the display, preventing new information from being displayed.
l	Monitors a different LSP. After you type l, you can type the new LSP name.
n	Displays information about the next LSP (whose name is alphabetically higher than the current LSP name) configured on the router.
p	Goes to the previous LSP (whose name is alphabetically lower than the current LSP name) configured on the router.
q or Esc	Quits the command and returns to the command prompt.
t	Thaws, or restarts, the data display for this LSP.

Required Privilege Level trace

List of Sample Output monitor label-switched-path on page 2427

Output Fields Table 116 on page 2426 describes the output fields for the **monitor label-switched-path** command. Output fields are listed in the approximate order in which they appear.

Table 116: monitor label-switched-path Output Fields

Field Name	Field Description
(1)	Displays the following information: • ***hostname***—Name of the router. • **Seconds**—Time elapsed since this display was started. • **Time**—Current local time.
(2)	**Delay**—Length of the time delay, in milliseconds, required to obtain the information in the monitor display. The first number shows the current sampling delay. The second number shows the shortest delay recorded to date. The third number shows the worst delay recorded to date. This delay can vary substantially depending on the system load.
(3)	Displays the following: • **To**—Destination address of the LSP. • **From**—Originating address of the LSP. • **State**—Current state of the LSP: **Up** or **Down**.
(4)	Displays the following: • **LSPName**—Name of the LSP. • **Type**—Type of LSP: **Ingress**, **Egress**, or **Transit**.
(5)	Displays the following: • **Label in**—Incoming label of the LSP. • **Label out**—Outgoing label of the LSP.
(6)	**Port number**—Port number for the sending router, the port number for the receiving router, and the protocol ID. For MPLS traffic engineering applications, the protocol ID is always **0**.
(7/8)	**Record route**—All intermediate and egress router addresses for this LSP.
(9/10/11)	Displays traffic statistics: • **Output packets**—Number of packets that have traversed this LSP, and the change (delta) in the number since the last sample, typically 1 second ago. • **Output bytes**—Number of bytes that have traversed this LSP, and the change (delta) in the number since the last sample, typically 1 second ago.
(12)	Displays any errors the router encountered while attempting to retrieve information on the LSP.
(13)	Lists the keyboard commands you can use to navigate to other LSPs. For a description of the keyboard commands, see Table 115 on page 2425.

Sample Output

monitor label-switched-path

```
user@host> monitor label-switched-path
```

```

ping mpls rsvp

Syntax

```
ping mpls rsvp
<lsp-name>
<count count>
<destination address>
<detail>
<dynamic-bypass>
<egress egress-address>
<exp forwarding-class>
<interface interface-name>
<logical-system (all | logical-system-name)>
<manual-bypass>
<multipoint>
<size bytes>
<source source-address>
<standby standby-path-name>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.
The **egress** and **multipoint** options were introduced in Junos OS Release 9.2.
The **size** and **sweep** options were introduced in Junos OS Release 9.6.
The **dynamic-bypass** and **manual-bypass** options were introduced in Junos OS Release 10.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS RSVP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

NOTE: When using the **detail** option, the reported time is based on the system time configured on the local and remote routers. Differences in these system times can result in inaccurate one way ping trip times being reported.

In practice, it is difficult to synchronize the system times of independent Juniper Networks routers with sufficient accuracy to provide a meaningful time value for the **detail** option (even when synchronized using NTP).

dynamic-bypass—(Optional) Ping dynamically generated bypass LSPs, used for protecting other LSPs.

egress ***egress-address***—(Optional) Only the specified egress router or switch responds to the ping request.

exp ***forwarding-class***—(Optional) Value of the forwarding class for the MPLS ping packets.

interface—(Optional) Specify the name of the interface protected by the manual bypass LSP. This option is only available when you have also used the **manual-bypass** option.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on the specified logical system.

lsp-name—Ping an RSVP-signaled LSP using an LSP name.

manual-bypass—(Optional) Ping manually configured bypass LSPs, used for protecting other LSPs. For this option, you must also specify the interface protected by the manual bypass LSP using the **interface** option.

multipoint—(Optional) Send ping requests to each of the egress routers or switches participating in a point-to-multipoint LSP. You can also include the **egress** option to ping a specific egress router or switch participating in a point-to-multipoint LSP.

size ***bytes***—(Optional) Size of the LSP ping request packet (**100** through **65468** bytes). Packets are 4-byte aligned. For example, if you enter a size of 101, 102, 103, or 104, the router or switch uses a size value of 104 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 100-byte minimum.

source ***source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface.

standby ***standby-path-name***—(Optional) Name of the standby path.

sweep —(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level network

List of Sample Output

Output Fields When you enter this command, you are provided feedback on the status of your request. An exclamation point (**!**) indicates that an echo reply was received. A period (**.**) indicates that an echo reply was not received within the timeout period. An **x** indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls rsvp (Echo Reply Received)

```
user@host> ping mpls rsvp test1
!!!!!--- lsping statistics ---5 packets transmitted, 5 packets received, 0% packet
 loss
```

ping mpls rsvp (Echo Reply with Error Code)

```

<link-management>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display the status of Resource Reservation Protocol (RSVP)-enabled interfaces and packet statistics. The RSVP input/input module collects statistics for certain events on a per-interface basis. Most of these events were tracked on a routing-instance basis in Junos OS releases earlier than Release 17.2. The **show rsvp interface detail** command displays these event counters under the **Events** section of the output only when the values of these fields are higher than zero. These statistics are also maintained at the global level (per routing-instance) and are also displayed in the output of the **show rsvp statistics** command.

Options

none—Display standard information about the status of RSVP-enabled interfaces and packet statistics.

brief | detail | extensive | link-management—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display RSVP status information for the specified instance. If **instance-name** is omitted, RSVP status information is displayed for the master instance.

link-management—(Optional) Use the link-management option to display the control peers and corresponding TE-link information created by the Link Management Protocol (LMP).

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

show rsvp interface detail RSVP interface: 9 active on page 2439

Output Fields

Table 117 on page 2435 lists the output fields for the **show rsvp interface** command. Output fields are listed in the approximate order in which they appear.

Table 117: show rsvp interface Output Fields

Field Name	Field Description	Level of Output
RSVP interface	Number of interfaces on which RSVP is active. Each interface has one line of output.	All levels
Interface	Name of the interface.	All levels
Index	Index of the interface.	**detail**
State	State of the interface. • **Disabled**—No traffic engineering information is displayed. • **Down**—Interface is not operational. • **Enabled**—Displays traffic engineering information. • **Up**—Interface is operational.	All levels
NoAuthentication	Interface does not support RSVP authentication.	**detail**
NoAggregate	Interface does not support refresh reduction.	**detail**
NoReliable	Interface does not support refresh reduction message ID extension.	**detail**
NoLinkProtection	Interface does not support link protection.	**detail**
HelloInterval	Frequency at which RSVP hellos are sent on this interface (in seconds). Prior to Junos OS Release 18.2R2, when the **no-interface-hello** statement is configured under the **[edit protocols rsvp]** hierarchy, and there is no interface-specific configuration for the hello interval, the **HelloInteval** output field displayed the default hello interval time of 9 seconds. Starting in Junos OS Release 18.2R2, with a similar configuration, the **HelloInterval** output field displays 0 as the hello interval.	**detail**
Address	IP address of the local interface.	**detail**
Active control channel	Next-hop link address to transmit messages.	None specified
TElink	Traffic-engineered links that are managed by the peer they are associated with.	None specified
Active resv	Number of reservations that are actively reserving bandwidth on the interface.	All levels

Table 117: show rsvp interface Output Fields (continued)

Field Name	Field Description	Level of Output
PreemptionCnt	Number of times an RSVP session was preempted on this interface.	**detail**
Update threshold	Percentage change in reserved bandwidth to trigger an IGP update.	**detail**
Subscription	User-configured subscription factor.	All levels
Actual	Available RSVP bandwidth that is recalculated after considering SPRING bandwidth utilization.	**extensive**
bc *number*	Bandwidth allocated for the specified bandwidth constraint.	**extensive**
ct *number*	Bandwidth allocated for the specified class type.	**extensive**
Static BW	Total interface bandwidth, in bps.	All levels
Available BW	Amount of bandwidth that RSVP is allowed to reserve, in bps. It is equal to (static bandwidth * subscription factor).	al levels
Reserved BW	Currently reserved bandwidth, in bps.	All levels
SoftPreemptionCnt	Number of times a soft preemption occurred on this interface. This number is not included in the **PreemptionCnt** value.	**detail**
Overbooked BW	Currently overbooked bandwidth, in bps, by class type (**ct0** through **ct3**).	**detail**
Highwater mark	Highest bandwidth that has ever been reserved on this interface, in bps.	**brief**
PacketType	Type of RSVP packet.	**detail**
Total Sent	Total number of packets sent.	**detail**
Total Received	Total number of packets received since RSVP was enabled.	**detail**
Last 5 seconds Sent	Number of packets sent in the last 5 seconds.	**detail**
Last 5 seconds Received	Number of packets received in the last 5 seconds.	**detail**
Path	Statistics about Path messages, which are sent from the RSVP sender along the data paths and store path state information in each node along the path.	**detail**
PathErr	Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.	**detail**
PathTear	Statistics about PathTear messages, which remove path states and dependent reservation states in any routers along a path.	**detail**

Table 117: show rsvp interface Output Fields (continued)

Field Name	Field Description	Level of Output
Resv	Statistics about Resv messages, which are sent from the RSVP receiver along the data paths and store reservation state information in each node along the path.	**detail**
ResvErr	Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.	**detail**
ResvTear	Statistics about ResvTear messages, which remove reservation states along a path.	**detail**
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.	**detail**
Ack	Acknowledge message for refresh reductions.	**detail**
Srefresh	Summary refresh messages.	**detail**
EndtoEnd RSVP	Statistics for the number of end-to-end RSVP messages sent.	**detail**
Queue	CoS transmit queue number and its associated forwarding class designation.	**extensive**
TxRate	Configured bandwidth in Mbps and configured bandwidth as a percentage of the specified queue.	**extensive**
Priority	Weight of the queue relative to other configured queues, in percentage.	**extensive**
queue-priority-value	**Low**, **High**, **None**, or **Exact**. **None** indicates no rate limiting. **Exact** indicates the queue transmits at the configured rate only.	**extensive**

```

Release Information
Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance option added in Junos OS Release 15.1 for the MX Series.

Description
Display Resource Reservation Protocol (RSVP) neighbors that were discovered dynamically during the exchange of RSVP packets.

Options
none—Display standard information about RSVP neighbors.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display the RSVP neighbor information for the specified instance. If **instance-name** is omitted, RSVP neighbor information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
view

List of Sample Output
show rsvp neighbor on page 2445
show rsvp neighbor detail on page 2445

Output Fields
Table 118 on page 2441 lists the output fields for the **show rsvp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 118: show rsvp neighbor Output Fields

Field Name	Field Description	Level of Output
RSVP neighbor	Number of neighbors that the routing device has learned of. Each neighbor has one line of output.	All levels

Table 118: show rsvp neighbor Output Fields (continued)

Field Name	Field Description	Level of Output
via	Name of the interface where the neighbor has been detected. In the case of generalized MPLS (GMPLS) LSPs, the name of the peer where the neighbor has been detected.	**detail**
Address	Address of a learned neighbor.	All levels
Idle	Length of time the neighbor has been idle, in seconds. NOTE: Until Junos OS Release 15.1, in the output of the show rsvp neighbor command, the value under the Idle field immediately reflects the changed idle time when a link in the neighboring router is brought down. Starting with Junos OS Release 15.2, a router does not declare a neighbor as idle when a hello adjacency exists and has not timed out. When an interface is brought down, RSVP brings down the neighbor because of the notification it receives from IGP. The reason for considering the IGP-down notification is to support BFD-triggered fast reroute (FRR) and RSVP-TE is not directly a client for BFD notifications. When RSVP brings down the neighbor, the input/output process is not impacted. As a result, the idle time in the output of the show command is not immediately updated.	All levels
Up/Dn	Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.	All levels
Up cnt and Down cnt	Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.	**detail**

status	State of the RSVP neighbor:
	
	• **Up**—Routing device can detect RSVP Hello messages from the neighbor.
	• **Down**—Routing device has received one of the following indications:
	  ◦ Communication failure from the neighbor.
	  ◦ Communication from IGP that the neighbor is unavailable.
	  ◦ Change in the sequence numbers in the RSVP Hello messages sent by the neighbor.
	• **Restarting**—RSVP neighbor is unavailable and might be restarting. The neighbor remains in this state until it has restarted or is declared dead. This state is possible only when graceful restart is enabled.
	• **Restarted**—RSVP neighbor has restarted and is undergoing state recovery (graceful restart) procedures.
	• **Dead**—Routing device has lost all communication with the RSVP neighbor. Any RSVP sessions with that neighbor are torn down.
		detail

LastChange	Time elapsed since the neighbor state changed either from up to down or from down to up. The format is ***hh:mm:ss***.	All levels

Table 118: show rsvp neighbor Output Fields (continued)

