#### YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

#### END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <https://support.juniper.net/support/eula/>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

# Table of Contents

	About the Documentation . . . . .	lvii
	Documentation and Release Notes . . . . .	lvii
	Using the Examples in This Manual . . . . .	lvii
	Merging a Full Example . . . . .	lviii
	Merging a Snippet . . . . .	lviii
	Documentation Conventions . . . . .	lix
	Documentation Feedback . . . . .	lx
	Requesting Technical Support . . . . .	lx
	Self-Help Online Tools and Resources . . . . .	lxii
	Creating a Service Request with JTAC . . . . .	lxii
<b>Part 1</b>	<b>MPLS Overview</b>	
<b>Chapter 1</b>	<b>Introduction to MPLS . . . . .</b>	<b>3</b>
	MPLS Overview . . . . .	4
	Why Use MPLS? . . . . .	4
	Why Not Use MPLS? . . . . .	5
	How Do I Configure MPLS? . . . . .	5
	Configure the MPLS LER (Ingress) Switch and the Egress Switch . . . . .	5
	Configure LSRs for MPLS . . . . .	6
	What Does the MPLS Protocol Do? . . . . .	6
	How Does MPLS Interface to Other Protocols? . . . . .	7
	If I Have Used Cisco MPLS, What Do I Need to Know? . . . . .	7
	MPLS Overview for ACX Series Universal Metro Routers . . . . .	8
	MPLS for EX Series Switches Overview . . . . .	9
	Benefits of MPLS . . . . .	9
	Additional Benefits of MPLS and Traffic Engineering . . . . .	10
	MPLS Applications . . . . .	10
	Link-Layer Support in MPLS . . . . .	11
	Supported MPLS Scaling Values . . . . .	11
	Supported MPLS Standards . . . . .	13
	IP and MPLS Packets on Aggregated Interfaces . . . . .	16
	BGP Destinations . . . . .	17
	IGP and BGP Destinations . . . . .	18
	Install Prefix IGP Overview . . . . .	19
	MPLS Feature Support on QFX Series and EX4600 Switches . . . . .	20
	MPLS Commands Supported by QFX Series and EX4600 Switches . . . . .	20
	MPLS Features Supported by QFX Series and EX4600 Switches . . . . .	20

	Understanding MPLS Components for QFX Series and EX4600 Switches . . . . .	30
	Provider Edge Switches . . . . .	30
	MPLS Protocol and Label-Switched Paths . . . . .	30
	IP Over MPLS for Customer Edge Interfaces . . . . .	30
	BGP Layer 3 VPN Configuration . . . . .	31
	Routing Instances for Layer 3 VPN . . . . .	31
	Routing Instances for Layer 2 VPN and Layer 3 VPN . . . . .	31
	Ethernet Encapsulation for Layer 2 VPN . . . . .	31
	Provider Switch . . . . .	31
	Components Required for All Switches in the MPLS Network . . . . .	32
	Interior Gateway Protocol . . . . .	32
	Traffic Engineering . . . . .	32
	MPLS Protocol . . . . .	32
	RSVP . . . . .	33
	Family mpls . . . . .	33
	Understanding MPLS and Path Protection on EX Series Switches . . . . .	34
	MPLS Limitations on QFX Series and EX4600 Switches . . . . .	34
	MPLS Limitations on QFX10000 Switches . . . . .	35
	MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches . . . . .	35
	MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches . . . . .	37
	MPLS Limitations on QFX3500 Switches . . . . .	38
	MPLS Configuration Overview . . . . .	39
	MPLS Configuration Guidelines . . . . .	39
	TTL Processing on Incoming MPLS Packets . . . . .	40
<b>Part 2</b>	<b>Configuring MPLS and Associated Features</b>	
<b>Chapter 2</b>	<b>Configuring MPLS . . . . .</b>	<b>45</b>
	Configuring MPLS . . . . .	45
	Example: Enabling MPLS . . . . .	45
	Example: Configuring MPLS on EX8200 and EX4500 Switches . . . . .	48
	Verifying That MPLS Is Working Correctly . . . . .	64
	Verifying the Physical Layer on the Switches . . . . .	64
	Verifying the Routing Protocol . . . . .	65
	Verifying the Core Interfaces Being Used for the MPLS Traffic . . . . .	65
	Verifying RSVP . . . . .	65
<b>Chapter 3</b>	<b>Configuring MPLS on Provider and Provider Edge Devices . . . . .</b>	<b>67</b>
	Configuring MPLS on Provider Edge Switches . . . . .	67
	Configuring the Ingress PE Switch . . . . .	68
	Configuring the Egress PE Switch . . . . .	69
	Configuring MPLS on Provider Switches . . . . .	71
	Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure) . . . . .	72
	Configuring the Ingress PE Switch . . . . .	73
	Configuring the Egress PE Switch . . . . .	75
	Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure) . . . . .	77

	Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure) . . . . .	81
<b>Chapter 4</b>	<b>Configuring Bidirectional Forwarding Detection (BFD) for MPLS . . . . .</b>	<b>83</b>
	Configuring Bidirectional Forwarding Detection for MPLS (CLI Procedure) . . . . .	83
	Configuring BFD on Provider Edge and Provider Switches for an LDP-Based LSP . . . . .	84
	Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP . . . . .	86
	BFD-Triggered Local Repair for Rapid Convergence . . . . .	87
	Understanding BFD-Triggered Local Protection . . . . .	87
	Purpose of BFD-Triggered Local Repair . . . . .	87
	Configuring BFD-Triggered Local Repair . . . . .	88
	Disabling BFD-Triggered Local Repair . . . . .	88
	Configuring BFD for MPLS IPv4 LSPs . . . . .	89
	Configuring BFD for RSVP-Signaled LSPs . . . . .	90
	Configuring a Failure Action for the BFD Session on an RSVP LSP . . . . .	91
<b>Chapter 5</b>	<b>Configuring Firewall Filters, System Log Messages, and SNMP for MPLS . . . . .</b>	<b>93</b>
	Configuring MPLS Firewall Filters and Policers on Switches . . . . .	93
	Configuring an MPLS Firewall Filter . . . . .	95
	Applying an MPLS Firewall Filter to an MPLS Interface . . . . .	95
	Configuring Policers for LSPs . . . . .	95
	Configuring MPLS Firewall Filters and Policers on Routers . . . . .	96
	Configuring MPLS Firewall Filters . . . . .	96
	Examples: Configuring MPLS Firewall Filters . . . . .	97
	Configuring Policers for LSPs . . . . .	98
	LSP Policer Limitations . . . . .	99
	Example: Configuring an LSP Policer . . . . .	100
	Configuring Automatic Policers . . . . .	100
	Configuring Automatic Policers for LSPs . . . . .	101
	Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs . . . . .	102
	Configuring Automatic Policers for Point-to-Multipoint LSPs . . . . .	103
	Disabling Automatic Policing on an LSP . . . . .	103
	Example: Configuring Automatic Policing for an LSP . . . . .	103
	Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets . . . . .	104
	Configuring System Log Messages and SNMP Traps for LSPs . . . . .	104
<b>Chapter 6</b>	<b>Configuring Graceful Restart for MPLS . . . . .</b>	<b>107</b>
	Configuring MPLS-Signaled LSPs to Use GRE Tunnels . . . . .	107
	Example: Configuring MPLS-Signaled LSPs to Use GRE Tunnels . . . . .	107
	Graceful Restart and MPLS-Related Protocols . . . . .	108
	LDP . . . . .	108
	RSVP . . . . .	109
	CCC and TCC . . . . .	109

<b>Chapter 7</b>	<b>Configuring Link, Node, and Path Protection for MPLS</b> . . . . .	<b>111</b>
	Node-Link Protection Overview . . . . .	111
	Path Protection Overview . . . . .	113
	Configuring Path Protection in an MPLS Network (CLI Procedure) . . . . .	113
	Configuring the Primary Path . . . . .	115
	Configuring the Secondary Path . . . . .	115
	Configuring the Revert Timer . . . . .	116
	Preventing Use of a Path That Previously Failed . . . . .	117
	Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP . . . . .	117
	Understanding MPLS Inter-AS Link Protection . . . . .	117
	Example: Configuring MPLS Inter-AS Link-Node Protection . . . . .	119
	Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services . . . . .	133
	Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services . . . . .	137
	Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector . . . . .	156
	Verifying Path Protection in an MPLS Network . . . . .	183
	Verifying the Primary Path . . . . .	183
	Verifying the RSVP-Enabled Interfaces . . . . .	184
	Verifying a Secondary Path . . . . .	185
<b>Chapter 8</b>	<b>Configuring MPLS Load Balancing and Statistics</b> . . . . .	<b>187</b>
	MPLS Encapsulated Payload Load-balancing Overview . . . . .	187
	Configuring MPLS Encapsulated Payload for Load Balancing . . . . .	189
	Configuring MPLS to Gather Statistics . . . . .	189
	On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview . . . . .	191
	Importance of Measuring Packet Loss and Delay . . . . .	191
	Defining Packet Loss, Delay, and Throughput . . . . .	191
	Packet Loss and Delay Measurement Mechanisms . . . . .	192
	Packet Loss and Delay Metrics . . . . .	192
	Packet Loss and Delay Measurement Concepts . . . . .	193
	Packet Loss and Delay Measurement Functionality . . . . .	195
	Packet Loss and Delay Features . . . . .	196
	Example: Configuring On-Demand Loss and Delay Measurement . . . . .	198
	Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs . . . . .	207
	Configuring On-Demand Loss and Delay Measurement . . . . .	215
	Configuring Pro-Active Loss and Delay Measurements . . . . .	216
<b>Chapter 9</b>	<b>Configuring Shared Risk Link Group (SRLG)</b> . . . . .	<b>219</b>
	SRLG Overview . . . . .	219
	Example: Configuring SRLG . . . . .	220
	Example: Excluding SRLG Links Completely for the Secondary LSP . . . . .	230
	Example: Configuring SRLG with Link Protection . . . . .	236
	Example: Configuring SRLG with Link Protection with the exclude-srlg Option . . . . .	258

<b>Chapter 10</b>	<b>Configuring MPLS Tunnels</b>	<b>281</b>
	Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks	281
	Configuring IPv6 Tunneling for MPLS (CLI Procedure)	290
	Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels	291
	Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels Overview	305
	Example: Configuring Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels	308
	Next-Hop-Based Dynamic Tunnel Localization Overview	319
	Benefits of Next-Hop-Based Dynamic Tunnel Localization	320
	Use Cases for Next-Hop-Based Dynamic Tunnel Localization	320
	Traffic Handling with Localization of Next-Hop-Based Dynamic Tunnels	320
	Configuring Next-Hop-Based Dynamic Tunnels Localization	321
	Configuring Localization for New Next-Hop-Based Dynamic Tunnels	321
	Configuring Localization for Existing Next-Hop-Based Dynamic Tunnels	322
	Troubleshooting Localized Next-Hop-Based Dynamic Tunnels	323
	Unsupported Features for Next-Hop-Based Dynamic Tunnels Localization	325
<b>Part 3</b>	<b>MPLS Label-Switched Paths</b>	
<b>Chapter 11</b>	<b>MPLS Label Operations</b>	<b>329</b>
	MPLS Label Overview	329
	MPLS Label Allocation	329
	Operations on MPLS Labels	331
	Understanding MPLS Label Operations	332
	MPLS Label-Switched Paths and MPLS Labels	332
	Reserved Labels	333
	MPLS Label Operations	333
	Penultimate-Hop Popping and Ultimate-Hop Popping	335
	Understanding MPLS Label Manager	335
	Understanding MPLS Label Operations on EX Series Switches	336
	MPLS Label-Switched Paths and MPLS Labels on the Switches	336
	Reserved Labels	337
	MPLS Label Operations on the Switches	337
	Penultimate-Hop Popping and Ultimate-Hop Popping	338
	How a Packet Travels Along an LSP	339
	Types of LSPs	339
	Scope of LSPs	340
	Special MPLS Labels	340
	Entropy Label Support in Mixed Mode Overview	342
	Abstract Hops for MPLS LSPs Overview	342
	Understanding Abstract Hops	342
	Benefits of Using Abstract Hops	343
	Specifying a Sequence of Constraint Combinations	343
	Avoiding New Network Configuration on Transit Nodes	344
	Combining Centralized and Distributed Path Computation Paradigms	344

	Junos OS Implementation of Abstract Hops . . . . .	345
	Defining Abstract Hops . . . . .	345
	Using Abstract Hops in Path Constraint . . . . .	348
	Path Computation and Backtracking . . . . .	352
	Sample Backtracking . . . . .	352
	Example: Configuring Abstract Hops for MPLS LSPs . . . . .	353
	Configuring the Maximum Number of MPLS Labels . . . . .	370
	Configuring MPLS to Pop the Label on the Ultimate-Hop Router . . . . .	371
	Advertising Explicit Null Labels to BGP Peers . . . . .	372
<b>Chapter 12</b>	<b>MPLS LSP Routes . . . . .</b>	<b>375</b>
	MPLS and Routing Tables . . . . .	376
	MPLS and Traffic Protection . . . . .	378
	Fast Reroute Overview . . . . .	379
	Configuring Fast Reroute . . . . .	381
	Detour Merging Process . . . . .	382
	Detour Computations . . . . .	383
	Fast Reroute Path Optimization . . . . .	384
	Configuring the Optimization Interval for Fast Reroute Paths . . . . .	384
	Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table . . . . .	384
	Constrained-Path LSP Computation . . . . .	386
	How CSPF Selects a Path . . . . .	387
	CSPF Path Selection Tie-Breaking . . . . .	388
	Computing CSPF Paths Offline . . . . .	389
	Configuring CSPF Tie Breaking . . . . .	389
	Disabling Constrained-Path LSP Computation . . . . .	390
	Configuring Load Balancing Based on MPLS Labels . . . . .	391
	Configuring Load Balancing Based on MPLS Labels on ACX Series Routers . . .	395
	Example: Configuring a Constrained-Path LSP for Which Junos OS Makes All	
	Forwarding Decisions . . . . .	399
	Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most	
	Forwarding Decisions and Considers Hop Constraints . . . . .	399
	Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most	
	Forwarding Decisions and the Secondary Path Is Explicit . . . . .	400
	Path Computation for LSPs on an Overloaded Router . . . . .	401
	Computing Backup Paths for LSPs Using Fate Sharing . . . . .	402
	Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts . .	402
	Enabling IGP Shortcuts . . . . .	404
	LSPs Qualified in IGP Shortcut Computations . . . . .	404
	IGP Shortcut Applications . . . . .	404
	IGP Shortcuts and Routing Tables . . . . .	405
	IGP Shortcuts and VPNs . . . . .	405
	Advertising LSPs into IGP . . . . .	406
	Selecting a Forwarding LSP Next Hop . . . . .	407
	Example: Assigning Different Forwarding Next-Hop LSPs to Different Destination	
	Prefixes . . . . .	407
	ECMP Flow-Based Forwarding on ACX Series Routers . . . . .	408

<b>Chapter 13</b>	<b>MPLS LSP Routers</b>	<b>411</b>
	Routers in an LSP	411
	Configuring the Ingress and Egress Router Addresses for LSPs	412
	Configuring the Ingress Router Address for LSPs	412
	Configuring the Egress Router Address for LSPs	412
	Preventing the Addition of Egress Router Addresses to Routing Tables	413
	Configuring the Ingress Router for MPLS-Signaled LSPs	414
	Creating Named Paths	414
	Examples: Creating Named Paths	415
	Configuring Alternate Backup Paths Using Fate Sharing	416
	Configuring Fate Sharing	416
	Implications for CSPF	417
	Implications for CSPF When Fate Sharing with Bypass LSPs	418
	Example: Configuring Fate Sharing	418
	Configuring the Intermediate and Egress Routers for MPLS-Signaled LSPs	418
	Configuring the Connection Between Ingress and Egress Routers	419
	Pinging LSPs	419
	Pinging MPLS LSPs	420
	Pinging Point-to-Multipoint LSPs	420
	Pinging the Endpoint Address of MPLS LSPs	420
	Pinging CCC LSPs	421
	Pinging Layer 3 VPNs	421
	Support for LSP Ping and Traceroute Commands Based on RFC 4379	421
<b>Chapter 14</b>	<b>Configuring MPLS LSPs</b>	<b>423</b>
	Configuring LSP Metrics	424
	Configuring Dynamic LSP Metrics	424
	Configuring Static LSP Metrics	424
	Configuring a Text Description for LSPs	425
	Configuring MPLS Soft Preemption	427
	Configuring Priority and Preemption for LSPs	428
	Configuring Administrative Groups for LSPs	429
	Configuring Extended Administrative Groups for LSPs	431
	Configuring Preference Values for LSPs	433
	Disabling Path Route Recording by LSPs	434
	Achieving a Make-Before-Break, Hitless Switchover for LSPs	434
	Specifying the Amount of Time the Router Waits to Switch Over to New Paths	435
	Specifying the Amount of Time to Delay the Tear Down of Old Paths	436
	Achieving a Hitless, MBB Switchover Without Artificial Delays	436
	Optimizing Signaled LSPs	437
	Configuring the Smart Optimize Timer for LSPs	440
	Limiting the Number of Hops in LSPs	442
	Configuring the Bandwidth Value for LSPs	442
	Automatic Bandwidth Allocation for LSPs	442

Configuring Automatic Bandwidth Allocation for LSPs .....	443
Configuring Automatic Bandwidth Allocation on LSPs .....	444
Configuring the Automatic Bandwidth Allocation Interval .....	445
Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth .....	446
Configuring the Automatic Bandwidth Adjustment Threshold .....	447
Configuring a Limit on Bandwidth Overflow and Underflow Samples .....	447
Configuring Passive Bandwidth Utilization Monitoring .....	449
Requesting Automatic Bandwidth Allocation Adjustment .....	450
Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs .....	451
Configuring an LSP Across ASs .....	455
Disabling Normal TTL Decrementing .....	456
Configuring Adaptive LSPs .....	457
Damping Advertisement of LSP State Changes .....	459
Configuring Primary and Secondary LSPs .....	459
Configuring Primary and Secondary Paths for an LSP .....	459
Configuring the Revert Timer for LSPs .....	460
Specifying the Conditions for Path Selection .....	461
Configuring Hot Standby of Secondary Paths for LSPs .....	462
Configuring Corouted Bidirectional LSPs .....	463
Configuring the Entropy Label for LSPs .....	466
Example: Configuring an Entropy Label for a BGP Labeled Unicast LSP .....	467
Configuring Ultimate-Hop Popping for LSPs .....	487
Configuring Static LSPs .....	491
Configuring the Ingress Router for Static LSPs .....	491
Example: Configuring the Ingress Router .....	493
Configuring the Intermediate (Transit) and Egress Routers for Static LSPs .....	494
Example: Configuring an Intermediate Router .....	495
Example: Configuring an Egress Router .....	496
Configuring a Bypass LSP for the Static LSP .....	497
Configuring the Protection Revert Timer for Static LSPs .....	497
Configuring Static Unicast Routes for Point-to-Multipoint LSPs .....	497
Configuring Static Label Switched Paths for MPLS (CLI Procedure) .....	498
Configuring the Ingress PE Switch .....	499
Configuring the Provider and the Egress PE Switch .....	500
Configuring Static Label Switched Paths for MPLS .....	501
Configuring the Ingress PE Switch .....	502
Configuring the Provider and the Egress PE Switch .....	502
Static Segment Routing Label Switched Path .....	503
Understanding Static Segment Routing LSP in MPLS Networks .....	503
Static Segment Routing Provisioning .....	504
Benefits of using Static Segment Routing of Label Switched Path ...	505
Non-Colored Static Segment Routing LSP .....	505
Static Segment Routing LSP Provisioning .....	506
Limitations .....	506
Example: Configuring Static Segment Routing Label Switched Path .....	507

	Configuring Explicit-Path LSPs . . . . .	522
	Example: Configuring an Explicit-Path LSP . . . . .	523
	Configuring Static Adjacency Segment Identifier for Aggregate Ethernet Member Links Using Single-hop Static LSP . . . . .	524
<b>Chapter 15</b>	<b>Configuring Point-to-Multipoint LSPs . . . . .</b>	<b>527</b>
	Point-to-Multipoint LSPs Overview . . . . .	527
	Understanding Point-to-Multipoint LSPs . . . . .	529
	Point-to-Multipoint LSP Configuration Overview . . . . .	530
	Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP . . . . .	531
	Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs . . . . .	551
	Configuring the Primary Point-to-Multipoint LSP . . . . .	552
	Configuring a Branch LSP for Point-to-Multipoint LSPs . . . . .	552
	Configuring the Branch LSP as a Dynamic Path . . . . .	553
	Configuring the Branch LSP as a Static Path . . . . .	553
	Configuring Inter-Domain Point-to-Multipoint LSPs . . . . .	553
	Configuring Link Protection for Point-to-Multipoint LSPs . . . . .	554
	Configuring Graceful Restart for Point-to-Multipoint LSPs . . . . .	555
	Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs . . . . .	556
	Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP . . . . .	556
	Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs . . . . .	557
	Enabling Point-to-Point LSPs to Monitor Egress PE Routers . . . . .	557
	Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases . . . . .	558
<b>Chapter 16</b>	<b>Configuring Container LSPs . . . . .</b>	<b>559</b>
	Dynamic Bandwidth Management Using Container LSP Overview . . . . .	559
	Understanding RSVP Multipath Extensions . . . . .	559
	Junos OS RSVP Multipath Implementation . . . . .	560
	Current Traffic Engineering Challenges . . . . .	560
	Using Container LSP as a Solution . . . . .	564
	Accommodating the New Demand X . . . . .	564
	Creating New LSPs to Meet Demand X . . . . .	565
	Assigning Bandwidth to the New LSPs . . . . .	565
	Controlling the LSP Paths . . . . .	565
	Junos OS Container LSP Implementation . . . . .	566
	Container LSP Terminology . . . . .	566
	LSP Splitting . . . . .	567
	LSP Merging . . . . .	569
	Node and Link Protection . . . . .	571
	Naming Convention . . . . .	571
	Normalization . . . . .	572
	Constraint-Based Routing Path Computation . . . . .	577
	Sampling . . . . .	578
	Support for NSR, IPG-FA, and Static Routes . . . . .	578
	Configuration Statements Supported for Container LSPs . . . . .	581
	Impact of Configuring Container LSPs on Network Performance . . . . .	585

	Supported and Unsupported Features . . . . .	586
	Example: Configuring Dynamic Bandwidth Management Using Container LSP . . . . .	587
	Configuring Dynamic Bandwidth Management Using Container LSP . . . . .	615
<b>Chapter 17</b>	<b>Configuring Pop-and-Forward LSPs . . . . .</b>	<b>621</b>
	RSVP-TE Pop-and-Forward LSP Tunnels Overview . . . . .	621
	Benefits of RSVP-TE Pop-and-Forward LSP Tunnels . . . . .	621
	Pop-and-Forward LSP Tunnel Terminology . . . . .	622
	Pop-and-Forward LSP Tunnel Label and Signaling . . . . .	622
	Pop-and-Forward LSP Tunnel Label Stacking . . . . .	623
	Construction of Label Stack at the Ingress . . . . .	623
	Auto-Delegation of Label Stack . . . . .	624
	Pop-and-Forward LSP Tunnel Link Protection . . . . .	625
	RSVP-TE Pop-and-Forward LSP Tunnel Supported and Unsupported Features . . . . .	626
<b>Part 4</b>	<b>MPLS Signalling Protocols</b>	
<b>Chapter 18</b>	<b>Configuring RSVP . . . . .</b>	<b>631</b>
	RSVP Overview . . . . .	633
	RSVP Operation Overview . . . . .	633
	Understanding the RSVP Signaling Protocol . . . . .	634
	RSVP Fundamentals . . . . .	634
	Bandwidth Reservation Requirement . . . . .	635
	Explicit Route Objects . . . . .	635
	Constrained Shortest Path First . . . . .	636
	Link Coloring . . . . .	637
	RSVP-TE protocol extensions for FRR . . . . .	637
	Junos OS RSVP Protocol Implementation . . . . .	640
	RSVP Authentication . . . . .	640
	Supported RSVP Standards . . . . .	640
	RSVP and IGP Hello Packets and Timers . . . . .	642
	RSVP Message Types . . . . .	642
	Understanding RSVP Automatic Mesh . . . . .	643
	Path Messages . . . . .	644
	Resv Messages . . . . .	644
	PathTear Messages . . . . .	644
	ResvTear Messages . . . . .	645
	PathErr Messages . . . . .	645
	ResvErr Messages . . . . .	645
	ResvConfirm Messages . . . . .	645
	RSVP Reservation Styles . . . . .	645
	RSVP Refresh Reduction . . . . .	646
	MTU Signaling in RSVP . . . . .	647
	How the Correct MTU Is Signaled in RSVP . . . . .	648
	Determining an Outgoing MTU Value . . . . .	649

MTU Signaling in RSVP Limitations . . . . .	649
Minimum RSVP Configuration . . . . .	649
Configuring RSVP and MPLS . . . . .	650
Example: Configuring RSVP and MPLS . . . . .	651
Configuring RSVP Interfaces . . . . .	651
Configuring RSVP Refresh Reduction . . . . .	651
Determining the Refresh Reduction Capability of RSVP Neighbors . . . . .	653
Configuring the RSVP Hello Interval . . . . .	653
Configuring RSVP Authentication . . . . .	654
Configuring the Bandwidth Subscription for Class Types . . . . .	655
Configuring the RSVP Update Threshold on an Interface . . . . .	655
Configuring RSVP for Unnumbered Interfaces . . . . .	656
Configuring RSVP Node-ID Hellos . . . . .	656
Example: Configuring RSVP-Signaled LSPs . . . . .	657
Example: Configuring RSVP Automatic Mesh . . . . .	662
Configuring Hello Acknowledgments for Nonsession RSVP Neighbors . . . . .	665
Switching LSPs Away from a Network Node . . . . .	666
Configuring RSVP Setup Protection . . . . .	667
Configuring Load Balancing Across RSVP LSPs . . . . .	668
Configuring RSVP Automatic Mesh . . . . .	669
Configuring Timers for RSVP Refresh Messages . . . . .	670
Preempting RSVP Sessions . . . . .	671
Configuring MTU Signaling in RSVP . . . . .	671
Enabling MTU Signaling in RSVP . . . . .	672
Enabling Packet Fragmentation . . . . .	672
Configuring Ultimate-Hop Popping for LSPs . . . . .	672
Configuring RSVP to Pop the Label on the Ultimate-Hop Router . . . . .	676
Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs . . . . .	677
Tracing RSVP Protocol Traffic . . . . .	678
Examples: Tracing RSVP Protocol Traffic . . . . .	679
Link Protection . . . . .	681
Multiple Bypass LSPs for Link Protection . . . . .	682
Node Protection . . . . .	682
Fast Reroute, Node Protection, and Link Protection . . . . .	684
LSP Protection Overview . . . . .	684
LSP Protection Types Comparison . . . . .	684
One-to-One Backup Implementation . . . . .	685
Facility Backup Implementation . . . . .	686
Configuring Link Protection on Interfaces Used by LSPs . . . . .	687
Configuring Bypass LSPs . . . . .	689
Configuring the Next-Hop or Next-Next-Hop Node Address for Bypass LSPs . . . . .	689
Configuring Administrative Groups for Bypass LSPs . . . . .	689
Configuring the Bandwidth for Bypass LSPs . . . . .	690
Configuring Class of Service for Bypass LSPs . . . . .	691
Configuring the Hop Limit for Bypass LSPs . . . . .	691
Configuring the Maximum Number of Bypass LSPs . . . . .	691
Disabling CSPF for Bypass LSPs . . . . .	692
Disabling Node Protection for Bypass LSPs . . . . .	692

	Configuring the Optimization Interval for Bypass LSPs . . . . .	693
	Configuring an Explicit Path for Bypass LSPs . . . . .	693
	Configuring the Amount of Bandwidth Subscribed for Bypass LSPs . . . . .	694
	Configuring Priority and Preemption for Bypass LSPs . . . . .	694
	Configuring Node Protection or Link Protection for LSPs . . . . .	695
	Configuring Inter-AS Node and Link Protection . . . . .	696
	RSVP Graceful Restart . . . . .	696
	RSVP Graceful Restart Standard . . . . .	697
	RSVP Graceful Restart Terminology . . . . .	697
	RSVP Graceful Restart Operation . . . . .	697
	Processing the Restart Cap Object . . . . .	698
	Configuring RSVP Graceful Restart . . . . .	699
	Enabling Graceful Restart for All Routing Protocols . . . . .	699
	Disabling Graceful Restart for RSVP . . . . .	699
	Disabling RSVP Helper Mode . . . . .	700
	Configuring the Maximum Helper Recovery Time . . . . .	700
	Configuring the Maximum Helper Restart Time . . . . .	700
	RSVP LSP Tunnels Overview . . . . .	700
	Example: RSVP LSP Tunnel Configuration . . . . .	702
	Verifying Your Work . . . . .	715
	Router 0 . . . . .	715
	Router 1 . . . . .	719
	Configuring Link Management Protocol Peers . . . . .	721
	Configuring Link Management Protocol Traffic Engineering Links . . . . .	721
	Configuring Peer Interfaces in OSPF and RSVP . . . . .	722
	Defining Label-Switched Paths for the FA-LSP . . . . .	722
	Establishing FA-LSP Path Information . . . . .	723
	Option: Tearing Down RSVP LSPs Gracefully . . . . .	723
<b>Chapter 19</b>	<b>Configuring LDP . . . . .</b>	<b>725</b>
	LDP Introduction . . . . .	726
	Understanding the LDP Signaling Protocol . . . . .	727
	Example: Configuring LDP-Signaled LSPs . . . . .	727
	Supported LDP Standards . . . . .	730
	Junos OS LDP Protocol Implementation . . . . .	731
	LDP Operation . . . . .	731
	LDP Message Types . . . . .	732
	Discovery Messages . . . . .	732
	Session Messages . . . . .	732
	Advertisement Messages . . . . .	733
	Notification Messages . . . . .	733
	Discovery Messages . . . . .	733
	Session Messages . . . . .	733
	Advertisement Messages . . . . .	734
	Notification Messages . . . . .	734
	Tunneling LDP LSPs in RSVP LSPs . . . . .	734
	Tunneling LDP LSPs in RSVP LSPs Overview . . . . .	734
	Benefits of Tunneling LDP LSPs in RSVP LSPs . . . . .	735
	Label Operations . . . . .	736

LDP Session Protection . . . . .	737
LDP Native IPv6 Support Overview . . . . .	738
Longest Match Support for LDP Overview . . . . .	738
Minimum LDP Configuration . . . . .	739
Enabling and Disabling LDP . . . . .	739
Configuring the LDP Timer for Hello Messages . . . . .	740
Configuring the LDP Timer for Link Hello Messages . . . . .	740
Configuring the LDP Timer for Targeted Hello Messages . . . . .	740
Configuring the Delay Before LDP Neighbors Are Considered Down . . . . .	741
Configuring the LDP Hold Time for Link Hello Messages . . . . .	741
Configuring the LDP Hold Time for Targeted Hello Messages . . . . .	742
Enabling Strict Targeted Hello Messages for LDP . . . . .	742
Configuring the Interval for LDP Keepalive Messages . . . . .	742
Configuring the LDP Keepalive Timeout . . . . .	743
Configuring Longest Match for LDP . . . . .	743
Example: Configuring Longest Match for LDP . . . . .	744
Configuring LDP Route Preferences . . . . .	760
LDP Graceful Restart . . . . .	760
Configuring LDP Graceful Restart . . . . .	761
Enabling Graceful Restart . . . . .	761
Disabling LDP Graceful Restart or Helper Mode . . . . .	762
Configuring Reconnect Time . . . . .	763
Configuring Recovery Time and Maximum Recovery Time . . . . .	763
Filtering Inbound LDP Label Bindings . . . . .	764
Examples: Filtering Inbound LDP Label Bindings . . . . .	765
Filtering Outbound LDP Label Bindings . . . . .	766
Examples: Filtering Outbound LDP Label Bindings . . . . .	767
Specifying the Transport Address Used by LDP . . . . .	768
Configuring the Prefixes Advertised into LDP from the Routing Table . . . . .	768
Example: Configuring the Prefixes Advertised into LDP . . . . .	769
Configuring FEC Deaggregation . . . . .	770
Configuring Policers for LDP FECs . . . . .	771
Configuring LDP IPv4 FEC Filtering . . . . .	772
Configuring BFD for LDP LSPs . . . . .	773
Configuring ECMP-Aware BFD for LDP LSPs . . . . .	776
Configuring a Failure Action for the BFD Session on an LDP LSP . . . . .	777
Configuring the Holddown Interval for the BFD Session . . . . .	778
Configuring LDP Link Protection . . . . .	778
Example: Configuring LDP Link Protection . . . . .	780
LDP Link Protection Overview . . . . .	780
Introduction to LDP . . . . .	780
Junos OS LDP Protocol Implementation . . . . .	780
Understanding Multipoint Extensions to LDP . . . . .	781
Using Multipoint Extensions to LDP on Targeted LDP Sessions . . . . .	781
Current Limitations of LDP Link Protection . . . . .	782
Using RSVP LSP as a Solution . . . . .	783
Understanding Multicast LDP Link Protection . . . . .	785
Different Modes for Providing LDP Link Protection . . . . .	786
Label Operation for LDP Link Protection . . . . .	788