Field Name	Field Description	Level of Output
Last changed time	Time elapsed since the neighbor state changed either from up to down or from down to up.	**detail**
HelloInt	Frequency at which RSVP hellos are sent on this interface (in seconds).	All levels
HelloTx/Rx	Number of hello packets sent to and received from the neighbor.	All levels
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.	**detail**
Message received	Number of Path and Resv messages that this routing device has received from the neighbor.	**detail**
Remote Instance	Identification provided by the remote routing device during Hello message exchange.	**detail**
Local Instance	Identification sent to the remote routing device during Hello message exchange.	**detail**
Refresh reduction	Measure of processing overhead requests of refresh messages. Refresh reduction extensions improve routing device performance by reducing the process overhead, thus increasing the number of LSPs a routing device can support. **Refresh reduction** can have the following values: • **operational**—All four RSVP refresh reduction extensions—message ack, bundling, summary refresh, and staged refresh timer—are functional between the two neighboring routing devices. For a detailed explanation of these extensions, see RFC 2961. • **incomplete**—Some RSVP refresh reduction extensions are functional between the two neighboring routing devices. • **not operational**—Either the refresh reduction feature has been turned off, or the remote routing device cannot support the refresh reduction extensions.	**detail**
Remote end	Neighboring routing device's status with regard to refresh reduction: • **enabled**—Remote routing device has requested refresh reduction during RSVP message exchanges. • **disabled**—Remote routing device does not require refresh reduction.	**detail**
Pop label	Pop labels of the RSVP-TE pop-and-forward LSP tunnels.	**detail**
Ack-extension	An RSVP refresh reduction extension: • **enabled**—Both local and remote routing devices support the ack-extension (RFC 2961). • **disabled**—Remote routing device does not support the ack-extension.	**detail**
Link protection	Status of the MPLS fast reroute mechanism that protects traffic from link failure: • **enabled**—Link protection feature has been turned on, protecting the neighbor with a bypass LSP. • **disabled**—No link protection feature has been enabled for this neighbor.	**detail**

Table 118: show rsvp neighbor Output Fields (continued)

Field Name	Field Description	Level of Output
LSP name	Name of the bypass LSP.	**detail**
Bypass LSP	Status of the bypass LSP. It can have the following values: • **does not exist**—Bypass LSP is not available. • **connecting**—Routing device is in the process of establishing a bypass LSP, and the LSP is not available for link protection at the moment. • **operational**—Bypass LSP is up and running. • **down**—Bypass LSP has gone down, with the most probable cause a node or a link failure on the bypass path.	**detail**
Backup routes	Number of user LSPs (or routes) that are being protected by a bypass LSP (before link failure).	**detail**
Backup LSPs	Number of LSPs that have been temporarily established to maintain traffic by refreshing the downstream LSPs during link failure (not a one-to-one correspondence).	**detail**
Bypass explicit route	Explicit route object's (ERO) path that is taken by the bypass LSP.	**detail**
Restart time	Length of time a neighbor waits to receive a Hello from the restarting node before declaring the node dead and deleting the states (in milliseconds).	**detail**
Recovery time	Length of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds). Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.	**detail**

Sample Output

show rsvp neighbor

```
user@host> show rsvp neighbor
RSVP neighbor: 2 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx
192.168.207.203       0  3/2       13:01        3   366/349
192.168.207.207       0  1/0       22:49        3   448/448
```

show rsvp neighbor detail

Starting in Junos OS Release 16.1, this command also shows whether enhanced FRR procurers are enabled on the neighbor. Neighbors with Point of Local Repair (PLR) or Node Protecting Merge Point (NP-MP) also show the Hellos sent /received count.

```
user@host> show rsvp neighbor detail
RSVP neighbor: 2 learned
Address: 192.168.207.203   via: ecstasyl status: Up
   Last changed time: 28:47, Idle: 0 sec, Up cnt: 3, Down cnt: 2
   Message received: 632
   Hello: sent 673, received 656, interval 3 sec
   Remote instance: 0x6432838a, Local instance: 0x74b72e36
   Refresh reduction:  operational
     Remote end: enabled,  Ack-extension: enabled
   Enhanced FRR local protection: enabled
     LSPs (total 76): Phop 0, PPhop 0, Nhop 76, NNhop 0
   Pop Label: 299808(unprotected) 299840(link-protected)
Link protection:  enabled
     LSP name: Bypass_to_192.168.207.203
     Bypass LSP: operational,  Backup routes: 1,  Backup LSPs: 0
     Bypass explicit route: 192.168.207.207 192.168.207.224
  Restart time: 60000 msec, Recovery time: 0 msec
```

show rsvp route-session-id

Syntax show rsvp route-session-id

Release Information Command introduced in Junos OS Release 16.1 for the MX Series.

Description Display the session ID and the version information associated with the ingress route added by the Resource Reservation Protocol (RSVP) in the inet.3 table.

Session ID is a pre-populated identifier used for indirect next hops in BGP Prefix Independent Convergence (PIC) enabled router. Session ID is used to identify the session or path.

NOTE: **protect core configuration is not required to display the route-session-id.**

Options **none**—Validate and display RSVP route session details.

Required Privilege Level view

List of Sample Output show rsvp route-session-id on page 2447

Output Fields Table 119 on page 2446 describes the output fields for the **show rsvp route-session-id** command. Output fields are listed in the approximate order in which they appear.

Table 119: show rsvp route-session-id Output Fields

Field Name	Field Description
Ingress Route Destination	Destination (egress routing device) of the session.
Ingress Route Preference	RSVP preference value of the ingress session.
Ingress Route Metric 1	Metric 1 associated with the RSVP ingress route.
Ingress Route Metric 2	Metric 2 associated with the RSVP ingress route.
Ingress Route Session ID	Session ID associated with the RSVP ingress route.
Version	Version number associated with the RSVP ingress route.

Sample Output

show rsvp route-session-id

```
user@host> show rsvp route-session-id

RSVP Ingress Route Session ID Database:
=======================================
   Ingress Route Destination: 1.1.1.5/32
   Ingress Route Preference:  7
   Ingress Route Metric 1:    20,        Metric 2:  0
   Ingress Route Session ID:  0x146,     Version:   0
```

show rsvp pop-and-forward

Syntax

```
show rsvp pop-and-forward
<brief | detail | extensive>
<instance routing-instance-name>
<label label>
<logical-system (all | logical-system-name)>
```

Release Information Command introduced in Junos OS Release 18.1R1 on MX Series routers, PTX Series routers, and vMX series routers.

Description Display RSVP-TE pop-and-forward LSP tunnel information. This information includes the set of in-labels (one-hop pop label or a delegation label), the number of session using each label and the next segment-label (if there is another delegation hop downstream), and whether the in-label is used for unprotected or protected LSPs.

Options

none—Display the standard level of information for the RSVP-TE pop-and-forward LSP tunnels.

brief | detail | extensive—(Optional) Display the desired level of output. The brief option is the default level of output.

The detail option provides more information about the hops in a delegation segment (whether its one-hop or multi-hop).

The extensive option lists the set of LSPs that are using a given pop or delegation label.

instance *routing-instance-name*—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for the specified routing instance.

label *label*—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for the specified label.

logical-system (all | *logical-system-name*)—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for all or the specified logical system.

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
externally-provisioned option added in Junos OS Release 13.3.
Command introduced in Junos OS Release 13.2X51-D15 for QFX Series.
instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display information about Resource Reservation Protocol (RSVP) sessions.

Options

none—Display standard information about all RSVP sessions.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

bidirectional | unidirectional—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.

bypass—(Optional) Display RSVP sessions for bypass LSPs.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

externally-provisioned—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

instance *instance-name*—(Optional) Display RSVP sessions for the specified instance. If **instance-name** is omitted, RSVP session information is displayed for the master instance.

interface *interface-name*—(Optional) Display RSVP sessions for the specified interface only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

name *session-name*—(Optional) Display information about the named session.

p2mp—(Optional) Display point-to-multipoint information.

session-type—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this routing device.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that transit through this routing device.

statistics—(Optional) Display packet statistics.

te-link *te-link*—(Optional) Display sessions with reservations on the specified TE link.

show rsvp session p2mp (Transit Router) on page 2460

Output Fields Table 120 on page 2452 describes the output fields for the **show rsvp session** command. Output fields are listed in the approximate order in which they appear.

Table 120: show rsvp session Output Fields

Field Name	Field Description	Level of Output
Ingress RSVP	Information about ingress RSVP sessions.	**detail**
Ingress RSVP	Information about ingress RSVP sessions. Each session has one line of output.	All levels
Egress RSVP	Information about egress RSVP sessions.	All levels
Transit RSVP	Information about the transit RSVP sessions.	All levels
P2MP name	(Appears only when the **p2mp** option is specified). Name of the point-to-multipoint LSP path.	All levels
P2MP branch count	(Appears only when the **p2mp** option is specified). Number of LSPs receiving packets from the point-to-multipoint LSP.	All levels
To	Destination (egress routing device) of the session.	All levels
From	Source (ingress routing device) of the session.	All levels
State	State of the path: **Up**, **Down**, or **AdminDn**. **AdminDn** indicates that the LSP is being taken down gracefully.	All levels
Address	Destination (egress routing device) of the LSP.	**detail**
From	Source (ingress routing device) of the session.	**detail**
LSPstate	State of the LSP that is being handled by this RSVP session. It can be either **Up**, **Dn** (down), or **AdminDn**. **AdminDn** indicates that the LSP is being taken down gracefully.	**brief detail**
Rt	Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (**inet.0**). For transit and egress RSVP sessions, the routing table is the primary MPLS table **mpls.0**).	**brief**

Table 120: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
Active Route	Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table (**inet.0**). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (**mpls.0**).	**detail**
LSPname	Name of the LSP.	**brief detail**
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. **LSPpath** can be either **primary** or **secondary** and can be displayed on the ingress, egress, and transit routing devices. **LSPpath** can also indicate when a graceful LSP deletion has been triggered.	**detail**
Bypass	(Egress routing device) Destination address for the bypass LSP.	**detail**
Bidir	(When LSP is bidirectional) LSP will allow data to travel in both directions between GMPLS devices.	**detail**
Bidirectional	(When LSP is bidirectional) LSP will allow data to travel both ways between GMPLS devices.	**detail**
Upstream label in	(When LSP is bidirectional) Incoming label for reverse direction traffic for this LSP.	**detail**
Upstream label out	(When LSP is bidirectional) Outgoing label for reverse direction traffic for this LSP.	**detail**
Recovery label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	**detail**
Recovery label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.	**detail**
Suggested label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	**detail**
Suggested label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.	**detail**
Resv style or **Style**	RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be **FF** (fixed filter), **SE** (shared explicit), or **WF** (wildcard filter).	**brief detail**
Label in	Incoming label for this LSP.	**brief detail**
Label out	Outgoing label for this LSP.	**brief detail**
Time left	Number of seconds remaining in the lifetime of the reservation.	**brief detail**
Since	Date and time when the RSVP session was initiated.	**detail**

Table 120: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	**detail**
DiffServ info	Indicates whether the LSP is a multiclass LSP (**multiclass diffServ-TE LSP**) or a Differentiated-Services-aware traffic engineering LSP (**diffServ-TE LSP**).	**detail**
bandwidth	Bandwidth for each class type (**ct0**, **ct1**, **ct2**, or **ct3**).	**detail**
Port number	Protocol ID and sender/receiver port used in this RSVP session.	**detail**
Attrib flags	**Non-PHP** indicates that ultimate hop popping has been requested by the LSP using this RSVP session	extensive
FastReroute desired	Fast reroute has been requested by the ingress routing device.	**detail**
Soft preemption desired	Soft preemption has been requested by the ingress routing device.	**detail**
FastReroute desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Fast reroute (one-to-one backup) has been requested by the ingress routing device.	**detail extensive**
Link protection desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Link protection (many-to-one backup) has been requested by the ingress routing device.	**detail extensive**
Node/Link protection desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Node and link protection (many-to-one backup) has been requested by the ingress routing device.	**detail extensive**
Type	LSP type: • **Link protected LSP**—LSP has been protected by link protection at the outgoing interface. The name of the bypass used is also listed here (**extensive**). • **Node/Link protected LSP**—LSP has been protected by node and link protection at the outgoing interface. The name of the bypass used is also listed here (**extensive**). • **Protection down**—LSP is not currently protected. • **Bypass LSP**—LSP that is used to protected one or more user LSPs in case of link failure. • **Backup LSP at Point-of-Local-Repair (PLR)**—LSP that has been temporarily established to protected a user LSP at the ingress of a failed link. • **Backup LSP at Merge Point (MP)**—LSP that has been temporarily established to protected a user LSP at the egress of a failed link.	**detail extensive**
New bypass	New bypass (the bypass name is also displayed) has been activated to protect the LSP.	**extensive**
Link protection up, using *bypass-name*	Link protection (the bypass name is also displayed) has been activated for the LSP.	**extensive**

Table 120: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
Creating backup LSP, link down	A **link down** event occurred, and traffic is being switched over to the bypass LSP.	**extensive**
Deleting backup LSP, protected LSP restored	Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.	**extensive**
Path mtu	Displays the value of the path MTU received from the network (through signaling) and the value used for forwarding. This value is only displayed on ingress routing devices with the **allow-fragmentation** statement configured at the **[edit protocols mpls path-mtu]** hierarchy level. If there is a detour LSP, the path MTU for the detour is also displayed.	**detail**
Egress protection PLR as protector	RSVP state on the Protector or the point-of-local-repair (PLR) routing device: • **Active**— Egress protection is available at the Protector or the PLR routing device. • **In Use**— Local repair has been completed.	**detail**
PATH rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor.	**detail**
Adspec	MTU signaled from the ingress routing device to the egress routing device by means of the adspec object.	**detail**
PATH sentto	Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor (or peer-name in the GMPLS LSP case), and number of packets sent to the downstream routing device.	**detail**
Explct route	Explicit route for the session. Normally this value will be the same as that of record route. Differences indicate that path rerouting has occurred, typically during fast reroute.	**detail**
Record route	Recorded route for the session, taken from the record route object. Normally this value will be the same as that of explct route. Differences indicate that path rerouting has occurred, typically during fast reroute.	**detail**

Sample Output

show rsvp session

```
user@host> show rsvp session

show rsvp session extensive transit

Starting in Junos OS Release 16.1, this command also shows node-related details, including whether enhanced local protection is enabled for the LSP and whether the node is a merge point. If the latter is true, both the IP address of the Point of Local Repair (PLR) and the status (LP-MP, NP-MP, or Non-MP) are shown.