Sample Multicast LDP Link Protection Configuration . . . . .	794
Make-Before-Break . . . . .	795
Caveats and Limitations . . . . .	797
Example: Configuring LDP Link Protection . . . . .	797
Understanding Multicast-Only Fast Reroute . . . . .	807
PIM Functionality . . . . .	809
Multipoint LDP Functionality . . . . .	810
Packet Forwarding . . . . .	811
Limitations and Caveats . . . . .	812
Configuring Multicast-Only Fast Reroute . . . . .	814
Example: Configuring Multicast-Only Fast Reroute in a Multipoint LDP Domain . . . . .	817
Example: Configuring LDP Downstream on Demand . . . . .	834
Configuring LDP Native IPv6 Support . . . . .	840
Example: Configuring LDP Native IPv6 Support . . . . .	841
Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs . . . . .	855
Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs . . . . .	856
How M-LDP Works . . . . .	857
Terminology . . . . .	861
Ingress Join Translation and Pseudo Interface Handling . . . . .	862
Ingress Splicing . . . . .	862
Reverse Path Forwarding . . . . .	862
LSP Root Detection . . . . .	862
Egress Join Translation and Pseudo Interface Handling . . . . .	863
Egress Splicing . . . . .	863
Supported Functionality . . . . .	863
Unsupported Functionality . . . . .	864
LDP Functionality . . . . .	864
Egress LER Functionality . . . . .	864
Transit LSR Functionality . . . . .	865
Ingress LER Functionality . . . . .	865
Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs . . . . .	865
LDP Mapping Server for Interoperability of Segment Routing with LDP Overview . . . . .	888
Interoperability of Segment Routing with LDP Using OSPF . . . . .	888
Interoperability of Segment Routing with LDP Using ISIS . . . . .	889
Configuring Miscellaneous LDP Properties . . . . .	892
Configuring LDP to Use the IGP Route Metric . . . . .	893
Preventing Addition of Ingress Routes to the inet.0 Routing Table . . . . .	893
Multiple-Instance LDP and Carrier-of-Carriers VPNs . . . . .	893
Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router . . . . .	894
Enabling LDP over RSVP-Established LSPs . . . . .	894
Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks . . . . .	895
Configuring the TCP MD5 Signature for LDP Sessions . . . . .	895
Configuring LDP Session Protection . . . . .	897

	Disabling SNMP Traps for LDP . . . . .	897
	Configuring LDP Synchronization with the IGP on LDP Links . . . . .	897
	Configuring LDP Synchronization with the IGP on the Router . . . . .	898
	Configuring the Label Withdrawal Timer . . . . .	898
	Ignoring the LDP Subnet Check . . . . .	899
	Configuring LDP LSP Traceroute . . . . .	899
	Collecting LDP Statistics . . . . .	900
	LDP Statistics Output . . . . .	901
	Disabling LDP Statistics on the Penultimate-Hop Router . . . . .	902
	LDP Statistics Limitations . . . . .	902
	Tracing LDP Protocol Traffic . . . . .	903
	Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels . . . . .	903
	Tracing LDP Protocol Traffic Within FECs . . . . .	904
	Examples: Tracing LDP Protocol Traffic . . . . .	904
<b>Part 5</b>	<b>MPLS Traffic Engineering</b>	
<b>Chapter 20</b>	<b>Understanding MPLS Traffic Engineering . . . . .</b>	<b>909</b>
	MPLS and Traffic Engineering . . . . .	909
	MPLS Traffic Engineering and Signaling Protocols Overview . . . . .	910
	Traffic Engineering Capabilities . . . . .	911
	Components of Traffic Engineering . . . . .	912
	Configuring Traffic Engineering for LSPs . . . . .	912
	Using LSPs for Both BGP and IGP Traffic Forwarding . . . . .	913
	Using LSPs for Forwarding in Virtual Private Networks . . . . .	913
	Using RSVP and LDP Routes for Forwarding but Not Route Selection . . . . .	913
	Advertising the LSP Metric in Summary LSAs . . . . .	914
	Enabling Interarea Traffic Engineering . . . . .	915
	Enabling Inter-AS Traffic Engineering for LSPs . . . . .	915
	Inter-AS Traffic Engineering Requirements . . . . .	916
	Inter-AS Traffic Engineering Limitations . . . . .	917
	Configuring OSPF Passive TE Mode . . . . .	917
	Packet Forwarding Component . . . . .	918
	Packet Forwarding Based on Label Swapping . . . . .	919
	How a Packet Traverses an MPLS Backbone . . . . .	919
	Information Distribution Component . . . . .	919
	Path Selection Component . . . . .	920
	Offline Path Planning and Analysis . . . . .	921
	Signaling Component . . . . .	921
	Flexible LSP Calculation and Configuration . . . . .	921
	Link-State Distribution Using BGP Overview . . . . .	922
	Role of an Interior Gateway Protocol . . . . .	923
	Limitations of an Interior Gateway Protocol . . . . .	923
	Need for Spanning Link-State Distribution . . . . .	924
	Using BGP as a Solution . . . . .	924
	Overview . . . . .	924
	Implementation . . . . .	925
	Supported and Unsupported Features . . . . .	930

	BGP Link-State Extensions for Source Packet Routing in Networking (SPRING) . . . . .	930
	Source Packet Routing in Networking (SPRING) . . . . .	931
	Flow of BGP Link-State SPRING Data . . . . .	931
	Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING . . . . .	933
	Example: Configuring Link State Distribution Using BGP . . . . .	934
	Configuring Link State Distribution Using BGP . . . . .	953
	Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages . . . . .	955
	PathErr Messages . . . . .	956
	Identifying the Problem Link . . . . .	957
	Configuring the Router to Improve Traffic Engineering Database Accuracy . . . . .	957
<b>Chapter 21</b>	<b>Configuring DiffServ-Aware Traffic Engineering to Achieve Service Level Guarantees on an MPLS network . . . . .</b>	<b>959</b>
	DiffServ-Aware Traffic Engineering Introduction . . . . .	960
	DiffServ-Aware Traffic Engineering Standards . . . . .	960
	DiffServ-Aware Traffic Engineering Terminology . . . . .	960
	DiffServ-Aware Traffic Engineering Features . . . . .	961
	DiffServ-Aware Traffic Engineered LSPs . . . . .	962
	DiffServ-Aware Traffic Engineered LSPs Overview . . . . .	962
	DiffServ-Aware Traffic Engineered LSPs Operation . . . . .	963
	Multiclass LSP Overview . . . . .	963
	Multiclass LSPs . . . . .	964
	Establishing a Multiclass LSP on the Differentiated Services Domain . . . . .	964
	Configuring Routers for DiffServ-Aware Traffic Engineering . . . . .	965
	Configuring the Bandwidth Model . . . . .	966
	Configuring Traffic Engineering Classes . . . . .	967
	Requirements and Limitations for the Traffic Engineering Class Matrix . . . . .	968
	Configuring Class of Service for DiffServ-Aware Traffic Engineering . . . . .	969
	LSP Bandwidth Oversubscription Overview . . . . .	969
	LSP Size Oversubscription . . . . .	970
	LSP Link Size Oversubscription . . . . .	970
	Class Type Oversubscription and Local Oversubscription Multipliers . . . . .	971
	Class Type Bandwidth and the LOM . . . . .	971
	LOM Calculation for the MAM and Extended MAM Bandwidth Models . . . . .	972
	LOM Calculation for the Russian Dolls Bandwidth Model . . . . .	972
	Example: LOM Calculation . . . . .	973
	Configuring the Bandwidth Subscription Percentage for LSPs . . . . .	974
	Constraints on Configuring Bandwidth Subscription . . . . .	975
	Configuring LSPs for DiffServ-Aware Traffic Engineering . . . . .	976
	Configuring Class of Service for the Interfaces . . . . .	976
	Configuring IGP . . . . .	977
	Configuring Traffic-Engineered LSPs . . . . .	977
	Configuring Policing for LSPs . . . . .	978
	Configuring Fast Reroute for Traffic-Engineered LSPs . . . . .	978

	Configuring Multiclass LSPs . . . . .	979
	Configuring Class of Service for the Interfaces . . . . .	979
	Configuring the IGP . . . . .	980
	Configuring Class-Type Bandwidth Constraints for Multiclass LSPs . . . . .	980
	Configuring Policing for Multiclass LSPs . . . . .	981
	Configuring Fast Reroute for Multiclass LSPs . . . . .	981
<b>Part 6</b>	<b>MPLS Transport Profile</b>	
<b>Chapter 22</b>	<b>Configuring Operation, Administration, and Maintenance (OAM) for MPLS . . . . .</b>	<b>985</b>
	Configuring the MPLS Transport Profile for OAM . . . . .	985
	MPLS Transport Profile Overview . . . . .	985
	Example: Configuring the MPLS Transport Profile for OAM . . . . .	986
	Configuring OAM Ingress Policies for LDP . . . . .	999
	Tracing MPLS and LSP Packets and Operations . . . . .	1000
<b>Chapter 23</b>	<b>Configuring MPLS Pseudowires . . . . .</b>	<b>1003</b>
	Ethernet Pseudowire Overview . . . . .	1003
	Example: Ethernet Pseudowire Base Configuration . . . . .	1004
	Pseudowire Overview for ACX Series Universal Metro Routers . . . . .	1007
	Understanding Multisegment Pseudowire for FEC 129 . . . . .	1008
	Understanding Multisegment Pseudowire . . . . .	1008
	Using FEC 129 for Multisegment Pseudowire . . . . .	1010
	Establishing a Multisegment Pseudowire Overview . . . . .	1010
	Pseudowire Status Support for Multisegment Pseudowire . . . . .	1011
	Pseudowire Status Behavior on T-PE . . . . .	1011
	Pseudowire Status Behavior on S-PE . . . . .	1011
	Pseudowire TLV Support for MS-PW . . . . .	1012
	Supported and Unsupported Features . . . . .	1012
	Example: Configuring a Multisegment Pseudowire . . . . .	1013
	MPLS Stitching For Virtual Machine Connection . . . . .	1058
	When Would I Use Stitching? . . . . .	1058
	How Does MPLS Stitching Work? . . . . .	1058
	How Do I Configure Stitching? . . . . .	1059
	Which Switches Support Stitching? . . . . .	1059
	Q&A . . . . .	1059
	TDM Pseudowires Overview . . . . .	1060
	Example: TDM Pseudowire Base Configuration . . . . .	1060
	Configuring Load Balancing for Ethernet Pseudowires . . . . .	1064
	Configuring Load Balancing Based on MAC Addresses . . . . .	1065
<b>Chapter 24</b>	<b>Configuring Class-of-Service (CoS) for MPLS . . . . .</b>	<b>1067</b>
	Configuring Class of Service for MPLS LSPs . . . . .	1067
	Class of Service for MPLS Overview . . . . .	1067
	Configuring the MPLS CoS Values . . . . .	1068

Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value . . . . .	1070
Configuring MPLS Rewrite Rules . . . . .	1071
Rewriting the EXP Bits of All Three Labels of an Outgoing Packet . . . . .	1071
Rewriting MPLS and IPv4 Packet Headers . . . . .	1071
Configuring CoS Bits for an MPLS Network (CLI Procedure) . . . . .	1073
Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS (CLI Procedure) . . . . .	1073
Configuring CoS . . . . .	1074
Configuring an LSP Policer . . . . .	1075
Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect (CLI Procedure) . . . . .	1076
Configuring CoS . . . . .	1076
Configuring an LSP Policer . . . . .	1077
Configuring CoS on Provider Switches of an MPLS Network (CLI Procedure) . . . . .	1078
Understanding Using CoS with MPLS Networks on EX Series Switches . . . . .	1079
EXP Classifiers and EXP rewrite Rules . . . . .	1079
Guidelines for Using CoS Classifiers on CCCs . . . . .	1080
Using CoS Classifiers with IP over MPLS . . . . .	1080
Setting CoS Bits in an MPLS Header . . . . .	1081
EXP Rewrite Rules . . . . .	1082
Policer . . . . .	1082
Schedulers . . . . .	1083
Example: Combining CoS with MPLS on EX Series Switches . . . . .	1083
Understanding CoS MPLS EXP Classifiers and Rewrite Rules . . . . .	1097
EXP Classifiers . . . . .	1098
EXP Rewrite Rules . . . . .	1099
Schedulers . . . . .	1100
Configuring Rewrite Rules for MPLS EXP Classifiers . . . . .	1100
Configuring CoS Bits for an MPLS Network . . . . .	1102
Configuring a Global MPLS EXP Classifier . . . . .	1103
<b>Chapter 25 Configuring Generalized MPLS (GMPLS) . . . . .</b>	<b>1105</b>
Introduction to GMPLS . . . . .	1105
GMPLS Terms and Acronyms . . . . .	1106
Supported GMPLS Standards . . . . .	1107
GMPLS Operation . . . . .	1108
GMPLS and OSPF . . . . .	1109
GMPLS and CSPF . . . . .	1109
GMPLS Features . . . . .	1110
LMP Configuration Overview . . . . .	1110
Configuring LMP Traffic Engineering Links . . . . .	1111
Configuring the Local IP Address for Traffic Engineering Links . . . . .	1112
Configuring the Remote IP Address for Traffic Engineering Links . . . . .	1112
Configuring the Remote ID for Traffic Engineering Links . . . . .	1113
Configuring LMP Peers . . . . .	1113
Configuring the ID for LMP Peers . . . . .	1114
Configuring the Interface for Control Channels Between LMP Peers . . . . .	1114
Configuring the LMP Control Channel Interface for the Peer . . . . .	1115
Configuring the Remote IP Address for LMP Control Channels . . . . .	1116

Configuring Hello Message Intervals for LMP Control Channels . . . . .	1116
Controlling Message Exchange for LMP Control Channels . . . . .	1117
Preventing the Local Peer from Initiating LMP Negotiation . . . . .	1117
Associating Traffic Engineering Links with LMP Peers . . . . .	1118
Disabling the Traffic Engineering Link for LMP Peers . . . . .	1118
Configuring RSVP and OSPF for LMP Peer Interfaces . . . . .	1118
Configuring RSVP Signaling for LMP Peer Interfaces . . . . .	1119
Configuring OSPF Routing for LMP Peer Interfaces . . . . .	1119
Configuring the Hello Interval for LMP Peer Interfaces . . . . .	1119
Configuring MPLS Paths for GMPLS . . . . .	1120
Tracing LMP Traffic . . . . .	1120
Configuring MPLS LSPs for GMPLS . . . . .	1121
Configuring the Encoding Type . . . . .	1122
Configuring the GPID . . . . .	1122
Configuring the Signal Bandwidth Type . . . . .	1123
Configuring GMPLS Bidirectional LSPs . . . . .	1123
Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers	
Running Junos OS . . . . .	1123
Gracefully Tearing Down GMPLS LSPs . . . . .	1124
Temporarily Deleting GMPLS LSPs . . . . .	1124
Permanently Deleting GMPLS LSPs . . . . .	1124
Configuring the Graceful Deletion Timeout Interval . . . . .	1125
GMPLS RSVP-TE VLAN LSP Signaling Overview . . . . .	1125
Understanding GMPLS RSVP-TE Signaling . . . . .	1125
Need for GMPLS RSVP-TE VLAN LSP Signaling . . . . .	1126
GMPLS RSVP-TE VLAN LSP Signaling Functionality . . . . .	1127
LSP Hierarchy with GMPLS RSVP-TE VLAN LSP . . . . .	1128
Path Specification for GMPLS RSVP-TE VLAN LSP . . . . .	1128
GMPLS RSVP-TE VLAN LSP Configuration . . . . .	1128
Associated Bidirectional Packet LSP . . . . .	1130
Make-Before-Break for Associated Bidirectional Packet and GMPLS	
RSVP-TE VLAN LSP . . . . .	1130
Supported and Unsupported Features . . . . .	1131
Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling . . . . .	1132

## Part 7

### Chapter 26

## MPLS BGP VPNs

Configuring MPLS VPNs . . . . .	1159
MPLS VPN Overview . . . . .	1160
MPLS VPN Topology . . . . .	1160
MPLS VPN Routing . . . . .	1162
VRF Instances . . . . .	1162
Route Distinguishers . . . . .	1162
Understanding IPv6 Layer 3 VPNs . . . . .	1163
Understanding Using MPLS-Based Layer 3 VPNs on Switches . . . . .	1164
MPLS-Based Layer 3 VPNs . . . . .	1164
Configuring a BGP Session for MPLS VPNs (CLI Procedure) . . . . .	1165
Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure) . . . . .	1166
Configuring Routing Options for MPLS VPNs (CLI Procedure) . . . . .	1166

Configuring a Routing Instance for MPLS VPNs (CLI Procedure) . . . . .	1167
Chained Composite Next Hops for Transit Devices for VPNs . . . . .	1168
Understanding MPLS Layer 2 VPNs . . . . .	1169
Understanding Ethernet-over-MPLS (L2 Circuit) . . . . .	1170
Ethernet-over-MPLS in Data Centers . . . . .	1170
MPLS Layer 2 VPN Configuration Overview . . . . .	1171
Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure) . . . . .	1172
Configuring Interfaces for Layer 2 VPNs (CLI Procedure) . . . . .	1174
Configuring Ethernet over MPLS (L2 Circuit) . . . . .	1175
Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) . . . . .	1176
Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire) . . . . .	1176
Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit . . . . .	1177
Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit . . . . .	1178
Example: Configuring MPLS-Based Layer 2 VPNs . . . . .	1178
Understanding Using MPLS-Based Layer 2 and Layer 3 VPNs on EX Series Switches . . . . .	1193
MPLS-Based Layer 2 VPNs . . . . .	1194
Layer 2 Circuits . . . . .	1194
MPLS-Based Layer 3 VPNs . . . . .	1195
Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN . . . . .	1195
Verifying an MPLS Layer 2 VPN Configuration . . . . .	1196
Configuring an MPLS-Based Layer 2 VPN (CLI Procedure) . . . . .	1197
Understanding MPLS Layer 2 Circuits . . . . .	1199
MPLS Layer 2 Circuit Configuration Overview . . . . .	1200
Configuring an MPLS Layer 2 Circuit (CLI Procedure) . . . . .	1201
Verifying an MPLS Layer 2 Circuit Configuration . . . . .	1201
Configuring an IGP and the LDP Signaling Protocol (CLI Procedure) . . . . .	1202
Configuring an MPLS-Based Layer 2 VPN (CLI Procedure) . . . . .	1203
Understanding MPLS Layer 3 VPNs . . . . .	1205
MPLS Layer 3 VPN Configuration Overview . . . . .	1206
Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure) . . . . .	1208
Verifying an MPLS Layer 3 VPN Configuration . . . . .	1208
Example: Configuring MPLS-Based Layer 3 VPNs . . . . .	1209
Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks . . . . .	1219
Example: Configuring MPLS-Based Layer 3 VPNs on EX Series Switches . . . . .	1228
Configuring an MPLS-Based Layer 3 VPN (CLI Procedure) . . . . .	1240
<b>Chapter 27</b>	
<b>Configuring CLNS VPNs . . . . .</b>	<b>1243</b>
CLNS Overview . . . . .	1243
CLNS Configuration Overview . . . . .	1244
Understanding ES-IS for CLNS . . . . .	1245
Example: Configuring ES-IS for CLNS . . . . .	1246
Understanding IS-IS for CLNS . . . . .	1248
Example: Configuring IS-IS for CLNS . . . . .	1248
Understanding Static Routes for CLNS . . . . .	1251
Example: Configuring Static Routes for CLNS When No IGP is Present . . . . .	1251

	Understanding BGP for CLNS VPNs . . . . .	1253
	Example: Configuring BGP for CLNS VPNs . . . . .	1254
	Example: Configuring a VPN Routing Instance for CLNS . . . . .	1256
	Verifying a CLNS VPN Configuration . . . . .	1258
<b>Chapter 28</b>	<b>Configuring VPLS . . . . .</b>	<b>1261</b>
	VPLS Overview . . . . .	1262
	Sample VPLS Topology . . . . .	1262
	VPLS on PE Routers . . . . .	1263
	Using an Ethernet Switch as the VPLS CE Device . . . . .	1265
	VPLS Exceptions on SRX Series Devices . . . . .	1265
	VPLS Configuration Overview . . . . .	1266
	Migrating from FEC128 LDP-VPLS to EVPN Overview . . . . .	1267
	Technology Overview and Benefits . . . . .	1268
	FEC128 LDP-VPLS to EVPN Migration . . . . .	1269
	Sample Configuration for LDP-VPLS to EVPN Migration . . . . .	1270
	LDP-VPLS Configuration . . . . .	1270
	EVPN Migration Configuration . . . . .	1272
	Reverting to VPLS . . . . .	1273
	LDP-VPLS to EVPN Migration and Other Features . . . . .	1274
	Understanding VPLS Interfaces . . . . .	1275
	Interface Name . . . . .	1275
	Encapsulation Type . . . . .	1275
	Flexible VLAN Tagging . . . . .	1276
	VLAN Rewrite . . . . .	1276
	Example: Configuring Routing Interfaces on the VPLS PE Router . . . . .	1277
	Example: Configuring the Interface to the VPLS CE Device . . . . .	1278
	VPLS Filters and Policers Overview . . . . .	1279
	Example: Configuring VPLS Filters . . . . .	1279
	Example: Configuring VPLS Policers . . . . .	1282
	Understanding VPLS Routing Instances . . . . .	1284
	BGP Signaling . . . . .	1285
	VPLS Routing Table . . . . .	1285
	Trace Options . . . . .	1286
	Example: Configuring the VPLS Routing Instance . . . . .	1287
	Example: Configuring Automatic Site Identifiers for VPLS . . . . .	1289
	Example: Configuring OSPF on the VPLS PE Router . . . . .	1291
	Example: Configuring RSVP on the VPLS PE Router . . . . .	1292
	Example: Configuring MPLS on the VPLS PE Router . . . . .	1293
	Example: Configuring LDP on the VPLS PE Router . . . . .	1294
	Example: Configuring VPLS over GRE with IPsec VPNs . . . . .	1296
	Example: Configuring VPLS with BGP Signaling . . . . .	1315
	Example: Configuring BGP on the VPLS PE Router . . . . .	1329
	Example: Configuring Routing Options on the VPLS PE Router . . . . .	1331
	Understanding VPLS VLAN Encapsulation . . . . .	1332
	Understanding VPLS VLAN Encapsulation on a Logical Interface . . . . .	1333
	Example: Configuring VPLS VLAN Encapsulation . . . . .	1333
	Example: Configuring VPLS VLAN Encapsulation on Gigabit Ethernet Interfaces . . . . .	1336

## Chapter 29

Example: Configuring Extended VLAN VPLS Encapsulation . . . . .	1338
<b>Configuring Circuit Cross-Connect (CCC) and Translational Cross-Connect (TCC) . . . . .</b>	<b>1341</b>
CCC Overview . . . . .	1341
Understanding Carrier-of-Carriers VPNs . . . . .	1343
Internet Service Provider as the Customer . . . . .	1344
VPN Service Provider as the Customer . . . . .	1344
Understanding Interprovider and Carrier-of-Carriers VPNs . . . . .	1345
Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure) . . . . .	1346
VLAN CCC Encapsulation on Transport Side of Pseudowire Client Logical Interfaces Overview . . . . .	1348
Pseudowire Configuration from Access Node . . . . .	1349
Pseudowire Configuration from Aggregation Node . . . . .	1350
Transmitting Nonstandard BPDUs . . . . .	1351
TCC Overview . . . . .	1351
Configuring Layer 2 Switching Cross-Connects Using CCC . . . . .	1352
Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1353
Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1354
Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1354
Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1355
Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1356
Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1357
Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects . . . . .	1357
Configuring the CCC Connection for Layer 2 Switching Cross-Connects . . . . .	1358
Configuring MPLS for Layer 2 Switching Cross-Connects . . . . .	1358
Example: Configuring a Layer 2 Switching Cross-Connect . . . . .	1359
Configuring MPLS LSP Tunnel Cross-Connects Using CCC . . . . .	1360
Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects . . . . .	1362
Configuring the CCC Connection for LSP Tunnel Cross-Connects . . . . .	1363
Example: Configuring an LSP Tunnel Cross-Connect . . . . .	1364
Configuring TCC . . . . .	1365
Configuring the Encapsulation for Layer 2 Switching TCCs . . . . .	1365
Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs . . . . .	1366
Configuring ATM Encapsulation for Layer 2 Switching TCCs . . . . .	1366
Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs . . . . .	1366
Configuring Ethernet Encapsulation for Layer 2 Switching TCCs . . . . .	1367
Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs . . . . .	1368

	Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations . . . . .	1368
	Configuring the Connection for Layer 2 Switching TCCs . . . . .	1369
	Configuring MPLS for Layer 2 Switching TCCs . . . . .	1369
	CCC and TCC Graceful Restart . . . . .	1370
	Configuring CCC and TCC Graceful Restart . . . . .	1371
	Configuring an MPLS-Based VLAN CCC Using the Connection Method (CLI Procedure) . . . . .	1372
	Configuring CCC Switching for Point-to-Multipoint LSPs . . . . .	1374
	Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers . . . . .	1374
	Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers . . . . .	1375
	Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers . . . . .	1375
	Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure) . . . . .	1376
	Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure) . . . . .	1380
<b>Part 8</b>	<b>MPLS for Software Defined Network (SDN)</b>	
<b>Chapter 30</b>	<b>Introduction to Path Computation Element Protocol (PCEP) . . . . .</b>	<b>1385</b>
	PCEP Overview . . . . .	1385
<b>Chapter 31</b>	<b>Configuring PCEP for MPLS RSVP-TE . . . . .</b>	<b>1387</b>
	Support of the Path Computation Element Protocol for RSVP-TE Overview . . . . .	1387
	Understanding MPLS RSVP-TE . . . . .	1388
	Current MPLS RSVP-TE Limitations . . . . .	1389
	Use of an External Path Computing Entity . . . . .	1390
	Components of External Path Computing . . . . .	1391
	Path Computation Element . . . . .	1391
	Path Computation Client . . . . .	1392
	Path Computation Element Protocol . . . . .	1393
	Interaction Between a PCE and a PCC Using PCEP . . . . .	1393
	LSP Behavior with External Computing . . . . .	1396
	LSP Types . . . . .	1396
	LSP Control Mode . . . . .	1397
	Configuration Statements Supported for External Computing . . . . .	1397
	PCE-Controlled LSP Protection . . . . .	1398
	PCE-Controlled LSP ERO . . . . .	1398
	PCE Controlled Point-to-Multipoint RSVP-TE LSPs . . . . .	1399
	Auto-Bandwidth and PCE-Controlled LSP . . . . .	1400
	TCP-MD5 Authentication for PCEP Sessions . . . . .	1400
	Impact of Client-Side PCE Implementation on Network Performance . . . . .	1401
	Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE . . . . .	1402
	Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs . . . . .	1416
	Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs . . . . .	1427

	Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Controlled Point-to-Multipoint LSPs . . . . .	1430
	Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs . . . . .	1448
	Benefits of PCE-Initiated Point-to-Multipoint LSPs . . . . .	1448
	Signaling of PCE-Initiated Point-to-Multipoint LSPs . . . . .	1448
	Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure . . . . .	1449
	Configuring PCE-Initiated Point-to-Multipoint LSP Capability . . . . .	1449
	Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs . . . . .	1449
<b>Chapter 32</b>	<b>Configuring PCEP for MPLS SPRING-TE . . . . .</b>	<b>1451</b>
	Support of SPRING-TE for the Path Computation Element Protocol Overview . . . . .	1451
	SPRING for Traffic Engineering . . . . .	1451
	Junos OS Implementation of PCEP for SPRING-TE LSPs . . . . .	1452
	SPRING-TE Module . . . . .	1452
	Traffic Engineering Database . . . . .	1453
	PCEP Interaction . . . . .	1453
	Configuration of PCEP for SPRING-TE . . . . .	1453
	Limitations and Unsupported Features for PCEP SPRING-TE . . . . .	1455
	Example: Configuring Path Computation Element Protocol for SPRING-TE LSPs . . . . .	1455
	Static Segment Routing Label Switched Path . . . . .	1479
	Understanding Static Segment Routing LSP in MPLS Networks . . . . .	1479
	Static Segment Routing Provisioning . . . . .	1480
	Benefits of using Static Segment Routing of Label Switched Path . . . . .	1480
	Non-Colored Static Segment Routing LSP . . . . .	1480
	Static Segment Routing LSP Provisioning . . . . .	1481
	Limitations . . . . .	1482
	Example: Configuring Static Segment Routing Label Switched Path . . . . .	1482
<b>Part 9</b>	<b>Troubleshooting MPLS</b>	
<b>Chapter 33</b>	<b>Troubleshooting MPLS . . . . .</b>	<b>1501</b>
	Verify MPLS Interfaces . . . . .	1507
	Verify the MPLS Configuration . . . . .	1509
	Checklist for Checking the MPLS Layer . . . . .	1511
	Checking the MPLS Layer . . . . .	1512
	Verify the LSP . . . . .	1514
	Verify the LSP Route on the Transit Router . . . . .	1517
	Verify the LSP Route on the Ingress Router . . . . .	1518
	Verify MPLS Labels with the traceroute Command . . . . .	1520
	Verify MPLS Labels with the ping Command . . . . .	1521
	Verify the MPLS Configuration . . . . .	1522
	Take Appropriate Action . . . . .	1524
	Verify the LSP Again . . . . .	1525
	Verify That Node-Link Protection Is Up . . . . .	1528

Verify That Link Protection Is Up . . . . .	1535
Many-to-One Link Protection (Facility Backup) Overview . . . . .	1539
Verify One-to-One Backup . . . . .	1540
Verify That the Primary Path Is Operational . . . . .	1547
Verify That the Secondary Path Is Established . . . . .	1549
Verify the LSP . . . . .	1551
Verify the LSP Route on the Transit Router . . . . .	1553
Verify the LSP Route on the Ingress Router . . . . .	1555
Verify MPLS Labels with the traceroute Command . . . . .	1556
Verify MPLS Labels with the ping Command . . . . .	1557
Take Appropriate Action . . . . .	1559
Verify the LSP Again . . . . .	1560
Checklist for Working with the Layered MPLS Troubleshooting Model . . . . .	1563
Understanding the Layered MPLS Troubleshooting Model . . . . .	1563
Checklist for Verifying the Physical Layer . . . . .	1570
Verifying the Physical Layer . . . . .	1571
Verify the LSP . . . . .	1573
Verify Router Connection . . . . .	1575
Verify Interfaces . . . . .	1576
Take Appropriate Action . . . . .	1576
Verify the LSP Again . . . . .	1577
Verify the LSP . . . . .	1579
Verify Router Connection . . . . .	1580
Verify Interfaces . . . . .	1581
Take Appropriate Action . . . . .	1582
Verify the LSP Again . . . . .	1582
Checklist for Checking the Data Link Layer . . . . .	1584
Checking the Data Link Layer . . . . .	1584
Verify the LSP . . . . .	1586
Verify Interfaces . . . . .	1587
Take Appropriate Action . . . . .	1591
Verify the LSP Again . . . . .	1592
Verify the LSP . . . . .	1595
Verify Interfaces . . . . .	1596
Take Appropriate Action . . . . .	1600
Verify the LSP Again . . . . .	1601
Checklist for Verifying the IP and IGP Layers . . . . .	1604
Verifying the IP and IGP Layers . . . . .	1606
Verifying the IP Layer . . . . .	1608
Verify the LSP . . . . .	1609
Verify IP Addressing . . . . .	1610
Verify Neighbors or Adjacencies at the IP Layer . . . . .	1612
Take Appropriate Action . . . . .	1615
Verify the LSP Again . . . . .	1616
Verify the LSP . . . . .	1619
Verify IP Addressing . . . . .	1620
Verify Neighbors or Adjacencies at the IP Layer . . . . .	1621
Take Appropriate Action . . . . .	1625
Verify the LSP Again . . . . .	1626

Verifying the OSPF Protocol .....	1629
Verify the LSP .....	1629
Verify OSPF Interfaces .....	1633
Verify OSPF Neighbors .....	1634
Verify the OSPF Protocol Configuration .....	1635
Take Appropriate Action .....	1636
Verify the LSP Again .....	1637
Verify the LSP .....	1640
Verify OSPF Interfaces .....	1643
Verify OSPF Neighbors .....	1645
Verify the LSP Again .....	1645
Verify the LSP .....	1648
Verify IS-IS Adjacencies and Interfaces .....	1649
Verify the IS-IS Configuration .....	1651
Verify the LSP Again .....	1652
Checklist for Checking the RSVP Layer .....	1655
Checking the RSVP Layer .....	1655
Verify the LSP .....	1658
Verify RSVP Sessions .....	1659
Verify RSVP Neighbors .....	1661
Verify RSVP Interfaces .....	1662
Verify the RSVP Protocol Configuration .....	1663
Take Appropriate Action .....	1664
Verify the LSP Again .....	1665
Verify the LSP .....	1668
Verify RSVP Sessions .....	1669
Verify RSVP Neighbors .....	1671
Verify RSVP Interfaces .....	1672
Verify the RSVP Protocol Configuration .....	1674
Take Appropriate Action .....	1675
Verify the LSP Again .....	1676
Checklist for Determining LSP Status .....	1679
Determining LSP Statistics .....	1679
Checklist for Verifying LSP Use .....	1681
Verifying LSP Use in Your Network .....	1682
Verifying an LSP on the Ingress Router .....	1682
Verifying an LSP on a Transit Router .....	1684
Verifying an LSP on the Ingress Router .....	1685
Verifying an LSP on a Transit Router .....	1686
Verify That Load Balancing Is Working .....	1688
Example: Load-Balanced MPLS Network .....	1691
Router Configurations for the Load-Balanced MPLS Network .....	1692
Traffic Flows Before Load Balancing .....	1703
Verify the Operation of Uneven Bandwidth Load Balancing .....	1705
Checklist for Collecting Crash Data .....	1707
Understand Crash Data Collection .....	1709

Collect Crash Data for a Routing Engine Kernel . . . . .	1709
Check the Routing Engine Core Files . . . . .	1709
List the Core Files . . . . .	1710
Compress the vmcore File . . . . .	1711
Log Software Version Information . . . . .	1711
Open a Case with JTAC . . . . .	1712
Check the Routing Engine Core Files . . . . .	1712
List the Core Files . . . . .	1713
Compress the vmcore File . . . . .	1714
Log Software Version Information . . . . .	1714
Open a Case with JTAC . . . . .	1715
Collect Crash Data for Routing Engine Daemons . . . . .	1715
Check for Daemon Core Files . . . . .	1716
List the Daemon Core Files . . . . .	1717
Compress the Daemon Core Files . . . . .	1718
Log Software Version Information . . . . .	1718
Open a Case with JTAC . . . . .	1719
Collect and Send Routing Engine Crash Data to JTAC . . . . .	1719
Check for Daemon Core Files . . . . .	1720
List the Daemon Core Files . . . . .	1721
Compress the Daemon Core Files . . . . .	1722
Collect Crash Data for the Packet Forwarding Engine Microkernel . . . . .	1723
Display the Crash Stack Traceback and Registration Information . . . . .	1724
Clear the NVRAM Contents . . . . .	1727
Check Packet Forwarding Engine Microkernel Core Files . . . . .	1728
List the Core Files Generated by the Crash . . . . .	1728
Compress the Core Files . . . . .	1729
Log Software Version Information . . . . .	1729
Open a Case with JTAC . . . . .	1730
Display the Crash Stack Traceback and Registration Information . . . . .	1730
Clear the NVRAM Contents . . . . .	1734
Check Packet Forwarding Engine Microkernel Core Files . . . . .	1734
List the Core Files Generated by the Crash . . . . .	1735
Compress the Core Files . . . . .	1736
Configure a Primary Path . . . . .	1736
Ensuring That Secondary Paths Establish When Resources Are Diminished . . .	1738
One-to-One Backup Overview . . . . .	1739
Configure Link Protection . . . . .	1740
Configuring and Verifying Link Protection . . . . .	1742
Configure Link Protection . . . . .	1742
Verify That Link Protection Is Up . . . . .	1744
Configure Node-Link Protection . . . . .	1748
Configuring and Verifying Node-Link Protection . . . . .	1750
Configure Node-Link Protection . . . . .	1750
Verify That Node-Link Protection Is Up . . . . .	1752
Configure IS-IS as the IGP . . . . .	1759
Enable IS-IS on Routers in Your Network . . . . .	1760
Configure ISO Addressing . . . . .	1763

Enable IS-IS on Router Interfaces . . . . .	1764
Verify That IS-IS Adjacencies Are Established . . . . .	1765
Verify That IS-IS Adjacencies Are Established . . . . .	1766
Configure OSPF as the IGP . . . . .	1767
Enable OSPF on Routers in Your Network . . . . .	1769
Verify That OSPF Neighbors Are Established . . . . .	1771
Set Up BGP on Routers in Your Network . . . . .	1772
Define the Local Autonomous System . . . . .	1773
Configure BGP Neighbor Connections . . . . .	1774

# About the Documentation

- Documentation and Release Notes on page lvii
- Using the Examples in This Manual on page lvii
- Documentation Conventions on page lix
- Documentation Feedback on page lxi
- Requesting Technical Support on page lxi

## Documentation and Release Notes

---

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <https://www.juniper.net/documentation/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <https://www.juniper.net/books>.