```

show rsvp session

Syntax

```
show rsvp session
<brief | detail | extensive | terse>
<bidirectional | unidirectional>
<down | up>
<interface interface-name>
<lsp-type>
<name session-name>
<session-type>
<statistics>
<te-link te-link>
```

Release Information Command introduced in Junos OS Release 9.5 for EX Series switches.

Description Display information about Resource Reservation Protocol (RSVP) sessions.

Options **none**—Display standard information about all RSVP sessions.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

bidirectional | unidirectional—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

interface *interface-name*—(Optional) Display RSVP sessions for the specified interface only.

lsp-type —(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

name *session-name*—(Optional) Display information about the named session.

session-type—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this switch.
- **ingress**—Sessions that originate from this switch.
- **transit**—Sessions that transit through this switch.

statistics—(Optional) Display packet statistics.

te-link *te-link*—(Optional) Display sessions with reservations on the specified traffic-engineered link name.

Required Privilege Level view

Output Fields Table 121 on page 2462 describes the output fields for the **show rsvp session** command. Output fields are listed in the approximate order in which they appear.

Table 121: show rsvp session Output Fields

Field Name	Field Description	Level of Output
Ingress RSVP	Information about ingress RSVP sessions.	**detail**
Ingress RSVP	Information about ingress RSVP sessions. Each session has one line of output.	All levels
Egress RSVP	Information about egress RSVP sessions.	All levels
Transit RSVP	Information about the transit RSVP sessions.	All levels
To	Destination (egress switch) of the session.	All levels
From	Source (ingress switch) of the session.	All levels
State	State of the path: **Up**, **Down**, or **AdminDn**. **AdminDn** indicates that the LSP is being taken down gracefully.	All levels
Address	Destination (egress switch) of the LSP.	**detail**
LSPstate	State of the LSP that is being handled by this RSVP session. It can be either **Up**, **Dn** (down), or **AdminDn**. **AdminDn** indicates that the LSP is being taken down gracefully.	**brief, detail**
Rt	Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (**inet.0**). For transit and egress RSVP sessions, the routing table is the primary MPLS table **mpls.0**).	**brief**

Table 121: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
ActiveRoute	Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table (**inet.0**). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (**mpls.0**).	**detail**
LSPname	Name of the LSP.	**brief, detail**
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. **LSPpath** can be either **primary** or **secondary** and can be displayed on the ingress, egress, and transit switches. **LSPpath** can also indicate when a graceful LSP deletion has been triggered.	**detail**
Recovery label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	**detail**
Recovery label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.	**detail**
Suggested label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	**detail**
Suggested label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.	**detail**
Resv style or **Style**	RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be **FF** (fixed filter), **SE** (shared explicit), or **WF** (wildcard filter).	**brief detail**
Label in	Incoming label for this LSP.	**brief, detail**
Label out	Outgoing label for this LSP.	**brief, detail**
Time left	Number of seconds remaining in the lifetime of the reservation.	**brief, detail**
Since	Date and time when the RSVP session was initiated.	**detail**
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	**detail**
Port number	Protocol ID and sender/receiver port used in this RSVP session.	**detail**
Creating backup LSP, link down	A **link down** event occurred, and traffic is being switched over to the bypass LSP.	**extensive**
Deleting backup LSP, protected LSP restored	Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.	**extensive**
PATH rcvfrom	Address of the previous-hop (upstream) switch or client, interface the neighbor used to reach this switch, and number of packets received from the upstream neighbor.	**detail**

Sample Output

```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.
instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display Resource Reservation Protocol (RSVP) packet and error statistics. The RSVP input/input module collects statistics for certain events on a per-interface basis. Most of these events were tracked on a routing-instance basis in Junos OS releases earlier than Release 17.2. The "show rsvp interface detail" command displays these event counters under the Events section of the output only when the values of these fields are higher than zero. These statistics are also maintained at the global level (per routing-instance) and are also displayed in the output of the "show rsvp statistics" command.

Options

none—Display RSVP packet and error statistics.

instance *instance-name*—(Optional) Display RSVP packet and error statistics for the specified instance. If **instance-name** is omitted, RSVP statistics are displayed for the master instance.

logical-system (all |*logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

Output Fields

Table 122 on page 2467 describes the output fields for the **show rsvp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 122: show rsvp statistics Output Fields

Field Name	Field Description
Packet Type	Statistics about different RSVP messages.
Total Sent	Total number of packets sent since RSVP was enabled.
Total Received	Total number of packets received since RSVP was enabled.
Last 5 seconds Sent	Total number of packets sent in the last 5 seconds.
Last 5 seconds Received	Number of packets received in the last 5 seconds.
Path	Statistics about Path messages, which are sent from the RSVP sender along the data paths and which store path state information in each node along the path.
PathErr	Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.
PathTear	Statistics about PathTear messages, which remove path states and dependent reservation states in any routing devices along a path.
Resv FF	Statistics about fixed-filter reservation style messages, which consist of distinct reservations among explicit senders.
Resv WF	Statistics about wildcard-filter reservation style messages, which consist of shared reservations among wildcard senders.
Res SE	Statistics about shared-explicit reservation style messages, which consist of shared reservations among explicit senders.
ResvErr	Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.
ResvTear	Statistics about ResvTear messages, which remove reservation states along a path.
ResvConf	Statistics about ResvConfirm messages, which are responses to confirm a reservation request.
Ack	Acknowledge message for refresh reductions.
SRefresh	Summary refresh messages.
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.
EndtoEnd RSVP	Statistics for the number of End-to-end RSVP messages.
Errors	Statistics about errored RSVP packets.
Rcv pkt bad length	The packet was not processed because its length is inappropriate.

Table 122: show rsvp statistics Output Fields (continued)

Field Name	Field Description
Rcv pkt unknown type	The packet is not one of the well-known RSVP types, as defined in RFC 2205, *Resource ReSerVation Protocol (RSVP)*.
Rcv pkt bad version	The packet is not an RSVP version 1 packet.
Rcv pkt auth fail	The packet failed authentication checks.
Rcv pkt bad checksum	The RSVP checksum check failed.
Rcv pkt bad format	General packet processing failed because the packet was badly formed.
Memory allocation fail	An internal resource failure occurred.
No path information	A reservation was received, but no sender is active.
Resv style conflict	The same session contains inconsistent reservation styles.
Port conflict	There were inconsistent port numbers for the same session.
Resv no interface	An interface for the receive reservation packets cannot be located.
PathErr to client	Number of PathErr packets delivered to the local client.
ResvErr to client	Number of ResvErr packets delivered to the local client.
Path timeout	Number of times the sender timed out because the path was removed.
Resv timeout	Number of times the receiver timed out because the reservation was removed.
Message out-of-order	Records the number of RSVP incoming messages that are considered out of order. This is detected from the message ID object's sequence number.
Unknown ack msg	A neighboring routing device replies with an ACK object that contains an unknown message ID. This can indicate a message ID handshake problem. For example, a router receives an ACK for message IDs 1, 2, and 3. However, it only has state for message IDs 1 and 3. The router increments the unknown ack counter by 1.
Recv nack	If a neighboring router receives an unknown message ID in an RSVP refresh message, the router sends a Resv nack message back to the sender. This can happen if that neighbor has been rebooted. For this case, the router sends a regular RSVP refresh message to recover the state and start the message-ID handshake process again.
Recv duplicated msg-id	Number of times the same message ID is used by two different RSVP messages. This duplication is usually caused when a neighboring routing device restarts.
No TE-link to recv Hop	Counter of packets discarded because a TE link was not found.
Rcv pkt disabled interface	Number of RSVP packets received on an interface that is not enabled for RSVP.

Table 122: show rsvp statistics Output Fields (continued)

Field Name	Field Description
Transmit buffer full	Number of times the buffer for assembling an outgoing RSVP message was not large enough.
Transmit failure	Number of times the RSVP task failed to send out a packet.
Receive failure	Number of times the RSVP task failed to read an incoming packet.
P2MP RESV discarded by appl	Number of Resv messages discarded because the MPLS label is not valid for the P2MP LSP application.
Rate limit	Number of RSVP packets dropped due to rate limiting.
Err msg loop detected	Number of RSVP error messages that have looped back to their originator. This is detected by checking the error node address in the ERROR_SPEC object.

Sample Output

show rsvp statistics

Starting in Junos OS Release 16.1, this command also shows conditional PathTear statistics and the number of times an LSP state has been retained because of Link Protecting Merge Point (LP-MP) or Node Protecting Merge Point (NP-MP) determination.

```
user@host> show rsvp statistics

```

Syntax (EX Series Switches)
```
show rsvp version
```

Release Information
Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.

Description
Display information about the Resource Reservation Protocol (RSVP) protocol settings, such as the version of the RSVP software, the refresh timer and keep multiplier, and local RSVP graceful restart capabilities on a routing device.

Options
none—Display RSVP protocol settings.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
view

List of Sample Output
show rsvp version on page 2474

Output Fields
Table 123 on page 2472 describes the output fields for the **show rsvp version** command. Output fields are listed in the approximate order in which they appear.

Table 123: show rsvp version Output Fields

Field Name	Field Description
Resource ReSerVation Protocol, version	RSVP software version.
RSVP protocol	Status of RSVP: **Enabled** or **Disabled**.
R(refresh timer)	Configured time interval used to generate periodic RSVP messages.
K(keep multiplier)	Number of RSVP messages that can be lost before an RSVP state is declared stale.
Preemption	Currently configured preemption capability: **Aggressive**, **Disabled**, or **Normal**. The default is **Normal**.
Soft-preemption cleanup	Time, in seconds, that an LSP is kept after it has been soft preempted. This is a global property of the RSVP protocol.

Table 123: show rsvp version Output Fields (continued)

Field Name	Field Description
Graceful deleting timeout	Currently configured value for the **graceful-deletion-timeout** statement. The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.
NSR Mode	Status of the nonstop active routing feature for RSVP on the restarting device: **Disabled**, **Enabled/Master**, or **Enabled/Standby**.
NSR State	State of the nonstop active routing feature for RSVP on the restarting device. Possible values are: • **Idle** • **TE-link sync complete** • **Neighbor sync complete** • **Path state sync complete** • **Resv state sync complete** • **Bypass sync complete** • **Init sync complete**
Setup protection	Status of point-to-point and point-to-multipoint LSP setup protection configuration on the device: **Enabled** or **Disabled**.
Route Session-Id count	Total count of session IDs associated with the combination of all the RSVP ingress routes. NOTE: Starting in Junos OS Release 16.1, the **show rsvp version** command output displays the **Route Session-Id count** output field by default, irrespective of the presence of associated session IDs. When there are no session IDs associated with any RSVP ingress route, the *Route Session-Id count* value is zero (0).
Graceful restart	Status of the graceful restart feature for RSVP on the restarting routing device: **Enabled** or **Disabled**.
Restart helper mode	Status of the helper mode feature: **Enabled** or **Disabled**. When this feature is enabled, the restarting routing device can help the neighbor with its RSVP restart procedures.
Maximum helper restart time	Number of milliseconds (ms) configured for the maximum helper restart time. The maximum helper restart time is the length of time the routing device waits before declaring that an RSVP neighbor attempting to restart gracefully is down.
Maximum helper recovery time	Number of milliseconds configured for the maximum helper recovery time. The maximum helper recovery time is the amount of time the routing device maintains the state of an RSVP neighbor attempting to restart gracefully.
Restart time	Number of milliseconds that a neighbor waits to receive a Hello message from the restarting node before declaring the node dead and deleting the states.
Recovery time	Number of milliseconds during which the restarting node attempts to recover its lost states with help from its neighbors. Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.

Table 123: show rsvp version Output Fields (continued)

Field Name	Field Description
P2p transit LSP nexthop mode	Point-to-point transit LSP next-hop mode on PTX Series devices. The possible values are **Chained** or **Unchained**.
P2mp transit LSP nexthop mode	Point-to-multipoint transit LSP next-hop mode on PTX Series devices. The possible values are **Chained** or **Unchained**.

Sample Output

show rsvp version

Starting with Junos OS Release 16.1, this command also shows whether enhanced FRR procurers are enabled on the router.