## Using the Examples in This Manual

---

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

## Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

## Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

## Documentation Conventions

Table 1 on page [lix](#) defines notice icons used in this guide.

*Table 1: Notice Icons*

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page [lx](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
<b>Bold text like this</b>	Represents text that you type.	To enter configuration mode, type the <b>configure</b> command:  user@host> <b>configure</b>
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> <b>show chassis alarms</b>  No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> <li>Introduces or emphasizes important new terms.</li> <li>Identifies guide names.</li> <li>Identifies RFC and Internet draft titles.</li> </ul>	<ul style="list-style-type: none"> <li>A policy <i>term</i> is a named structure that defines match conditions and actions.</li> <li><i>Junos OS CLI User Guide</i></li> <li>RFC 1997, <i>BGP Communities Attribute</i></li> </ul>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name:  [edit] root@# <b>set system domain-name</b> <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> <li>To configure a stub area, include the <b>stub</b> statement at the [edit protocols <b>ospf area area-id</b>] hierarchy level.</li> <li>The console port is labeled <b>CONSOLE</b>.</li> </ul>
< > (angle brackets)	Encloses optional keywords or variables.	<b>stub</b> <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	<b>broadcast   multicast</b>  ( <i>string1</i>   <i>string2</i>   <i>string3</i> )
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	<b>rsvp { # Required for dynamic MPLS only</b>
[ ] (square brackets)	Encloses a variable for which you can substitute one or more values.	<b>community name members [</b> <i>community-ids</i> <b>]</b>
Indentation and braces ( { } )	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

---

#### GUI Conventions

Table 2: Text and Syntax Conventions (continued)

Convention	Description	Examples
<b>Bold text like this</b>	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> <li>In the Logical Interfaces box, select <b>All Interfaces</b>.</li> <li>To cancel the configuration, click <b>Cancel</b>.</li> </ul>
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select <b>Protocols&gt;Ospf</b> .

## Documentation Feedback

We encourage you to provide feedback so that we can improve our documentation. You can use either of the following methods:

- Online feedback system—Click TechLibrary Feedback, on the lower right of any page on the [Juniper Networks TechLibrary](#) site, and do one of the following:

- Click the thumbs-up icon if the information on the page was helpful to you.
- Click the thumbs-down icon if the information on the page was not helpful to you or if you have suggestions for improvement, and use the pop-up form to provide feedback.
- E-mail—Send your comments to [techpubs-comments@juniper.net](mailto:techpubs-comments@juniper.net). Include the document or topic name, URL or page number, and software version (if applicable).

## Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <https://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <https://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

## Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <https://www.juniper.net/customers/support/>
- Search for known bugs: <https://prsearch.juniper.net/>
- Find product documentation: <https://www.juniper.net/documentation/>
- Find solutions and answer questions using our Knowledge Base: <https://kb.juniper.net/>
- Download the latest versions of software and review release notes: <https://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <https://kb.juniper.net/InfoCenter/>
- Join and participate in the Juniper Networks Community Forum: <https://www.juniper.net/company/communities/>
- Create a service request online: <https://myjuniper.juniper.net>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://entitlementsearch.juniper.net/entitlementsearch/>

## Creating a Service Request with JTAC

You can create a service request with JTAC on the Web or by telephone.

- Visit <https://myjuniper.juniper.net>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <https://support.juniper.net/support/requesting-support/>.

## MPLS Overview

---

Multiprotocol Label Switching (MPLS) is a protocol that uses labels to route packets instead of using IP addresses. In a traditional network, each switch performs an IP routing lookup, determines a next-hop based on its routing table, and then forwards a packet to that next-hop. With MPLS, only the first device does a routing lookup, and, instead of finding the next-hop, finds the ultimate destination along with a path to that destination. The path of an MPLS packet is called a label-switched path (LSP).

MPLS applies one or more labels to a packet so it can follow the LSP to the destination. Each switch pops off its label and sends the packet to the next switch label in the sequence.

The Junos OS includes everything you need to configure MPLS. You do not need to install any additional programs or protocols. MPLS is supported on switches with a subset of the commands supported on routers. The Junos MPLS-configured switches can interact with each other and with Junos MPLS-configured routers.

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

This topic describes:

- [Why Use MPLS? on page 4](#)
- [Why Not Use MPLS? on page 5](#)
- [How Do I Configure MPLS? on page 5](#)
- [What Does the MPLS Protocol Do? on page 6](#)
- [How Does MPLS Interface to Other Protocols? on page 7](#)
- [If I Have Used Cisco MPLS, What Do I Need to Know? on page 7](#)

## Why Use MPLS?

MPLS reduces the use of the forwarding table by using labels instead of the forwarding table. The size of forwarding tables on a switch are limited by silicon and using exact matching for forwarding to destination devices is cheaper than buying more sophisticated hardware. In addition, MPLS allows you to control where and how traffic is routed on your network – this is called traffic engineering.

Some reasons to use MPLS instead of another switching solution are:

- MPLS can connect different technologies that would not otherwise be compatible---service providers have this compatibility issue when connecting clients with different autonomous systems in their networks. In addition, MPLS has a feature called Fast Reroute that provides alternate backups for paths – this prevents network degradation in case of a switch failure.
- Other IP-based encapsulations such as Generic Route Encapsulation (GRE) or Virtual Extensible Local Area Networks (VXLAN) support only two levels of hierarchy, one for the transport tunnel and one piece of metadata. Using virtual servers means that you need multiple hierarchy levels. For example, one label is needed for top-of-rack (ToR), one label for the egress port that identifies the server, and one for the virtual server.

## Why Not Use MPLS?

There are no protocols to auto-discover MPLS enabled nodes. MPLS protocol just exchanges label values for an LSP. They do not create the LSPs.

You must build the MPLS mesh, switch by switch. We recommend using scripts for this repetitive process.

MPLS hides suboptimal topologies from BGP where multiple exits may exist for the same route.

Large LSPs are limited by the circuits they traverse. You can work around this by creating multiple, parallel LSPs.

## How Do I Configure MPLS?

There are three types of switches you must set up for MPLS:

- Label Edge Router/Switch (LER) or ingress node to the MPLS network. This switch encapsulates the packets.
- Label Switching Routers/Switches (LSR). One or more switches that transfer MPLS packets in the MPLS network.
- Egress router/switch is the final MPLS device that removes the last label before packets leave the MPLS network.

Service providers (SP) use the term provider router (P) for a backbone router/switch doing label switching only. The customer-facing router at the SP is called a provider edge router (PE). Each customer needs a customer edge router (CE) to communicate with the PE. Customer facing routers typically can terminate IP addresses, L3VPNs, L2VPNs/pseudowires, and VPLS before packets are transferred to the CE.

---

### Configure the MPLS LER (Ingress) Switch and the Egress Switch

To configure MPLS, you must first create one or more named paths on the ingress and egress routers. For each path, you can specify some or all transit routers in the path, or you can leave it empty. See [“Configuring the Ingress and Egress Router Addresses for](#)

LSPs” on page 412 and “Configuring the Connection Between Ingress and Egress Routers” on page 419.

### Configure LSRs for MPLS

---

Configure one or more MPLS LSRs by following these steps:

1. Configure interfaces on each switch to transmit and receive MPLS packets using the usual interface command with MPLS appended. For example:

```
[edit interfaces ge-0/0/0 unit 0] family mpls;
```

2. Add those same interfaces under [edit protocols mpls]. For example:

```
[edit protocols mpls]
interface ge-0/0/0;
```

3. Configure the interfaces on each switch to handle MPLS labels with a protocol. For example, for LDP:

```
[edit protocols ldp]
Interface ge-0/0/0.0;
```

To watch a demo of these configurations, see  
<https://www.youtube.com/watch?v=xegWBCUJ4tE>.

## What Does the MPLS Protocol Do?

Multiprotocol Label Switching (MPLS) is an Internet Engineering Task Force (IETF)-specified framework that provides for the designation, routing, forwarding and switching of traffic flows through the network. In addition, MPLS:

- Specifies mechanisms to manage traffic flows of various granularities, such as flows between different hardware, machines, or even flows between different applications.
- Remains independent of the layer-2 and layer-3 protocols.
- Provides a means to map IP addresses to simple, fixed-length labels used by different packet-forwarding and packet-switching technologies.
- Interfaces to existing routing protocols, such as Resource ReSerVation Protocol (RSVP) and Open Shortest PathFirst (OSPF).
- Supports IP, ATM, and Frame Relay layer-2 protocols.
- Uses these additional technologies:
  - FRR: MPLS Fast Reroute improves convergence during a failure by mapping out alternate LSPs in advance.
  - Link Protection/ Next-hop backup: A bypass LSP is created for every possible link failure.

- Node Protection/ Next-hop backup: A bypass LSP is created for every possible switch (node) failure.
- VPLS: Creates Ethernet multipoint switching service over MPLS and emulates functions of an L2 switch.
- L3VPN: IP-based VPN customers get individual virtual routing domains.

## How Does MPLS Interface to Other Protocols?

Some of the protocols that work with MPLS are:

- RSVP-TE: Resource Reservation Protocol - Traffic Engineering reserves bandwidth for LSPs.
- LDP: Label Distribution Protocol is the defacto protocol used for distribution of MPLS packets and is usually configured to tunnel inside RSVP-TE.
- IGP: Interior Gateway Protocol is a routing protocol. Edge routers (PE-routers) run BGP between themselves to exchange external (customer) prefixes. Edge and core (P) routers run IGP (usually OSPF or IS-IS) to find optimum path toward BGP next hops. P- and PE-routers use LDP to exchange labels for known IP prefixes (including BGP next hops). LDP indirectly builds end-to-end LSPs across the network core.
- BGP: Border Gateway Protocol (BGP) allows policy-based routing to take place, using TCP as its transport protocol on port 179 to establish connections. The Junos OS routing protocol software includes BGP version 4. You do not configure BGP---configuring interfaces with MPLS and LDP/RSVP establishes the labels and the ability to transmit packets. BGP automatically determines the routes packets take.
- OSPF and ISIS: These protocols are used for routing between the MPLS PE and CE. Open Shortest Path First (OSPF) is perhaps the most widely used interior gateway protocol (IGP) in large enterprise networks. IS-IS, another link-state dynamic routing protocol, is more common in large service provider networks. Assuming you're running L3VPN to your customers, on the SP edge between the PE and the CE you can run any protocol that your platform supports as a VRF aware instance.

## If I Have Used Cisco MPLS, What Do I Need to Know?

Cisco Networks and Juniper Networks use different MPLS terminology.

What Cisco Calls:	Juniper Calls:
affinities	admin-groups
autoroute announce	TE shortcuts
forwarding adjacency	LSP-advertise
tunnel	LSP
make-before-break	adaptive

What Cisco Calls:	Juniper Calls:
application-window	adjust-interval
shared risk link groups	fate-sharing

## MPLS Overview for ACX Series Universal Metro Routers

Multiprotocol Label Switching (MPLS) provides a mechanism for engineering network traffic patterns that is independent of routing tables by assigning short labels to network packets, which describe how to forward them through the network. MPLS is independent of any routing protocol and can be used for unicast packets. On the ACX Series routers, the following MPLS features are supported:

- The configuration of a label-switching router (LSR) for processing of label-switched packets and forwarding of packets based on their labels.
- The configuration of an ingress label edge router (LER) where IP packets are encapsulated within MPLS packets and forwarded to the MPLS domain, and as an egress LER where MPLS packets are decapsulated and the IP packets contained within the MPLS packets are forwarded using information in the IP forwarding table. Configuring MPLS on the LER is the same as configuring an LSR.
- Uniform and pipe mode configuration providing different types of visibility in the MPLS network. Uniform mode makes all the nodes that a label-switched path (LSP) traverses visible to nodes outside the LSP tunnel. Uniform mode is the default. Pipe mode makes only the LSP ingress and egress points visible to nodes outside the LSP tunnel. Pipe mode acts like a circuit and must be enabled with the global **no-propagate-ttl** statement at the **[edit protocols mpls]** hierarchy level on each router that is in the path of the LSP. The **no-propagate-ttl** statement disables time-to-live (TTL) propagation at the router level and affects all RSVP-signalled or LDP-signalled LSPs. Only the global configuration of TTL propagation is supported.
- Exception packet handling of IP packets not processed by the normal packet flow through the Packet Forwarding Engine. The following types of exception packet handling are supported:
  - Router alert
  - Time-to-live (TTL) expiry value
  - Virtual circuit connection verification (VCCV)

- LSP hot standby for secondary paths configuration to maintain a path in a hot-standby state enabling swift cut over to the secondary path when downstream routers on the current active path indicate connectivity problems.
- Redundancy for a label-switched path (LSP) path with the configuration of fast reroute.
- Configuration of link protection to ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails.

## MPLS for EX Series Switches Overview

You can configure Junos OS MPLS on Juniper Networks EX Series Ethernet Switches to increase transport efficiency in the network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

**NOTE:** MPLS configurations on EX Series switches are compatible with configurations on other Juniper Networks devices that support MPLS and MPLS-based circuit cross-connect (CCC). MPLS features available on the switches depend upon which switch you are using. For information about the software features on the EX Series switches, see [Feature Explorer](#).

**NOTE:** MPLS configurations on the switches do not support:

- Q-in-Q tunneling

This topic describes:

- [Benefits of MPLS on page 9](#)
- [Additional Benefits of MPLS and Traffic Engineering on page 10](#)

## Benefits of MPLS

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

### Additional Benefits of MPLS and Traffic Engineering

MPLS is the packet-forwarding component of the Junos OS traffic engineering architecture. Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide efficient use of available aggregate bandwidth and long-haul fiber by ensuring that certain subsets of the network are not overutilized while other subsets of the network along potential alternate paths are underutilized.
- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservice Internet.

### MPLS Applications

---

In the Junos OS implementation of MPLS, establishing an LSP installs on the ingress router a host route (a 32-bit mask) toward the egress router. The address of the host route is the destination address of the LSP. By default, the route has a preference value of 7, a value that is higher than all routes except direct interface and static routes. The 32-bit mask ensures that the route is more specific (that is, a longer match) than all other subnet routes. The host routes can be used to traffic-engineer BGP destinations only, or both IGP and BGP destinations.

This section discusses the following topics:

- [BGP Destinations on page 17](#)
- [IGP and BGP Destinations on page 18](#)

- [Selecting a Forwarding LSP Next Hop on page 407](#)

## Link-Layer Support in MPLS

MPLS supports the following link-layer protocols, which are all supported in the Junos OS MPLS implementation:

- Point-to-Point Protocol (PPP)—Protocol ID 0x0281, Network Control Protocol (NCP) protocol ID 0x8281.
- Ethernet/Cisco High-level Data Link Control (HDLC)—Ethernet type 0x8847.
- Asynchronous Transfer Mode (ATM)—Subnetwork attachment point encoded (SNAP-encoded) Ethernet type 0x8847. Support is included for both point-to-point mode or nonbroadcast multiaccess (NBMA) mode. Support is not included for encoding MPLS labels as part of ATM virtual path identifier/virtual circuit identifier (VPI/VCI).
- Frame Relay—SNAP-encoded, Ethernet type 0x8847. Support is not included for encoding MPLS labels as part of Frame Relay data-link connection identifier (DLCI).
- Generic routing encapsulation (GRE) tunnel—Ethernet type 0x8847.

## Supported MPLS Scaling Values

This topic lists the MPLS scaling values supported on the QFX Series and EX4600 switches.

[Table 3 on page 11](#) lists the MPLS scaling values supported on the QFX3500, QFX5100, QFX5110, QFX5120, QFX5200, QFX5210, aEX4600, and EX4650 switches.

**Table 3: MPLS Scaling Values for QFX3500, QFX5100, QFX5110, QFX5120, QFX5200, QFX5210, EX4600, and EX4650 Switches**

Feature	QFX3500	QFX5100, EX4600	QFX5120, EX4650	QFX5110	QFX5200	QFX5210

## Supported MPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for MPLS and traffic engineering.

- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3031, *Multiprotocol Label Switching Architecture*
- RFC 3032, *MPLS Label Stack Encoding*
- RFC 3140, *Per Hop Behavior Identification Codes*
- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*

Only E-LSPs are supported.

- RFC 3443, *Time To Live (TTL) Processing in Multi-Protocol Label Switching (MPLS) Networks*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*

Node protection in facility backup is not supported.

- RFC 4124, *Protocol Extensions for Support of Diffserv-aware MPLS Traffic Engineering*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*
- RFC 4385, *Pseudowire Emulation Edge-to-Edge (PWE3) Control Word for Use over an MPLS PSN.*

Supported on MX Series routers with the Channelized OC3/STM1 (Multi-Rate) Circuit Emulation MIC with SFP.

- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*
- RFC 4950, *ICMP Extensions for Multiprotocol Label Switching*
- RFC 5317, *Joint Working Team (JWT) Report on MPLS Architectural Considerations for a Transport Profile*
- RFC 5586, *MPLS Generic Associated Channel*
- RFC 5654, *Requirements of an MPLS Transport Profile*

The following capabilities are supported in the Junos OS implementation of MPLS Transport Profile (MPLS-TP):

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.
- RFC 5712, *MPLS Traffic Engineering Soft Preemption*
- RFC 5718, *An In-Band Data Communication Network For the MPLS Transport Profile*
- RFC 5860, *Requirements for Operations, Administration, and Maintenance (OAM) in MPLS Transport Networks*
- RFC 5884, *Bidirectional Forwarding Detection (BFD) for MPLS Label Switched Paths (LSPs)*
- RFC 5921, *A Framework for MPLS in Transport Networks*
- RFC 5950, *Network Management Framework for MPLS-based Transport Networks*
- RFC 5951, *Network Management Requirements for MPLS-based Transport Networks*
- RFC 5960, *MPLS Transport Profile Data Plane Architecture*

- RFC 6215, *MPLS Transport Profile User-to-Network and Network-to-Network Interfaces*
- RFC 6291, *Guidelines for the Use of the “OAM” Acronym in the IETF.*
- RFC 6370, *MPLS Transport Profile (MPLS-TP) Identifiers*
- RFC 6371, *Operations, Administration, and Maintenance Framework for MPLS-Based Transport Networks.*
- RFC 6372, *MPLS Transport Profile (MPLS-TP) Survivability Framework*
- RFC 6373, *MPLS-TP Control Plane Framework*
- RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*  
Only Point-to-Multipoint LSPs are supported.
- RFC 6424, *Mechanism for Performing Label Switched Path Ping (LSP Ping) over MPLS Tunnels*
- RFC 6425, *Detecting Data-Plane Failures in Point-to-Multipoint MPLS - Extensions to LSP Ping*
- RFC 6426, *MPLS On-Demand Connectivity Verification and Route Tracing*
- RFC 6428, *Proactive Connectivity Verification, Continuity Check, and Remote Defect Indication for the MPLS Transport Profile*
- RFC 6510, *Resource Reservation Protocol (RSVP) Message Formats for Label Switched Path (LSP) Attributes Objects*
- Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*

The following RFCs and Internet drafts do not define standards, but provide information about MPLS, traffic engineering, and related technologies. The IETF classifies them variously as “Experimental,” “Historic,” or “Informational.”

- RFC 2547, *BGP/MPLS VPNs*
- RFC 2702, *Requirements for Traffic Engineering Over MPLS*
- RFC 2917, *A Core MPLS IP VPN Architecture*
- RFC 3063, *MPLS Loop Prevention Mechanism*
- RFC 3208, *PGM Reliable Transport Protocol Specification*  
Only the network element is supported.
- RFC 3469, *Framework for Multi-Protocol Label Switching (MPLS)-based Recovery*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

Junos OS differs from the Internet draft in the following ways:

- A packet with a sequence number of 0 is treated as out of sequence.
- Any packet that does not have the next incremental sequence number is considered out of sequence.
- When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.
- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*
- Internet draft draft-raggarwa-mpls-p2mp-te-02.txt, *Establishing Point to Multipoint MPLS TE LSPs*

The features discussed in the indicated sections of the draft are not supported:

- Nonadjacent signaling for branch LSPs (section 7.1)
- Make-before-break and fast reroute (section 9)
- LSP hierarchy using point-to-point LSPs (section 10)

## IP and MPLS Packets on Aggregated Interfaces

You can send IP and MPLS packets over aggregated interfaces. To the IP or MPLS session, there is a single LSP composed of the aggregated interfaces. Packets sent to an LSP that is part of an aggregated interface are redistributed over the aggregated member interfaces.

Sending IP and MPLS packets over aggregated interfaces has the following benefits:

- Bandwidth aggregation—You can increase the number of MPLS packet flows sent over each connection. In MPLS, a set of packets sharing the same label is considered a part of the same flow.
- Link redundancy—If a link or a line card failure affects an aggregate member link, the traffic flowing across that link is immediately forwarded across one of the remaining links.

The Junos OS supports aggregated SONET and Ethernet interfaces.

Note that the Junos implementation of IP and MPLS over aggregated interfaces (aggregated Ethernet devices only) complies with IEEE 802.3ad.

For information about how to configure aggregated Ethernet or aggregated SONET interfaces, see *Ethernet Interfaces Feature Guide for Routing Devices* and *Configuring Aggregated SONET/SDH Interfaces*.

## BGP Destinations

You can configure MPLS to control the paths that traffic takes to destinations outside an AS.

Both IBGP and EBGp take advantage of the LSP host routes without requiring extra configuration. BGP compares the BGP next-hop address with the LSP host route. If a match is found, the packets for the BGP route are label-switched over the LSP. If multiple BGP routes share the same next-hop address, all the BGP routes are mapped to the same LSP route, regardless of which BGP peer the routes are learned from. If the BGP next-hop address does not match an LSP host route, BGP routes continue to be forwarded based on the IGP routes within the routing domain. In general, when both an LSP route and an IGP route exist for the same BGP next-hop address, the one with the lowest preference is chosen.

Figure 1 on page 17 shows an MPLS topology that illustrates how MPLS and LSPs work. This topology consists of a single domain with four routers. The two routers at the edges of the domain, Router 1 and Router 4, are running EBGp to communicate with peers outside the domain and IBGP to communicate between themselves. For intradomain communication, all four routers are running an IGP. Finally, an LSP tunnel exists from Router 1 to Router 4.

Figure 1: MPLS Application Topology

When BGP on Router 1 receives prefixes from Router 4, it must determine how to reach a BGP next-hop address. Typically, when traffic engineering is not enabled, BGP uses IGP routes to determine how to reach next-hop addresses. (See the left side of [Figure 2 on page 18](#).) However, when traffic engineering is enabled, if the BGP next-hop matches the LSP tunnel endpoint (that is, the MPLS egress router), those prefixes enter the LSP tunnel. (To track these prefixes, look at the **Active Route** field in the **show mpls lsp** command output or at the output of the **show route label-switched-path path-name** command.) If the BGP next hop does not match an LSP tunnel endpoint, those prefixes are sent following the IGP's shortest path. (See [Figure 2 on page 18](#).)

*Figure 2: How BGP Determines How to Reach Next-Hop Addresses*

## IGP and BGP Destinations

You can configure MPLS to control the paths that traffic takes to destinations within an AS.

When traffic engineering is for BGP destinations only, the MPLS host routes are installed in the inet.3 routing table (see [Figure 31 on page 376](#)), separate from the routes learned from other routing protocols. Not all inet.3 routes are downloaded into the forwarding table. Packets directly addressed to the egress router do not follow the LSP, which prevents routes learned from LSPs from overriding routes learned from IGP or other sources.

Traffic within a domain, including BGP control traffic between BGP peers, is not affected by LSPs. MPLS affects interdomain traffic only; that is, it affects only those BGP prefixes that are learned from an external domain. MPLS does not disrupt intradomain traffic, so IS-IS or OSPF routes remain undisturbed. If you issue a **ping** or **traceroute** command to any destination within the domain, the **ping** or **traceroute** packets follow the IGP path. However, if you issue a **ping** or **traceroute** command from Router 1 in [Figure 1 on page 17](#) (the LSP ingress router) to a destination outside of the domain, the packets use the LSP tunnel.

When traffic engineering for IGP and BGP destinations is enabled, the MPLS host routes are installed in the inet.0 table (see [Figure 32 on page 377](#)) and downloaded into the forwarding table. Any traffic destined to the egress router could enter the LSP. In effect, it moves all the routes in inet.3 into inet.0, causing the inet.3 table to be emptied.

RSVP packets automatically avoid all MPLS LSPs, including those established by RSVP or LDP. This prevents placing one RSVP session into another LSP, or in other words, nesting one LSP into another.

## Install Prefix IGP Overview

---

When an RSVP LSP is working, the RSVP protocol installs a set of route entries in one or more of the following tables:

- inet.3
- inet6.3
- inet.0
- inet6.0

The details of routes installed in the corresponding tables are controlled by configuration. The routes that may be installed for the LSP by the RSVP protocol are the destination address of the LSP and any number of prefixes configured with the **protocols mpls label-switched-patch *name* install** configuration option.

When installing RSVP protocol routes for an LSP, the resulting metric for the routes can either be a (per-LSP) statically configured value or it can follow the IGP's metric for the LSP's destination address. Before Junos OS release 18.4R1, all RSVP protocol routes would use the same metric. If the LSP had a statically configured metric, then the destination address and all install prefixes would use the statically configured metric. If the LSP used the default behavior of following the IGP metric, then all the install prefixes would use the IGP metric of the LSP's destination address.

From Junos OS release 18.4R1 onwards, a configuration option allows the install prefixes to follow the metric of their corresponding IGP prefix so that the various RSVP protocol routes installed for the LSP can now each have their individual metric value.

## MPLS Feature Support on QFX Series and EX4600 Switches

MPLS is a set of procedures for augmenting network layer packets with label stacks, thereby turning them into labeled packets. Service providers frequently use MPLS. Simply put, where routers in a traditional network each perform an IP lookup to determine the next hop, the first device in an MPLS network does a routing lookup for the final destination instead of the next hop. A label is then applied to the packet—this is called *packet switching*. The final destination device removes the label.

A number of Juniper Networks switches are capable of running a subset of MPLS and can, therefore, communicate not only with each other, but with Juniper Networks routers running MPLS. This topic describes the major MPLS features that are supported on QFX Series and EX4600 switches. Be sure to check for any exceptions to this support in [“MPLS Limitations on QFX Series and EX4600 Switches” on page 34](#).

**NOTE:** EX4600 switches use the same chipset as QFX5100 switches—this is why that EX Series switch is discussed here along with QFX Series switches. Other EX Series switches also support MPLS but with a different feature set.

This topic describes:

- [MPLS Commands Supported by QFX Series and EX4600 Switches on page 20](#)
- [MPLS Features Supported by QFX Series and EX4600 Switches on page 20](#)

### MPLS Commands Supported by QFX Series and EX4600 Switches

QFX Series and EX4600 switches support a subset of MPLS features. The CLI for switches displays all MPLS related configuration statements, even those that are not supported. However, configuring those unsupported statements on a switch has no effect on the operation of the switch.

### MPLS Features Supported by QFX Series and EX4600 Switches

The tables in this section lists the major MPLS features supported on the QFX Series and EX4600 switches, and the Junos OS release in which they were introduced.

[Table 5 on page 20](#) lists the features for the QFX10000 switches. [Table 6 on page 23](#) lists the features for the QFX3500, EX4600, EX4650, QFX5100, QFX5120, QFX5110, QFX5200, and QFX5210 switches.

**Table 5: QFX10000 MPLS Features with Junos OS Release Support**

Feature	QFX10002	QFX10008	QFX10016
QFX10000 standalone switch as an MPLS provider edge (PE) switch or provider switch	15.1X53-D10	15.1X53-D30	15.1X53-D60
Label edge router (LER)	15.1X53-D10	15.1X53-D30	15.1X53-D60

Table 5: QFX10000 MPLS Features with Junos OS Release Support (continued)

Feature	QFX10002	QFX10008	QFX10016
Label-switching router (LSR)	15.1X53-D10	15.1X53-D30	15.1X53-D60
BGP MPLS Ethernet VPN (EVPN)	17.4R1	17.4R1	17.4R1
BGP route reflectors	15.1X53-D10	15.1X53-D30	15.1X53-D60
Automatic bandwidth and dynamic label-switched path (LSP) count sizing	15.1X53-D60	15.1X53-D60, 17.2R1	15.1X53-D60, 17.2R1
BGP labeled unicast	15.1X53-D10	15.1X53-D30	15.1X53-D60
BGP link state distribution	17.1R1	17.1R1	17.1R1
Carrier-of-carriers and interprovider Layer 3 VPNs	17.1R1	17.1R1	17.1R1
Entropy labels	17.2R1	17.2R1	17.2R1
Ethernet-over-MPLS (L2 circuit)	15.1X53-D60	15.1X53-D60	15.1X53-D60
Fast reroute, one-to-one local protection and many-to-one local protection	15.1X53-D10	15.1X53-D30	15.1X53-D60
Fast reroute using detours and secondary LSP	15.1X53-D10	15.1X53-D30	15.1X53-D60
Flexible Ethernet services	17.3R1	17.3R1	17.3R1
Firewall filters	15.1X53-D30	15.1X53-D30	15.1X53-D60
RSVP graceful restart for OSPF	15.1X53-D10	15.1X53-D30	15.1X53-D60
IP-over-MPLS LSPs, both static and dynamic links	15.1X53-D10	15.1X53-D30	15.1X53-D60
IPv6 tunneling over an IPv4 network (6PE)	15.1X53-D10	15.1X53-D30	15.1X53-D60
LDP tunneling over RSVP	15.1X53-D10	15.1X53-D30	15.1X53-D60
L2 Circuit on aggregated interfaces	17.3R1	17.3R1	17.3R1
L3VPNs for both IPv4 and IPv6	15.1X53-D10	15.1X53-D30	15.1X53-D60
MPLS over integrated bridging and routing (IRB) interfaces	15.1X53-D10	15.1X53-D30	15.1X53-D60
MPLS over UDP	18.3R1	18.3R1	18.3R1

Table 5: QFX10000 MPLS Features with Junos OS Release Support (continued)

Feature	QFX10002	QFX10008	QFX10016
MTU signaling in RSVP	15.1X53-D10	15.1X53-D30	15.1X53-D60
Operation, Administration, and Maintenance (OAM) including ping, traceroute and Bidirectional Forwarding Detection (BFD)	15.1X53-D10	15.1X53-D30	15.1X53-D60
OSPF TE	15.1X53-D10	15.1X53-D30	15.1X53-D60
OSPFv2 as an interior gateway protocol (IGP)	15.1X53-D10	15.1X53-D30	15.1X53-D60
Path Computation Element Protocol for RSVP-TE	16.3R1	16.3R1	16.3R1
Pseudowire-over-aggregated Ethernet interfaces (core-facing interface)	15.1X53-D60 (supported only on network-to-network (NNI) interfaces)	15.1X53-D60 (supported only on NNI interfaces)	15.1X53-D60 (supported only on NNI interfaces)
RSVP support, including bandwidth allocation and traffic engineering	15.1X53-D10	15.1X53-D30	15.1X53-D60
RSVP fast reroute (FRR), including link-protection, node-link-protection, fast reroute using detours, and secondary LSP	15.1X53-D10	15.1X53-D30	15.1X53-D60
SNMP MIB support	15.1X53-D10	15.1X54-D30	15.1X53-D60
Static and dynamic LSPs	15.1X53-D10	15.1X53-D30	15.1X53-D60
Traffic engineering extensions (OSPF-TE, IS-IS-TE)	15.1X53-D10	15.1X53-D30	15.1X53-D60
Traffic engineering (TE)	15.1X53-D10	15.1X53-D30	15.1X53-D60
Automatic bandwidth allocation and RSVP bandwidth			
Dynamic bandwidth management using ingress LSP splitting and merging			
Virtual routing and forwarding (VRF) label support	15.1X53-D10	15.1X53-D30	15.1X53-D60

## Understanding MPLS Components for QFX Series and EX4600 Switches

---

MPLS devices include a number of components. While some components are required for all MPLS applications, others might not be, depending on the specific application.