```
user@host> show rsvp version
Resource ReSerVation Protocol, version 1. rfc2205
   RSVP protocol:                Enabled
   R(refresh timer):             30 seconds
   K(keep multiplier):           3
   Preemption:                   Normal
   Soft-preemption cleanup:      30 seconds
   Graceful deletion timeout:    30 seconds
   NSR mode:                     Enabled/Master
   NSR state:                    Init sync complete
   Setup protection:             Disabled
   Route Session-Id count:       1
   Graceful restart:             Disabled
   Restart helper mode:          Enabled
   Maximum helper restart time:  20000 msec
   Maximum helper recovery time: 180000 msec
   Restart time:                 0 msec
   P2p transit LSP nexthop mode: Unchained
   P2mp transit LSP nexthop mode: Unchained
   Enhanced FRR local protection: Enabled
```

traceroute mpls rsvp

Syntax

```
traceroute mpls <rsvp> lsp-name
<detail>
<egress>
<exp>
<logical-system>
<multipoint>
<no-resolve>
<retries>
<source source-address>
<ttl>
```

Release Information Command introduced in Junos OS Release 9.2.
egress, **multipoint**, and **ttl** options added in Junos OS Release 11.2.

Description Trace route to a remote host for an MPLS LSP signaled by RSVP. Use **traceroute mpls rsvp** as a debugging tool to locate MPLS label-switched path (LSP) forwarding issues in a network. (Currently supported for IPv4 packets only.)

Options ***lsp-name***—Specify the name of the LSP to be traced.

detail—(Optional) Display detailed output.

egress—(Optional) Request that a specific point-to-multipoint egress node reply to the trace route. The trace route would follow the associated sub-LSP to the egress node.

exp—(Optional) Specify the class of service to use when sending probes. The range of values is 0 through 7. The default value is 7.

logical-system—(Optional) Specify the name of the logical system for the traceroute attempt.

multipoint—(Optional) Perform a trace route on a point-to-multipoint LSP.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

retries—(Optional) Specify the number of times to resend probe. The range of values is 1 through 9. The default value is 3.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl—(Optional) Specify the number of hops to follow before forcing the trace route to quit.

Required Privilege Level network

List of Sample Output

Output Fields

Table 124 on page 2476 describes the output fields for the **traceroute mpls rsvp *lsp-name*** and **traceroute mpls rsvp *lsp-name* detail** commands. Output fields are listed in the approximate order in which they appear.

Table 124: traceroute mpls rsvp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the **traceroute mpls rsvp *lsp-name*** command.	all levels
ttl	Time-to-live value of the labeled packet.	none specified
Label	MPLS label used to forward the packets along the LSP.	none specified
Protocol	Signaling protocol used. For this command, it is RSVP-TE.	none specified
Address	Address of the next hop.	none specified
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null.	none specified
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths). Displays **Success** if the trace to a hop is successful or **Egress** if the trace has reached the last router on the path.	none specified
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	**detail**
Parent	Address of the previous hop. Parent value for the first hop is null.	**detail**
Return Code	Return code for reporting the result of processing the echo request by the receiver.	**detail**
Sender timestamp	Displays the timestamp when the MPLS echo request is sent to the next hop.	**detail**
Receiver timestamp	Timestamp when the echo request from the previous hop is received and acknowledged with an echo response by the next hop.	**detail**
Response time	Time for the echo request to reach the receiver.	**detail**

Table 124: traceroute mpls rsvp Output Fields (continued)

Field Name	Field Description	Level of Output
MTU	Size of the largest packet that includes the label stack forwarded to the next hop.	**detail**
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none.	**detail**
Label stack	Label stack used to forward the packet.	**detail**
Path	Displays the sub-lsp path number for this traceroute, the interface used, and the destination address.	all levels

Sample Output

clear ldp neighbor

Syntax

```
clear ldp neighbor
<instance instance-name>
<logical-system (all | logical-system-name)>
<neighbor>
```

Description Tear down Label Distribution Protocol (LDP) neighbor connections.

Options

none—Tear down connections with all LDP neighbors for all routing instances.

instance *instance name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

neighbor—(Optional) Clear an LDP session for the specified neighbor (IP address) only.

Required Privilege Level clear

Related Documentation

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

clear ldp neighbor

```
user@host> clear ldp neighbor
```

clear ldp session

Syntax

```
clear ldp session
<all>
<destination>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Clear Label Distribution Protocol (LDP) sessions.

Options

all—Clear LDP sessions for all destinations for all routing instances.

destination—(Optional) Clear an LDP session for the specified destination (IP address).

instance *instance-name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

Related Documentation

```

clear ldp statistics

Syntax

```
clear ldp statistics
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Set all Label Distribution Protocol (LDP) statistics to zero.

Options

none—Set all LDP statistics to zero for all routing instances.

instance *instance-name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
size and **sweep** options introduced in Junos OS Release 9.6.
instance option introduced in Junos OS Release 10.0.
p2mp, **root-address**, and **lsp-id** options introduced in Junos OS Release 11.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS LDP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr *ip-address* lsp-id *identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size *bytes*—(Optional) Size of the LSP ping request packet (**88** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

You can configure the ping interval for the **ping mpls ldp** command by specifying a new time in seconds using the **lsp-ping-interval** statement at the **[edit protocols ldp oam]** hierarchy level. For more information, see the *MPLS Applications Feature Guide*.

In asymmetric MTU scenarios, the echo response may be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

List of Sample Output

ping mpls ldp fec count on page 2485
ping mpls ldp p2mp root-addr lsp-id on page 2485

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (**!**) indicates that an echo reply was received. A period (**.**) indicates that an echo reply was not received within the timeout period. An **x** indicates that an

echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls ldp fec count

```
user@host> ping mpls ldp 10.255.245.222 count 10
!!!xxx...x--- lsping statistics ---10 packets transmitted, 3 packets received,
70% packet loss 4 packets received with error status, not counted as received.
```

ping mpls ldp p2mp root-addr lsp-id

```
user@host>ping mpls ldp p2mp root-addr 10.1.1.1/32 lsp-id 1 count 1

show ldp database

Syntax

```
show ldp database
<brief | detail | extensive>
<inet | l2circuit>
<instance instance-name>
<logical-system (all | logical-system-name)>
<p2mp>
<session session>
<summary>
```

Release Information

Command introduced before Junos OS Release 7.4.
summary option introduced in Junos OS Release 14.2.

Description

Display entries in the LDP database.

Options

none—Display standard information about all entries in the LDP database for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

inet | l2circuit—(Optional) Display only IPv4 or Layer 2 circuit bindings.

instance *instance-name*—(Optional) Display routing instance information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

p2mp—(Optional) Display point-to-multipoint binding information.

session *session*—(Optional) Display database for the specified session only. ***session*** is the destination address of the LDP session.

summary—(Optional)—Display summary output. This option displays the number of labels received and advertised for each LDP session.

Output Fields Table 125 on page 2487 describes the output fields for the **show ldp database** command. Output fields are listed in the approximate order in which they appear.

Table 125: show ldp database Output Fields

Field Name	Field Description	Level of Output
Input label database	Label received from the other router.	All levels
Output label database	Label advertised to the other router.	All levels
session-identifier	Session identifier, which includes the local and remote label space identifiers.	All levels
Labels received	Number of labels received from the other router.	All levels
Labels advertised	Number of labels advertised to the other router.	All levels.
Label	Label binding to a route prefix.	All levels

Table 125: show ldp database Output Fields (continued)

Field Name	Field Description	Level of Output

Prefix	Route prefix.
	
	It can be one of the following values:
	
	• IP prefix.
	• Point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.
	• Layer 2 encapsulation type.
	
	Layer 2 encapsulation types are displayed in the format **L2CKT *control word status encapsulation-type vc-number,*** for example, **L2CKT CtflWord FRAME RELAY VC 2**
	
	• ***control-word-status***—Displays whether the use of the control word has been negotiated for this virtual circuit:
	  • **NoCtrlWord**
	  • **CtrlWord**
	• ***encapsulation-type***—Encapsulation type:
	  • **FRAME RELAY**
	  • **ATM AAL5**
	  • **ATM CELL**
	  • **VLAN**
	  • **ETHERNET**
	  • **CISCO_HDLC**
	  • **PPP**
	• **VC number**—Virtual circuit number. It can have any numeric value.
	• **(Stale)**—When you display the LDP database for the neighbor of a restarting router, the bindings leaned from the restarting neighbor are displayed as (Stale). Stale bindings are deleted if they are not refreshed within the recovery time.
		All levels

MTU	MTU of the Layer 2 circuit. MTU is displayed for all encapsulation types except ATM cell encapsulations.	**detail**
VCCV Control Channel types	Virtual Circuit Connection Verification (VCCV) control channel types. • **MPLS router alert label** • **MPLS PW label with TTL=1**	**extensive**
VCCV Control Verification types	The only valid VCCV control verification type is **LSP ping**.	**extensive**
TDM payload size	Size of the Time Division Multiplex (TDM) payload.	All levels
TDM bitrate	Bit rate for the TDM traffic.	All levels
Requested VLAN ID	(VLANs) VLAN identifier of the Layer 2 circuit.	**detail**
Cell bundle size	(ATM cell encapsulations) Maximum number of cells that the Layer 2 circuit can receive in a packet.	**detail**

Table 125: show ldp database Output Fields (continued)

Field Name	Field Description	Level of Output

State	State of the label binding:
	• **Active**—Label binding has been installed and distributed appropriately. A label binding is almost always in this state.
	• **New**—New label that has not yet been distributed.
	  • **MapRcv**—Waiting to receive a label mapping message.
	  • **MapSend**—Waiting to send a label mapping message.
	  • **RelRcv**—Waiting to receive a label release message.
	  • **RelRsnd**—Waiting to receive a label release message before resending label mapping message.
	  • **RelSend**—Waiting to send a label release message.
	  • **ReqSend**—Waiting to send a label request message.
	  • **W/dSend**—Waiting to send a label withdrawal message.
		detail

Age	Time elapsed since the binding was created.	**detail**

show ldp fec-filters

Syntax

```
show ldp fec-filters
<fec>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display information about configured Label Distribution Protocol (LDP) forwarding equivalence class (FEC) filters.

Options

fec—(Optional) Display FEC filter information for the specified FEC.

instance *instance-name*—(Optional) Display FEC filter information for the specified instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

List of Sample Output

show ldp fec-filters on page 2495

Output Fields

Table 126 on page 2495 lists the output fields for the **show ldp fec-filters** command. Output fields are listed in the approximate order in which they appear.

Table 126: show ldp fec-filters Output Fields

Field Name	Field Description
Ingress	Names of the FEC filters on the ingress routers.
Transit	Names of the FEC filters on the transit routers.

Sample Output

show ldp fec-filters

```
user@host> show ldp fec-filters 10/8
10.22.1.2/32
    Ingress: f1-10.22.1.2/32 (index: 3)
    Transit: (null) (index: 0)
```

show ldp interface

Syntax

```
show ldp interface
<brief | detail | extensive>
<interface-name>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description Display the status of Label Distribution Protocol (LDP)-enabled interfaces.

Options

none—Display standard status information about all LDP-enabled interface for all routing instances.

interface-name—(Optional) Display information for the specified interface.

brief | detail | extensive—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display information for the specified routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

List of Sample Output show ldp interface extensive on page 2497

Output Fields Table 127 on page 2496 describes the output fields for the **show ldp interface** command. Output fields are listed in the approximate order in which they appear.

Table 127: show ldp interface Output Fields

Field Name	Field Description	Level of Output
Interface	Interface name.	All levels
Label space ID	Label space identifier that the router is advertising on the interface.	All levels
Nbr count	Number of neighbors on the interface.	All levels
Next hello	How long until the next hello packet is sent on this interface, in seconds.	All levels

Table 127: show ldp interface Output Fields (continued)

Field Name	Field Description	Level of Output
Hello interval	One-third of the negotiated hold time (in seconds). If the user-configured value for the hello interval is smaller than the computed value, the user-configured value is used.	**detail extensive**
Hold time	Configured hold time, in seconds.	**detail extensive**
Transport address	Address to which the neighbor wants the local route to establish the LDP session.	**extensive**
Local hello interval	Locally configured hello interval.	**extensive**

Sample Output

show ldp interface extensive

```
user@host> show ldp interface extensive

Interface            Label space ID        Nbr count   Next hello
 fe-0/0/3.0           10.255.245.6:0           2           0
   Hello interval: 1, Hold time: 15, Transport address: 10.255.245.6
   Local hello interval: 2, Index: 69
```

show ldp neighbor

Syntax

```
show ldp neighbor
<brief | detail | extensive>
<auto-targeted>
<instance instance-name>
<logical-system (all | logical-system-name)>
<neighbor-address>
```

Release Information

Command introduced before Junos OS Release 7.4.
neighbor-address option added in Junos OS Release 8.5.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
auto-targeted option added in Junos OS Release 14.2.

Description

Display Label Distribution Protocol (LDP) neighbor information.

Options

none—Display standard information about LDP neighbors for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

auto-targeted—(Optional) Display information about LDP neighbors that are automatically targeted using the loopback addresses.

instance *instance-name*—(Optional) Display information for the specified routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

neighbor-address—(Optional) Display information about the specified LDP neighbor.

Output Fields

Table 128 on page 2498 describes the output fields for the **show ldp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 128: show ldp neighbor Output Fields

Field Name	Field Description	Level of Output
Address	IP address of the neighbor.	All levels

Table 128: show ldp neighbor Output Fields (continued)

Field Name	Field Description	Level of Output
Interface	Interface over which the neighbor was discovered.	All levels
Label space ID	Label space identifier advertised by the neighbor.	All levels
Hold time	Remaining hold time before the neighbor expires, in seconds.	All levels
Transport address	Address to which the neighbor wants the local route to establish the LDP session.	**detail**
Configuration sequence	Counter that increments whenever the neighbor changes its configuration.	**detail**
Up for	Length of time the LDP neighbor has been in operation.	**detail extensive**
Reference count	Reference count for the LDP neighbor.	**extensive**
Hold time	Displays the neighbor's hold time. The hold time is the proposed hold times for the local and peer routers.	**extensive**
Proposed local/peer	Hold time value proposed by the local router and the peer router.	**extensive**

Sample Output

show ldp neighbor extensive

```
user@host> show ldp neighbor extensive
Address            Interface          Label space ID         Hold Time
 192.168.37.23      so-1/0/0.0         10.255.245.5:0            44

  Up for 00:10:53
  Reference count: 2
  Hold time: 45, Proposed local/peer: 45/45
  Hello interval: 15
  Hello flags: targeted
  Neighbor types: Auto-targeted
```

show ldp overview

Syntax

```
show ldp overview
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switch and QFX Series)

```
show ldp overview
<instance instance-name>
```

Release Information Command introduced in Junos OS Release 11.2.