This topic includes:

- [Provider Edge Switches on page 30](#)
- [Provider Switch on page 31](#)
- [Components Required for All Switches in the MPLS Network on page 32](#)

### Provider Edge Switches

To implement MPLS on a network, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch. In addition, you must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets.

The ingress PE switch (the entry point to the MPLS tunnel) receives a packet, analyzes it, and pushes an MPLS label onto it. This label places the packet in a forwarding equivalence class (FEC) and determines its handling and destination through the MPLS tunnel. The egress PE switch (the exit point from the MPLS tunnel) pops the MPLS label off the outgoing packet.

Within an MPLS tunnel, the network traffic is bidirectional. Therefore, each PE switch can be configured to be both an ingress switch and an egress switch, depending on the direction of the traffic.

The following MPLS components are configured on the PE switches but not on the provider switches:

- [MPLS Protocol and Label-Switched Paths on page 30](#)
- [IP Over MPLS for Customer Edge Interfaces on page 30](#)
- [BGP Layer 3 VPN Configuration on page 31](#)
- [Routing Instances for Layer 3 VPN on page 31](#)
- [Routing Instances for Layer 2 VPN and Layer 3 VPN on page 31](#)
- [Ethernet Encapsulation for Layer 2 VPN on page 31](#)

### MPLS Protocol and Label-Switched Paths

---

Each PE switch must be configured to support the MPLS protocol. You must also configure label-switched paths (LSPs) at the `[edit protocols mpls]` hierarchy level.

### IP Over MPLS for Customer Edge Interfaces

---

You can configure the customer edge interfaces of the PE switches for IP over MPLS using a Layer 3 interface and a static route from the ingress PE switch to the egress PE switch. See [“Configuring MPLS on Provider Edge Switches” on page 67](#).

### BGP Layer 3 VPN Configuration

---

If you are implementing a Layer 3 virtual private network (VPN), you must configure the BGP routing protocol on the PE switches.

### Routing Instances for Layer 3 VPN

---

If you are implementing a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

QFX Series and EX4600 devices support VPN routing and forwarding (VRF) routing instances for Layer 3 VPNs.

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

### Routing Instances for Layer 2 VPN and Layer 3 VPN

---

If you are implementing a Layer 2 VPN or a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

Starting in Junos OS Release 15.1, QFX Series devices support the following types of routing instances:

- Layer 2 VPN—To support a Layer 2 VPN (Layer 2 VPNs are not supported on the QFX5100 and EX4600 switches.)
- VPN routing and forwarding (VRF)—To support a Layer 3 VPN

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

### Ethernet Encapsulation for Layer 2 VPN

---

If you are implementing a Layer 2 VPN, you must also configure the physical layer encapsulation type on the customer edge interface and within the routing instance.

## Provider Switch

You must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets. You can add provider switches without changing the configuration of the PE switches.

A provider switch does not analyze packets. It refers to an MPLS label forwarding table and swaps one label for another. The new label determines the next hop along the MPLS tunnel. A provider switch cannot perform push or pop operations.

## Components Required for All Switches in the MPLS Network

The following MPLS components are configured on both the PE switches and the provider switches:

- [Interior Gateway Protocol on page 32](#)
- [Traffic Engineering on page 32](#)
- [MPLS Protocol on page 32](#)
- [RSVP on page 33](#)
- [Family mpls on page 33](#)

---

### Interior Gateway Protocol

MPLS works in coordination with OSPF as the interior gateway protocol (IGP). Therefore, you must configure OSPF as the IGP on the loopback interface and CE-facing interfaces of both the PE switches and the provider switches.

The CE-facing interfaces can be either Gigabit Ethernet or 10-Gigabit Ethernet interfaces, and they can be configured as either individual interfaces or as aggregated Ethernet interfaces.

.....

**NOTE:** The CE-facing interfaces cannot be configured with VLAN tagging or a VLAN ID. When you configure them to belong to family mpls, they are removed from the default VLAN if they were members of that VLAN. They operate as an exclusive tunnel for MPLS traffic.

.....

---

### Traffic Engineering

Traffic engineering maps traffic flows onto an existing physical topology and provides the ability to move traffic flow away from the shortest path selected by the IGP and to a potentially less congested physical path across a network.

Traffic engineering enables the selection of specific end-to-end paths to send given types of traffic through your network. You must configure OSPF traffic engineering on the PE switches and the provider switches.

---

### MPLS Protocol

You must enable the MPLS protocol on all switches that participate in the MPLS network and apply it to the core interfaces of both the PE and provider switches. You do not need to apply it to the loopback interface because the MPLS protocol uses the framework established by the RSVP signaling protocol to create LSPs. On the PE switches, the configuration of the MPLS protocol must also include the definition of an LSP.

## RSVP

RSVP is a signaling protocol that allocates and distributes labels throughout an MPLS network. RSVP sets up unidirectional paths between the ingress PE switch and the egress PE switch. RSVP makes the LSPs dynamic; it can detect topology changes and outages and establish new LSPs to allow traffic to move around a failure.

You must enable RSVP and apply it to the loopback interface and the core interface of both the PE and provider switches. The path message contains the configured information about the resources required for the LSP to be established.

When the egress PE switch receives the path message, it sends a reservation message back to the ingress PE switch. This reservation message is passed along from switch to switch along the same path as the original path message. Once the ingress PE switch receives this reservation message, an RSVP path is established.

The established LSP stays active as long as the RSVP session remains active. RSVP continues activity through the transmissions and responses to RSVP path and reservation messages. If the messages stop for three minutes, the RSVP session terminates and the LSP is lost.

RSVP runs as a separate software process in Junos OS and is not in the packet-forwarding path.

## Family mpls

You must configure the core interfaces used for MPLS traffic to belong to **family mpls**.

**NOTE:** You can enable **family mpls** on either individual interfaces or on aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

## Understanding MPLS and Path Protection on EX Series Switches

---

Junos OS MPLS for Juniper Networks EX Series Ethernet Switches provides path protection to protect your MPLS network from label switched path (LSP) failures.

By default, an LSP routes itself hop-by-hop from the ingress provider edge switch through the provider switches toward the egress provider edge switch. The LSP generally follows the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are “soft” in nature because they automatically reroute themselves whenever a change occurs in a routing table or in the status of a node or link.

Typically, when an LSP fails, the switch immediately upstream from the failure signals the outage to the ingress provider edge switch. The ingress provider edge switch calculates a new path to the egress provider edge switch, establishes the new LSP, and then directs traffic from the failed path to the new path. This rerouting process can be time-consuming and prone to failure. For example, the outage signals to the ingress switch might get lost or the new path might take too long to come up, resulting in significant packet drops.

You can configure path protection by configuring primary and secondary paths on the ingress switch. If the primary path fails, the ingress switch immediately reroutes traffic from the failed path to the standby path, eliminating the need for the ingress switch to calculate a new route and signal a new path. For information about configuring standby LSPs, see [“Configuring Path Protection in an MPLS Network \(CLI Procedure\)” on page 113](#).

## MPLS Limitations on QFX Series and EX4600 Switches

---

MPLS is a fully implemented protocol on routers, while switches support a subset of the MPLS features. The limitations of each switch are listed in a separate section here, although many of the limitations are duplicates that apply to more than one switch.

- [MPLS Limitations on QFX10000 Switches on page 35](#)
- [MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches on page 35](#)
- [MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches on page 37](#)
- [MPLS Limitations on QFX3500 Switches on page 38](#)

## MPLS Limitations on QFX10000 Switches

- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.
- These LDP features are not supported on the QFX10000 switches:
  - LDP multipoint
  - LDP link protection
  - LDP Bidirectional Forwarding Detection (BFD)
  - LDP Operation Administration and Management (OAM)
  - LDP multicast-only fast reroute (MoFRR)
- Pseudowire-over-aggregated Ethernet interfaces on UNI are not supported.
- MPLS-over-UDP tunnels are not supported on the following:
  - MPLS TTL propagation
  - IP fragmentation at the tunnel start point
  - CoS rewrite rules and priority propagation for RSVP LSP labels (ingress tunnels only)
  - Plain IPv6
  - Multicast traffic
  - Firewall filters on tunnel start and endpoints
  - CoS tunnel endpoints

**NOTE:** MPLS-over-UDP tunnels are created only if corresponding RSVP-TE, LDP, or BGP-LU tunnels are not available for the destination route.

## MPLS Limitations on EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 Switches

- MPLS support differs on the various switches. EX4600 switches support only basic MPLS functionality while the QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches support some of the more advanced features. See [“MPLS Feature Support on QFX Series and EX4600 Switches” on page 20](#) for details.
- On a QFX5100 switch, configuring integrated bridging and routing (IRB) interfaces on the MPLS core is implemented on the switch by using TCAM rules. This is the result of a chip limitation on the switch, which only allows for a limited amount of TCAM space. There is 1K TCAM space is allocated for IRB. If multiple IRBs exist, make sure that you have enough available TCAM space on the switch. To check the TCAM space, see

### TCAM Filter Space Allocation and Verification in QFX Devices from Junos OS 12.2x50-D20 Onward.

- (QFX5100, QFX5110, QFX5120, QFX5200, QFX5210, EX4600) When VLAN bridge encapsulation is enabled on a CE connected interface, the switch drops packets if both flexible Ethernet services and VLAN CCC encapsulations are configured on the same logical interface. Only one can be configured, not both. For example:

**set interfaces xe-0/0/18 encapsulation flexible-ethernet-services**, or **set interfaces xe-0/0/18 encapsulation vlan-ccc**.

- Layer 2 circuits on aggregated Ethernet (AE) interfaces are not supported on QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches.
- Layer 2 circuit local switching is not supported on the EX4600, EX4650, and QFX5100 switches.
- The QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches do not depend on the VRF match for loopback filters configured at different routing instances. Loopback filters per routing instance (such as lo0.100, lo0.103, lo0.105) are not supported and may cause unpredictable behavior. We recommend that you only apply the loopback filter (lo0.0) to the master routing instance.
- On EX4600 and EX4650 switches, when loopback filters with both accept and deny terms for the same IP address are configured and if RSVP packets have that IP address in either source IP or destination IP, then those RSVP packets will be dropped even if accept terms have higher priority than deny terms. As per design, if the switch receives an RSVP packet with IP OPTION, the packet is copied to the CPU and then the original packet is dropped. Because RSVP packets are marked for drop, the accept term will not process these packets and the deny term will drop the packets.
- On a link-protected, fast reroute Layer 2 circuit, you might see a traffic convergence delay of 200 to 300 milliseconds.
- Layer 2 circuit local switching is not supported on the EX4600, EX4650, and QFX5100 switches.
- If you configure the BGP labeled unicast address family (using the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level) on a QFX Series switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath information.
- Although fast reroute (FRR) on regular interfaces is supported, the **include-all** and **include-any** options for FRR are not supported. See [“Fast Reroute Overview” on page 379](#).
- FRR is not supported on MPLS over IRB interfaces.
- MPLS-based circuit cross-connects (CCC) are not supported—only circuit-based pseudowires are supported.
- Configuring link aggregation groups (LAGs) on user-to-network interface (UNI) ports for L2 circuits is not supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in the data plane.

- With L2 circuit-based pseudowires, if multiple equal-cost RSVP LSPs are available to reach an L2 circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2 circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Firewall filters and policers on **family mpls** are only supported on QFX5100 switches that act as pure label-switching routers (LSRs) in an MPLS network. A pure LSR is a transit router that switches paths solely on the incoming label's instructions. Firewall filters and policers on **family mpls** are not supported on QFX5100 ingress and egress provider edge (PE) switches. This includes switches that perform penultimate hop popping (PHP).
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.
- These are the hardware limitations for EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches:
  - Push of a maximum of three labels is supported in the MPLS edge switch if label swap is not done.
  - Push of a maximum of two labels is supported in the MPLS edge switch if label swap is done.
  - Pop at line rate is supported for a maximum of two labels.
  - Global label space is supported but interface-specific label space is not supported.
  - MPLS ECMP on PHY node with BOS=1 is not supported for single labels.
  - QFX Series switches with Broadcom chips do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes the QFX3500, QFX3600, EX4600, QFX5100, and QFX5200 switches.
  - On EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches, the MPLS MTU command can cause unexpected behavior—this is due to SDK chipset limitations on this platform.
- These LDP features are not supported on the EX4600, EX4650, QFX5100, QFX5110, QFX5120, QFX5200, and QFX5210 switches:
  - LDP multipoint
  - LDP link protection
  - LDP Bidirectional Forwarding Detection (BFD)
  - LDP Operation Administration and Management (OAM)
  - LDP multicast-only fast reroute (MoFRR)

## MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric Switches

The following MPLS features are not supported by the QFX5100 VC and QFX5100 VCF switches:

- Next-hop LSP
- BFD including BFD triggered FRR
- L2 VPN based on BGP (See [RFC 6624](#))
- VPLS
- Extended VLAN CCC
- Pseudowire protection using Ethernet OAM
- Local switching of pseudo-wire
- Pseudowire fault detection based on VCCV
- QFX Series switches with Broadcom chipsets do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes QFX3500, QFX3600, EX4600, QFX5100, and QFX5200 switches.

## MPLS Limitations on QFX3500 Switches

- If you configure the BGP labeled unicast address family (using the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level) on a QFX Series switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath information.
- Although fast reroute is supported, the **include-all** and **include-any** options for fast reroute are not supported. See “[Fast Reroute Overview](#)” on [page 379](#) for details.
- MPLS-based circuit cross-connects (CCC) are not supported—only circuit-based pseudowires are supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in the data plane.
- With Layer 2 (L2) circuit-based pseudowires, if multiple equal-cost RSVP label-switched paths (LSPs) are available to reach a L2 circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2 circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.

## MPLS Configuration Overview

---

When you first install Junos OS on your device, MPLS is disabled by default. You must explicitly configure your device to allow MPLS traffic to pass through. Complete the following steps for all devices in your MPLS network that are running Junos OS.

To enable MPLS:

1. Delete all configured security services from the device. If you do not complete this step, you will get a commit failure. See *Example: Deleting Security Services*.
2. Enable MPLS on the device. See “[Example: Enabling MPLS](#)” on page 45.
3. Commit the configuration.
4. Reboot the device.
5. Configure MPLS features such as traffic engineering, VPNs, and VPLS. See:
  - [MPLS Traffic Engineering and Signaling Protocols Overview](#) on page 910
  - [MPLS VPN Overview](#) on page 1160
  - [CLNS Overview](#) on page 1243
  - [VPLS Overview](#) on page 1262

**CAUTION:** When packet forwarding mode is changed to MPLS, all flow-based security features are deactivated, and the device performs packet-based processing only. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device. However, MPLS can be enabled in flow-based packet forwarding mode for selected traffic using firewall filters.

## MPLS Configuration Guidelines

---

When configuring MPLS on QFX Series devices or on EX4600, note that the number of IP prefixes supported depends on the specific platform being used. See the scale specifications in the data sheet of your device for additional information.

- We recommend the following:

- If your ingress provider edge (PE) switch needs to support more than 8000 external IP prefixes, use a larger capacity device as an ingress PE switch.
- If you use a switch as a route reflector for BGP labeled routes, use it as a dedicated route reflector (that is, the switch must not participate in managing data traffic).
- If you use a switch as a PE switch or as a route reflector for BGP labeled routes, configure routing policies on the PE switch and the route reflector to filter external IP routes from the routing table.

The configuration example for a routing policy named `fib_policy` (at the **[edit policy-options]** and **[edit routing-options]** hierarchy levels) to filter BGP labeled routes from the `inet.0` routing table is given below:

```
user@switch# show policy-options
policy-statement fib_policy {
  from {
    protocol bgp;
    rib inet.0;
  }
  then reject;
}
```

```
user@switch# show routing-options
forwarding-table {
  export fib_policy;
}
```

- Packet fragmentation using the **allow-fragmentation** statement at the **[edit protocols mpls path-mtu]** hierarchy level is not supported on QFX Series devices or on the EX4600 switch. Therefore, you must ensure that the maximum transmission unit (MTU) values configured on every MPLS interface is sufficient to handle MPLS packets. The packets whose size exceeds the MTU value of an interface will be dropped.

## TTL Processing on Incoming MPLS Packets

The flow chart on [Figure 3 on page 42](#) illustrates TTL processing on incoming MPLS packets. On a transit LSR or an egress LER, MPLS pops one or more labels and can push one or more labels. The incoming TTL of the packet is determined by the configured TTL processing tunnel model.

When all of the following conditions are met, the incoming TTL is set to the TTL value found in the immediate inner header:

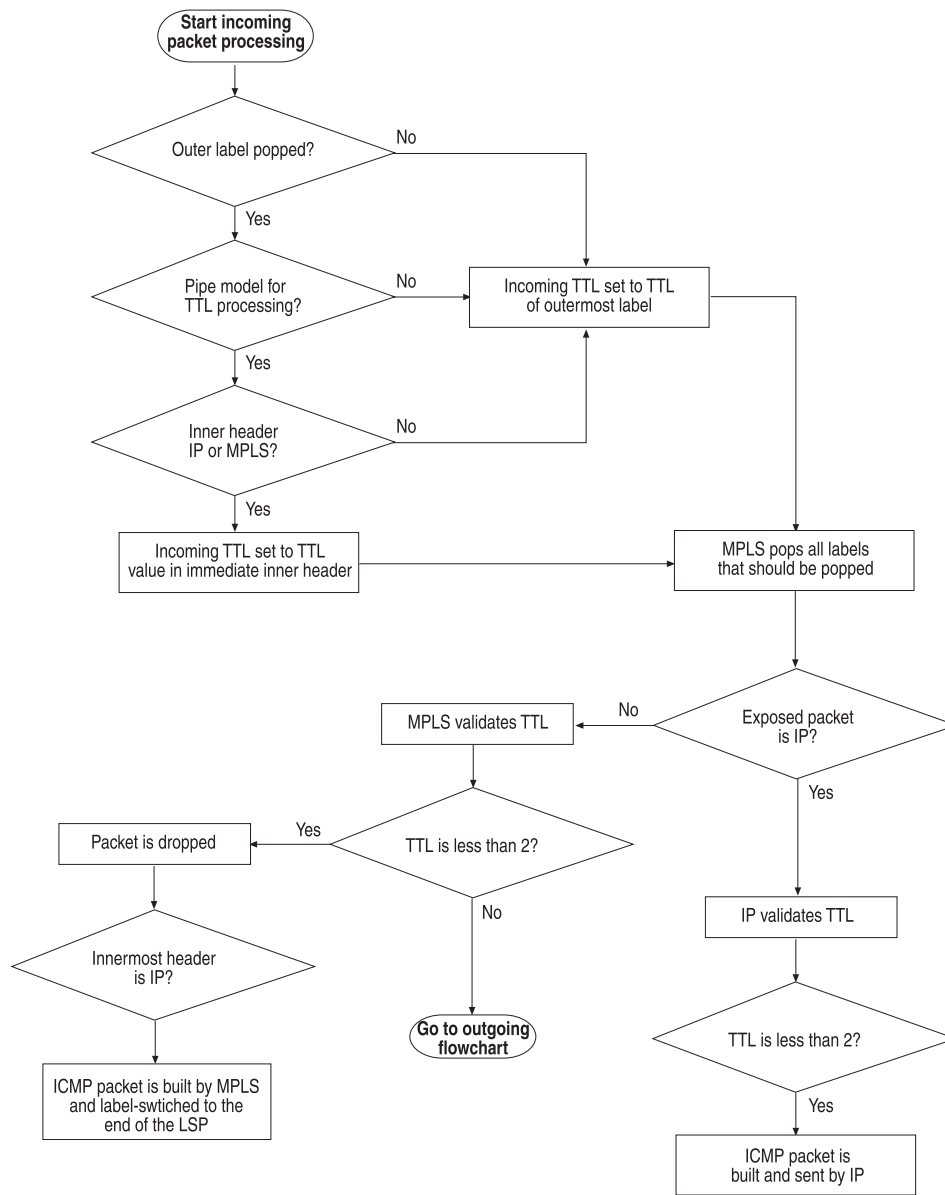

- The outer label is popped as opposed to being swapped
- The TTL processing model is configured to pipe
- The inner header is MPLS or IP

If any of those conditions is not met, then the incoming TTL is set to the TTL value found in the outermost label. In all cases, the TTL values of any further inner labels are ignored.

When an IP packet is exposed after MPLS pops all the labels that should be popped, MPLS passes the packet to IP for further processing, including TTL checking. When the uniform tunnel model for TTL processing is in effect, MPLS sets the TTL value of the IP packet to the incoming TTL value that was just set. In other words, the TTL value is copied from the outermost label to the IP packet. When the pipe model for TTL processing is in effect, the TTL value in the IP header is left unchanged.

If an IP packet is not exposed by the label popping, then MPLS performs the TTL validation. If the incoming TTL is less than 2, the packet is dropped. If innermost packet is IP, an ICMP packet is built and sent. If the TTL does not expire and the packet needs to be sent out, the outgoing TTL is determined by the rules for outgoing MPLS packets.

## Configuring MPLS

---

You must also configure MPLS for a Layer 2 cross-connect to work. The following is a minimal MPLS configuration:

```
[edit]
interfaces {
  interface-name {
    unit logical-unit-number;
  }
}
protocols {
  mpls {
    interface all;
  }
}
```

## Example: Enabling MPLS

---

This example shows how to enable MPLS for packet-based processing. It also shows how to enable the MPLS family and MPLS process on all of the transit interfaces in the network.

**NOTE:** When MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, IP packets, and IPsec VPNs are unavailable on the device.

Before changing from flow mode to packet mode, you must remove all security policies remaining under flow mode. To prevent management connection loss, you must bind the management interface to zones and enable host-inbound traffic to prevent the device from losing connectivity.

For information about configuring zones, see *Security Policies Feature Guide for Security Devices*.

---

## Requirements

Before you begin, delete all configured security services. See *Example: Deleting Security Services*.

## Overview

The instructions in this topic describe how to enable MPLS on the device. You must enable MPLS on the device before including a device running Junos OS in an MPLS network.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security forwarding-options family mpls mode packet-based
set interfaces ge-1/0/0 unit 0 family mpls
set protocols mpls ge-1/0/0 unit 0
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To enable MPLS:

1. Enable MPLS for packet-based processing.

```
[edit security forwarding-options]
user@host# set family mpls mode packet-based
```

2. Enable the MPLS family on each transit interface that you want to include in the MPLS network.

```
[edit interfaces]
user@host# set interfaces ge-1/0/0 unit 0 family mpls
```

3. Enable the MPLS process on all of the transit interfaces in the MPLS network.

```
[edit protocols mpls]
user@host# set interface ge-1/0/0 unit 0
```

**Results** From configuration mode, confirm your configuration by entering the **show security forwarding-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

**NOTE:** If you enable MPLS for packet-based processing by using the command **set security forward-option family mpls mode packet**, the mode will not change immediately and the system will display the following messages:

*warning: Reboot may required when try reset flow inet mode*

*warning: Reboot may required when try reset mpls flow mode please check security flow status for detail.*

You need to reboot your device for the configuration to take effect.

**CAUTION:** If you disable MPLS and switch back to using the security services (flow-based processing), the mode will not change immediately and the system will display warning messages instructing you to restart your device. You must reboot your device for the configuration to take effect. This will also result in management sessions being reset and transit traffic getting interrupted.

```
[edit]
user@host# show security forwarding-options
family {
  mpls {
    mode packet-based;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying MPLS Is Enabled at the Protocols Level on page 48](#)
- [Verifying MPLS Is Enabled at the Interfaces Level on page 48](#)

### Verifying MPLS Is Enabled at the Protocols Level

---

**Purpose** Verify that MPLS is enabled at the protocols level.

**Action** From operational mode, enter the **show protocols** command.

### Verifying MPLS Is Enabled at the Interfaces Level

---

**Purpose** Verify that MPLS is enabled at the interfaces level.

**Action** From operational mode, enter the **show interfaces** command.

## Example: Configuring MPLS on EX8200 and EX4500 Switches

---

You can configure MPLS on switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

To implement MPLS on the switches, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch— and at least one provider (transit) switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network as either circuit cross-connect (CCC) or IP (**family inet**) interfaces.

This example shows how to configure an MPLS tunnel using a simple interface as a CCC:

**NOTE:** This example shows how to configure MPLS using a simple interface as a CCC. For information on configuring a tagged VLAN interface as a CCC, see [“Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN \(CLI Procedure\)”](#) on page 1376 or [“Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit \(CLI Procedure\)”](#) on page 1346.

- [Requirements on page 49](#)
- [Overview and Topology on page 49](#)
- [Configuring the Local PE Switch on page 53](#)
- [Configuring the Remote PE Switch on page 56](#)
- [Configuring the Provider Switch on page 58](#)
- [Verification on page 60](#)

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for switches
- Three EX Series switches

Before you begin configuring MPLS, ensure that you have configured the routing protocol (OSPF or IS-IS) on the core interface and the loopback interface on all the switches. This example includes the configuration of OSPF on all the switches. For information on configuring IS-IS as the routing protocol, see the [Junos OS Routing Protocols Configuration Guide](#).

## Overview and Topology

This example includes an ingress or local PE switch, an egress or remote PE switch, and one provider switch. It includes CCCs that tie the customer edge interface of the local PE switch (PE-1) to the customer edge interface of the remote PE switch (PE-2). It also describes how to configure the core interfaces of the PE switches and the provider switch to support the transmission of the MPLS packets. In this example, the core interfaces that connect the local PE switch and the provider switch are individual interfaces, while the core interfaces that connect the remote PE switch and the provider switch are aggregated Ethernet interfaces.

**NOTE:**

- Core interfaces cannot be tagged VLAN interfaces.
- Core interfaces can be aggregated Ethernet interfaces. This example includes a LAG between the provider switch and the remote PE switch because this type of configuration is another option you can implement. For information on configuring LAGs, see [Configuring Aggregated Ethernet Links \(CLI Procedure\)](#).

Figure 4 on page 50 shows the topology used in this example.

Figure 4: Configuring MPLS on EX Series Switches

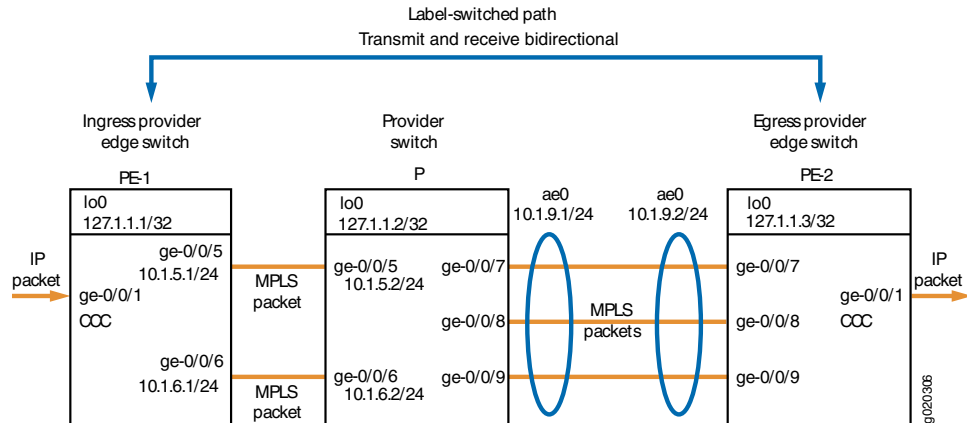

Table 7 on page 50 shows the MPLS configuration components used for the ingress PE switch in this example.

Table 7: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Loopback address	lo0 127.1.1.1/32	Identifies PE-1 for interswitch communications.
Routing protocol	ospf traffic-engineering	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol and definition of label-switched path	mpls label-switched-path lsp_to_pe2_ge1 to 127.1.13	Indicates that this PE switch is using the MPLS protocol with the specified LSP to reach the other PE switch (specified by the loopback address).  The statement must also specify the core interfaces to be used for MPLS traffic.
RSVP	rsvp	Indicates that this switch is using RSVP. The statement must specify the loopback address and the core interfaces that will be used for the RSVP session.
Interface family	family inet family mpls family ccc	The logical units of the core interfaces are configured to belong to both <b>family inet</b> and <b>family mpls</b> .  The logical unit of the customer edge interface is configured to belong to <b>family ccc</b> .

*Table 7: Components of the Ingress PE Switch in the Topology for MPLS with Interface-Based CCC (continued)*

Property	Settings	Description
Customer edge interface	<b>ge-0/0/1</b>	Interface that connects this network to devices outside the network.
Core interfaces	<b>ge-0/0/5.0</b> and <b>ge-0/0/6.0</b> with IP addresses 10.1.5.1/24 and 10.1.6.1/24	Interfaces that connect to other switches within the MPLS network.
CCC definition	<b>connections</b> <b>remote-interface-switch ge-1-to-pe2</b>  <b>interface ge-0/0/1.0</b>  <b>transmit-lsp lsp_to_pe2_ge1</b> <b>receive-lsp lsp_to_pe1_ge1</b>	Associates the circuit cross-connect (CCC), <b>ge-0/0/1</b> , with the LSPs that have been defined on the local and remote PE switches.

[Table 8 on page 51](#) shows the MPLS configuration components used for the egress PE switch in this example.

*Table 8: Components of the Egress PE Switch in the Topology for MPLS with Interface-Based CCC*

Property	Settings	Description
Remote PE switch hardware	EX Series switch	PE-2
Loopback address	<b>lo0 127.1.1.3/32</b>	Identifies PE-2 for interswitch communications.
Routing protocol	<b>ospf traffic-engineering</b>	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol and definition of label-switched path	<b>mpls</b>  <b>label-switched-path lsp_to_pe1_ge1</b>  <b>to 127.1.1.1</b>	<p>Indicates that this PE switch is using the MPLS protocol with the specified label-switched path (LSP) to reach the other PE switch.</p> <p>The statement must also specify the core interfaces to be used for MPLS traffic.</p>
RSVP	<b>rsvp</b>	Indicates that this switch is using RSVP. The statement must specify the loopback address and the core interfaces that will be used for the RSVP session.
Interface family	<b>family inet</b>  <b>family mpls</b>  <b>family ccc</b>	<p>The logical unit of the core interface is configured to belong to both <b>family inet</b> and <b>family mpls</b>.</p> <p>The logical unit of the customer edge interface is configured to belong to <b>family ccc</b>.</p>

**Table 8: Components of the Egress PE Switch in the Topology for MPLS with Interface-Based CCC (continued)**

Property	Settings	Description
Customer edge interface	<b>ge-0/0/1</b>	Interface that connects this network to devices outside the network.
Core interface	<b>ae0</b> with IP address <b>10.1.9.2/24</b>	Aggregated Ethernet interface on PE-2 that connects to aggregated Ethernet interface <b>ae0</b> of the provider switch and belongs to <b>family mpls</b> .
CCC definition	<b>connections remote-interface-switch ge-1-to-pe1</b>  <b>interface ge-0/0/1.0</b>  <b>transmit-lsp lsp_to_pe1_ge1;</b> <b>receive-lsp lsp_to_pe2_ge1;</b>	Associates the CCC, <b>ge-0/0/1</b> , with the LSPs that have been defined on the local and remote PE switches.

[Table 9 on page 52](#) shows the MPLS configuration components used for the provider switch in this example.

**Table 9: Components of the Provider Switch in the Topology for MPLS with Interface-Based CCC**

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Loopback address	<b>lo0 127.1.1.2/32</b>	Identifies provider switch for interswitch communications.
Routing protocol	<b>ospf traffic-engineering</b>	Indicates that this switch is using OSPF as the routing protocol and that traffic engineering is enabled.
MPLS protocol	<b>mpls</b>	Indicates that this switch is using the MPLS protocol.  The statement must specify the core interfaces that will be used for MPLS traffic.
RSVP	<b>rsvp</b>	Indicates that this switch is using RSVP. The statement must specify the loopback and the core interfaces that will be used for the RSVP session.
Interface family	<b>family inet</b>  <b>family mpls</b>	The logical units for the loopback interface and the core interfaces belong to <b>family inet</b> .  The logical units of the core interfaces are also configured to belong to <b>family mpls</b> .

Table 9: Components of the Provider Switch in the Topology for MPLS with Interface-Based CCC (continued)

Property	Settings	Description
Core interfaces	<code>ge-0/0/5.0</code> and <code>ge-0/0/6.0</code> with IP addresses <code>10.1.5.1/24</code> and <code>10.1.6.1/24</code> and <code>ae0</code> with IP address <code>10.1.9.1/24</code>	Interfaces that connect the provider switch (P) to PE-1.  Aggregated Ethernet interface on P that connects to aggregated Ethernet interface <code>ae0</code> of PE-2.

## Configuring the Local PE Switch

**CLI Quick Configuration** To quickly configure the local ingress PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
set protocols ospf area 0.0.0.0 interface ge-0/0/6.0
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
set protocols mpls interface ge-0/0/5.0
set protocols mpls interface ge-0/0/6.0
set protocols rsvp interface lo0.0
set protocols rsvp interface ge-0/0/5.0
set protocols rsvp interface ge-0/0/6.0
set interfaces lo0 unit 0 family inet address 127.1.1.1/32
set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
set interfaces ge-0/0/5 unit 0 family mpls
set interfaces ge-0/0/6 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family ccc
set protocols connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/1.0
set protocols connections remote-interface-switch ge-1-to-pe2 transmit-lsp lsp_to_pe2_ge1
set protocols connections remote-interface-switch ge-1-to-pe2 receive-lsp lsp_to_pe1_ge1
```

**Step-by-Step Procedure** To configure the local ingress PE switch:

1. Configure OSPF with traffic engineering enabled:

```
[edit protocols]
user@switchPE-1# set ospf traffic-engineering
```

2. Configure OSPF on the loopback address and the core interfaces:

```
[edit protocols]
user@switchPE-1# set ospf area 0.0.0.0 interface lo0.0
user@switchPE-1# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switchPE-1# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

3. Configure MPLS on this PE switch (PE-1) with a label-switched path (LSP) to the other PE switch (PE-2):

```
[edit protocols]
```

```
user@switchPE-1# set mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
```

4. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switchPE-1# set mpls interface ge-0/0/5.0
user@switchPE-1# set mpls interface ge-0/0/6.0
```

5. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switchPE-1# set rsvp interface lo0.0
user@switchPE-1# set rsvp interface ge-0/0/5.0
user@switchPE-1# set rsvp interface ge-0/0/6.0
```

6. Configure IP addresses for the loopback interface and the core interfaces:

```
[edit]
user@switchPE-1# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switchPE-1# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switchPE-1# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
```

7. Configure **family mpls** on the logical unit of the core interface addresses:

```
[edit]
user@switchPE-1# set interfaces ge-0/0/5 unit 0 family mpls
user@switchPE-1# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure the logical unit of the customer edge interface as a CCC:

```
[edit interfaces ge-0/0/1 unit 0]
-user@PE-1# set family ccc
```

9. Configure the interface-based CCC from PE-1 to PE-2:

**NOTE:** You can also configure a tagged VLAN interface as a CCC. See “Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)” on page 1376 or “Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)” on page 1346.

```
[edit protocols]
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/1.0
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp lsp_to_pe2_ge1
user@PE-1# set connections remote-interface-switch ge-1-to-pe2 receive-lsp lsp_to_pe1_ge1
```

**Results** Display the results of the configuration:

```
user@switchPE-1> show configuration
```

```
interfaces {
  ge-0/0/1 {
```

```
unit 0 {
    family ccc;
}
}
ge-0/0/5 {
    unit 0 {
        family inet {
            address 10.1.5.1/24;
        }
        family mpls;
    }
}
ge-0/0/6 {
    unit 0 {

        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 127.1.1.1/32;
        }
    }
}
protocols {
    rsvp {
        interface lo0.0;
        interface ge-0/0/5.0;
        interface ge-0/0/6.0;
    }
    mpls {
        label-switched-path lsp_to_pe2_ge1 {
            to 127.1.1.3;
        }
        interface ge-0/0/5.0;
        interface ge-0/0/6.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface lo0.0;
            interface ge-0/0/5.0;
            interface ge-0/0/6.0;
        }
    }
}
connections {
    remote-interface-switch ge-1-to-pe2 {
        interface ge-0/0/1.0;
        transmit-lsp lsp_to_pe2_ge1;
        receive-lsp lsp_to_pe1_ge1;
    }
}
```

## Configuring the Remote PE Switch

**CLI Quick Configuration** To quickly configure the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ae0
set protocols mpls label-switched-path lsp_to_pe1_ge1 to 127.1.1.1
set protocols mpls interface ae0
set protocols rsvp interface lo0.0
set protocols rsvp interface ae0
set interfaces lo0 unit 0 family inet address 127.1.1.3/32
set interfaces ae0 unit 0 family inet address 10.1.9.2/24
set interfaces ae0 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family ccc
set protocols connections remote-interface-switch ge-1-to-pe1 interface ge-0/0/1.0
set protocols connections remote-interface-switch ge-1-to-pe1 transmit-lsp lsp_to_pe1_ge1
set protocols connections remote-interface-switch ge-1-to-pe1 receive-lsp lsp_to_pe2_ge1
```

**Step-by-Step Procedure** To configure the remote PE switch (PE-2):

1. Configure OSPF with traffic engineering enabled:

```
[edit protocols]
user@switchPE-2# set ospf traffic-engineering
```

2. Configure OSPF on the loopback interface and the core interface:

```
[edit protocols]
user@switchPE-2# set ospf area 0.0.0.0 interface lo0.0
user@switchPE-2# set ospf area 0.0.0.0 interface ae0
```

3. Configure MPLS on this switch (PE-2) with a label-switched path (LSP) to the other PE switch (PE-1):

```
[edit protocols]
user@switchPE-2# set mpls label-switched-path lsp_to_pe1_ge1 to 127.1.1.1
```

4. Configure MPLS on the core interface:

```
[edit protocols]
user@switchPE-2# set mpls interface ae0
```

5. Configure RSVP on the loopback interface and the core interface:

```
[edit protocols]
user@switchPE-2# set rsvp interface lo0.0
user@switchPE-2# set rsvp interface ae0
```

6. Configure IP addresses for the loopback interface and the core interface:

```
[edit]
user@switchPE-2# set interfaces lo0 unit 0 family inet address 127.1.1.3/32
```

```
user@switchPE-2# set interfaces ae0 unit 0 family inet address 10.1.9.2/24
```

7. Configure **family mpls** on the logical unit of the core interface:

```
[edit]
user@switchPE-2# set interfaces ae0 unit 0 family mpls
```

8. Configure the logical unit of the customer edge interface as a CCC:

```
[edit interfaces ge-0/0/1 unit 0]
user@PE-2# set family ccc
```

9. Configure the interface-based CCC from PE-2 to PE-1:

```
[edit protocols]
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 interface ge-0/0/1.0
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 transmit-lsp lsp_to_pe1_ge1
user@PE-2# set connections remote-interface-switch ge-1-to-pe1 receive-lsp lsp_to_pe2_ge1
```

**Results** Display the results of the configuration:

```
user@switchPE-2> show configuration
```

```
interfaces {
  ge-0/0/1 {
    unit 0 {
      family ccc;
    }
  }
  ae0 {
    unit 0 {
      family inet {
        address 10.1.9.2/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 127.1.1.3/32;
      }
    }
  }
}
protocols {
  rsvp {
    interface lo0.0;
    interface ae0.0;
  }
  mpls {
    label-switched-path lsp_to_pe1_ge1 {
      to 127.1.1.1;
    }
  }
}
```

```

    interface ae0.0;
  }
  ospf {
    traffic-engineering;
    area 0.0.0.0 {
      interface ae0.0;
    }
  }
  connections {
    remote-interface-switch ge-1-to-pe1 {
      interface ge-0/0/1.0;
      transmit-lsp lsp_to_pe1_ge1;
      receive-lsp lsp_to_pe2_ge1;
    }
  }
}

```

## Configuring the Provider Switch

**CLI Quick Configuration** To quickly configure the provider switch, copy the following commands and paste them into the switch terminal window:

```

[edit]
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
set protocols ospf area 0.0.0.0 interface ge-0/0/6.0
set protocols ospf area 0.0.0.0 interface ae0
set protocols mpls interface ge-0/0/5.0
set protocols mpls interface ge-0/0/6.0
set protocols mpls interface ae0
set protocols rsvp interface lo0.0
set protocols rsvp interface ge-0/0/5.0
set protocols rsvp interface ge-0/0/6.0
set protocols rsvp interface ae0
set interfaces lo0 unit 0 family inet address 127.1.1.2/32
set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
set interfaces ae0 unit 0 family inet address 10.1.9.1/24
set interfaces ge-0/0/5 unit 0 family mpls
set interfaces ge-0/0/6 unit 0 family mpls
set interfaces ae0 unit 0 family mpls

```

**Step-by-Step Procedure** To configure the provider switch:

1. Configure OSPF with traffic engineering enabled:

```

[edit protocols]
user@switchP# set ospf traffic-engineering

```

2. Configure OSPF on the loopback interface and the core interfaces:

```

[edit protocols]
user@switchP# set ospf area 0.0.0.0 interface lo0.0

```

```

user@switchP# set ospf area 0.0.0.0 interface ge-0/0/5
user@switchP# set ospf area 0.0.0.0 interface ge-0/0/6
user@switchP# set ospf area 0.0.0.0 interface ae0

```

3. Configure MPLS on the core interfaces on the switch:

```

[edit protocols]
user@switchP# set mpls interface ge-0/0/5
user@switchP# set mpls interface ge-0/0/6
user@switchP# set mpls interface ae0

```

4. Configure RSVP on the loopback interface and the core interfaces:

```

[edit protocols]
user@switchP# set rsvp interface lo0.0
user@switchP# set rsvp interface ge-0/0/5
user@switchP# set rsvp interface ge-0/0/6
user@switchP# set rsvp interface ae0

```

5. Configure IP addresses for the loopback interface and the core interfaces:

```

[edit]
user@switchP# set interfaces lo0 unit 0 family inet address 127.1.1.2/32
user@switchP# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switchP# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switchP# set interfaces ae0 unit 0 family inet address 10.1.9.1/24

```

6. Configure **family mpls** on the logical unit of the core interface addresses:

```

[edit]
user@switchP# set interfaces ge-0/0/5 unit 0 family mpls
user@switchP# set interfaces ge-0/0/6 unit 0 family mpls
user@switchP# set interfaces ae0 unit 0 family mpls

```

**Results** Display the results of the configuration:

```

user@switchP> show configuration

```

```

interfaces {
  ge-0/0/5 {
    unit 0 {
      family inet {
        address 10.1.5.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/6 {
    unit 0 {
      family inet {
        address 10.1.6.1/24;
      }
      family mpls;
    }
  }
}

```

```
    }
  }
  ae0 {
    unit 0 {
      family inet {
        address 10.1.9.1/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 127.1.1.2/32;
      }
    }
  }
  protocols {
    rsvp {
      interface lo0.0;
      interface ge-0/0/5.0;
      interface ge-0/0/6.0;
      interface ae0.0;
    }
    mpls {
      interface ge-0/0/5.0;
      interface ge-0/0/6.0;
      interface ae0.0;
    }
    ospf {
      traffic-engineering;
      area 0.0.0.0 {
        interface lo0.0;
        interface ge-0/0/5.0;
        interface ge-0/0/6.0;
        interface ae0.0;
      }
    }
  }
}
```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Physical Layer on the Switches on page 61](#)
- [Verifying the Routing Protocol on page 61](#)
- [Verifying the Core Interfaces Being Used for MPLS Traffic on page 62](#)
- [Verifying the Status of the RSVP Sessions on page 62](#)
- [Verifying the Assignment of Interfaces for MPLS Label Operations on page 62](#)
- [Verifying the Status of the CCC on page 63](#)

### Verifying the Physical Layer on the Switches

**Purpose** Verify that the interfaces are up. Perform this verification task on each of the switches.

**Action** user@switchPE-1> **show interfaces terse**

Interface	Admin	Link	Proto	Local	Remote
ge-0/0/0	up	up			
ge-0/0/0.0	up	up	eth-switch		
ge-0/0/1	up	up			
ge-0/0/1.0	up	up	ccc		
ge-0/0/2	up	up			
ge-0/0/2.0	up	up	eth-switch		
ge-0/0/3	up	up			
ge-0/0/3.0	up	up	eth-switch		
ge-0/0/4	up	up			
ge-0/0/4.0	up	up	eth-switch		
ge-0/0/5	up	up			
ge-0/0/5.0	up	up	inet mpls	10.1.5.1/24	
ge-0/0/6	up	up			
ge-0/0/6.0	up	up	inet mpls	10.1.6.1/24	

**Meaning** The **show interfaces terse** command displays status information about the Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (**Proto** column) shows that interface **ge-0/0/1.0** is configured as a circuit cross-connect. The output for the protocol family of the core interfaces (**ge-0/0/5.0** and **ge-0/0/6.0**) shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

### Verifying the Routing Protocol

**Purpose** Verify the state of the configured routing protocol. Perform this verification task on each of the switches. The state must be **Full**.

**Action** user@switchPE-1> **show ospf neighbor**

Address	Interface	State	ID	Pri	Dead
127.1.1.2	ge-0/0/5	Full	10.10.10.10	128	39

**Meaning** The **show ospf neighbor** command displays the status of the routing protocol. This output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors.

### Verifying the Core Interfaces Being Used for MPLS Traffic

**Purpose** Verify that the state of the MPLS interface is **Up**. Perform this verification task on each of the switches.

**Action** user@switchPE-1> **show mpls interface**

Interface	State	Administrative groups
ge-0/0/5	Up	<none>
ge-0/0/6	Up	<none>

**Meaning** The **show mpls interface** command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is **Up**.

### Verifying the Status of the RSVP Sessions

**Purpose** Verify the status of the RSVP sessions. Perform this verification task on each of the switches.

**Action** user@switchPE-1> **show rsvp session**

```
Ingress RSVP: 1 sessions
To          From          State  Rt  Style Labelin Labelout LSPname
127.1.13    127.1.1.1    Up     0   1 FF      -    300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To          From          State  Rt  Style Labelin Labelout LSPname
127.1.1.1   127.1.1.3    Up     0   1 FF      299968 lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** This output confirms that the RSVP sessions are **Up**.

### Verifying the Assignment of Interfaces for MPLS Label Operations

**Purpose** Verify which interface is being used as the beginning of the CCC and which interface is being used to push the MPLS packet to the next hop. Perform this task only on the PE switches.

**Action** user@switchPE-1> `show route forwarding-table family mpls`

```
MPLS:
Destination          Type RtRef Next hop          Type Index NhRef Netif
default              perm  0                dscd   50    1
0                    user  0                recv   49    3
1                    user  0                recv   49    3
2                    user  0                recv   49    3
299776               user  0                Pop     541    2    ge-0/0/1.0
ge-0/0/1.0 (CCC)     user  0 2.0.0.1          Push 299792 540 2    ge-0/0/5.0
```

**Meaning** This output shows that the CCC has been set up on interface **ge-0/0/1.0**. The switch receives ingress traffic on **ge-0/0/1.0** and pushes label **299792** onto the packet, which goes out through interface **ge-0/0/5.0**. The output also shows when the switch receives an MPLS packet with label 29976, it pops the label and sends the packet out through interface **ge-0/0/1.0**.

After you have checked the local PE switch, run the same command on the remote PE switch.

### Verifying the Status of the CCC

**Purpose** Verify the status of the CCC. Perform this task only on the PE switches.

**Action** user@switchPE-1> `show connections`

```
CCC and TCC connections [Link Monitoring On]
Legend for status (St)          Legend for connection types
UN -- uninitialized            if-sw: interface switching
NP -- not present              rmt-if: remote interface switching
WE -- wrong encapsulation      lsp-sw: LSP switching
DS -- disabled                 tx-p2mp-sw: transmit P2MP switching
Dn -- down                     rx-p2mp-sw: receive P2MP switching
-> -- only outbound conn is up
<- -- only inbound conn is up
Up -- operational              Legend for circuit types
RmtDn -- remote CCC down       intf -- interface
Restart -- restarting           t1sp -- transmit LSP
                                r1sp -- receive LSP

Connection/Circuit          Type      St      Time last up    # Up trans
ge1-to-pe2                  rmt-if    Up      Feb 17 05:00:09  1
  ge-0/0/1.0                 intf      Up
    lsp_to_pe1_ge1           t1sp     Up
    lsp_to_pe2_ge1           r1sp     Up
```

**Meaning** The `show connections` command displays the status of the CCC connections. This output verifies that the CCC interface and its associated transmit and receive LSPs are **Up**. After you have checked the local PE switch, run the same command on the remote PE switch.

- Related Documentation**
- [Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\) on page 77](#)
  - [Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\) on page 72](#)
  - [Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\) on page 81](#)

## Verifying That MPLS Is Working Correctly

To verify that MPLS is working correctly, perform the following tasks:

1. [Verifying the Physical Layer on the Switches on page 64](#)
2. [Verifying the Routing Protocol on page 65](#)
3. [Verifying the Core Interfaces Being Used for the MPLS Traffic on page 65](#)
4. [Verifying RSVP on page 65](#)

### Verifying the Physical Layer on the Switches

**Purpose** Verify that the interfaces are up. Perform this verification task on each of the switches.

**Action** user@switch> **show interfaces xe-\* terse**

Interface	Admin	Link	Proto	Local	Remote
xe-0/0/0	up	up			
xe-0/0/0.0	up	up			
xe-0/0/1.0	up	up			
xe-0/0/2.0	up	up			
xe-0/0/3.0	up	up	inet	2.2.2.1/16	
xe-0/0/4.0	up	up	inet	10.1.5.1/24	
xe-0/0/5.0	up	up	mpls		
xe-0/0/6.0	up	up	inet mpls	10.1.6.1/24	

**Meaning** The **show interfaces terse** command displays status information about the 10-Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (Proto column) of the core interfaces (xe-0/0/5.0 and xe-0/0/6.0), shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

## Verifying the Routing Protocol

**Purpose** Verify the state of the configured routing protocol. You should perform this verification task on each of the switches. The state should be **Full**. If you have configured OSPF as the routing protocol, use the **show ospf neighbor** command to verify that the routing protocol is communicating with the switch neighbors.

**Action** user@switch> **show ospf neighbor**

Address	Interface	State	ID	Pri	Dead
127.1.1.1	xe-0/0/5	Full	10.10.10.10	128	39

**Meaning** The **show ospf neighbor** command displays the status of the routing protocol that has been configured on this switch. The output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors. For additional information on checking and monitoring routing protocols, see the [Junos OS Routing Protocols and Policies Command Reference](#).

## Verifying the Core Interfaces Being Used for the MPLS Traffic

**Purpose** Verify that the state of the MPLS interface is **Up**. You should perform this verification task on each of the switches.

**Action** user@switch> **show mpls interface**

Interface	State	Administrative groups
ge-0/0/5	Up	<none>
ge-0/0/6	Up	<none>

**Meaning** The **show mpls interface** command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is up.

## Verifying RSVP

**Purpose** Verify the state of the RSVP session. You should perform this verification task on each of the switches.

user@switch> **show mpls session**

```
Ingress RSVP: 1 sessions
To          From          State  Rt  Style Labelin Labelout LSPname
127.1.1.3    127.1.1.1              Up    0  1 FF      -    300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To          From          State  Rt  Style Labelin Labelout LSPname
127.1.1.1    127.1.1.3              Up    0  1 FF  299968      -  lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** This output confirms that the RSVP sessions are up.

## CHAPTER 3

# Configuring MPLS on Provider and Provider Edge Devices

- [Configuring MPLS on Provider Edge Switches on page 67](#)
- [Configuring MPLS on Provider Switches on page 71](#)
- [Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\) on page 72](#)
- [Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\) on page 77](#)
- [Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\) on page 81](#)

### Configuring MPLS on Provider Edge Switches

To implement MPLS, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network using IP over MPLS.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

1. [Configuring the Ingress PE Switch on page 68](#)
2. [Configuring the Egress PE Switch on page 69](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.10.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure OSPF traffic engineering:

```
[edit protocols ospf]
user@switch# set traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure MPLS traffic engineering.

```
[edit protocols mpls]
user@switch# set traffic-engineering
```

6. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 121.100.10.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3.0
```

10. Configure an LSP on the ingress PE switch (192.168.10.1) to send IP packets over MPLS to the egress PE switch (192.168.12.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 to 192.168.12.1
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 2.2.2.0/24 next-hop 192.168.10.1
user@switch# set static route 2.2.2.0/24 resolve
```

## Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.12.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.21.1/24
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface xe-0/0/5.0
user@switch# set rsvp interface xe-0/0/6.0
```

4. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

6. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 2.2.2.1/16
```

7. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3
```

8. Configure an LSP on the egress PE switch (192.168.12.1) to send IP packets over MPLS to the ingress PE switch (192.168.10.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 to 192.168.10.1
```

9. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 no-cspf
```

10. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 121.121.121.0/24 next-hop 192.168.12.1
user@switch# set static route 121.121.121.0/24 resolve
```

## Configuring MPLS on Provider Switches

To implement MPLS, you must configure at least one provider switch as a transit switch for the MPLS packets.

MPLS requires the configuration of an interior gateway protocol (OSPF) and a signaling protocol (RSVP) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch.

To configure the provider switch, complete the following tasks:

1. Configure OSPF on the loopback and core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
user@switch# set area 0.0.0.0 interface ae0
```

2. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

4. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set ae0 unit 0 family inet address 10.1.9.2/24
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
user@switch# set ae0 unit 0 family mpls
```

**NOTE:** You can configure **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot configure it on tagged VLAN interfaces.

## Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)

You can configure MPLS on EX Series switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network or to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

To implement MPLS on switches, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure customer edge (CE) interfaces on the PE switches of the MPLS network by using either IP over MPLS or MPLS over circuit cross-connect (CCC).

The main differences between configuring IP over MPLS and configuring MPLS over CCC are that for IP over MPLS you configure the customer edge interfaces to belong to **family inet** (rather than **family ccc**) and you configure a static route for the label-switched path (LSP). The configuration of the provider switch is the same regardless of whether you

have used IP over MPLS or MPLS over CCC. See “[Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)](#)” on page 81.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

1. [Configuring the Ingress PE Switch on page 73](#)
2. [Configuring the Egress PE Switch on page 75](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 100.100.100.100/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
```

2. Configure OSPF on the loopback and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

**NOTE:** If you want to use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as the core interfaces, replace ge-0/0/5.0 and ge-0/0/6.0 each with an RVI name (for example, *vlan.logical-interface-number*) or a subinterface name (for example, *interface-name.logical-unit-number*).

RVIs function as logical routers, eliminating the need to have both a switch and a router. Layer 3 subinterfaces allow you to route traffic among multiple VLANs along a single trunk line that connects an EX Series switch to a Layer 2 switch.

3. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
```

5. Configure MPLS traffic engineering:

```
[edit protocols]
```

```
user@switch# set protocols mpls traffic-engineering bgp-igp
```

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit]
user@switch# set interfaces ge-2/0/3 unit 0 family inet 121.121.121.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface ge-2/0/3.0
```

10. Configure an LSP on the ingress PE switch (100.100.100.100) to send IP packets over MPLS to the egress PE switch (208.208.208.208):

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lspjavae_29 from 100.100.100.100
user@switch# set label-switched-path ip_lspjavae_29 to 208.208.208.208
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lspjavae_29 no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

**NOTE:** Do not configure a static route if you are using this procedure to configure an MPLS-based Layer 3 VPN.

---

```
[edit]
user@switch# set routing-options static route 2.2.2.0/24 next-hop 100.100.100.100
user@switch# set routing-options static route 2.2.2.0/24 resolve
```

## Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 208.208.208.208/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.21.1/24
```

2. Configure OSPF on the loopback interface (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
```

**NOTE:** If you want to use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as the core interfaces, replace ge-0/0/5.0 and ge-0/0/6 each with an RVI name (for example, *vlan.logical-interface-number*) or a subinterface name (for example, *interface-name.logical-unit-number*).

RVIs function as logical routers, eliminating the need to have both a switch and a router. Layer 3 subinterfaces allow you to route traffic among multiple VLANs along a single trunk line that connects an EX Series switch to a Layer 2 switch.

3. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
```

5. Configure MPLS traffic engineering on both BGP and IGP destinations:

```
[edit protocols]
user@switch# set protocols mpls traffic-engineering bgp-igp
```

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit]
user@switch# set interfaces ge-2/0/3 unit 0 family inet address 2.2.2.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface ge-2/0/3
```

10. Configure an LSP on the egress PE switch (208.208.208.208) to send IP packets over MPLS to the ingress PE switch (100.100.100.100):

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lsp29_javae from 208.208.208.208
user@switch# set label-switched-path ip_lsp29_javae to 100.100.100.100
```

11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path ip_lsp29_javae no-cspf
```

12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

**NOTE:** Do not configure a static route if you are using this procedure to configure an MPLS-based Layer 3 VPN.

---

```
[edit]
user@switch# set routing-options static route 121.121.121.0/24 next-hop 208.208.208.208
user@switch# set routing-options static route 121.121.121.0/24 resolve
```

#### Related Documentation

- [Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\) on page 81](#)

## Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)

Junos OS MPLS for EX8200 and EX4500 switches supports Layer 2 protocols and Layer 2 virtual private networks (VPNs). You can configure MPLS on switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC). The customer edge interface can be either a simple interface or a tagged VLAN interface.

**NOTE:** If you are configuring a CCC on a tagged VLAN interface, you do not specify `family ccc`. See [Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN](#) and [Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit](#).

**NOTE:** If you are going through this procedure in preparation for configuring an MPLS-based Layer 2 VPN, you do not need to configure the association of the label-switched path (LSP) with the customer edge interface. The BGP signaling automates the connections, so manual configuration of the connections is not required.

The following guidelines apply to CCC configurations:

- When an interface is configured to belong to **family ccc**, it cannot belong to any other family.
- You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.
- If you are configuring a CCC on a tagged VLAN interface, you must explicitly enable VLAN tagging and specify a VLAN ID. The VLAN ID cannot be configured on logical interface unit 0. The logical unit number must be 1 or higher. See [Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN](#) and [Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit](#).

This procedure shows how to set up two CCCs:

- If you are configuring a CCC on a simple interface (**ge-0/0/1**), you do not need to enable VLAN tagging or specify a VLAN ID, so you skip those steps.
- If you are configuring a CCC on a tagged VLAN interface (**ge-0/0/2**), include all the steps in this procedure.

To configure a PE switch with a CCC:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@switch# set ospf area 0.0.0.0 interface ae0
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set interfaces ae0 unit 0 family inet address 10.1.9.1/24
```

4. Enable MPLS and define the LSP:

```
[edit protocols]
user@switch# set mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3
```

**TIP:** `lsp_to_pe2_ge1` is the LSP name. You will need to use the specified name again when configuring the CCC.

5. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
user@switch# set mpls interface ae0
```

6. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
user@switch# set rsvp interface ge-0/0/6.0
user@switch# set rsvp interface ae0
```

7. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
user@switch# set interfaces ae0 unit 0 family mpls
```

**NOTE:** You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

8. If you are configuring a CCC on a tagged VLAN interface, enable VLAN tagging on the customer edge interface **ge-0/0/2** of the local PE switch:

```
[edit interfaces ge-0/0/2]
user@switch# set vlan-tagging
```

If you are configuring a CCC on a simple interface (**ge-0/0/1**), omit this step.

9. If you are configuring a CCC on a tagged VLAN interface, configure the logical unit of the customer edge interface with a VLAN ID:

```
[edit interfaces ge-0/0/2 unit 1]
user@switch# set vlan-id 100
```

If you are configuring a CCC on a simple interface (**ge-0/0/1**), omit this step.

10. Configure the logical unit of the customer edge interface to belong to **family ccc**:

- On a simple interface:

```
[edit interfaces ge-0/0/1 unit 0]
user@switch# set family ccc
```

- On a tagged VLAN interface:

```
[edit interfaces ge-0/0/2 unit 1]
user@switch# set family ccc
```

11. Associate the CCC interface with two LSPs, one for transmitting MPLS packets and the other for receiving MPLS packets:

**NOTE:** If you are configuring a Layer 2 VPN, omit this step. The BGP signaling automates the connections, so manual configuration of the connections is not required.

- On a simple interface:

```
[edit protocols]
user@switch# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/1.0
user@switch# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp
lsp_to_pe2_ge1
user@switch# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

- On a tagged VLAN interface:

```
[edit protocols]
user@switch# set connections remote-interface-switch ge-1-to-pe2 interface ge-0/0/2.1
user@switch# set connections remote-interface-switch ge-1-to-pe2 transmit-lsp
lsp_to_pe2_ge1
user@switch# set connections remote-interface-switch ge-1-to-pe2 receive-lsp
lsp_to_pe1_ge1
```

**TIP:** The `transmit-lsp` option specifies the LSP name that was configured on PE-1 (the local PE switch) by the `label-switched-path` statement within the `[edit protocols mpls]` hierarchy.

The `receive-lsp` option specifies the LSP name that was configured on PE-2 (the remote PE switch) by the `label-switched-path` statement within the `[edit protocols mpls]` hierarchy.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

**Related  
Documentation**

- [Example: Configuring MPLS-Based Layer 2 VPNs on page 1178](#)

## Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)

You can configure MPLS on EX8200 and EX4500 switches to increase transport efficiency in your network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as VoIP and other business-critical functions.

To implement MPLS on EX Series switches, you must configure at least one provider switch as a transit switch for the MPLS packets. The configuration of all the provider switches remains the same regardless of whether the provider edge (PE) switches are using circuit cross-connect (CCC) or using MPLS over IP for the customer edge interfaces. Likewise, you do not need to change the configuration of the provider switches if you implement an MPLS-based Layer 2 VPN, Layer 3 VPN, or a Layer 2 circuit configuration.

MPLS requires the configuration of a routing protocol (OSPF or IS-IS) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch. For information on configuring IS-IS as the routing protocol, see [Junos OS Routing Protocols Configuration Guide](#).

To configure the provider switch, complete the following tasks:

1. Enable the routing protocol (OSPF or IS-IS) on the loopback interface and on the core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@switch# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@switch# set ospf area 0.0.0.0 interface ae0
```

2. Enable traffic engineering for the routing protocol (traffic engineering must be explicitly enabled for OSPF):

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Enable MPLS within the **protocols** stanza and apply it to the core interfaces:

```
[edit protocols]
user@switch# set mpls interface ge-0/0/5.0
user@switch# set mpls interface ge-0/0/6.0
user@switch# set mpls interface ae0
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface ge-0/0/5.0
```

```
user@switch# set rsvp interface ge-0/0/6.0
user@switch# set rsvp interface ae0
```

5. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set interfaces ge-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set interfaces ge-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set interfaces ae0 unit 0 family inet address 10.1.9.2/24
```

6. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces ge-0/0/5 unit 0 family mpls
user@switch# set interfaces ge-0/0/6 unit 0 family mpls
user@switch# set interfaces ae0 unit 0 family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

## CHAPTER 4

# Configuring Bidirectional Forwarding Detection (BFD) for MPLS

- [Configuring Bidirectional Forwarding Detection for MPLS \(CLI Procedure\) on page 83](#)
- [BFD-Triggered Local Repair for Rapid Convergence on page 87](#)
- [Configuring BFD for MPLS IPv4 LSPs on page 89](#)

### Configuring Bidirectional Forwarding Detection for MPLS (CLI Procedure)

You can configure the Bidirectional Forwarding Detection (BFD) protocol on EX8200 standalone switches and EX8200 Virtual Chassis to detect failures in the MPLS label-switch path (LSP). The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply from the neighbor after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than those of the failure detection mechanisms for static routes, and thus provide faster detection. These timers are also adaptive. For example, a timer can adapt to a higher value if an adjacency fails, or a neighbor can negotiate a higher value than the one configured.

This topic describes configuring the provider edge (PE) switches and the provider switches to support for LDP-based LSPs and RSVP-based LSPs.

This topic includes:

- [Configuring BFD on Provider Edge and Provider Switches for an LDP-Based LSP on page 84](#)
- [Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP on page 86](#)

## Configuring BFD on Provider Edge and Provider Switches for an LDP-Based LSP

You can enable BFD for the LDP-based LSPs or RSVP-based LSPs associated with a specific forwarding equivalence class (FEC). Alternatively, you can configure an Operation Administration and Maintenance (OAM) ingress policy to enable BFD on a range of FEC addresses.

Before you configure BFD for an LDP-based based LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See “[Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\)](#)” on page 72.
- Configure one or more provider switches. See “[Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)](#)” on page 81.

To configure BFD on PE and provider switches:

1. Define an OAM policy:

```
[edit]
user@switch# set protocols ldp oam ingress-policy policy-name
```

2. Specify the FEC on which you want to enable OAM:

```
[edit]
user@switch# set protocols ldp oam fec address
```

3. Specify the minimum transmit and receive interval for the BFD configuration:

**NOTE:** If you configure the minimum-interval statement, you do not need to configure the minimum-receive-interval statement or the minimum-transmit-interval statement.

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection minimum-interval time
```

or

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection minimum-receive-interval time
user@switch# set protocols ldp oam bfd-liveness-detection minimum-transmit-interval time
```

4. Specify the detection time multiplier. The negotiated transmit interval multiplied by this value gives the detection time for the receiving system in Asynchronous mode:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection multiplier multiplier
```

5. Specify the minimum transmit interval (or the minimum receive interval).

```
[edit]
```

```
user@switch# set protocols ldp oam bfd-liveness-detection transmit-interval
minimum-interval time
```

6. Specify a threshold for detecting the adaptation of the detection time:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection detection-time threshold time
```

7. Configure route and next-hop action in the event of a BFD session failure event on the LDP-based LSP:

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection failure-action action
```

**NOTE:** When a BFD session goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. You can configure a standby LSP path to handle traffic while the primary LSP path is unavailable. The switch can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

8. Specify how long the BFD session must be up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

```
[edit]
user@switch# set protocols ldp oam bfd-liveness-detection holddown-interval time
```

9. Enable tracing of FECs for LDP-based LSPs and specify a source address for sending probes. Then, specify a wait interval, after which to send the probe packet.