Description Display LDP overview information.

Options

none— Display standard overview information about LDP for all routing instances.

instance *instance-name*— (Optional) Display LDP overview information for the specified routing instance.

logical-system (all | *logical-system-name*)— (Optional) Display LDP information from systems or a particular logical system on the devices.

Required Privilege Level view

List of Sample Output show ldp overview on page 2503

Output Fields Table 129 on page 2500 lists the output fields for the **show ldp overview** command. Output fields are listed in the approximate order in which they appear.

Table 129: show ldp overview Output Fields

Field Name	Field description	Level of Output
Instance	LDP routing instance.	All Levels
Router ID	Router ID of the routing device.	All Levels
Message ID	Unique identifier of message.	All Levels
Configuration sequence	Value of configuration sequence.	All Levels
Deaggregate	Status of control forwarding equivalence class (FEC) deaggregation on the router. By default it is **disabled** on the router.	All Levels

Table 129: show ldp overview Output Fields (continued)

Field Name	Field description	Level of Output
Explicit null	Advertise label 0 to the egress routing device of an LSP. Explicit null: **enabled** or **disabled**. NOTE: If you do not include the explicit-null statement in the configuration, label 3 (implicit null) is advertised.	All Levels
IPv6 tunneling	Internet Protocol version 6 tunneling: **enabled** or **disabled**.	All Levels
Strict targeted hellos	Prevent LDP sessions from being established with remote neighbors that have not been specifically configured. Strict targeted hellos: **enabled** or **disabled**. NOTE: LDP peers will not respond to targeted hellos coming from a source that is not one of the configured remote neighbors.	All Levels
Loopback if added	Loopback interface is added: **yes** or **no**.	All Levels
Route preference	Default preference value (also known as an administrative distance) assigned to each route that the routing table receives. LDP preference is: **9**	All Levels
Unicast transit LSP chaining	Unicast transit LSP chaining: **enabled** or **disabled**.	All Levels
P2MP transit LSP chaining	P2MP transit LSP chaining: **enabled** or **disabled**.	All Levels
Transit LSP statistics based on route statistics	Transit LSP statistics based on route statistics: **enabled** or **disabled**.	All Levels
Longest match	Longest match for label mapping: **enabled** or **disabled**.	All Levels
Capabilities enabled	Enabled capabilities: **none**	All Levels
Timers	• **Keepalive interval:** Keepalive interval value. • **Keepalive timeout:** Time interval for which the neighbor LDP node waits before determining session failure. • **Link hello interval:** Specify how often the router sends Link Management Protocol (LMP) hello packets. • **Link hello hold time:** Time interval for which an LDP node waits for a hello message before declaring a neighbor is down. • **Targeted hello interval:** Specify how often LDP sends targeted hello messages. • **Targeted hello hold time:** Time interval for which a sending LSR maintains a record of targeted hello messages from the receiving LSR without receipt of another targeted hello message from that LSR. • **Label withdraw delay:** Time interval for withdrawing labels to reduce router workload during IGP convergence.	All Levels

Table 129: show ldp overview Output Fields (continued)

Field Name	Field description	Level of Output
Graceful restart	Graceful restart attributes. • **Restart**– Graceful restart capability: **enabled** or **disabled**. • **Helper**– Standard graceful restart helper capability: **enabled** or **disabled**. • **Restart in process**– Graceful restart in process. • **Reconnect time**– Period of time that a restarting LSR (label switched router) designates to LDP neighbors to wait until the former reestablishes the session after restarting. • **Max neighbor reconnect time**– Maximum reconnect time. • **Recovery time**– Period of time that an LSR preserves its state across the restart. • **Max neighbor recovery time**– Maximum recovery time designated to LDP neighbors by a restarting LSR.	All Levels
Traffic Engineering	• **Bgp igp**– BGP and IGP destinations: **enabled** or **disabled**. When enabled, IGPs use MPLS paths for forwarding traffic. • **Both ribs**– BGP and IGP destinations with routes in both RIBs: **enabled** or **disabled**. • **Mpls forwarding**– MPLS routes used for forwarding: **enabled** or **disabled**.	All Levels
IGP	• **Tracking igp metric**–Cause the IGP route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1). • **Sync session up delay**– Time interval to synchronize LDP session.	All Levels
Session protection	• **Session protection**– Remote neighbor added to LDP configuration which enables protection for all sessions in the corresponding LDP instance: **enabled** or **disabled**. • **Session protection timeout**– Period of time until which the remote neighbor is connected to LSR in the absence of link neighbors.	All Levels
Interface addresses advertising	Advertises interface address.	All Levels
Label allocation	Label accounting information. • **Current number of LDP labels allocated**—Number of labels currently in use. • **Total number of LDP labels allocated**—Cumulative number of labels being allocated. • **Total number of LDP labels freed**—Cumulative number of labels being freed. • **Total number of LDP label allocation failures**—Cumulative number of failures for allocating a label. • **Current number of labels allocated by all protocols**—Number of labels currently being used by routing protocols.	All Levels

Sample Output

show ldp overview

```
user@host> show ldp overview

  Longest Match: enabled
  Capabilities enabled: none
  Timers:
    Keepalive interval: 10, Keepalive timeout: 30
    Link hello interval: 5, Link hello hold time: 15
    Targeted hello interval: 15, Targeted hello hold time: 45
    Label withdraw delay: 60
  Graceful restart:
    Restart: enabled, Helper: enabled, Restart in process: false
    Reconnect time: 60000, Max neighbor reconnect time: 120000
    Recovery time: 160000, Max neighbor recovery time: 240000
  Traffic Engineering:
    Bgp igp: disabled
    Both ribs: disabled
    Mpls forwarding: disabled
  IGP:
    Tracking igp metric: disabled
    Sync session up delay: 10
  Session protection:
    Session protection: disabled
    Session protecton timeout: 0
  Interface addresses advertising:
    192.168.2.1
  Label allocation:
   Current number of LDP labels allocated: 3
   Total number of LDP labels allocated: 3
   Total number of LDP labels freed: 0
   Total number of LDP label allocation failure: 0
   Current number of labels allocated by all protocols: 3
```

show ldp p2mp tunnel

Syntax

```
show ldp p2mp tunnel
<brief | detail | extensive>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information Command introduced in Junos OS Release 13.3.

Description Display LDP point-to-multipoint tunnel table information.

Options

brief | detail | extensive—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Display LDP point-to-multipoint tunnel table information of all logical systems or a particular logical system.

Required Privilege Level View

Sample Output

show ldp p2mp tunnel

    Reference count 2
```

show ldp path

Syntax

```
show ldp path
<brief | detail | extensive>
<destination>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) label-switched paths (LSPs).

Options

none—Display standard information about all LDP LSPs for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

destination—(Optional) Restrict the output to entries that match the specified destination prefix.

instance *instance-name*—(Optional) Display information for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

show ldp path extensive on page 2506

Output Fields

Table 130 on page 2505 describes the output fields for the **show ldp path** command. Output fields are listed in the approximate order in which they appear.

Table 130: show ldp path Output Fields

Field Name	Field Description
Output Session (label)	Session ID and labels that this system has sent using LDP. These correspond to MPLS packets received.
Input Session (label)	Session ID and labels that this system has received using LDP. These correspond to MPLS packets transmitted.
route	MPLS route.
Attached route	Route corresponding to the LSP.
Ingress route	The router acts as the ingress for the LSP.

Table 130: show ldp path Output Fields (continued)

Field Name	Field Description
Reference count	Reference count for the LDP neighbor.
Transit route	Names of the forwarding equivalence class (FEC) filters on the transit routers.
Global label	MPLS label that is used globally.

Sample Output

show ldp path extensive

```
user@host> show ldp path extensive

Output Session (label)          Input Session (label)
10.255.14.220:0(3)              ( )
   Attached route:  10.255.14.221/32
   Reference count: 3, Global label: 3
10.255.14.220:0(100000)         10.255.14.220:0(3)
   Attached route:  10.255.14.220/32, Ingress route
   Reference count: 2, Transit route, Global label: 100000

```

show ldp route

Syntax

```
show ldp route
<brief | detail | extensive>
<destination>
<fec-and-route>
<fec-only>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display the entries in the Label Distribution Protocol (LDP) internal topology table. The internal topology table contains routes from inet.0 and inet.3 and is used when binding a label to a forwarding equivalence class (FEC).

Options

none—Display standard information about all entries in the LDP internal topology table for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

destination—(Optional) Restrict the output to entries that are longer than the specified destination prefix and prefix length.

fec-and-route—Display the show routes and the FECs.

fec-only—Display only LDP FECs.

instance *instance-name*—(Optional) Display entries for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 131 on page 2508 describes the output fields for the **show ldp route** command. Output fields are listed in the approximate order in which they appear.

Table 131: show ldp route Output Fields

Field Name	Field Description
Destination	Destination prefix.
Next-hop intf/lsp/table	Interface that is the next hop to the destination prefix.
Next-hop address	IP address of the next hop.
Session ID	LDP session ID.
Route flags	Information about the route. For example, the **Ingress TTL propagate** flag indicates that the time-to-live (TTL) value is being propagated with the route.
Bound to outgoing label	The route has been bound to LSPs with the label being distributed for that LSP.
Topology entry	The topology that the route is bound to.
Ingress route status	Status of the ingress route. For example, it could be **Active** or **Inactive**.
Last modified	The length of time since the ingress route status last changed.
Last event(s)	The last event that occurred.