```
[edit]
user@switch# set protocols ldp oam periodic-traceroute source address
user@switch# set protocols ldp oam periodic-traceroute wait time
```

10. Specify the duration of the LSP ping interval in seconds:

```
[edit]
user@switch# set protocols ldp oam lsp-ping-interval time
```

11. Specify the action to be taken for the OAM policy:

```
[edit]
user@switch# set policy-options policy-statement policy-name then accept
```

12. Apply the BFD configurations at the MPLS hierarchy level for the configuration to inherit the statements in the configuration group:

```
[edit]
user@switch# set apply-groups MPLS
```

## Configuring BFD on Provider Edge and Provider Switches for an RSVP-Based LSP

When BFD is configured for an RSVP-based LSP on the ingress switch, it is enabled on the primary path and on all standby secondary paths for that LSP. You can enable BFD for all LSPs on a switch or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden on that LSP. The BFD sessions originate only at the ingress switch and terminate at the egress switch.

Before you configure BFD for an RSVP-based LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See “Configuring MPLS on Provider Edge Switches Using IP Over MPLS (CLI Procedure)” on page 72.
- Configure one or more provider switches. See “Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)” on page 81.

To configure BFD on PE and provider switches:

1. Specify the minimum transmit and receive interval for the BFD configuration:

**NOTE:** If you configure the `minimum-interval` statement, you do not need to configure the `minimum-receive-interval` statement or the `minimum-transmit-interval` statement.

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
minimum-interval time
```

or

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
minimum-receive-interval time
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
minimum-transmit-interval time
```

2. Specify the detection time multiplier. The negotiated transmit interval multiplied by this value gives the detection time for the receiving system in Asynchronous mode:

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
multiplier multiplier
```

3. Specify the minimum transmit interval (or the minimum receive interval):

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
transmit-interval minimum-interval time
```

4. Configure route and next-hop actions in the event of a BFD session failure event on the RSVP-based LSP:

```
[edit]
user@switch# set protocols mpls label-switched-path lsp-name oam bfd-liveness-detection
failure-action action
```

**NOTE:** When a BFD session goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. You can configure a standby LSP path to handle traffic while the primary LSP path is unavailable. The switch can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged if you do not specifically configure a failure action.

## BFD-Triggered Local Repair for Rapid Convergence

- [Understanding BFD-Triggered Local Protection on page 87](#)

### Understanding BFD-Triggered Local Protection

The time it takes for a network to converge following a link or node failure can vary dramatically based on a number of factors, including network size, the protocols used, and network design. However, while each particular convergence event is different, the process of convergence is essentially consistent. The failure is detected, the failure is reported (flooded) in the network, an alternate path is found for traffic, and the forwarding plane is updated to pass traffic on a new path.

This overview discusses how Bidirectional Forwarding Detection (BFD)-triggered local repair contributes to a quicker restoration time for rapid convergence in an MPLS network.

- [Purpose of BFD-Triggered Local Repair on page 87](#)
- [Configuring BFD-Triggered Local Repair on page 88](#)
- [Disabling BFD-Triggered Local Repair on page 88](#)

#### Purpose of BFD-Triggered Local Repair

In Junos OS, general MPLS traffic protection for RSVP-signaled label-switched path (LSP) failures is provided by several complementary mechanisms. These protection mechanisms include local protection (fast reroute, link protection, and node-link protection) and path protection (primary and secondary paths). Local protection in conjunction with path protection can provide minimum packet loss for an LSP, and control the way the LSP is rerouted after a failure. Traditionally, both types of protection rely on fast detection of connectivity failure at the physical level. However, for transmission media without fast physical level detection, Junos OS supports BFD and MPLS ping for fast failure detection.

With links between routers, when a route goes down, the routing protocol process recalculates the next best path. When MPLS fast reroute (FRR) is enabled, ifl messages are flooded to all Flexible PIC Concentrators (FPCs). The edge FPC enables the bypass MPLS LSP tunnel. Lastly, all routes are repaired and sent through the bypass MPLS LSP tunnel. The amount of time it takes to repair all routes is proportional to the number of routes.

This repair scenario becomes more difficult when a switch lies between two links. See [Figure 5 on page 88](#).

**Figure 5: Topology with BFD-Triggered Local Repair**

When a link goes down at the remote end, the failure is not detected at the local end until the interior gateway protocol (IGP) goes down. To wait for the routing protocol process to recalculate the next best path takes too much time.

With BFD-triggered local repair enabled, the Packet Forwarding Engine completes the repair first, using the bypass MPLS LSP tunnel (that is preconfigured and installed), then informs the routing protocol process to recalculate a new route. By doing this, when the primary MPLS LSP tunnel goes down, the FPC can intermittently and immediately divert traffic to the FPC with the bypass MPLS LSP tunnel.

Using local repair in this way achieves a faster restoration time of less than 50 ms.

### Configuring BFD-Triggered Local Repair

BFD-triggered local repair is not configurable, but is part of the default configuration.

BFD-triggered local repair works within the legacy Junos OS features MPLS-FRR, BFD for IGP, and loop-free alternates (LFAs).

### Disabling BFD-Triggered Local Repair

By default, BFD-triggered local repair is enabled for all routing interfaces. If desired, you can disable BFD-triggered local repair at the `[edit routing-options]` hierarchy level.

To explicitly disable BFD-triggered local repair:

1. Include the `no-bfd-triggered-local-repair` statement at the `[edit routing-options]` hierarchy level:

```
user@host# set no-bfd-triggered-local-repair
```

2. (Optional) Verify your configuration settings before committing them by using the **show routing-options** command.

```
user@host# run show routing-options
```

Confirm your configuration by issuing the **show routing-options** command.

```
user@host# show routing-options
...
no-bfd-triggered-local-repair;
}
```

**NOTE:** When you disable this feature, you must also restart routing by including the **graceful-restart** statement for the IGP. For example, for OSPF, this is accomplished by including the **graceful-restart** statement at the `[edit protocols ospf]` hierarchy level.

## Configuring BFD for MPLS IPv4 LSPs

You can configure Bidirectional Forwarding Detection (BFD) protocol on MPLS IPv4 LSPs as outlined in the Internet draft `draft-ietf-bfd-mpls-02.txt`, *BFD for MPLS LSPs*. BFD is used as a periodic Operation, Administration, and Maintenance (OAM) feature for LSPs to detect LSP data plane faults. You can configure BFD for LSPs that use either LDP or RSVP as the signaling protocol.

**NOTE:** BFD for MPLS IPv4 LSP is based on the Routing Engine and is not distributed. As a result, the minimum supported BFD timer interval is (100 ms \* 3) per one LSP session, and for scaled LSP sessions, the minimum supported BFD timer interval is (300 ms \* 3). As you increase the number of LSP sessions with BFD, you must also increase (scale) the interval timers to support the network.

For Routing Engine switchover instances with nonstop active routing (NSR) support, the minimum supported BFD timer interval is (2.5 seconds \* 3).

You can also use the LSP **ping** commands to detect LSP data plane faults. However, BFD has a couple of benefits: it requires less computer processing than LSP **ping** commands and can quickly detect faults in large numbers of LSPs (LSP **ping** commands must be issued for each LSP individually). On the other hand, BFD cannot be used to verify the control plane against the data plane at the egress LSR, which is possible when an LSP **ping** echo request is associated with a forwarding equivalence class (FEC).

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down. To do so, you configure the **lsp-ping-interval** statement and the **lsp-ping-multiplier** statement at the **[edit protocols mpls oam]** hierarchy level.

For configuration instructions for LDP-signaled LSPs, see [“Configuring BFD for LDP LSPs” on page 773](#). For configuration instructions for RSVP-signaled LSPs, see the following section.

## Configuring BFD for RSVP-Signaled LSPs

BFD for RSVP supports unicast IPv4 LSPs. When BFD is configured for an RSVP LSP on the ingress router, it is enabled on the primary path and on all standby secondary paths for that LSP. The source IP address for outgoing BFD packets from the egress side of an MPLS BFD session is based on the outgoing interface IP address. You can enable BFD for all LSPs on a router or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden. The BFD sessions originate only at the ingress router and terminate at the egress router.

An error is logged whenever a BFD session for a path fails. The following example shows how BFD for RSVP LSP log messages might appear:

```
RPD_MPLS_PATH_BFD_UP: MPLS BFD session for path path1 up on LSP R0_to_R3
RPD_MPLS_PATH_BFD_DOWN: MPLS BFD session for path path1 down on LSP R0_to_R3
```

You can configure BFD for all of the RSVP LSPs on the router, a specific LSP, or the primary path of a specific LSP. To configure BFD for RSVP LSPs, include the **oam** and **bfd-liveness-detection** statements.

```
oam {
  bfd-liveness-detection {
```

```

failure-action {
    make-before-break teardown-timeout seconds;
    teardown;
}
failure-action teardown;
minimum-interval milliseconds;
minimum-receive-interval milliseconds;
minimum-transmit-interval milliseconds;
multiplier detection-time-multiplier;
}
lsp-ping-interval time-interval;
lsp-ping-multiplier multiplier;
}

```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit protocols mpls [label-switched-path](#) *lsp-name* [primary path-name](#)]

The **bfd-liveness-detection** statement includes the following options:

- **minimum-interval**—Specifies the minimum transmit and receive interval.
- **minimum-receive-interval**—Specifies the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- **minimum-transmit-interval**—Specifies the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- **lsp-ping-multiplier**—Specifies the detection time multiplier. The range is from 1 through 255.

**NOTE:** To avoid triggering false negatives, configure a BFD fault detection time that is longer than the fast reroute time.

You can also configure the **lsp-ping-interval** option to adjust the time interval between LSP pings. The LSP ping command for RSVP-signaled LSPs is **ping mpls rsvp**. For more information on the **ping mpls rsvp** command, see the [CLI Explorer](#).

## Configuring a Failure Action for the BFD Session on an RSVP LSP

When the BFD session for an RSVP LSP goes down, the LSP is torn down and resignaled. Traffic can be switched to a standby LSP, or you can simply tear down the LSP path. Any actions performed are logged.

When a BFD session for an RSVP LSP path goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. A standby LSP path could be configured to handle traffic while the primary LSP path is unavailable. The router can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

To enable the Junos OS to tear down an RSVP LSP path in the event of a BFD event, include the **failure-action** statement:

```
failure-action {
  make-before-break teardown-timeout seconds;
  teardown;
}
```

For a list of the hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can configure either the **teardown** or **make-before-break** options:

- **teardown**—Causes the LSP path to be taken down and resigaled immediately.
- **make-before-break**—Causes the Junos OS to attempt to signal a new LSP path before tearing down the old LSP path. You can also configure the **teardown-timeout** option to automatically tear down the LSP after the time period specified if the attempt to resignal the LSP fails within the **teardown-timeout** interval. If you specify a value of 0 for the **teardown-timeout** interval, the LSP is taken down and resigaled immediately (the same behavior as when you configure the **teardown** option).

To configure a failure action for all of the RSVP LSPs, include the **failure-action** statement at the **[edit protocols mpls oam bfd-liveness-detection]** hierarchy level. To configure a failure action for a specific RSVP LSP, include the **failure-action** statement at the **[edit protocols mpls label-switched-path *lsp-name* oam bfd-liveness-detection]** hierarchy level.

To configure a failure action for a specific primary path, include the **failure-action** statement at the **[edit protocols mpls label-switched path *lsp-name* primary *path-name* oam bfd-liveness-detection]** hierarchy level. To configure a failure action for a specific secondary LSP path, include the **failure-action** statement at the **[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam bfd-liveness-detection]** hierarchy level.

Release History Table

Release	Description
13.2R4	Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down.

## CHAPTER 5

# Configuring Firewall Filters, System Log Messages, and SNMP for MPLS

- [Configuring MPLS Firewall Filters and Policers on Switches on page 93](#)
- [Configuring MPLS Firewall Filters and Policers on Routers on page 96](#)
- [Configuring System Log Messages and SNMP Traps for LSPs on page 104](#)

## Configuring MPLS Firewall Filters and Policers on Switches

---

You can configure firewall filters to filter MPLS traffic. To use an MPLS firewall filter, you must first configure the filter and then apply it to an interface you have configured for forwarding MPLS traffic. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached.

**NOTE:** You can configure ingress MPLS firewall filters only. Egress MPLS firewall filters are not supported. You cannot apply MPLS firewall filters to loopback interfaces.

When you configure an MPLS firewall filter, you define filtering criteria (terms, with match conditions) for the packets and an action (action, or action modifier) for the switch to take if the packets match the filtering criteria.

- [Table 10 on page 94](#) describes the match conditions you can configure for MPLS firewall filters at the `[edit firewall family mpls filter filter-name term term-name from]` hierarchy level.

**NOTE:** If a packet has multiple MPLS labels, the filter applies the match conditions to only the bottom label in the label stack.

Table 10: Supported Match Conditions for MPLS Firewall Filters

Match Condition	Description
<b>exp <i>number</i></b>	<p>Experimental (EXP) bit number or range of bit numbers in the MPLS header of a packet.</p> <p>For <i>number</i>, you can specify one or more values from 0 through 7 in binary, decimal or hexadecimal format, as given below:</p> <ul style="list-style-type: none"> <li>• A single EXP bit—for example, <b>exp 3</b></li> <li>• Several EXP bits—for example, <b>exp 0,4</b></li> <li>• A range of EXP bits—for example, <b>exp [0-5]</b></li> </ul>
<b>label <i>number</i></b>	<p>MPLS label value or range of label values in the MPLS header of a packet.</p> <p>For <i>number</i>, you can specify one or more values from 0 through 1048575 in decimal or hexadecimal format, as given below:</p> <ul style="list-style-type: none"> <li>• A single label—for example, <b>label 3</b></li> <li>• Several labels—for example, <b>label 0,4</b></li> <li>• A range of labels—for example, <b>label [0-5]</b></li> </ul>

- [Table 11 on page 94](#) describes the actions you can configure for MPLS firewall filters at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level.

Table 11: Supported Actions for MPLS Firewall Filters

Action	Description
<b>accept</b>	Accept a packet
<b>count <i>counter-name</i></b>	<p>Count the number of packets that pass this filter or term.</p> <p><b>NOTE:</b> We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.</p>
<b>discard</b>	Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message
<b>policer</b>	Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer.
<b>three-color-policer</b>	Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a three-color policer.

- [Configuring an MPLS Firewall Filter on page 95](#)
- [Applying an MPLS Firewall Filter to an MPLS Interface on page 95](#)
- [Configuring Policers for LSPs on page 95](#)

## Configuring an MPLS Firewall Filter

To configure an MPLS firewall filter:

1. Configure the filter name, term name, and at least one match condition—for example, match on MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls]
user@switch# set filter ingress-exp-filter term term-one from exp 0,4
```

2. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term—for example, count MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls filter ingress-exp-filter term term-one then]
user@switch# set count counter0
user@switch# set accept
```

## Applying an MPLS Firewall Filter to an MPLS Interface

To apply the MPLS firewall filter to an interface you have configured for forwarding MPLS traffic (using the **family mpls** statement at the **[edit interfaces *interface-name* unit *unit-number*]** hierarchy level):

**NOTE:** You can apply firewall filters only to filter MPLS packets that enter an interface.

1. Apply the firewall filter to an MPLS interface—for example, apply the firewall filter to interface xe-0/0/5:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls filter input ingress-exp-filter
```

2. Review your configuration and issue the **commit** command:

```
[edit interfaces]
user@switch# commit
commit complete
```

## Configuring Policers for LSPs

Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer or three-color policer. MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each

multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.

**Related  
Documentation**

- [Supported MPLS Scaling Values on page 11](#)
- [Overview of Policers](#)

---

## Configuring MPLS Firewall Filters and Policers on Routers

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can also configure policers for MPLS LSPs.

The following sections discuss MPLS firewall filters and policers:

- [Configuring MPLS Firewall Filters on page 96](#)
- [Examples: Configuring MPLS Firewall Filters on page 97](#)
- [Configuring Policers for LSPs on page 98](#)
- [Example: Configuring an LSP Policar on page 100](#)
- [Configuring Automatic Policers on page 100](#)
- [Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets on page 104](#)

### Configuring MPLS Firewall Filters

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can then apply this filter to a specific interface.

You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic

on the interface to which the filter is attached. You cannot apply MPLS firewall filters to Ethernet (fxp0) or loopback (lo0) interfaces.

You can configure an MPLS firewall filter on the M Series Multiservice Edge Routers and the T Series Core Routers.

You can configure the following match criteria attributes for MPLS filters at the **[edit firewall family mpls filter *filter-name* term *term-name* from]** hierarchy level:

- **exp**
- **exp-except**

These attributes can accept EXP bits in the range 0 through 7. You can configure the following choices:

- A single EXP bit—for example, **exp 3**;
- Several EXP bits—for example, **exp 0, 4**;
- A range of EXP bits—for example, **exp [0-5]**;

If you do not specify a match criterion (that is, you do not configure the **from** statement and use only the **then** statement with the **count** action keyword), all the MPLS packets passing through the interface on which the filter is applied will be counted.

You also can configure any of the following action keywords at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level:

- **count**
- **accept**
- **discard**
- **next**
- **policer**

For more information about how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*. For more information about how to configure interfaces, see the *Junos OS Network Interfaces Library for Routing Devices* and the *Junos OS Services Interfaces Library for Routing Devices*.

## Examples: Configuring MPLS Firewall Filters

The following examples illustrate how you might configure an MPLS firewall filter and then apply the filter to an interface. This filter is configured to count MPLS packets with EXP bits set to either 0 or 4.

The following shows a configuration for an MPLS firewall filter:

```
[edit firewall]
family mpls {
  filter expf {
```

```

term expt0 {
  from {
    exp 0,4;
  }
  then {
    count counter0;
    accept;
  }
}

```

The following shows how to apply the MPLS firewall filter to an interface:

```

[edit interfaces]
so-0/0/0 {
  mtu 4474;
  encapsulation ppp;
  sonet-options {
    fcs 32;
  }
  unit 0 {
    point-to-point;
    family mpls {
      filter {
        input expf;
        output expf;
      }
    }
  }
}

```

The MPLS firewall filter is applied to the input and output of an interface (see the **input** and **output** statements in the preceding example).

## Configuring Policers for LSPs

MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different

families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

You can configure only those match conditions that apply across all types of traffic. The following are the supported match conditions for LSP policers:

- **forwarding-class**
- **packet-length**
- **interface**
- **interface-set**

To enable a policer on an LSP, first you need to configure a policing filter and then include it in the LSP configuration. For information about how to configure policers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

To configure a policer for an LSP, specify a filter by including the **filter** option to the **policing** statement:

```
policing {  
  filter filter-name;  
}
```

You can include the **policing** statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

---

### LSP Policer Limitations

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- LSP policers are not supported on aggregated interfaces.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.
- LSP policers work on all T Series routers and on M Series routers that have the Internet Processor II application-specific integrated circuit (ASIC).

**NOTE:** Starting with Junos OS Release 12.2R2, on T Series routers only, you can configure an LSP policer for a specific LSP to be shared across different protocol family types. To do so, you must configure the *logical-interface-policer* statement at the [edit firewall policer *policer-name*] hierarchy level.

## Example: Configuring an LSP Policer

The following example shows how you can configure a policing filter for an LSP:

```
[edit firewall]
policer police-ct1 {
  if-exceeding {
    bandwidth-limit 50m;
    burst-size-limit 1500;
  }
  then {
    discard;
  }
}
policer police-ct0 {
  if-exceeding {
    bandwidth-limit 200m;
    burst-size-limit 1500;
  }
  then {
    discard;
  }
}
family any {
  filter bar {
    term discard-ct0 {
      then {
        policer police-ct0;
        accept;
      }
    }
    term discard-ct1 {
      then {
        policer police-ct1;
        accept;
      }
    }
  }
}
```

## Configuring Automatic Policers

Automatic policing of LSPs allows you to provide strict service guarantees for network traffic. Such guarantees are especially useful in the context of Differentiated Services for traffic engineered LSPs, providing better emulation for ATM wires over an MPLS

network. For more information about Differentiated Services for LSPs, see [“DiffServ-Aware Traffic Engineering Introduction” on page 960](#).

Differentiated Services for traffic engineered LSPs allow you to provide differential treatment to MPLS traffic based on the EXP bits. To ensure these traffic guarantees, it is insufficient to simply mark the traffic appropriately. If traffic follows a congested path, the requirements might not be met.

LSPs are guaranteed to be established along paths where enough resources are available to meet the requirements. However, even if the LSPs are established along such paths and are marked properly, these requirements cannot be guaranteed unless you ensure that no more traffic is sent to an LSP than there is bandwidth available.

It is possible to police LSP traffic by manually configuring an appropriate filter and applying it to the LSP in the configuration. However, for large deployments it is cumbersome to configure thousands of different filters. Configuration groups cannot solve this problem either, since different LSPs might have different bandwidth requirements, requiring different filters. To police traffic for numerous LSPs, it is best to configure automatic policers.

When you configure automatic policers for LSPs, a policer is applied to all of the LSPs configured on the router. However, you can disable automatic policing on specific LSPs.

**NOTE:** When you configure automatic policers for DiffServ-aware traffic engineering LSP, GRES is not supported.

**NOTE:** You cannot configure automatic policing for LSPs carrying CCC traffic.

The following sections describe how to configure automatic policers for LSPs:

- [Configuring Automatic Policers for LSPs on page 101](#)
- [Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs on page 102](#)
- [Configuring Automatic Policers for Point-to-Multipoint LSPs on page 103](#)
- [Disabling Automatic Policing on an LSP on page 103](#)
- [Example: Configuring Automatic Policing for an LSP on page 103](#)

### Configuring Automatic Policers for LSPs

To configure automatic policers for standard LSPs (neither DiffServ-aware traffic engineered LSPs nor multiclass LSPs), include the **auto-policing** statement with either the **class all** *policer-action* option or the **class ct0** *policer-action* option:

```
auto-policing {
  class all policer-action;
  class ct0 policer-action;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You can configure the following policer actions for automatic policers:

- **drop**—Drop all packets.
- **loss-priority-high**—Set the packet loss priority (PLP) to high.
- **loss-priority-low**—Set the PLP to low.

These policer actions are applicable to all types of LSPs. The default policer action is to do nothing.

Automatic policers for LSPs police traffic based on the amount of bandwidth configured for the LSPs. You configure the bandwidth for an LSP using the **bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-path-name*]** hierarchy level. If you have enabled automatic policers on a router, change the bandwidth configured for an LSP, and commit the revised configuration, the change does not take effect on the active LSPs. To force the LSPs to use the new bandwidth allocation, issue a **clear mpls lsp** command.

**NOTE:** You cannot configure automatic policers for LSPs that traverse aggregated interfaces or Multilink Point-to-Point Protocol (MLPPP) interfaces.

---

### Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs

---

To configure automatic policers for DiffServ-aware traffic engineering LSPs and for multiclass LSPs, include the **auto-policing** statement:

```
auto-policing {  
  class all policer-action;  
  class ctnumber policer-action;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You include either the **class all *policer-action*** statement or a **class *ctnumber* *policer-action*** statement for each of one or more classes (you can configure a different policer action for each class). For a list of the actions that you can substitute for the ***policer-action*** variable, see “[Configuring Automatic Policers for LSPs](#)” on page 101. The default policer action is to do nothing.

**NOTE:** You cannot configure automatic policers for LSPs that traverse aggregated interfaces or MLPPP interfaces.

### Configuring Automatic Policers for Point-to-Multipoint LSPs

You can configure automatic policers for point-to-multipoint LSPs by including the **auto-policing** statement with either the **class all** ***policer-action*** option or the **class ct0** ***policer-action*** option. You only need to configure the **auto-policing** statement on the primary point-to-multipoint LSP (for more information on primary point-to-multipoint LSPs, see “[Configuring the Primary Point-to-Multipoint LSP](#)” on page 552). No additional configuration is required on the subLSPs for the point-to-multipoint LSP. Point-to-multipoint automatic policing is applied to all branches of the point-to-multipoint LSP. In addition, automatic policing is applied to any local VRF interfaces that have the same forwarding entry as a point-to-multipoint branch. Feature parity for automatic policers for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

The automatic policer configuration for point-to-multipoint LSPs is identical to the automatic policer configuration for standard LSPs. For more information, see “[Configuring Automatic Policers for LSPs](#)” on page 101.

### Disabling Automatic Policing on an LSP

When you enable automatic policing, all of the LSPs on the router or logical system are affected. To disable automatic policing on a specific LSP on a router where you have enabled automatic policing, include the **policing** statement with the **no-auto-policing** option:

```
policing no-auto-policing;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]

### Example: Configuring Automatic Policing for an LSP

Configure automatic policing for a multiclass LSP, specifying different actions for class types ct0, ct1, ct2, and ct3.

```
[edit protocols mpls]
diffserv-te {
  bandwidth-model extended-mam;
}
auto-policing {
  class ct1 loss-priority-low;
  class ct0 loss-priority-high;
  class ct2 drop;
  class ct3 loss-priority-low;
```

```
}
traffic-engineering bgp-igp;
label-switched-path sample-lsp {
  to 3.3.3.3;
  bandwidth {
    ct0 11;
    ct1 1;
    ct2 1;
    ct3 1;
  }
}
interface fxp0.0 {
  disable;
}
interface t1-0/5/3.0;
interface t1-0/5/4.0;
```

## Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets

You can selectively set the DiffServ code point (DSCP) field of MPLS-tagged IPv4 and IPv6 packets to 0 without affecting output queue assignment, and continue to set the MPLS EXP field according to the configured rewrite table, which is based on forwarding classes. You can accomplish this by configuring a firewall filter for the MPLS-tagged packets.

For instructions on how to write different DSCP and EXP values in MPLS-tagged IP packets, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*. For instructions on how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

**Related Documentation** • [Firewall Filter Match Conditions for MPLS Traffic](#)

---

## Configuring System Log Messages and SNMP Traps for LSPs

Whenever an LSP makes a transition from up to down, or down to up, and whenever an LSP switches from one active path to another, the ingress router generates a system log message and sends an SNMP trap. The following shows a sample system log message:

```
RPD_MPLS_LSP_UP: MPLS LSP sheep1 up on primary(any) Route 192.168.1.1 192.168.1.2
192.168.1.3
RPD_MPLS_LSP_CHANGE: MPLS LSP sheep1 change on primary(any) Route 192.168.1.1
192.168.1.2 192.168.1.3
RPD_MPLS_LSP_DOWN: MPLS LSP sheep1 down on primary(any)
```

For information about the MPLS SNMP traps and the proprietary MPLS MIBs, see the *Network Management and Monitoring Guide*.

System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the **no-syslog** option under the **log-updown** statement:

```
log-updown {  
  no-syslog;  
}
```

To generate SNMP traps for LSPs, include the **trap** option to the **log-updown** statement:

```
log-updown {  
  trap;  
}
```

To generate SNMP traps whenever an LSP path goes down, include the **trap-path-down** option to the **log-updown** statement:

```
log-updown {  
  trap-path-down;  
}
```

To generate SNMP traps whenever an LSP path comes up, include the **trap-path-up** option to the **log-updown** statement:

```
log-updown {  
  trap-path-up;  
}
```

To disable the generation of system log messages, include the **no-syslog** option to the **log-updown** statement:

```
log-updown {  
  no-syslog;  
}
```

To disable the generation of SNMP traps, include the **no-trap** statement:

```
no-trap {  
  mpls-lsp-traps;  
  rfc3812-traps;  
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **log-updown**]
- [edit logical-systems *logical-system-name* protocols mpls **log-updown**]

For scalability reasons, only the ingress router generates SNMP traps. By default, MPLS issues traps for all configured LSPs. If you have many LSPs, the number of traps can become quite large. To disable the generation of SNMP traps, configure the **no-trap** statement.

The **no-trap** statement also includes the following options which allow you to block certain categories of MPLS SNMP traps:

- **mpls-lsp-traps**—Blocks the MPLS LSP traps defined in the **jnx-mpls.mib**, but allows the **rfc3812.mib** traps.
- **rfc-3812-traps**—Blocks the traps defined in the **rfc3812.mib**, but allows the MPLS LSP traps defined in the **jnx-mpls.mib**.

# Configuring Graceful Restart for MPLS

- [Configuring MPLS-Signaled LSPs to Use GRE Tunnels on page 107](#)
- [Graceful Restart and MPLS-Related Protocols on page 108](#)

## Configuring MPLS-Signaled LSPs to Use GRE Tunnels

---

MPLS LSPs can use generic routing encapsulation (GRE) tunnels to cross routing areas, autonomous systems, and ISPs. Bridging MPLS LSPs over an intervening IP domain is possible without disrupting the outlying MPLS domain.

LSPs can reach any destination that the GRE tunnels can reach. MPLS applications can be deployed without requiring all transit nodes to support MPLS, or requiring all transit nodes to support the same label distribution protocols (LDP or RSVP). If you use CSPF, you must configure OSPF or IS-IS through the GRE tunnel. Traffic engineering is not supported over GRE tunnels; for example, you cannot reserve bandwidth or set priority or preemption.

**NOTE:** Use the `no-control word` statement to disable the control word when the topology uses GRE as the connection mechanism between provider edge routers and one of the provider edge routers is an M Series Multiservice Edge Router.

For more information about GRE tunnels, see the *Junos OS Services Interfaces Library for Routing Devices*.

### Example: Configuring MPLS-Signaled LSPs to Use GRE Tunnels

To configure MPLS over GRE tunnels:

1. Enable **family mpls** under the GRE interface configuration:

```
[edit interfaces]
interface gr-1/2/0 {
  unit 0 {
    tunnel {
      source 192.168.1.1;
      destination 192.168.1.2;
    }
  }
}
```

```
family inet {  
    address 5.1.1.1/30;  
}  
family iso;  
family mpls;  
}  
}
```

2. Enable RSVP and MPLS over the GRE tunnel:

```
[edit protocols]  
rsvp {  
    interface gr-1/2/0.0;  
}  
mpls {  
    ...  
    interface gr-1/2/0.0;  
}
```

3. Configure LSPs to travel through the GRE tunnel endpoint address:

```
[edit protocols]  
mpls {  
    label-switched-path gre-tunnel {  
        to 5.1.1.2;  
        ...  
    }  
}
```

Standard LSP configuration options apply. If the routing table specifies that a particular route will traverse a GRE tunnel, the RSVP packets will traverse the tunnel as well.

---

## Graceful Restart and MPLS-Related Protocols

This section contains the following topics:

- [LDP on page 108](#)
- [RSVP on page 109](#)
- [CCC and TCC on page 109](#)

### LDP

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

The reconnect time is configured in Junos OS as 60 seconds and is not user-configurable. The reconnect time is how long the helper router waits for the restarting router to establish a connection. If the connection is not established within the reconnect interval, graceful restart for the LDP session is terminated. The maximum reconnect time is 120 seconds and is not user-configurable. The maximum reconnect time is the maximum value that a helper router accepts from its restarting neighbor.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, so it can continue to forward traffic.

You can configure LDP graceful restart both in the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and for a specific routing instance only.

## RSVP

RSVP graceful restart enables a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

## CCC and TCC

CCC and TCC graceful restart enables Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the provider edge (PE) routers and provider (P) routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

## Node-Link Protection Overview

---

Node-link protection (many-to-one or facility backup) extends the capabilities of link protection and provides slightly different protection from fast reroute. While link protection is useful for selecting an alternate path to the same router when a specific link fails, and fast reroute protects interfaces or nodes along the entire path of an LSP, node-link protection establishes a bypass path that avoids a particular node in the LSP path.

When you enable node-link protection for an LSP, you must also enable link protection on all RSVP interfaces in the path. Once enabled, the following types of bypass paths are established:

- **Next-hop bypass LSP**—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass path is established when you enable either node-link protection or link protection.
- **Next-next-hop bypass LSP**—Provides an alternate route for an LSP through a neighboring router en route to the destination router. This type of bypass path is established exclusively when node-link protection is configured.

Figure 6 on page 112 illustrates the example MPLS network topology used in this topic. The example network uses OSPF as the interior gateway protocol (IGP) and a policy to create traffic.

Figure 6: Node-Link Protection

The MPLS network in Figure 6 on page 112 illustrates a router-only network that consists of unidirectional LSPs between R1 and R5, (*lsp2-r1-to-r5*) and between R6 and R0 (*lsp1-r6-to-r0*). Both LSPs have strict paths configured that go through interface *fe-0/1/0*.

In the network shown in Figure 6 on page 112, both types of bypass paths are preestablished around the protected node (R2). A next-hop bypass path avoids interface *fe-0/1/0* by going through R7, and a next-next-hop bypass path avoids R2 altogether by going through R7 and R9 to R4. Both bypass paths are shared by all protected LSPs traversing the failed link or node (many LSPs protected by one bypass path).

Node-link protection (many-to-one or facility backup) allows a router immediately upstream from a node failure to use an alternate node to forward traffic to its downstream neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link.

When an outage occurs, the router immediately upstream from the outage switches protected traffic to the bypass node, and then signals the failure to the ingress router. Like fast reroute, node-link protection provides local repair, restoring connectivity faster than the ingress router can establish a standby secondary path or signal a new primary LSP.

Node-link protection is appropriate in the following situations:

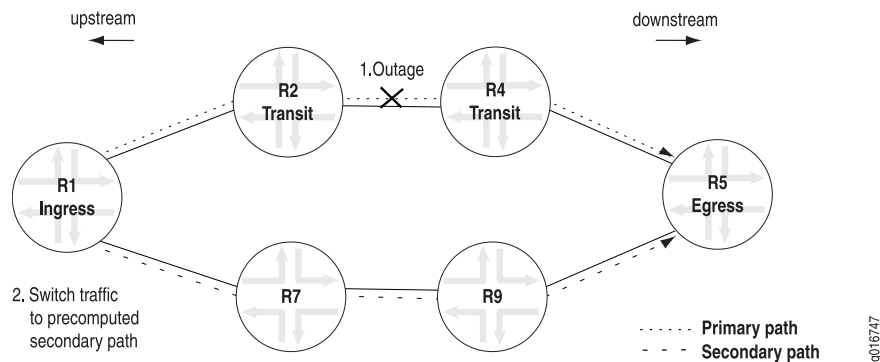

- Protection of the downstream link and node is required.
- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

## Path Protection Overview

The main advantages of path protection are control over where the traffic goes after a failure and minimum packet loss when combined with fast reroute (one-to-one backup or link protection). Path protection is the configuration, within a label-switched path (LSP), of two types of paths: a primary path, used in normal operations, and a secondary path used when the primary fails, as shown in [Figure 7 on page 113](#).

In [Figure 7 on page 113](#), an MPLS network consisting of eight routers has a primary path between **R1** and **R5** which is protected by the secondary path between **R1** and **R5**. When a failure is detected, such as an interface down event, an Resource Reservation Protocol (RSVP) error message is sent to the ingress router which switches traffic to the secondary path, maintaining traffic flow.

**Figure 7: Path Protection**

If the secondary path is pre-sigaled or on standby, recovery time from a failure is faster than if the secondary path is not pre-sigaled. When the secondary path is not pre-sigaled a call-setup delay occurs during which the new physical path for the LSP is established, extending the recovery time. If the failure in the primary path is corrected, and after a few minutes of hold time, the ingress router switches traffic back from the secondary path to the primary path.

Because path protection is provided by the ingress router for the entire path, there can be some disadvantages, for example, double-booking of resources and unnecessary protection of links. By protecting a single resource at a time, local protection can remedy these disadvantages.

## Configuring Path Protection in an MPLS Network (CLI Procedure)

The Junos OS implementation of MPLS on EX Series switches provides path protection as a mechanism for protecting against label switched path (LSP) failures. Path protection reduces the time required to recalculate a route in case of a failure within the MPLS tunnel. You configure path protection on the ingress provider edge switch in your MPLS network. You do not configure the egress provider edge switch or the provider switches for path protection. You can explicitly specify which provider switches are used for the

primary and secondary paths, or you can let the software calculate the paths automatically.

Before you configure path protection, be sure you have:

- Configured an ingress provider edge switch and an egress provider edge switch. See [“Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\)” on page 72](#) or [“Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\)” on page 77](#).
- Configured at least one provider (transit) switch. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 81](#).
- Verified the configuration of your MPLS network.

To configure path protection, complete the following tasks on the ingress provider edge switch:

1. [Configuring the Primary Path on page 115](#)
2. [Configuring the Secondary Path on page 115](#)
3. [Configuring the Revert Timer on page 116](#)

## Configuring the Primary Path

The **primary** statement creates the primary path, which is the LSP's preferred path. The **secondary** statement creates an alternative path if the primary path can no longer reach the egress provider edge switch.

In the tasks described in this topic, the **lsp-name** has already been configured on the ingress provider edge switch as **lsp\_to\_240** and the loopback interface address on the remote provider edge switch has already been configured as **127.0.0.8**.

When the software switches from the primary to the secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable but no sooner than the retry time specified in the **revert-timer** statement.

You can configure zero primary paths or one primary path. If you do not configure a primary path, the first secondary path (if a secondary path has been configured) is selected as the path. If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary for the packets to reach the egress provider edge switch.

To configure a primary path:

1. Create the primary path for the LSP:

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set primary primary_path_lsp_to_240
```

2. Configure an explicit route for the primary path by specifying the IP address of the loopback interface or the switch IP address or hostname of each switch used in the MPLS tunnel. You can specify the link types as either **strict** or **loose** in each **path** statement. If the link type is **strict**, the LSP must go to the next address specified in the **path** statement without traversing other switches. If the link type is **loose**, the LSP can traverse through other switches before reaching this switch. This configuration uses the default **strict** designation for the paths.

**NOTE:** You can enable path protection without specifying which provider switches are used. If you do not list the specific provider switches to be used for the MPLS tunnel, the switch calculates the route.

**TIP:** Do not include the ingress provider edge switch in these statements. List the IP address of the loopback interface or switch address or hostname of all other switch hops in sequence, ending with the egress provider edge switch.

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set path primary_path_lsp_to_240 127.0.0.2
user@switch# set path primary_path_lsp_to_240 127.0.0.3
user@switch# set path primary_path_lsp_to_240 127.0.0.8
```

## Configuring the Secondary Path

You can configure zero or more secondary paths. All secondary paths are equal, and the software tries them in the order that they are listed in the configuration. The software does not attempt to switch among secondary paths. If the first secondary path in the configuration is not available, the next one is tried, as so on. To create a set of equal paths, specify secondary paths without specifying a primary path. If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress provider edge switch.

To configure the secondary path:

1. Create a secondary path for the LSP:

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set secondary secondary_path_lsp_to_240 standby
```

2. Configure an explicit route for the secondary path by specifying the IP address of the loopback interface or the switch IP address or hostname of each switch used in the MPLS tunnel. You can specify the link types as either **strict** or **loose** in each **path** statement. This configuration uses the default **strict** designation for the paths.

**TIP:** Do not include the ingress provider edge switch in these statements. List the IP address of the loopback interface or switch address or hostname of all other switch hops in sequence, ending with the egress provider edge switch.

```
[edit protocols mpls label-switched-path lsp_to_240 to 127.0.0.8]
user@switch# set path secondary_path_lsp_to_240 127.0.0.4
user@switch# set path primary_path_lsp_to_240 127.0.0.8
```

## Configuring the Revert Timer

For LSPs configured with both primary and secondary paths, you can optionally configure a revert timer. If the primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to the primary path. If the primary path experiences any connectivity problems or stability problems during this time, the timer is restarted.

**TIP:** If you do not explicitly configure the revert timer, it is set by default to 60 seconds.

To configure the revert timer for LSPs configured with primary and secondary paths:

- For all LSPs on the switch:

```
[edit protocols mpls]
user@switch# set revert-timer 120
```

- For a specific LSP on the switch:

```
[edit protocols mpls label-switched-path]
user@switch# set lsp_to_240 revert-timer 120
```

#### Related Documentation

- [Understanding MPLS and Path Protection on EX Series Switches on page 34](#)

## Preventing Use of a Path That Previously Failed

If you configure an alternate path through the network in case the active path fails, you may not want traffic to revert back to the failed path, even if it is no longer failing. When you configure a primary path, the traffic switches over to the secondary path during a failure, and reverts back to the primary path when it returns.

At times, switching traffic back to a primary path that has previously failed may not be a particularly sound idea. In this case, only configure secondary paths, resulting in the next configured secondary path establishing when the first secondary path fails. Later, if the first secondary path becomes operational, the Junos OS will not revert to it, but will continue using the second secondary path.

## Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP

- [Understanding MPLS Inter-AS Link Protection on page 117](#)
- [Example: Configuring MPLS Inter-AS Link-Node Protection on page 119](#)

### Understanding MPLS Inter-AS Link Protection

Link protection is essential in an MPLS network to ensure traffic restoration in case of an interface failure. The ingress router chooses an alternate link through another interface to send traffic to its destination.

In [Figure 8 on page 118](#), autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices. If the link from Device ASBR3 to Device ASBR1 goes down, until Device ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped. A fast traffic restoration can be achieved if Device ASBR3 preprograms a backup path either through Device ASBR4 or through a direct path to Device ASBR2 if one exists (not shown in the diagram). This assumes that Device ASBR3 learns a loop-free MPLS path for routes that need to be protected either through IBGP or EBGP.

This solution does not handle a failure on Device ASBR3 for traffic going toward AS 64511 from AS 64510 through the ASBR3-ASBR1 link. This solution is limited to downstream inter-AS link-node protection with labeled BGP. This solution does not support service restoration between provider (P) and ASBR routers when there is an ASBR failure. For example, this solution does not handle a failure on the P3-ASBR3 link.

This supported functionality is similar to BGP multipath, except only one next hop is used for active forwarding, and a second path is in protected mode.

*Figure 8: MPLS Inter-AS Link-Node Protection Conceptual Topology*

In an MPLS inter-AS environment, link protection can be enabled when **labeled-unicast** is used to send traffic between ASs. Hence, MPLS inter-AS link protection is configured on the link between two routers in different ASs.

To configure link protection on an interface, use the **protection** statement at the **[edit protocols bgp group group-name family inet labeled-unicast]** hierarchy level:

```
protocols {
  bgp {
    group test1 {
      type external;
      local-address 192.168.1.2;
      family inet {
        labeled-unicast {
          protection;
        }
      }
    }
  }
}
```

**NOTE:** MPLS inter-AS link protection is supported only with labeled-unicast and external peers in a master routing instance.

The link on which protection is configured is known as the protection path. A protection path is selected only after the best path selection and is not selected in the following cases:

- The best path is a non-BGP path.
- Multiple next hops are active, as in BGP multipath.

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In [Figure 9 on page 120](#), autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices.

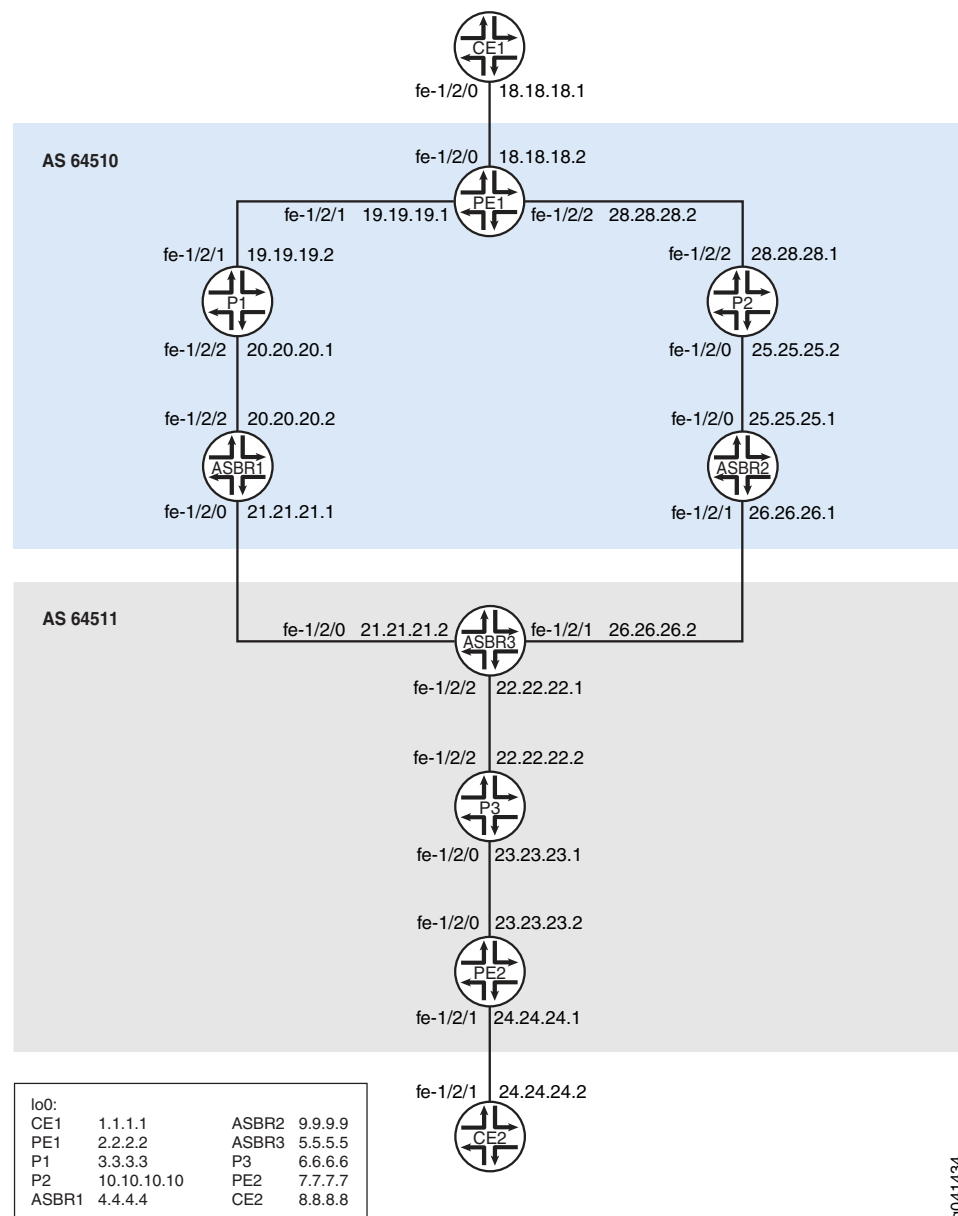

If the link from Device ASBR3 to Device ASBR1 goes down, until ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped.

This example shows how to achieve fast traffic restoration by configuring Device ASBR3 to preprogram a backup path through Device ASBR2.

**NOTE:** This solution does not handle the Device P3 to Device ASBR3 failure. Nor does it handle a failure on Device ASBR3 for traffic going toward AS 64511 from AS 64510 through the ASBR3-ASBR1 link. This traffic is dropped.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

### Device ASBR1

```
set interfaces fe-1/2/2 unit 0 family inet address 20.20.20.2/30
set interfaces fe-1/2/2 unit 0 family mpls
set interfaces fe-1/2/0 unit 0 family inet address 21.21.21.1/30
```

```

set interfaces fe-1/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 4.4.4.4/32
set protocols rsvp interface fe-1/2/2.0
set protocols rsvp interface lo0.0
set protocols mpls traffic-engineering bgp-igp-both-ribs
set protocols mpls label-switched-path To_PE1 to 2.2.2.2
set protocols mpls interface fe-1/2/2.0
set protocols mpls interface fe-1/2/0.0
set protocols mpls interface lo0.0
set protocols bgp group To-PE1 type internal
set protocols bgp group To-PE1 local-address 4.4.4.4
set protocols bgp group To-PE1 family inet unicast
set protocols bgp group To-PE1 family inet labeled-unicast

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the EBGp scenario:

1. Configure the router interfaces.

```
[edit interfaces]
user@ASBR3# set fe-1/2/0 unit 0 description to-ASBR1
user@ASBR3# set fe-1/2/0 unit 0 family inet address 21.21.21.2/30
user@ASBR3# set fe-1/2/0 unit 0 family mpls
user@ASBR3# set fe-1/2/2 unit 0 description to-P3
user@ASBR3# set fe-1/2/2 unit 0 family inet address 22.22.22.1/30
user@ASBR3# set fe-1/2/2 unit 0 family mpls
user@ASBR3# set fe-1/2/1 unit 0 description to-ASBR2
user@ASBR3# set fe-1/2/1 unit 0 family inet address 26.26.26.2/30
user@ASBR3# set fe-1/2/1 unit 0 family mpls
user@ASBR3# set lo0 unit 0 family inet address 5.5.5.5/32
```

2. Configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf]
user@ASBR3# set traffic-engineering
[edit protocols ospf area 0.0.0.0]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0 passive
user@ASBR3# set interface fe-1/2/1.0
```

3. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@ASBR3# set autonomous-system 64511
```

4. Configure the routing policy.

```
[edit policy-options policy-statement To-ASBR1]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
[edit policy-options policy-statement To-ASBR2]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
[edit policy-options policy-statement next-hop-self]
user@ASBR3# set then next-hop self
```

5. Configure the EBGp sessions.

```
[edit protocols bgp group To-ASBR1]
```

```

user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR1
user@ASBR3# set neighbor 21.21.21.1 peer-as 64510
[edit protocols bgp group To-ASBR2]
user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR2
user@ASBR3# set neighbor 26.26.26.1 peer-as 64510

```

6. Configure the IBGP sessions.

```

[edit protocols bgp group To-PE2]
user@ASBR3# set type internal
user@ASBR3# set local-address 5.5.5.5
user@ASBR3# set family inet unicast
user@ASBR3# set export next-hop-self
user@ASBR3# set neighbor 7.7.7.7 family inet labeled-unicast

```

7. Configure MPLS.

```

[edit protocols mpls]
user@ASBR3# set traffic-engineering bgp-igp-both-ribs
user@ASBR3# set label-switched-path To_PE2 to 7.7.7.7
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface fe-1/2/1.0

```

8. Configure a signaling protocol.

```

[edit protocols rsvp]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/1.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options**, commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@ASBR3# show interfaces
fe-1/2/0 {
  unit 0 {
    description to-ASBR1;
  }
}

```

```
    family inet {
        address 21.21.21.2/30;
    }
    family mpls;
}
}
fe-1/2/1 {
    unit 0 {
        description to-ASBR2;
        family inet {
            address 26.26.26.2/30;

## Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

Figure 1 shows a simplified topology of the use case that explains this feature.

*Figure 10: Egress Protection LSP Configured from Router PE1 to Router PE2*

CE1 is multihomed to PE1 and PE2. There are two paths connecting CE1 and CE2. The working path is CE2-PE3-P-PE1-CE1, via pseudowire PW21. The protecting path is CE2-PE3-P-PE2-CE1, via pseudowire PW22. Traffic is flowing through the working path under normal circumstances. When the end-to-end OAM between CE1 and CE2 detects failure on the working path, traffic will be switched from the working path to the protecting path. The end-to-end failure detection and recovery relies on control plane hence should be relatively slow. To achieve faster protection, local repair mechanisms similar to those used by MPLS fast reroute should be used. In Figure 1 above, if link or node failed in the core network (like link failure on P-PE1, P-PE3, or node failure on P), the MPLS fast reroute will happen on the transport LSPs between PE1 and PE3. The failure could be locally repaired within tens of milliseconds. However, if link or node failure happens at the edge (like link failure on PE3-CE2 or node failure on PE3), there is no local repair currently so we have to rely on the CE1-CE2 end-to-end protection to repair the failure.

- Device CE2—Traffic origin
- Router PE3—Ingress PE router

- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes down, PE1 will briefly redirect that traffic towards CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was; CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be; CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path; CE2 – PE3 – P – PE2 – CE1.

1. Configure RSVP on PE1, PE2, and PE3.

```
[edit protocols]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

3. Set PE1 as **primary** and PE2 as **protector** nodes.

```
[edit protocols mpls]
user@PE1# set egress-protection context-identifier address primary
user@PE2# set egress-protection context-identifier address protector
```

4. Enable **egress-protection** on PE1 and PE2.

```
[edit protocols bgp]
user@PE1# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp family l2vpn egress-protection
```

5. Configure LDP and ISIS on PE1, PE2, and PE3.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

```
[edit protocols isis]
user@PE1# set interface all point-to-point
```

```

user@PE2# set interface all point-to-point
user@PE3# set interface all point-to-point

```

6. Configure a load balancing policy at PE1, PE2, and PE3.

```

[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
user@PE2# set policy-options policy-statement lb then load-balance per-packet
user@PE3# set policy-options policy-statement lb then load-balance per-packet

```

7. Configure the routing options at PE1, PE2, and PE3, to export routes based on the load balancing policy.

```

[edit]
user@PE1# set routing-options traceoptions file ro.log
user@PE1# set routing-options traceoptions flag normal
user@PE1# set routing-options traceoptions flag route
user@PE1# set routing-options autonomous-system 100
user@PE1# set routing-options forwarding-table export lb

```

```

[edit]
user@PE2# set routing-options traceoptions file ro.log
user@PE2# set routing-options traceoptions flag normal
user@PE2# set routing-options traceoptions flag route
user@PE2# set routing-options autonomous-system 100
user@PE2# set routing-options forwarding-table export lb

```

```

[edit]
user@PE3# set routing-options traceoptions file ro.log
user@PE3# set routing-options traceoptions flag normal
user@PE3# set routing-options traceoptions flag route
user@PE3# set routing-options autonomous-system 100
user@PE3# set routing-options forwarding-table export lb

```

8. Configure BGP at PE1 to advertise nrli from the routing instance with context-ID as next-hop.

```

[edit]
user@PE1# set routing-instances foo egress-protection context-identifier
context-identifier

```

9. Configure l2vpn at PE1, PE2, and PE3

At PE1:

```

[edit routing-instances]
foo {
  instance-type l2vpn;
  egress-protection {

```

```

context-identifier {
  198.51.100.0;
}
}
interface ge-2/0/2.0;
route-distinguisher 10.255.183.58:1;
vrf-target target:9000:1;
protocols {
  l2vpn {
    encapsulation-type ethernet-vlan;
    site foo {
      site-identifier 1;
      multi-homing;
      site-preference primary;
      interface ge-2/0/2.0 {
        remote-site-id 2;
      }
    }
  }
}
}
}

```

At PE2:

```

[edit routing-instances]
foo {
  instance-type l2vpn;
  egress-protection {
    protector;
  }
  interface ge-2/0/2.0;
  route-distinguisher 10.255.183.57:1;
  vrf-target target:9000:1;
  protocols {
    l2vpn {
      encapsulation-type ethernet-vlan;
      site foo{
        site-identifier 1;
        multi-homing;
        site-preference backup;
        interface ge-2/0/2.0 {
          remote-site-id 2;
        }
      }
    }
  }
}
}

```

At PE3:

```

[edit routing-instances]
foo {
  instance-type l2vpn;
  interface ge-2/1/2.0;
}

```

```

route-distinguisher 10.255.183.61:1;
vrf-target target:9000:1;
protocols {
  l2vpn {
    encapsulation-type ethernet-vlan;
    site foo {
      site-identifier 2;
      interface ge-2/1/2.0;
    }
  }
}

```

**Release History Table**

Release	Description
14.2	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.

## Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example shows how to configure link protection for BGP signaled Layer 2 services.

- [Requirements on page 137](#)
- [Overview on page 137](#)
- [Configuration on page 139](#)
- [Verification on page 152](#)

### Requirements

MX Series Routers running Junos OS Release 14.2 or later.

### Overview

If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the

connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example includes the following configuration concepts and statements that are unique to the configuration of an egress protection LSP:

- **context-identifier**—Specifies an IPv4 or IPv6 address used to define the pair of PE routers participating in the egress protection LSP. It is assigned to each ordered pair of primary PE and the protector to facilitate protection establishment. This address is globally unique, or unique in the address space of the network where the primary PE and the protector reside.
- **egress-protection**—Configures the protector information for the protected Layer 2 circuit and configures the protector Layer 2 circuit at the `[edit protocols mpls]` hierarchy level. Configures an LSP as an egress protection LSP at the `[edit protocols mpls]` hierarchy level.
- **protector**—Configures the creation of standby pseudowires on the backup PE for link or node protection for the instance.

*Figure 11: Egress Protection LSP Configured from Router PE1 to Router PE2*

In the event of a failure of the egress PE Router PE1, traffic is switched to the egress protection LSP configured between Router PE1 and Router PE2 (the protector PE router):

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes down, PE1 will briefly redirect that traffic toward CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was: CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be: CE2 – PE3 – P – PE1 – PE2 – CE1. PE3 then recalculates the path: CE2 – PE3 – P – PE2 – CE1.

This example shows how to configure routers PE1, PE2, and PE3.

## Configuration

- [Step-by-Step Procedure on page 141](#)
- [Results on page 146](#)

### CLI Quick Configuration

To quickly configure an egress protection LSP, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configurations, copy and then paste the commands into the CLI and enter **commit** from configuration mode.

PE1

```
set protocols rsvp interface all

```

### Step-by-Step Procedure

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP for router PE1:

1. Configure RSVP.

```

[edit protocols rsvp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable

```

2. Configure MPLS to use the egress protection LSP to protect against a link failure to Device CE1.

```

[edit protocols mpls]

```

```
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set egress-protection context-identifier 198.51.100.3 primary
user@PE1# set egress-protection context-identifier 198.51.100.3 advertise-mode
stub-alias
user@PE1# set egress-protection traceoptions file ep size 100m
user@PE1# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set traceoptions file bgp.log world-readable
user@PE1# set group ibgp type internal
user@PE1# set group ibgp local-address 10.255.183.58
user@PE1# set group ibgp family inet unicast
user@PE1# set group ibgp family l2vpn signaling egress-protection
user@PE1# set group ibgp neighbor 192.0.2.3
user@PE1# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE1# set traceoptions file isis-edge size 10m world-readable
user@PE1# set traceoptions flag error
user@PE1# set level 1 disable
user@PE1# set level 2 wide-metrics-only
user@PE1# set interface all point-to-point
user@PE1# set interface all level 2 metric 10
user@PE1# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE1# set traceoptions file ro.log
user@PE1# set traceoptions flag all
user@PE1# set autonomous-system 100
user@PE1# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE1# set foo instance-type l2vpn
user@PE1# set foo egress-protection context-identifier 198.51.100.3
user@PE1# set foo interface ge-2/0/2.0
user@PE1# set foo route-distinguisher 10.255.183.58:1
user@PE1# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE1# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE1# set foo protocols l2vpn site foo site-identifier 1
user@PE1# set foo protocols l2vpn site foo multi-homing
user@PE1# set foo protocols l2vpn site foo site-preference primary
user@PE1# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```

10. If you are done configuring the device, enter **commit** from configuration mode.

#### Step-by-Step Procedure

To configure an egress protection LSP for Router PE2:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

2. Configure MPLS and the LSP that acts as the egress protection LSP.

```
[edit protocols mpls]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 198.51.100.3 protector
user@PE2# set egress-protection context-identifier 198.51.100.3 advertise-mode
stub-alias
user@PE2# set egress-protection traceoptions file ep size 100m
user@PE2# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE2# set traceoptions file bgp.log world-readable
user@PE2# set group ibgp type internal
user@PE2# set group ibgp local-address 10.255.183.57
user@PE2# set group ibgp family inet unicast
user@PE2# set group ibgp family l2vpn signaling
user@PE2# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp neighbor 192.0.2.3
```

```
user@PE2# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set traceoptions file isis-edge size 10m world-readable
user@PE2# set traceoptions flag error
user@PE2# set level 1 disable
user@PE2# set level 2 wide-metrics-only
user@PE2# set interface all point-to-point
user@PE2# set interface all level 2 metric 10
user@PE2# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE2# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE2# set traceoptions file ro.log
user@PE2# set traceoptions flag all
user@PE2# set autonomous-system 100
user@PE2# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE2# set foo instance-type l2vpn
user@PE2# set foo egress-protection protector
user@PE2# set foo interface ge-2/0/2.0
user@PE2# set foo route-distinguisher 10.255.183.57:1
user@PE2# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE2# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE2# set foo protocols l2vpn site foo hot-standby
user@PE2# set foo protocols l2vpn site foo site-identifier 1
user@PE2# set foo protocols l2vpn site foo multi-homing
```

```

user@PE2# set foo protocols l2vpn site foo site-preference backup
user@PE2# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2

```

10. If you are done configuring the device, enter **commit** from configuration mode.

### Step-by-Step Procedure

To configure an egress protection LSP for Router PE3:

1. Configure RSVP.

```

[edit protocols rsvp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable

```

2. Configure MPLS.

```

[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable

```

3. Configure BGP.

```

[edit protocols bgp]
user@PE3# set traceoptions file bgp.log world-readable
user@PE3# set group ibgp type internal
user@PE3# set group ibgp local-address 10.255.183.61
user@PE3# set group ibgp family inet unicast
user@PE3# set group ibgp family l2vpn signaling
user@PE3# set group ibgp neighbor 192.0.2.3
user@PE3# set group ibgp neighbor 192.0.2.4

```

4. Configure IS-IS.

```

[edit protocols isis]
user@PE3# set traceoptions file isis-edge size 10m world-readable
user@PE3# set traceoptions flag error
user@PE3# set level 1 disable
user@PE3# set level 2 wide-metrics-only
user@PE3# set protocols isis interface all point-to-point
[edit protocols isis]
user@PE3# set protocols isis interface all level 2 metric 10
[edit protocols isis]
user@PE3# set protocols isis interface fxp0.0 disable

```

5. Configure LDP.

```

[edit protocols ldp]
user@PE3# set interface all

```

```
user@PE3# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE3# set traceoptions file ro.log
user@PE3# set traceoptions flag normal
user@PE3# set traceoptions flag route
user@PE3# set autonomous-system 100
user@PE3# set forwarding-table export lb
```

8. Configure BGP to advertise nlri from the routing instance with context-ID as next-hop.

```
[edit]
user@PE3# set routing-instances foo instance-type l2vpn
user@PE3# set routing-instances foo interface ge-2/1/2.0
user@PE3# set routing-instances foo route-distinguisher 10.255.183.61:1
user@PE3# set routing-instances foo vrf-target target:9000:1
```

9. Configure l2vpn to specify the interface that connects to the site and the remote interface to which you want the specified interface to connect.

```
[edit routing-instances]
user@PE3# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE3# set foo protocols l2vpn site foo site-identifier 2
user@PE3# set foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1
```

10. If you are done configuring the device, enter **commit** from configuration.

## Results

From configuration mode, confirm your configuration on Router PE1 by entering the **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@PE1# show protocols

    }
}
```

## Verification

Confirm that the configuration is working properly.

- [Verifying the L2VPN Configuration on page 153](#)
- [Verifying the Routing Instance Details on page 154](#)

- [Verifying the IS-IS Configuration on page 154](#)
- [Verifying the MPLS Configuration on page 155](#)

### Verifying the L2VPN Configuration

**Purpose** Verify that LSP is protected by the connection protection logic.

**Action** From operational mode, run the **show l2vpn connections extensive** command.

```
user@PE2> show l2vpn connections extensive
```

```
Layer-2 VPN connections:
Legend for connection status (St)
EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch     WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down   NP -- interface hardware not present
CM -- control-word mismatch     -> -- only outbound connection is up
CN -- circuit not provisioned   <- -- only inbound connection is up
OR -- out of range             Up -- operational
OL -- no outgoing label        Dn -- down
LD -- local site signaled down  CF -- call admission control failure
RD -- remote site signaled down SC -- local and remote site ID collision
LN -- local site not designated LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status IL -- no incoming label
MM -- MTU mismatch            MI -- Mesh-Group ID not available
BK -- Backup connection       ST -- Standby connection
PF -- Profile parse failure    PB -- Profile busy
RS -- remote site standby      SN -- Static Neighbor
LB -- Local site not best-site RB -- Remote site not best-site
VM -- VLAN ID mismatch

Legend for interface status
Up -- operational
Dn -- down
Instance: foo
Local site: foo (1)
  connection-site      Type  St  Time last up      # Up trans
    2                  rmt   Up   Aug 3 00:08:14 2001      1
    Local circuit: ge-2/0/2.0, Status: Up
    Remote PE: 192.0.2.3
    Incoming label: 32769, Outgoing label: 32768
    Egress Protection: Yes
      Time              Event                  Interface/Lbl/PE
    Aug 3 00:08:14 2001 PE route up
    Aug 3 00:08:14 2001 Out lbl Update          32768
    Aug 3 00:08:14 2001 In lbl Update           32769
    Aug 3 00:08:14 2001 ckt0 up                  fe-0/0/0.0
```

**Meaning** The **Egress Protection: Yes** output shows that the given PVC is protected by connection protection logic.

### Verifying the Routing Instance Details

**Purpose** Verify the routing instance information and the context identifier configured on the primary, which is used as the next-hop address in case of node-link failure.

**Action** From operational mode, run the **show route foo detail** command.

```
user@PE2> show route foo detail
```

```
foo:
  Router ID: 0.0.0.0
  Type: l2vpn non-forwarding State: Active
  Interfaces:
    lt-1/2/0.56
  Route-distinguisher: 10.255.255.11:1
  Vrf-import: [ __vrf-import-foo-internal__ ]
  Vrf-export: [ __vrf-export-foo-internal__ ]
  Vrf-import-target: [ target:100:200 ]
  Vrf-export-target: [ target:100:200 ]
  Fast-reroute-priority: low
  Vrf-edge-protection-id: 198.51.100.3
  Tables:
    foo.l2vpn.0          : 5 routes (3 active, 0 holddown, 0 hidden)
    foo.l2id.0           : 6 routes (2 active, 0 holddown, 0 hidden)
```

**Meaning** The context-id is set to **198.51.100.3** and the **Vrf-import: [ \_\_vrf-import-foo-internal\_\_ ]** in the output mentions the policy used for rewriting the next-hop address.

### Verifying the IS-IS Configuration

**Purpose** Verify the IS-IS context identifier information.

**Action** From operational mode, run the **show isis context-identifier detail** command.

```
user@PE2> show isis context-identifier detail
```

```
IS-IS context database:
Context      L  Owner   Role      Primary      Metric
198.51.100.3  2  MPLS    Protector  pro17-b-lr-R1 0
  Advertiser pro17-b, Router ID 10.255.107.49, Level 2, tlv protector
  Advertiser pro17-b-lr-R1, Router ID 10.255.255.11, Metric 1, Level 2, tlv prefix
```

**Meaning** Router PE2 is the protector and the configured context identifier is in use for the MPLS protocol.

## Verifying the MPLS Configuration

**Purpose** Verify the context identifier details on the primary and protector PEs.

**Action** From operational mode, run the **show mpls context-identifier detail** command.

```
user@PE1> show mpls context-identifier detail
```

```
ID: 198.51.100.3
Type: primary, Metric: 1, Mode: alias
Total 1, Primary 1, Protector 0
```

```
user@PE2> show mpls context-identifier detail
```

```
ID: 198.51.100.3
Type: protector, Metric: 16777215, Mode: alias
Context table: __198.51.100.3__.mpls.0, Label out: 299968
```

```
user@PE2> show mpls egress-protection detail
```

```
Instance          Type      Protection-Type
foo               local-l2vpn Protector
Route Target 100:200
```

**Meaning** Context-id is **198.51.100.3**, advertise-mode is **alias**, the MPLS table created for egress protection is **\_\_198.51.100.3\_\_.mpls.0**, and the egress instance name is **foo**, which is of type **local-l2vpn**.

### Release History Table

Release	Description
<a href="#">14.2</a>	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.

## Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector

---

This example shows how to configure fast service restoration at the egress of a Layer 3 VPN when the customer is multihomed to the service provider.

Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair. Instead, the PLR or the protector can send the traffic directly to the target CE (in Co-located protector model where the PLR or the protector is also the backup PE that is directly connected to the CE) or to the backup PE (in Centralized protector model where the backup PE is a separate router).