Sample Output

show ldp session

Syntax

```
show ldp session
<brief | detail | extensive>
<auto-targeted>
<destination>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.
auto-targeted option added in Junos OS Release 14.2.

Description

Display information about Label Distribution Protocol (LDP) sessions.

Options

none—Display standard information about all LDP sessions for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

auto-targeted—(Optional) Display information about LDP sessions that are automatically targeted using loopback addresses.

destination—(Optional) Restrict LDP session display to the specified address.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If ***instance-name*** is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

Output Fields

Table 132 on page 2516 describes the output fields for the **show ldp session** command. Output fields are listed in the approximate order in which they appear.

Table 132: show ldp session Output Fields

Field Name	Field Description	Level of Output
Address	Transport address of the session.	any

Table 132: show ldp session Output Fields (continued)

Field Name	Field Description	Level of Output
State	State of the session: **Nonexistent**, **Connecting**, **Initialized**, **OpenRec**, **OpenSent**, **Operational**, or **Closing**. The states correspond to the state diagram specified in Internet Draft LDP Specification draft-ietf-mpls-rfc3036bis-01.txt.	any
Connection	TCP connection state: **Closed**, **Opening**, or **Open**.	any
Hold time	Time remaining until the session will be closed, in seconds.	any
Session ID	LDP identifiers of the peers of this session.	detail extensive
Next keepalive	Time until next keepalive is sent, in seconds.	**detail extensive**
Active	Whether the local router is playing the active role in the session and during session establishment.	**detail extensive**
Passive	Whether the local router is playing the passive role in the session and during session establishment.	**detail extensive**
Maximum PDU	Maximum protocol data unit (PDU) size (packet size) for the session.	**detail extensive**
Hold time	Time remaining until the session will be closed, in seconds. This value corresponds to the one configured using the **keepalive-timeout** statement configured at the **[edit protocols ldp]** hierarchy level.	**detail extensive**
Neighbor count	Number of neighbors that are contributing to the session.	**detail extensive**
Neighbor types	Category of LDP session: **discovered** or **auto-targeted**.	any
Keepalive interval	Keepalive interval, in seconds.	**detail extensive**
Connect retry interval	TCP connection retry interval, in seconds.	**detail extensive**
Local address	Local transport address.	**detail extensive**
Remote address	Remote transport address.	**detail extensive**
Up for	Time that this session has been up.	**detail extensive**
Last down	Time since the session last went down.	**detail extensive**

Table 132: show ldp session Output Fields (continued)

Field Name	Field Description	Level of Output
Reason	Reason the session went down: • **Aborted graceful restart** • **Authentication key was changed** • **Bad type length value (TLV)** • **Bad protocol data unit (PDU) packets** • **Command-line interface (CLI) command** • **Connect time expired** • **Connection error** • **Connection reset** • **Error during initialization** • **Hold time expired** • **No adjacency or all adjacencies down** • **Notification received** • **Received notification from peer** • **Unexpected End of File (EOF)** • **Unknown reason**	**detail extensive**
Number of session flaps	Number of times the session changes from up to down.	**detail extensive**
Restarting	LDP is in the process of gracefully restarting.	**detail extensive**
Capabilities advertised	LDP capabilities advertised to a peer.	**detail extensive**
Capabilities received	LDP capabilities received from a peer.	**detail extensive**
Protection	Information about the status of MPLS LDP session protection.	**detail extensive**
restart complete in *nnn* msec	Amount of time (in milliseconds) remaining until graceful restart is declared complete.	**detail extensive**
Authentication type	Shows the longest match MD5 authentication	**detail extensive**

Table 132: show ldp session Output Fields (continued)

Field Name	Field Description	Level of Output
Local	Information about graceful restart for the local end of an LDP session. Graceful restart and helper mode are independent. • **Restart**—Status of the grateful restart feature at the local end of the LDP session: **enabled** or **disabled**. • **Helper mode**—Status of the helper mode feature at the local end of the LDP session: **enabled** or **disabled**. When this feature is enabled, the local end of the LDP session can help the restarting router with its LDP restart procedures. • **Reconnect time**—Amount of time to wait from when a restart is initiated until the router can exchange LDP messages with its neighbors. The default is **60000 msec** and is not configurable. (**Reconnect timeout** refers to "FT Reconnect timeout" in draft-ietf-mpls-ldp-restart-06, *Internet Draft Graceful Restart Mechanism for LDP.)*	**detail extensive**
Remote	Information about graceful restart at the remote end of an LDP session. Graceful restart and helper mode are independent. • **Restart**—Status of the grateful restart feature at the remote end of the LDP session: **enabled** or **disabled**. • **Helper mode**—Status of the helper mode feature at the remote end of the LDP session: **enabled** or **disabled**. When this feature is enabled, the remote end of the LDP session can help the restarting router with its LDP restart procedures. • **Reconnect time**—Amount of time in milliseconds from when a restart is initiated until the remote router can exchange LDP messages with its neighbors.	**detail extensive**
Local maximum recovery time	Amount of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds).	**detail extensive**
Next-hop addresses received	Next-hop addresses received on the session.	**detail extensive**
Queue depth	Number of messages that are queued for sending to the peers in the group.	**extensive**

Table 132: show ldp session Output Fields (continued)

Field Name	Field Description	Level of Output
Message type	Type of message being sent: • **Initialization**—Session initialization negotiation messages sent by an LSR to an LDP peer when the transport connection is established. • **Keeaplive**—Keepalive timer messages sent by an LSR to an LDP peer to keep the session active when there is no information or PDU exchanged between them. • **Notification**—Notification messages (such as state of the LDP session) or error information (such as bad PDU length) sent by an LSR to an LDP peer. • **Address**—Message sent by an LSR to an LDP peer to advertise interface addresses. • **Address withdraw**—Message sent by an LSR to an LDP peer to withdraw a previously advertised interface address. • **Label mapping**—Message sent by an LSR to an LDP peer to advertise label mapping for a forwarding equivalence class (FEC). • **Label request**—Message sent by an LSR to an LDP peer to request a label mapping for an FEC. • **Label withdraw**— Message sent by an LSR to an LDP peer to withdraw a previously advertised FEC-label mapping. • **Label release**—Message sent by an LSR to an LDP peer to notify the peer that a specific FEC-label mapping has been released. • **Label abort**—Message sent by an LSR to an LDP peer to abort a label request message. • **Total**—Messages sent and received during the lifetime of the session. • **Last 5 seconds**—Messages sent and received during the current session.	**extensive**

show ldp statistics

Syntax

```
show ldp statistics
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) statistics.

Options

none—Display LDP statistics for all routing instances.

instance *instance-name*—(Optional) Display information for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

List of Sample Output

show ldp statistics on page 2526

Output Fields

Table 133 on page 2523 lists the output fields for the **show ldp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 133: show ldp statistics Output Fields

Field Name	Field Description
Total Sent, Received	Total number of each message type sent and received.
Last 5 seconds Sent, Received	Number of each message type sent and received in the last 5 seconds.

Table 133: show ldp statistics Output Fields (continued)

Field Name	Field Description
Message type	LDP message types: • **Hello**—Messages that enable LDP nodes to discover one another and to detect the failure of a neighbor or of the link to the neighbor. • **Initialization**—Messages that indicate an LDP session has started. • **Keepalive**—Messages that ensure that the keepalive timeout is not exceeded. • **Notification**—Advisory information and signal error information. • **Address**—Messages with address information. • **Address withdrawal**—Messages regarding address withdrawal. • **Label mapping**—Messages with label mapping information. • **Label request**—Request for a label mapping from a neighboring router. • **Label withdrawal**—Withdrawal message sent by the downstream LSR to recall a label that it previously mapped. If an LSR that has received a label mapping subsequently determines that it no longer needs that label, it can send a label release message that frees the label for use. • **Label release**—Message sent by the downstream LSR to recall a label that it previously mapped. If an LSR that has received a label mapping subsequently determines that it no longer needs that label, it can send a label release message that frees the label for use. • **Label abort**—Messages about label interruptions. • **All UDP**—All hello messages sent by LSRs to the well-known UDP port, 646. • **All TCP**—All LDP session messages.

Table 133: show ldp statistics Output Fields (continued)

Field Name	Field Description
Event type	LDP events and errors: • **Sessions opened**—Number of LDP sessions that have been opened. • **Sessions closed**—Number of LDP sessions that have been closed. • **Topology changes**—Number of changes to the known LDP topology. • **No interface**—Number of missing interface address messages. When a new LDP session is initialized and before sending label lapping or label request messages, the LSR advertises its interface addresses with one or more address messages. • **No session**—Number of missing session messages. Session messages are used to establish, maintain, and terminate sessions between LDP peers. • **No adjacency**—The exchange of hello adjacency messages results in the creation of an adjacency. The LDP identifier, together with the sender's LDP identifier in the PDU header, enables the receiver to match the initialization message with one of its hello adjacencies. If there is no matching hello adjacency, the LSR sends a session the initialization message is rejected. • **Unknown version**—The LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment. • **Malformed PDU**—An LDP PDU received on a TCP connection for an LDP session is malformed if the LDP identifier in the PDU header is unknown to the receiver, or if it is known but is not the LDP identifier associated by the receiver with the LDP peer for this LDP session. An LDP PDU is considered to be malformed if the LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment. An LDP PDU is considered malformed if the PDU length field is too small (less than 14) or too large (greater than maximum PDU length). • **Malformed message**—Malformed LDP messages that are part of the LDP discovery mechanism are handled by silently discarding them. An LDP message is malformed if the message type is unknown. If the message type is less than 0x8000 (high order bit = 0), it is an error signaled by the unknown message type status code. An LDP message is considered to be malformed If the message length is too large, meaning that the message extends beyond the end of the containing LDP PDU. The LDP message is considered to be malformed if the message length is too small, meaning that it is smaller than the smallest possible value component. The LDP message is considered to be malformed if the message is missing one or more mandatory parameters. • **Unknown message type**—If the message type is less than 0x8000 (high order bit = 0) or greater than or equal to 0x8000 (high order bit = 1) it is considered to be an unknown message. • **Inappropriate message**—The message is not of the type that the receiver expects to receive. • **Malformed TLV**—The TLV lLength is too large or the receiver cannot decode the TLV value. This can indicate an issue in either the sending or receiving LSR. • **Bad TLV value**—The TLV Length is too large. • **Missing TLV**—The TLV is missing one or more mandatory parameters. • **PDU too large**—The PDF is greater than the maximum PDU length. Section "Initialization Message" in RFC 5036 describes how the maximum PDU length for a session is determined.
Total	Total number of each event or error.
Last 5 seconds	Number of each event or error in the last 5 seconds.

Sample Output

show ldp statistics

```
user@host> show ldp statistics

Message type                Total                 Last 5 seconds
                          Sent      Received          Sent      Received

Malformed PDU                           0                0
Malformed message                       0                0
Unknown message type                    0                0
Inappropriate message                   0                0
Malformed TLV                           0                0
Bad TLV value                           0                0
Missing TLV                             0                0
PDU too large                           0                0
```

show ldp traffic-statistics

Syntax

```
show ldp traffic-statistics
<instance instance-name>
<logical-system (all | logical-system-name)>
<p2mp>
```

Release Information

Command introduced before Junos OS Release 7.4.
p2mp option added in Junos OS Release 11.2.
Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) traffic statistics.

NOTE: If nonstop active routing features is configured, **show ldp traffic-statistics** command is not supported on backup Routing Engines.

Options

none—Display LDP traffic statistics for all routing instances.

instance *instance-name*—(Optional) Display LDP traffic statistics for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

p2mp—(Optional) Display only the data traffic statistics for a point-to-multipoint LSP.

Additional Information

To collect output from this command on a periodic basis, configure the traffic-statistics statement for the LDP protocol. For more information, see the *Junos MPLS Applications Configuration Guide*.

show ldp traffic-statistics p2mp (Multipoint LDP with Multicast-Only Fast Reroute) on page 2529

Output Fields Table 134 on page 2528 lists the output fields for the **show ldp traffic-statistics** command. Output fields are listed in the approximate order in which they appear.

Table 134: show ldp traffic-statistics Output Fields

Field Name	Field Description
Message type	LDP message types.
FEC	Forwarding equivalence class (FEC) for which LDP traffic statistics are collected. For P2MP LSPs, FEC appears as a combination of root address and the LSP ID (**root_addr:lsp_id**). For M-LDP P2MP LSPs, FEC appears as a combination of root address multicast source address, and multicast group address (**root_addr:lsp_id/grp,src**).
Type	Type of traffic originating from a router, either **Ingress** (originating from this router) or **Transit** (forwarded through this router).
Packets	Number of packets passed by the FEC since its LSP came up.
Bytes	Number of bytes of data passed by the FEC since its LSP came up.
Shared	Whether a label is shared by prefixes: **Yes** or **No**. A **Yes** value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
Nexthop	The next hop address for P2MP LSPs. (This is the downstream LDP Session ID.)
Label	For multipoint LDP with multicast-only fast reroute (MoFRR), the multipoint LDP node selects two separate upstream peers and sends two separate labels, one to each upstream peer. The same algorithm described in RFC 6388 is used to select the primary upstream path. The backup upstream path selection again uses the same algorithm but excludes the primary upstream LSR as a candidate. Two streams of MPLS traffic are sent to the egress node from the two different upstream peers. The MPLS traffic from only one of the upstream neighbors is selected as the primary path to accept the traffic, and the other becomes the backup path. The traffic on the backup path is dropped. When the primary upstream path fails, the traffic from the backup path is then accepted. The multipoint LDP node selects the two upstream paths based on the interior gateway protocol (IGP) root node next hop. Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.
Backup route	For multipoint LDP with MoFRR, the route that is used if the primary route becomes unavailable.

Sample Output

show ldp traffic-statistics

```
user@host> show ldp traffic-statistics

Release Information

Command introduced in Junos OS Release 11.2.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display information about authentication keychains configured for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol.

Options

none—Display information about authentication keychains.

brief | detail—(Optional) Display the specified level of output.

Output Fields

Table 135 on page 2531 describes the output fields for the **show security keychain** command. Output fields are listed in the approximate order in which they appear.

Table 135: show security keychain Output Fields

Field Name	Field Description	Level of Output
keychain	The name of the keychain in operation.	All levels
Active-ID Send	Number of routing protocols packets sent with the active key.	All levels
Active-ID Receive	Number of routing protocols packets received with the active key.	All levels
Next-ID Send	Number of routing protocols packets sent with the next key.	All levels
Next-ID Receive	Number of routing protocols packets received with the next key.	All levels
Transition	Amount of time until the current key will be replaced with the next key in the keychain.	All levels
Tolerance	Configured clock-skew tolerance, in seconds, for accepting keys for a key chain.	All levels
Id	Identification number configured for the current key.	**detail**

Table 135: show security keychain Output Fields (continued)

Field Name	Field Description	Level of Output
Algorithm	Authentication algorithm configured for the current key.	**detail**
State	State of the current key. The value can be: • **receive** • **send** • **send-receive** For the active key, the **State** can be **send-receive**, **send**, or **receive**. For keys that have a future start time, the **State** is **inactive**. Compare the **State** field to the **Mode** field.	**detail**
Option	For IS-IS only, the option determines how Junos OS encodes the message authentication code in routing protocol packets. The values can be: • **basic**—Based on RFC 5304. • **isis-enhanced**—Based on RFC 5310. The default value is **basic**. When you configure the **isis-enhanced** option, Junos OS sends RFC 5310-encoded routing protocol packets and accepts both RFC 5304-encoded and RFC 5310-encoded routing protocol packets that are received from other devices. When you configure **basic** (or do not include the **options** statement in the key configuration) Junos OS sends and receives RFC 5304-encoded routing protocols packets, and drops 5310-encoded routing protocol packets that are received from other devices. Because this setting is for IS-IS only, the TCP and the BFD protocol ignore the encoding option configured in the key.	**detail**
Start-time	Time that the current key became active.	**detail**
Mode	Mode of each key (Informational only.) The value can be • **receive** • **send** • **send-receive** The mode of the key is based on the configuration. Suppose you configure two keys, one with a start-time of today and the other with a start-time of next week. For both keys, the **Mode** can be **send-receive**, **send**, or **receive**, regardless of the configured start-time. Compare the **Mode** field to the **State** field.	**detail**

```

Release Information

Command introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Trace route to a remote host for an MPLS label-switched path signaled by the LDP. Use **traceroute mpls ldp** as a debugging tool to locate MPLS label-switched path forwarding issues in a network. (Currently supported for IPv4 packets only.)

Options

fec—Specify the IP address and optional prefix of the forwarding equivalence class (FEC).

destination *ip-address*—(Optional) Specify the destination address to use when sending probes.

Values: The destination IP address must be within the 127.0.0.0/8 IP address space for Operation, Administration, and Maintenance (OAM) packets.

detail—(Optional) Display detailed output.

exp *exp*—(Optional) Specify the class-of-service to use when sending probes.

Range: 0 through 7

Default: 7

fanout *fanout-number*—(Optional) Specify the maximum number of nexthops to search per node.

Range: 1 through 16

Default: 16

logical-system—(Optional) Specify the name of the logical system for the traceroute attempt.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

paths ***maximum-paths***—(Optional) Specify the maximum number of paths to search.

Range: 1 through 255

Default: 16

pipe-mode—(Optional) Specify to trace only nodes that understand LDP FEC.

In an interoperation with other vendor devices or devices running Junos OS Release that do not support tracing of hierarchical LSPs as described in RFC 6424, continuous non-complaint probe status is displayed in the **traceroute mpls ldp** command output. To avoid this LDP loop creation, use the **pipe-mode** option with the **traceroute mpls ldp** ***fec*** command.

NOTE: Even after using the **traceroute mpls ldp** ***fec*** **pipe-mode** command, one or more intermediate transit nodes that do not understand LDP FEC can return non-complaint probe status in the command output.

retries ***retries-number***—(Optional) Specify the number of times to resend probe values.

Range: 1 through 9

Default: 3

routing-instance ***routing-instance-name***—(Optional) Specify the name of the routing instance for the traceroute attempt.

source ***source-address***—(Optional) Specify the source address of the outgoing traceroute packets.

ttl ***value***—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds.

Range: 1 through 125

Default: 64

update—(Optional) Update database contents with traceroute results.

wait ***seconds***—(Optional) Specify the number of seconds to wait before resending a probe.

Range: 5 through 15

Default: 10

Required Privilege Level network

traceroute mpls ldp on page 2536
traceroute mpls ldp detail on page 2537

Output Fields Table 114 on page 2415 describes the output fields for the **traceroute mpls ldp** ***fec*** command and the **traceroute mpls ldp** ***fec*** **detail** commands. Output fields are listed in the approximate order in which they appear.

Table 136: traceroute mpls ldp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the **traceroute mpls ldp** *fec* command.	all levels
ttl	Time to live value of the labeled packet.	none specified
Label	Outgoing label used for forwarding the packet along the label-switched paths.	none specified
Protocol	Signaling protocol used. For this command, it is LDP.	none specified
Address	Address of the next hop.	none specified
Previous Hop	Address of the previous hop. Previous hop address of the first hop is **null**.	none specified
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).	none specified
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	**detail**
Parent	Address of the previous hop. Parent value for the first hop is **null**.	**detail**
Return Code	Return code for reporting the result of processing the echo request by the receiver.	**detail**
Response time	Time for the echo request to reach the receiver.	**detail**
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is **none**.	**detail**
Label Stack	Label stack used to forward the packet.	**detail**

<status>
```

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about the configured circuit cross-connect (CCC) connections.

Options

none—Display the standard level of output for all configured CCC connections.

all—(Optional) Display all connections.

brief | extensive—(Optional) Display the specified level of output. Use history to display information about connection history. Use labels to display labels used for transmit and receive LSPs. Use status to display information about the connection and interface status.

interface-switch—(Optional) Display interface switch connections only.

lsp-switch—(Optional) Display LSP switch connections only.

p2mp-receive-switch—(Optional) Display point-to-multipoint LSP to local interfaces switch connections only.

p2mp-transmit-switch—(Optional) Display local interface to point-to-multipoint LSP switch connections only.

remote-interface-switch—(Optional) Display remote interface switch connections only.

down | up | up-down—(Optional) Display nonoperational, operational, or both kinds of connections.

history—(Optional) Display information about connection history.

labels—(Optional) Display labels used for transmit and receive.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name—(Optional) Display information about the specified connection only.

status—(Optional) Display information about the connection and interface status.

Required Privilege Level view

Output Fields Table 79 on page 2261 describes the output fields for the **show connections** command. Output fields are listed in the approximate order in which they appear.

Table 137: show connections Output Fields

Field Name	Field Description
CCC and TCC connections [Link Monitoring On I Off]	Whether link monitoring is enabled: **On** or **Off**.
Legend for Status (St)	Connection or circuit status. See the output's legend for an explanation of the status field values.
Legend for connection types	Type of connection: • **if-sw**—Layer 2 switching cross-connect. • **rmt-if**—Remote interface switch. While graceful restart is in progress, **rmt-if** will display a state **(St)** of **Restart**. • **lsp-sw**—LSP stitching cross-connect. While graceful restart is in progress, **lsp-sw** will display a state **(St)** of **Restart**.
Legend for circuit types	Type of circuits: • **intf**—Interface circuit. • **tlsp**—Transmit LSP circuit. • **rlsp**—Receive LSP circuit.
Connection/Circuit	Name of the configured CCC connection.
Type	Type of connection.
St	State of the connection.

Table 137: show connections Output Fields (continued)

Field Name	Field Description
Time last up	Time that the connection or circuit last transitioned to the **Up** (operational) state.
# Up trans	Number of times that the connection or circuit has transitioned to the **Up** (operational) state.

Sample Output

show connections

```
user@switch> show connections
CCC and TCC connections [Link Monitoring On]
  Legend for status (St)              Legend for connection types
  UN -- uninitialized                 if-sw:  interface switching
  NP -- not present                   rmt-if: remote interface switching
  WE -- wrong encapsulation           lsp-sw: LSP switching
  DS -- disabled
  Dn -- down                          Legend for circuit types

Release Information Command introduced before Junos OS Release 7.4.
Option **bridge-domain** introduced in Junos OS Release 7.5
Option **learning-vlan-id** introduced in Junos OS Release 8.4
Options **all** and **vlan** introduced in Junos OS Release 9.6.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

NOTE: The Routing Engine copies the forwarding table to the Packet Forwarding Engine, the part of the router that is responsible for forwarding packets. To display the entries in the Packet Forwarding Engine's forwarding table, use the **show pfe route** command.

Options **none**—Display the routes in the forwarding tables. By default, the **show route forwarding-table** command does not display information about private, or internal, forwarding tables.

detail | extensive | summary—(Optional) Display the specified level of output.

all—(Optional) Display routing table entries for all forwarding tables, including private, or internal, tables.

bridge-domain (all | *bridge-domain-name*)—(MX Series routers only) (Optional) Display route entries for all bridge domains or the specified bridge domain.

ccc *interface-name*—(Optional) Display route entries for the specified circuit cross-connect interface.

destination *destination-prefix*—(Optional) Destination prefix.

family *family*—(Optional) Display routing table entries for the specified family: **bridge (ccc | destination | detail | extensive | interface-name | label | learning-vlan-id | matching | multicast | summary | table | vlan | vpn)**, **ethernet-switching**, **evpn**, **fibre-channel**, **fmembers**, **inet**, **inet6**, **iso**, **mcsnoop-inet**, **mcsnoop-inet6**, **mpls**, **satellite-inet**, **satellite-inet6**, **satellite-vpls**, **tnp**, **unix**, **vpls**, or **vlan-classification**.

interface-name *interface-name*—(Optional) Display routing table entries for the specified interface.

label *name*—(Optional) Display route entries for the specified label.

lcc *number*—(TX Matrix and TX matrix Plus routers only) (Optional) On a routing matrix composed of a TX Matrix router and T640 routers, display information for the

specified T640 router (or line-card chassis) connected to the TX Matrix router. On a routing matrix composed of the TX Matrix Plus router and T1600 or T4000 routers, display information for the specified router (line-card chassis) connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

learning-vlan-id *learning-vlan-id*—(MX Series routers only) (Optional) Display learned information for all VLANs or for the specified VLAN.

matching *matching*—(Optional) Display routing table entries matching the specified prefix or prefix length.

multicast—(Optional) Display routing table entries for multicast routes.

table —(Optional) Display route entries for all the routing tables in the main routing instance or for the specified routing instance. If your device supports logical systems, you can also display route entries for the specified logical system and routing instance. To view the routing instances on your device, use the **show route instance** command.

vlan (all | *vlan-name*)—(Optional) Display information for all VLANs or for the specified VLAN.

vpn *vpn*—(Optional) Display routing table entries for a specified VPN.

Output Fields Table 106 on page 2353 lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified, or when the **detail** keyword is used instead of the **extensive** keyword.

Table 138: show route forwarding-table Output Fields

Field Name	Field Description	Level of Output
Logical system	Name of the logical system. This field is displayed if you specify the **table** ***logical-system-name/routing-instance-name*** option on a device that is configured for and supports logical systems.	All levels
Routing table	Name of the routing table (for example, inet, inet6, mpls).	All levels

Table 138: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Enabled protocols	The features and protocols that have been enabled for a given routing table. This field can contain the following values: • BUM hashing—BUM hashing is enabled. • MAC Stats—Mac Statistics is enabled. • Bridging—Routing instance is a normal layer 2 bridge. • No VLAN—No VLANs are associated with the bridge domain. • All VLANs—The **vlan-id all** statement has been enabled for this bridge domain. • Single VLAN—Single VLAN ID is associated with the bridge domain. • MAC action drop—New MACs will be dropped when the MAC address limit is reached. • Dual VLAN—Dual VLAN tags are associated with the bridge domain • No local switching—No local switching is enabled for this routing instance.. • Learning disabled—Layer 2 learning is disabled for this routing instance. • MAC limit reached—The maximum number of MAC addresses that was configured for this routing instance has been reached. • VPLS—The VPLS protocol is enabled. • No IRB l2-copy—The no-irb-layer-2-copy feature is enabled for this routing instance. • ACKed by all peers—All peers have acknowledged this routing instance. • BUM Pruning—BUM pruning is enabled on the VPLS instance. • Def BD VXLAN—VXLAN is enabled for the default bridge domain. • EVPN—EVPN protocol is enabled for this routing instance. • Def BD OVSDB—Open vSwitch Database (OVSDB) is enabled on the default bridge domain. • Def BD Ingress replication—VXLAN ingress node replication is enabled on the default bridge domain. • L2 backhaul—Layer 2 backhaul is enabled. • FRR optimize—Fast reroute optimization • MAC pinning—MAC pinning is enabled for this bridge domain. • MAC Aging Timer—The MAC table aging time is set per routing instance. • EVPN VXLAN—This routing instance supports EVPN with VXLAN encapsulation. • PBBN—This routing instance is configured as a provider backbone bridged network. • PBN—This routing instance is configured as a provider bridge network. • ETREE—The ETREE protocol is enabled on this EVPN routing instance. • ARP/NDP suppression—EVPN ARP NDP suppression is enabled in this routing instance. • Def BD EVPN VXLAN—EVPN VXLAN is enabled for the default bridge domain. • MPLS control word—Control word is enabled for this MPLS routing instance.	All levels
Address family	Address family (for example, **IP**, **IPv6**, **ISO**, **MPLS**, and **VPLS**).	All levels
Destination	Destination of the route.	**detail extensive**

Table 138: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Route Type (Type)	How the route was placed into the forwarding table. When the **detail** keyword is used, the route type might be abbreviated (as shown in parentheses): • **cloned** (**clon**)—(TCP or multicast only) Cloned route. • **destination** (**dest**)—Remote addresses directly reachable through an interface. • **destination down** (**iddn**)—Destination route for which the interface is unreachable. • **interface cloned** (**ifcl**)—Cloned route for which the interface is unreachable. • **route down** (**ifdn**)—Interface route for which the interface is unreachable. • **ignore** (**ignr**)—Ignore this route. • **interface** (**intf**)—Installed as a result of configuring an interface. • **permanent** (**perm**)—Routes installed by the kernel when the routing table is initialized. • **user**—Routes installed by the routing protocol process or as a result of the configuration.	All levels
Route Reference (RtRef)	Number of routes to reference.	**detail extensive**
Flags	Route type flags: • **none**—No flags are enabled. • **accounting**—Route has accounting enabled. • **cached**—Cache route. • **incoming-iface** ***interface-number***—Check against incoming interface. • **prefix load balance**—Load balancing is enabled for this prefix. • **rt nh decoupled**—Route has been decoupled from the next hop to the destination. • **sent to PFE**—Route has been sent to the Packet Forwarding Engine. • **static**—Static route.	**extensive**
Next hop	IP address of the next hop to the destination.	**detail extensive**

Table 138: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Next hop Type (Type)	Next-hop type. When the **detail** keyword is used, the next-hop type might be abbreviated (as indicated in parentheses): • **broadcast (bcst)**—Broadcast. • **deny**—Deny. • **discard (dscd)** —Discard. • **hold**—Next hop is waiting to be resolved into a unicast or multicast type. • **indexed (idxd)**—Indexed next hop. • **indirect (indr)**—Indirect next hop. • **local (locl)**—Local address on an interface. • **routed multicast (mcrt)**—Regular multicast next hop. • **multicast (mcst)**—Wire multicast next hop (limited to the LAN). • **multicast discard (mdsc)**—Multicast discard. • **multicast group (mgrp)**—Multicast group member. • **receive (recv)**—Receive. • **reject (rjct)**—Discard. An ICMP unreachable message was sent. • **resolve (rslv)**—Resolving the next hop. • **unicast (ucst)**—Unicast. • **unilist (ulst)**—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.	**detail extensive**
Index	Software index of the next hop that is used to route the traffic for a given prefix.	**detail extensive** none
Route interface-index	Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.	**extensive**
Reference (NhRef)	Number of routes that refer to this next hop.	**detail extensive** none
Next-hop interface (Netif)	Interface used to reach the next hop.	**detail extensive** none
Weight	Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible (see the **Balance** field description).	**extensive**
Balance	Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a router is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.	**extensive**
RPF interface	List of interfaces from which the prefix can be accepted. Reverse path forwarding (RPF) information is displayed only when **rpf-check** is configured on the interface.	**extensive**

Sample Output

show route forwarding-table

```
user@host> show route forwarding-table

show route forwarding-table extensive (RPF)

The next example is based on the following configuration, which enables an RPF check on all routes that are learned from this interface, including the interface route:

```
so-1/1/0 {
    unit 0 {
        family inet {
            rpf-check;
            address 192.0.2.2/30;
        }
```

```
    }
}
```

```
user@host> show route forwarding-table extensive
```

```
Routing table: inet [Index 0]
Internet:
...
...
Destination:  192.0.2.3/32
  Route type: destination
  Route reference: 0                   Route interface-index: 67
  Flags: sent to PFE
  Nexthop: 192.0.2.3
  Next-hop type: broadcast             Index: 328      Reference: 1
  Next-hop interface: so-1/1/0.0
  RPF interface: so-1/1/0.0
```

show route forwarding-table (dynamic list next hop)

The **show route forwarding table** output shows the two next hop elements for a multihomed EVPN destination.

```
user@host> show route forwarding-table label 299952 extensive
```

```
MPLS:

Destination:  299952
  Route type: user
  Route reference: 0                   Route interface-index: 0
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: sent to PFE, rt nh decoupled
  Next-hop type: indirect              Index: 1048575  Reference: 2
  Nexthop:
  Next-hop type: composite             Index: 601      Reference: 2
  Next-hop type: indirect              Index: 1048574  Reference: 3
  Nexthop: 1.0.0.4
  Next-hop type: Push 301632, Push 299776(top) Index: 600 Reference: 2
  Load Balance Label: None
  Next-hop interface: ge-0/0/1.0
  Next-hop type: indirect              Index: 1048577  Reference: 3
  Nexthop: 1.0.0.4

CHAPTER 44

PCEP Operational Commands

- clear path-computation-client statistics
- request path-computation-client active-pce
- show path-computation-client active-pce
- show path-computation-client lsp
- show path-computation-client statistics
- show path-computation-client status
- show spring-traffic-engineering

clear path-computation-client statistics

Syntax

```
clear path-computation-client statistics
<pce-id | all>
```

Release Information

Statement introduced in Junos OS Release 12.3.
Statement introduced in Junos OS Release 16.1R3 for QFX Series switches.
Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Clear Path Computation Element (PCE) statistics.

Options

pce-id—(Optional) Clear statistics of the specified PCE.

all—(Optional) Clear statistics of all available PCEs configured on the path computation client (PCC).

Required Privilege Level

clear

Related Documentation

- show path-computation-client statistics on page 2572

List of Sample Output

clear path-computation-client statistics pce-id on page 2564
clear path-computation-client statistics all on page 2564

Output Fields

When you enter this command, you are not provided feedback on the status of your request.

Sample Output

clear path-computation-client statistics pce-id

```
user@host> clear path-computation-client statistics pce1
```

clear path-computation-client statistics all

```
user@host> clear path-computation-client statistics all
```

request path-computation-client active-pce

Syntax request path-computation-client active-pce *pce-id*

Release Information Command introduced in Junos OS Release 12.3.
Command introduced in Junos OS Release 16.1R3 for QFX Series switches.
Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description Request a new active Path Computation Element (PCE).

Options ***pce-id***—Unique user defined ID for this PCE.

Required Privilege Level request

Related Documentation
- show path-computation-client active-pce on page 2566

List of Sample Output request path-computation-client active-pce pce-id on page 2565

Sample Output

request path-computation-client active-pce pce-id

```
user@host> request path-computation-client active-pce pce1
```

show path-computation-client active-pce

Syntax

```
show path-computation-client active-pce
<brief | detail>
```

Release Information

Command introduced in Junos OS Release 12.3.
Command introduced in Junos OS Release 16.1R3 for QFX Series switches.
Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Displays information about the current active Path Computation Element (PCE).

Options

none—Display brief information about the current active PCE.

brief | detail—(Optional) Display the specific level of output.

Required Privilege Level

view

Related Documentation

List of Sample Output

show path-computation-client active-pce on page 2568
show path-computation-client active-pce detail on page 2569

Output Fields

Table 139 on page 2566 describes the output fields for the **show path-computation-client active-pce** command. Output fields are listed in the approximate order in which they appear.

Table 139: show path-computation-client active-pce Output Fields

Field Name	Field Description	Level of Output
IP address	IP address of the current active PCE.	All levels
Priority	Active PCE priority.	All levels
PCE status	Active PCE state: • PCE_STATE_NEW— Initial PCEP session state. • PCE_STATE_RECONNECT—Trying to re-establish TCP connection with the PCEP peer. • PCE_STATE_CONNECTING—Establishing TCP connection with the PCEP peer. • PCE_STATE_CONNECTED—TCP connection established with the PCEP peer. • PCE_STATE_SYNC—Open messages exchanged with the PCEP peer and entering SYNC state. • PCE_STATE_UP—PCEP session established.	All levels

Table 139: show path-computation-client active-pce Output Fields (continued)

Field Name	Field Description	Level of Output
Session type	Active PCE type: • PCE_TYPE_STATELESS—Does not learn LSP state information form PCC. • PCE_TYPE_STATEFUL—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update LSP state. A PCC maintains synchronization with the PCE. • PCE_TYPE_STATEFULACTIVE—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegate control of their LSPs to the PCE.	All levels
PCE-mastership	PCE mastership state: • main—Current active PCE. • backup—Backup PCE.	All levels
PCRpts	Number of PC report (PCRpt) messages sent by PCC to a stateful PCE to report current state of LSP(s).	All levels
PCUpdates	Number of PC update (PCUpd) messages sent by a PCE to a PCC to update LSP parameters.	All levels
Local Keepalive timer	Keepalive timer used by or for the PCC.	All levels
Local Dead timer	Dead timer used by or for the PCC.	All levels
Remote Keepalive timer	Keepalive timer used by or for the PCE.	All levels
Remote Dead timer	Dead timer used by or for the PCE.	All levels
PCErr-recv	Information about type, value, and number of PC Error messages received.	All levels
Max unknown messages	Maximum number of unknown messages received for a PCEP session. Recommended value is **5**. If the number of unknown messages received by a PCC or PCE is greater than or equal to the maximum number, the PCEP session is closed.	detail
Keepalives received	Number of Keepalive messages received by a PCC from a PCE.	detail
Keepalives sent	Number of Keepalive messages sent by a PCC to a PCE.	detail
Dead timer	Dead timer used by the current active PCE.	detail
Elapsed as main current	Time (in seconds) the PCE is in the main mastership state.	detail
Elapsed as main total	Time (in seconds) the PCE became main from the last PCCD restart.	detail

Table 139: show path-computation-client active-pce Output Fields (continued)

Field Name	Field Description	Level of Output
Unknown msgs/min rate	Number of unknown messages received per minute.	detail
Session failures	Number of PCEP session failures with the PCE.	detail
Delegation timeout in	Time (in seconds) left for LSP delegation to timeout.	detail
Delegation failures	Number of LSP delegation failures.	detail
Connection down	Time (in seconds) since the PCEP session is down.	detail
PCErr-sent	Information about type, value, and number of PC Error messages sent.	All levels

show path-computation-client lsp

Syntax

```
show path-computation-client lsp
<extensive>
<p2mp>
```

Release Information

Command introduced in Junos OS Release 17.2R1 on MX Series routers.
extensive and **p2mp** options introduced in Junos OS Release 18.3R1 on MX Series routers.

Description

Display the state of label-switched paths (LSPs) known to the Path Computation Client (PCC).

Options

none—Display information about LSPs known to the PCC.

extensive—(Optional) Display extensive level of output about each known LSP - point-to-point and point-to-multipoint LSPs.

p2mp—(Optional) Display information about known point-to-multipoint Path Computation Element (PCE)-initiated LSPs.

Output Fields

Table 140 on page 2570 describes the output fields for the **show path-computation-client lsp** command. Output fields are listed in the approximate order in which they appear.

Table 140: show path-computation-client lsp Output Fields

Field Name	Field Description
Name	Name of the LSP.
Status	LSP status: • Up • Down
PLSP-Id	PCEP-specific unique identifier for each LSP. The ID is created by the PCC for the lifetime of a PCEP session.

Table 140: show path-computation-client lsp Output Fields (continued)

Field Name	Field Description
LSP-Type	Type of LSP: • External provisioned • Local
Controller	Name of the external path computing entity.
Path-Setup-Type	Protocol used to set up the LSP: • RSVP-TE • SPRING-TE
Template	Name of template used.
P2MP name	Name of the point-to-multipoint tree that includes the sub-LSPs of the PCE-initiated LSP.
P2MP Branch Name	Name of the branch sub-LSP that makes up the point-to-multipoint tree of the PCE-initiated LSP.

Sample Output

show path-computation-client lsp

```
user@host> show path-computation-client lsp

  Name                                Status            PLSP-Id  LSP-Type

```

show path-computation-client status

Syntax

```
show path-computation-client status
<extensive>
```

Release Information

Command introduced in Junos OS Release 17.2R1 on MX Series routers.
extensive option introduced in Junos OS Release 18.3R1 on MX Series routers.

Description

Display the status of the Path Computation Client (PCC).

Options

none—Display the status of the PCC.

extensive—(Optional) Display extensive information about the PCC including point-to-point and point-to-multipoint PCE-initiated LSPs.

For point-to-multipoint PCE-initiated LSPs, the extensive output displays the point-to-multipoint LSP tree and branches separately for a PCEP session.

List of Sample Output

show path-computation-client status on page 2578

Output Fields

Table 142 on page 2577 describes the output fields for the **show path-computation-client status** command. Output fields are listed in the approximate order in which they appear.

Table 142: show path-computation-client status Output Fields

Field Name	Field Description
Total number of LSPs	Number of LSPs in total.
Static LSPs	Status of point-to-point and point-to-multipoint static LSPs.
Externally controlled LSPs	Status of point-to-point and point-to-multipoint LSPs that are controlled by a PCE.
Externally provisioned LSPs	Status of point-to-point and point-to-multipoint LSPs that are provisioned by a PCE.
Orphaned LSPs	Status of LSPs that are in the orphaned state because of PCEP session failure.

Sample Output

show path-computation-client status

```
user@host> show path-computation-client status extensive
Session Type Provisioning Status
pce1 Stateful Active On Up

LSP Summary
Total number of LSPs : 0

Static LSPs : 0
P2P : 0
P2MP : 0/0 (branches/trees)

Externally controlled LSPs : 0
P2P : 0
P2MP : 0/0 (branches/trees)

Externally provisioned LSPs : 0/16000 (current/limit)
P2P : 0
P2MP : 0/0 (branches/trees)

Orphaned LSPs : 0
pce1 (main)
Delegated : 0
P2P : 0
P2MP : 0/0 (branches/trees)

Externally provisioned : 0
P2P : 0
P2MP : 0/0 (branches/trees)
```

show spring-traffic-engineering

Syntax

```
show spring-traffic-engineering (lsp | overview)
<brief | detail>
<logical-system (all | logical-system-name)>
<name lsp-name>
```

Release Information Command introduced in Junos OS Release 17.2 on MX Series routers.

Description Display ingress details of SPRING traffic engineering.

Options

lsp—Display details of SPRING traffic engineered LSPs on the ingress router or the Path Computation Client (PCC).

overview—Display overview of SPRING traffic engineered LSPs on the ingress router, or the PCC.

brief | detail—(Optional) Display the specific level of output.

name *lsp-name*—(Optional) Regular expression for LSP names to match for displaying SPRING traffic engineering details.

Output Fields Table 143 on page 2579 describes the output fields for the **show spring-traffic-engineering** command. Output fields are listed in the approximate order in which they appear.

Table 143: show spring-traffic-engineering Output Fields

Field Name	Field Description
To	IP address of the SPRING-TE LSP destination.
State	State of the SPRING-TE LSP: • Up • Down

Table 143: show spring-traffic-engineering Output Fields (continued)

Field Name	Field Description
LSP Name	Name of the SPRING-TE LSP.
S-ERO	Source Explicit Route Object (ERO), or LSP path.
Bandwidth	Bandwidth allocated for the SPRING-TE LSP.
Route preference	Route preference of the SPRING-TE LSP.
Number of LSPs	Statistics of the total number of SPRING-TE LSPs and the LSP state.
External controllers	Name of the LSP external controller. By default the only supported external controller is **pccd**.

Sample Output

show spring-traffic-engineering lsp name

```
user@host> show spring-traffic-engineering lsp name lsp-name
```

```
To          State        LSP Name
    10.1.1.7   Up           to-R1
```

show spring-traffic-engineering lsp detail

```
user@host> show spring-traffic-engineering lsp detail
```

```
10.1.1.7
    State: Up
    S-ERO: 24.1.1.1(80001) 10.1.1.3(4509) 11.2.1.2(9875)
    Bandwidth: 100M
    The above line is in IP address(label) format.
```

show spring-traffic-engineering overview

```
user@host> show spring-traffic-engineering overview