- [Requirements on page 156](#)
- [Overview on page 156](#)
- [Configuration on page 157](#)
- [Verification on page 175](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

This example requires Junos OS Release 15.1 or later.

### Overview

As a special scenario of egress node protection, if a router is both a Protector and a PLR, it installs backup next hops to protect the transport LSP. In particular, it does not need a bypass LSP for local repair.

In the Co-located protector model, the PLR or the Protector is directly connected to the CE via a backup AC, while in the Centralized protector model, the PLR or the protector has an MPLS tunnel to the backup PE. In either case, the PLR or the Protector will install a backup next hop with a label followed by a lookup in a **context label** table, i.e. **\_\_context\_\_.mpls.0**. When the egress node fails, the PLR or the Protector will switch traffic to this backup next hop in PFE. The outer label (the transport LSP label) of packets is popped, and the inner label (the layer 3 VPN label allocated by the egress node) is looked up in **\_\_context\_\_.mpls.0**, which results in forwarding the packets directly to the CE (in Collocated protector model) or the backup PE (in Centralized protector model).

### Topology

---

Figure 12 on page 157 shows the sample network.

Figure 12: Co-located PLR and protector in collocated protector model

set interfaces lo0 unit 0 family inet6 address abcd::10:255:162:88/128 primary

```

### Configuring Device CE1

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure interfaces.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 0 family inet address 10.10.20.2/30
user@CE1# set lo0 unit 0 family inet address 10.255.162.87/32
```

### Configuring Device PE1

**Step-by-Step Procedure** 1. Configure the interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 10.10.20.1/30
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/30
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE1# set lo0 unit 0 family inet address 10.255.162.84/32 primary
user@PE1# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2084.00
user@PE1# set lo0 unit 0 family inet6 address abcd::10:255:162:84/128 primary
```

2. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set autonomous-system 65000
user@PE1# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE1# set interface all link-protection
user@PE1# set interface fxp0.0 disable
```

4. Enable MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group vpn type internal
user@PE1# set group vpn local-address 10.255.162.84
user@PE1# set group vpn family inet-vpn unicast
user@PE1# set group vpn neighbor 10.255.162.91
user@PE1# set group vpn neighbor 10.255.162.89
user@PE1# set vpn-apply-export
```

6. Enable IS-IS.

```
[edit protocols isis]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set interface lo0.0 passive
```

7. (Optional) Configure OSPF

```
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface all
user@PE1# set area 0.0.0.0 interface fxp0.0 disable
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set traffic-engineering
```

8. Configure the routing instance.

```
[edit routing-instances]
user@PE1# set vpn instance-type vrf
user@PE1# set vpn interface ge-1/0/0.0
user@PE1# set vpn route-distinguisher 100:100
user@PE1# set vpn vrf-import vpn-imp
user@PE1# set vpn vrf-export vpn-exp
user@PE1# set vpn vrf-table-label
user@PE1# set vpn protocols bgp group vpn type external
user@PE1# set vpn protocols bgp group vpn family inet unicast
user@PE1# set vpn protocols bgp group vpn family inet6 unicast
user@PE1# set vpn protocols bgp group vpn peer-as 65001
user@PE1# set vpn protocols bgp group vpn as-override
user@PE1# set vpn protocols bgp group vpn neighbor 10.10.20.2
```

9. Configure the routing policy.

```
[edit]
user@PE1# set policy-options policy-statement vpn-exp term 1 from protocol direct
user@PE1# set policy-options policy-statement vpn-exp term 1 from route filter
  10.10.20.0/24 exact
user@PE1# set policy-options policy-statement vpn-exp term 1 then community
  add vpn
user@PE1# set policy-options policy-statement vpn-exp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 1 from community
  vpn
```

```

user@PE1# set policy-options policy-statement vpn-imp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 2 then reject
user@PE1# set policy-options community vpn members traget:1:1

```

## Configuring Device P

### Step-by-Step Procedure

1. Configure the device interfaces.

```

[edit interfaces]
user@P# set ge-0/0/0 unit 0 family inet address 10.10.11.2/30
user@P# set ge-0/0/0 unit 0 family inet6
user@P# set ge-0/0/0 unit 0 family iso
user@P# set ge-0/0/0 unit 0 family mpls
user@P# set ge-0/0/1 unit 0 family inet address 10.10.10.2/30
user@P# set ge-0/0/1 unit 0 family inet6
user@P# set ge-0/0/1 unit 0 family iso
user@P# set ge-0/0/1 unit 0 family mpls
user@P# set lo0 unit 0 family inet address 127.0.0.1/32
user@P# set lo0 unit 0 family inet address 10.255.162.86/32 primary
user@P# set lo0 unit 0 family inet6 address abcd::10:255:162:86/128 primary
user@P# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2086.00

```

2. Enable IS-IS.

```

[edit protocols isis]
user@P# set interface all
user@P# set interface fxp0.0 disable

```

3. Enable MPLS.

```

[edit protocols mpls ]
user@P# set interface all
user@P# set interface fxp0.0 disable

```

4. Configure RSVP.

```

[edit protocols rsvp]
user@P# set interface all link-protection
user@P# set interface fxp0.0 disable

```

5. (Optional) Configure OSPF.

```

[edit protocols ospf]
user@P# set area 0.0.0.0 interface all
user@P# set area 0.0.0.0 interface fxp0.0 disable
user@P# set area 0.0.0.0 interface lo0.0 passive
user@P# set traffic-engineering

```

## Configuring Device PE2

### Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/0 unit 0 family inet address 10.10.11.1/30
user@PE2# set ge-0/0/0 unit 0 family iso
user@PE2# set ge-0/0/0 unit 0 family inet6
user@PE2# set ge-0/0/0 unit 0 family mpls
user@PE2# set ge-0/0/1 unit 0 family inet address 10.10.12.1/30
user@PE2# set ge-0/0/1 unit 0 family iso
user@PE2# set ge-0/0/1 unit 0 family inet6
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 10.10.30.1/30
user@PE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE2# set lo0 unit 0 family inet address 10.255.162.91/32 primary
user@PE2# set lo0 unit 0 family iso address
  47.0005.80ff.f800.0000.0108.0001.0102.5516.2091.00
user@PE2# set lo0 unit 0 family inet6 address abcd::10:255:162:91/128 primary
```

2. Configure autonomous number(AS).

```
[edit routing-options]
user@PE2# set autonomous-system 65000
user@PE2# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE2# set interface all link-protection
user@PE2# set interface fxp0.0 disable
```

4. Configure MPLS.

```
[edit protocols mpls]
user@PE2# set label-switched-path to_PE1 to 10.255.162.84
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 1.1.1.1 protector
user@PE2# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE2# set group vpn family inet-vpn unicast egress-protection
user@PE2# set group vpn local-address 10.255.162.91
user@PE2# set group vpn neighbor 10.255.162.84
user@PE2# set group vpn neighbor 10.255.162.89
user@PE2# set group vpn type internal
```

```
user@PE2# set vpn-apply-export
```

6. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set interface lo0.0 passive
user@PE2# set level 2 disable
user@PE2# set traceoptions file isis.log
user@PE2# set traceoptions flag all detail
```

7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE2# set area 0.0.0.0 interface all
user@PE2# set area 0.0.0.0 interface fxp0.0 disable
user@PE2# set area 0.0.0.0 interface lo0.0 passive
user@PE2# set traffic-engineering
```

8. Configure the routing policy.

```
[edit policy-options]
user@PE2# set community vpn members target:1:1
user@PE2# set policy-statement pplb term 1 then load-balance per-packet
user@PE2# set policy-statement vpn-exp term 1 from protocol bgp
user@PE2# set policy-statement vpn-exp term 1 then community add vpn
user@PE2# set policy-statement vpn-exp term 1 then accept
user@PE2# set policy-statement vpn-imp term 1 from community vpn
user@PE2# set policy-statement vpn-imp term 1 then accept
user@PE2# set policy-statement vpn-imp term 2 then reject
```

9. Configure the routing instance.

```
[edit routing-instances]
user@PE2# set vpn instance-type vrf
user@PE2# set vpn interface ge-3/2/4.0
user@PE2# set vpn route-distinguisher 100:100
user@PE2# set vpn vrf-import vpn-imp
user@PE2# set vpn vrf-export vpn-exp
user@PE2# set vpn vrf-table-label
user@PE2# set vpn protocols bgp group vpn type external
user@PE2# set vpn protocols bgp group vpn family inet unicast
user@PE2# set vpn protocols bgp group vpn family inet6 unicast
user@PE2# set vpn protocols bgp group vpn peer-as 65001
user@PE2# set vpn protocols bgp group vpn as-override
user@PE2# set vpn protocols bgp group vpn neighbor 10.10.30.2
```

## Configuring Device PE3

### Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@PE3# set ge-0/0/0 unit 0 family inet address 10.10.40.1/30
user@PE3# set ge-0/0/1 unit 0 family inet address 10.10.12.2/30
user@PE3# set ge-0/0/1 unit 0 family iso
user@PE3# set ge-0/0/1 unit 0 family inet6
user@PE3# set ge-0/0/1 unit 0 family mpls
user@PE3# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE3# set lo0 unit 0 family inet address 10.255.162.89/32 primary
user@PE3# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2089.00
user@PE3# set lo0 unit 0 family inet6 address abcd::10:255:162:89/128 primary
```

2. Configure the autonomous number (AS).

```
[edit routing-options]
user@PE3# set autonomous-system 65000
user@PE3# set forwarding-table export pplb
```

3. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all link-protection
user@PE3# set interface fxp0.0 disable
```

4. Configure MPLS.

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set egress-protection context-identifier 1.1.1.1 primary
user@PE3# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
user@PE3# set label-switched-path to_PE2 to 10.255.162.91
user@PE3# set label-switched-path to_PE1 to 10.255.162.84
```

5. Configure BGP.

```
[edit protocols bgp]
user@PE3# set group vpn type internal
user@PE3# set group vpn local-address 10.255.162.89
user@PE3# set group vpn family inet-vpn unicast
user@PE3# set group vpn neighbor 10.255.162.84 local-preference 300
user@PE3# set group vpn neighbor 10.255.162.91
user@PE3# set vpn-apply-export
```

6. Configure IS-IS.

```
[edit protocols isis]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set interface lo0.0 passive
user@PE3# set level 2 disable
```

7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface all
user@PE3# set area 0.0.0.0 interface fxp0.0 disable
user@PE3# set area 0.0.0.0 interface lo0.0 passive
user@PE3# set traffic-engineering
```

8. Configure the routing instance.

```
[edit routing-instances]
user@PE3# set vpn egress-protection context-identifier 1.1.1.1
user@PE3# set vpn instance-type vrf
user@PE3# set vpn interface ge-1/1/0.0
user@PE3# set vpn protocols bgp group vpn type external
user@PE3# set vpn protocols bgp group vpn family inet unicast
user@PE3# set vpn protocols bgp group vpn family inet6 unicast
user@PE3# set vpn protocols bgp group vpn peer-as 65001
user@PE3# set vpn protocols bgp group vpn as-override
user@PE3# set vpn protocols bgp group vpn neighbor 10.10.40.2
user@PE3# set vpn route-distinguisher 100:100
user@PE3# set vpn vrf-export vpn-exp
user@PE3# set vpn vrf-import vpn-imp
user@PE3# set vpn vrf-table-label
```

## Configuring Device CE2

### Step-by-Step Procedure

1. Configure the interfaces.

```
[edit interfaces]
user@CE2# set ge-0/0/0 unit 0 family inet address 10.10.40.2/30
user@CE2# set ge-0/0/2 unit 0 family inet address 10.10.30.2/30
user@CE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@CE2# set lo0 unit 0 family inet address 10.255.162.88/32 primary
user@CE2# set lo0 unit 0 family iso address
  47.0005.80ff.f800.0000.0108.0001.0102.5516.2088.00
user@CE2# set lo0 unit 0 family inet6 address abcd::10:255:162:88/128 primary
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

### Device CE1

```
user@CE1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 10.10.20.2/30;
    }
  }
}
```

### Device PE1

```
user@PE1# show interfaces

## Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair.

## Verifying Path Protection in an MPLS Network

To verify that path protection is working correctly on EX Series switches, perform the following tasks:

1. [Verifying the Primary Path on page 183](#)
2. [Verifying the RSVP-Enabled Interfaces on page 184](#)
3. [Verifying a Secondary Path on page 185](#)

### Verifying the Primary Path

**Purpose** Verify that the primary path is operational.

**Action** user@switch> show mpls lsp extensive ingress

```
Ingress LSP: 2 sessions

127.1.8.8
  From: 127.1.9.9, State: Up, ActiveRoute: 0, LSPname: lsp_to_240
  ActivePath: primary_path_lsp_to_240 (primary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  *Primary primary_path_lsp_to_240 State: Up
    Priorities: 7 0
    SmartOptimizeTimer: 180
    Exclude: red
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 2)
    10.3.3.2 S 10.3.4.2 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt
    20=Node-ID):
      10.3.3.2 10.3.4.2
      6 Mar 11 23:58:01.684 Selected as active path: due to 'primary'
      5 Mar 11 23:57:00.750 Record Route: 10.3.3.2 10.3.4.2
      4 Mar 11 23:57:00.750 Up
      3 Mar 11 23:57:00.595 Originate Call
      2 Mar 11 23:57:00.595 CSPF: computation result accepted 10.3.3.2 10.3.4.2
      1 Mar 11 23:56:31.135 CSPF failed: no route toward 10.3.2.2[25 times]
  Standby secondary_path_lsp_to_240 State: Up
  Standby secondary_path_lsp_to_240 State: Up
    Priorities: 7 0
    SmartOptimizeTimer: 180
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 1)
    10.3.5.2 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt
    20=Node-ID):
      10.3.5.2
      7 Mar 11 23:58:01.684 Deselected as active: due to 'primary'
      6 Mar 11 23:46:17.298 Selected as active path
      5 Mar 11 23:46:17.295 Record Route: 5.5.5.2
      4 Mar 11 23:46:17.287 Up
      3 Mar 11 23:46:16.760 Originate Call
      2 Mar 11 23:46:16.760 CSPF: computation result accepted 10.3.5.2
      1 Mar 11 23:45:48.095 CSPF failed: no route toward 10.5.5.5[2 times]
  Created: Wed Mar 11 23:44:37 2009
  [Output truncated]
```

**Meaning** As indicated by the **ActivePath** in the output, the LSP **primary\_path\_lsp\_to\_240** is active.

## Verifying the RSVP-Enabled Interfaces

**Purpose** Verify the status of Resource Reservation Protocol (RSVP)-enabled interfaces and packet statistics.

**Action** user@switch> show rsvp interfaces

```

RSVP interface: 1 active
      Active Subscr- Static      Available  Reserved  Highwater
Interface State resv  iption  BW      BW      BW      mark
ge-0/0/20.0 Up      2    100%  1000Mbps  1000Mbps  0bps    0bps

```

**Meaning** This output verifies that RSVP is enabled and operational on interface **ge-0/0/20.0**.

## Verifying a Secondary Path

**Purpose** Verify that a secondary path is established.

**Action** Deactivate a switch that is critical to the primary path and then issue the following command:

user@switch> show mpls lsp extensive

```

Ingress LSP: 1 sessions

127.0.0.8
  From: 127.0.0.1, State: Up, ActiveRoute: 0, LSName: lsp_to_240
  ActivePath: secondary_path_lsp_to_240 (secondary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary primary_path_lsp_to_240 State: Dn
  Priorities: 7 0
  SmartOptimizeTimer: 180
  Exclude: red
  Will be enqueued for recomputation in 8 second(s).

### MPLS Encapsulated Payload Load-balancing Overview

Routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on the information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm.

In case of multiple transport layer networks such as Ethernet over MPLS or Ethernet pseudowire, the hash algorithm needs to look beyond the outer header of the payload and into the inner headers to generate an even distribution. To determine the inner encapsulation, the PFE relies on the presence of certain codes or numbers at fixed payload offsets; for example the presence of payload type 0X800 or the presence of protocol number 4 for an IPv4 packet. In Junos OS, you can configure **zero-control-word** option to

indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, which is four bytes having a numerical value of all zeros, the hash generator assumes the start of an Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

**NOTE:** For DPC I-chip-based cards, configure the `zero-control-word` option at the `[edit forwarding-options hash-key family mpls ether-pseudowire]` hierarchy level; and for MPC cards, configure the `zero-control-word` option at the `[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]` hierarchy level.

**Related  
Documentation**

## Configuring MPLS Encapsulated Payload for Load Balancing

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. Configure the **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, four bytes having a numerical value of all zeros, the hash generator assumes the start of the Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

Before you begin to configure MPLS encapsulated payload for load balancing, configure routing and signaling protocols.

To configure MPLS encapsulated payload for load balancing:

1. Configure the **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.

- For DPC I-chip-based cards, configure the **zero-control-word** option at the **[edit forwarding-options hash-key family mpls ether-pseudowire]** hierarchy level.

```
[edit forwarding-options hash-key family mpls ether-pseudowire]
user@host# set zero-control-word
```

- For MPC cards, configure the **zero-control-word** option at the **[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]** hierarchy level.

```
[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]
user@host# set zero-control-word
```

## Configuring MPLS to Gather Statistics

You can configure MPLS so that it periodically gathers traffic statistics about all MPLS sessions, including transit sessions, by configuring the **statistics** statement. You must configure the **statistics** statement if you want to collect MPLS traffic statistics using SNMP polling of MPLS Management Information Bases (MIBs).

To enable or disable MPLS statistics collection, include the **statistics** statement:

```
statistics {
```

```

auto-bandwidth (MPLS Statistics);
file filename <files number> <size size> <world-readable | no-world-readable>;
interval seconds;
no-transit-statistics;
transit-statistics-polling;
}

```

You can configure these statements at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The default interval is 300 seconds.

If you configure the **file** option, the statistics are placed in a file, with one entry per LSP. During the specified interval, the following information is recorded in this file:

- The number of packets, number of bytes, packets per second, and bytes per second transmitted by each LSP. Feature parity for the display of packet and byte statistics for sub-LSPs of a point-to-multipoint LSP on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.
- The percent of bandwidth transmitted over a given LSP in relation to the bandwidth percentage configured for that LSP. If no bandwidth is configured for an LSP, 0 percent is recorded in the percentage column.

At the end of each periodic report, a summary shows the current time, total number of sessions, number of sessions read, number of sessions ignored, and read errors, if any. Ignored sessions are typically those not in the up state or those with a reserved (0 through 15) incoming label (typically the egress point of an LSP). The reason for a read error appears on the same line as the entry for the LSP on which the error occurred. Gathering statistics is an unreliable process; occasional read errors might affect their accuracy. Sample output follows:

lsp6	0 pkt	0 Byte	0 pps	0 Bps	0
lsp5	0 pkt	0 Byte	0 pps	0 Bps	0
lsp6.1	34845 pkt	2926980 Byte	1049 pps	88179 Bps	132
lsp5.1	0 pkt	0 Byte	0 pps	0 Bps	0
lsp4	0 pkt	0 Byte	0 pps	0 Bps	0
Dec 7 17:28:38 Total 6 sessions: 5 success, 0 fail, 1 ignored

## On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview

---

This topic describes methods for measuring packet loss, delay, and throughput for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to enable monitoring of network performance.

- [Importance of Measuring Packet Loss and Delay on page 191](#)
- [Defining Packet Loss, Delay, and Throughput on page 191](#)

### Importance of Measuring Packet Loss and Delay

The rise of bandwidth-consuming applications, such as IPTV and mobile video, coupled with the pressure to minimize the cost per bit and maximize the value per bit, is forcing carriers to transition their transport networks from circuit-based technologies to packet-based technologies. MPLS is a widely successful, connection-oriented packet transport technology that is ideally suited for packet-based transport networks.

With the emergence of new applications on data networks, it is becoming increasingly important for service providers to accurately predict the impact of new application rollouts. Understanding and modelling network performance in the network is especially relevant for deployment of new-world applications to ensure successful implementations. In packet networks, packet loss and delay are two of the most fundamental measures of performance. Their role is even more central when it comes to end-to-end measurements.

The traffic belonging to most of the end-to-end user applications is either loss sensitive (file transfer), delay sensitive (voice or video applications), or both (interactive computing applications). The service-level agreements (SLAs) of service providers depend on the ability to measure and monitor these network performance metrics, as the SLAs are directly or indirectly dependent on the loss and delay the customer traffic experiences in the service provider network.

To ensure compliance to the SLA, service providers need tools to measure and monitor the performance metrics for packet loss, one-way delay and two-way delay, and related metrics, such as delay variation and channel throughput. This measurement capability provides service providers with greater visibility into the performance characteristics of their networks, thereby facilitating planning, troubleshooting, and network performance evaluation.

### Defining Packet Loss, Delay, and Throughput

In packet networks, packet loss and delay are two of the most fundamental measures of performance.

- **Loss**—Packet loss is the failure of one or more transmitted packets to arrive at their destination. Packet loss refers to the packets of data that are dropped by the network to manage congestion.

Data applications are very tolerant to packet loss, as they are generally not time sensitive and can retransmit the packets that were dropped. However, in video conference environments and pure audio communications, such as VoIP, packet loss can create jitter.

- **Delay**—Packet delay (also called latency) is the amount of time it takes for a packet of data to get from one designated point to another, depending on the speed of the transmission medium, such as copper wire, optical fiber, or radio waves, and the delays in transmission by devices along the way, such as routers and modems.

A low latency indicates a high network efficiency.

- **Throughput**—Packet delay measures the amount of time between the start of an action and its completion, whereas throughput is the total number of such actions that occur in a given amount of time.

## Packet Loss and Delay Measurement Mechanisms

Packet delay and loss are two fundamental measures of network performance. Junos OS provides an on-demand mechanism to measure packet loss and delay over associated bidirectional MPLS ultimate hop popping (UHP) label-switched paths (LSPs).

The on-demand delay and packet loss measurement mechanism is initiated using the following CLI commands:

- **monitor mpls loss rsvp**—Performs an on-demand loss measurement for associated bidirectional UHP LSPs.
- **monitor mpls delay rsvp**—Performs an on-demand delay measurement for associated bidirectional UHP LSPs.
- **monitor mpls loss-delay rsvp**—Performs an on-demand combined loss and delay measurement for associated bidirectional UHP LSPs.

For initiating the delay and packet loss measuring mechanism, the desired parameters for measurement, such as the type of measurement and LSP name, need to be entered. On receiving the parameters, a summary of the performance monitoring data is displayed and the mechanism is terminated.

## Packet Loss and Delay Metrics

The following performance metrics are measured using the on-demand packet loss and delay mechanisms:

- Loss measurement (packet and octet)
- Throughput measurement (packet and octet)
- Two-way channel delay

- Round-trip delay
- Inter-packet delay variation (IPDV)

The **monitor mpls loss rsvp** command performs the loss and throughput measurement, and the **monitor mpls delay rsvp** command performs the two-way channel delay, round-trip delay, and IPDV measurements. The **monitor mpls loss-delay rsvp** command performs a combined loss and delay measurement and measures all of the above-mentioned performance metrics simultaneously.

## Packet Loss and Delay Measurement Concepts

The following concepts help to better understand the functionality of packet loss and delay:

- **Querier**—A querier is the ingress provider edge (PE) router, which originates the query message for loss or delay measurement.
- **Responder**—A responder is the egress PE router, which receives and responds to the query messages from a querier.
- **Associated bidirectional LSP**—An associated bidirectional LSP consists of two unidirectional LSPs that are tied together (or associated with each other) through configuration on both of the LSP end points.

The on-demand loss and delay measurement can be carried out only on associated bidirectional UHP LSPs.

- **Generic associated channel (G-Ach)**—The performance monitoring messages for the on-demand loss and delay measurement flow over the MPLS G-Ach. This type of channel supports only in-band responses, and does not provide support for out-of-band or no-response modes.
- **Measurement point (MP)**—MP is the location at which a condition is described for the measurement.

The MP for packet loss on the transmit side is between the switching fabric and the transmit interface. The counter value is stamped in the loss measurement message in the hardware before it is queued for transmission.

The MP for packet loss on the receive side is between the receive interface and the switching fabric. The MP is distributed on the receive side. Furthermore, when the transmit interface is an aggregate interface, the MP is distributed as well.

- **Query rate**—Query rate is the interval between two queries sent for loss and delay measurement.

Because the loss and delay measurement messages originate from the Routing Engine, a high query rate for multiple channels puts a heavy burden on the Routing Engine. The minimum query interval supported is 1 second.

The query rate should be high for 32-bit counters, because the counters might wrap quickly when data traffic rate is very high. The query rate can be low when 64-bit counters are in use at all the four measurement point locations involved in loss measurement. Junos OS supports only 64-bit counters.

- **Traffic class**—By default, loss measurement is supported for the whole channel. Junos OS also supports traffic class scoped packet loss measurement, where counters that maintain data traffic statistics per traffic class have to be created.

Per traffic class counters are not created by default. To configure traffic class scoped loss measurement, include the **traffic-class-statistics** statement at the **[edit protocols mpls statistics]** hierarchy level.

When **traffic-class-statistics** is configured, control packets flowing over the G-Ach are not counted in the transmit and receive counters.

**NOTE:** Enabling and disabling of traffic class statistics results in the resetting of all counters (aggregate counter and per-class counters) for the LSPs.

- **Loss measurement mode**—Junos OS supports the direct-mode of on-demand loss measurement, and does not provide support for the inferred-mode.

Direct loss measurement requires data traffic statistics to be maintained at the ingress and egress of two unidirectional LSPs of the associated bidirectional LSP. When an MX Series router is using only MPCs and MICs, counters to maintain data traffic statistics are created by default at the ingress of all types of LSPs and egress of UHP LSPs.

However, the direct-mode of loss measurement is not fully accurate due to the following reasons:

- Parallel forwarding nature of the hardware.
- Presence of equal cost multipath (ECMP) in the network, such as aggregated Ethernet interfaces, which can result in re-ordering of data packets relative to the loss measurement messages.
- Control packets that do not flow over G-Ach are not counted at the LSP ingress, but are counted at the LSP egress.
- Data traffic re-ordering relative to the loss measurement message when a Diffserv is implemented in the MPLS network and loss measurement scope is the complete channel and not traffic class scoped.

To overcome this limitation, perform traffic class scoped loss measurement when a Diffserv is implemented.

**NOTE:** Direct mode loss measurement is vulnerable to disruption when the ingress or egress interface associated with the LSP changes.

- **Loss measurement synchronization**—The synchronization conditions specified in section 2.9.8 of RFC 6374 do not hold true in the absolute sense. However, as the loss measurement counters are stamped in hardware, the errors introduced due to not satisfying the synchronization conditions are relatively small. These errors need to be quantified.

When the transmit or receive interface of the LSP is an aggregate interface, more errors are introduced as compared to when the interfaces are non-aggregate interfaces. In any case, the loss measurement counters are stamped in hardware, and the error needs to be quantified.

- **Delay measurement accuracy**—When the transmit and receive interfaces reside on different Packet Forwarding Engines, the clock must be synchronized on these Packet Forwarding Engines for two-way delay measurements. This condition holds true for the platform on which the on-demand delay measurement feature is implemented.

When there are aggregate interfaces or ECMP, the delay is measured for only one of the potential paths.

When a combined loss and delay message is used for delay calculation, the accuracy of delay is lower compared to when the delay measurement message is used in some cases, such as when the transmit or receive interface is an aggregate interface.

Delay measurement is always performed on a per-traffic-class basis, and the accuracy of the measurement needs to be quantified after testing.

- **Timestamp format**—Junos OS supports only the IEEE 1588 Precision Time Protocol (PTP) [IEEE1588] format for recording delay measurement messages. Network Time Format (NTP) is not supported.
- **Operations, administration, and maintenance (OAM)**—To indicate that all the OAM messages for MPLS LSPs flow over the MPLS G-Ach, and to enable the MPLS performance monitoring messages to be carried over the MPLS G-Ach, the **oam mpls-tp-mode** statement must be included at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level.

## Packet Loss and Delay Measurement Functionality

Figure 13 on page 195 illustrates the basic methods used for the bidirectional measurement of packet loss and delay. A bidirectional channel exists between the two routers, Router A and Router B. The temporal reference points – T1, T2, T3, and T4 – are associated with a measurement operation that takes place at Router A. The operation consists of Router A sending a query message to Router B, and Router B sending back a response. Each reference point indicates the point of time at which either the query or the response message is transmitted or received over the channel.

*Figure 13: Basic Bidirectional Measurement*

In Figure 13 on page 195, Router A can arrange to measure the packet loss over the channel in the forward and reverse directions by sending loss measurement query messages to Router B. Each of the forward and reverse messages contain the count of packets transmitted prior to time T1 over the channel to Router B (A\_TxP).

When the message reaches Router B, two values are appended to the message and the message is reflected back to Router A. The two values are the count of packets received prior to time T2 over the channel from Router A (B\_RxP) and the count of packets transmitted prior to time T3 over the channel to Router A (B\_TxP).

When the response reaches Router A, a fourth value is appended to the message – the count of packets received prior to time T4 over the channel from Router B (A\_RxP).

These four counter values – (A\_TxP), (B\_RxP), (B\_TxP), and (A\_RxP) – enable Router A to compute the desired loss statistics. Because the transmit count at Router A and the receive count at Router B (and vice versa) might not be synchronized at the time of the first message, and to limit the effects of counter wrap, the loss is computed in the form of a delta between the messages.

The transmit loss (A\_TxLoss[n-1,n]) and receive loss (A\_RxLoss[n-1,n]) within the measurement interval marked by the messages LM[n-1] and LM[n] are computed by Router A as follows:

$$A\_TxLoss[n-1,n] = (A\_TxP[n] - A\_TxP[n-1]) - (B\_RxP[n] - B\_RxP[n-1])$$

$$A\_RxLoss[n-1,n] = (B\_TxP[n] - B\_TxP[n-1]) - (A\_RxP[n] - A\_RxP[n-1])$$

The arithmetic is modulo the counter size.

To measure at Router A the delay over the channel to Router B, a delay measurement query message is sent from Router A to Router B containing a timestamp recording the instant at which it is transmitted. In [Figure 13 on page 195](#), the timestamp is recorded in T1.

When the message reaches Router B, a timestamp is added, recording the instant at which it is received (T2). The message can now be reflected from Router B to Router A, with Router B adding its transmit timestamp (T3) and Router A adding its receive timestamp (T4).

These four timestamps – T1, T2, T3, and T4 – enable Router A to compute the one-way delay in each direction, as well as the two-way delay for the channel. The one-way delay computations require that the clocks of Routers A and B be synchronized.

At this point, Router A can compute the two-way channel delay and round-trip delay associated with the channel as follows:

$$\text{Two-way channel delay} = (T4 - T1) - (T3 - T2)$$

$$\text{Round-trip delay} = T4 - T1$$

## Packet Loss and Delay Features

### Supported Features of Packet Loss and Delay

Junos OS supports the following features with on-demand loss and delay measurement:

- Performance monitoring for associated bidirectional MPLS point-to-point UHP LSPs only
- Loss measurement
- Throughput measurement
- Two-way delay measurement (channel delay and round-trip delay)
- Inter-packet delay variation (IPDV)
- Direct-mode loss measurement
- Aggregated Ethernet and aggregated SONET interfaces
- Multichassis support
- 64-bit compatible

#### **Unsupported Features of Packet Loss and Delay**

Junos OS does not support the following on-demand loss and delay measurement functionality:

- Loss and delay measurement for pseudowires (section 2.9.1 of RFC 6374)
- Unidirectional measurement (section 2.6 of RFC 6374)
- Dyadic measurement (section 2.7 of RFC 6374)
- Loss and delay measurement in loopback mode (section 2.8 of RFC 6374)
- Loss and delay measurement to an intermediate node from an LSP endpoint (section 2.9.5 of RFC 6374)
- External post-processing (section 2.9.7 of RFC 6374)
- Inferred-mode loss measurement (section 2.9.8 of RFC 6374)
- Pro-active mode
- Logical systems
- SNMP

#### **Related Documentation**

- [monitor mpls loss-delay rsvp on page 2508](#)

## Example: Configuring On-Demand Loss and Delay Measurement

---

This example shows how to enable on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance.

- [Requirements on page 198](#)
- [Overview on page 198](#)
- [Configuration on page 199](#)
- [Verification on page 202](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series 5G Universal Routing Platforms that contain MPC/MICs only
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - OSPF

### Overview

Starting with Junos OS Release 14.2, an on-demand tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs) is introduced. The tool can be enabled using the following CLI commands – **monitor mpls loss rsvp**, **monitor mpls delay rsvp**, and **monitor mpls loss-delay rsvp**.

These commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

### Topology

---

[Figure 14 on page 199](#) illustrates the on-demand loss and delay measurement using a simple two-router topology.

Figure 14: Configuring On-Demand Loss and Delay Measurement

In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics is measured.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

R1
set chassis fpc 0 pic 3 tunnel-services bandwidth 1g

```

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R1:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```

[edit chassis]
user@R1# set fpc 0 pic 3 tunnel-services bandwidth 1g
user@R1# set network-services enhanced-ip

```

2. Configure the interfaces for Router R1.

```

[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls

```

3. Configure the router ID for Router R1.

```

[edit routing-options]
user@R1# set router-id 10.0.0.1

```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```

[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable

```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```

[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable

```

6. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

8. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

## Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
fpc 0 {
  pic 3 {
    tunnel-services {
      bandwidth lg;
    }
  }
}
network-services enhanced-ip;
```

```
user@R1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 1.1.1.1/30;
    }
    family mpls;
  }
}
```

```
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.1/32;
    }
    family mpls;
  }
}
```

```
user@R1# show routing-options
router-id 10.0.0.1;
```

```
user@R1# show protocols
rsvp {
  interface ge-0/0/0.0;
  interface lo0.0;
  interface fxp0.0 {
    disable;
  }
}
mpls {
  statistics {
    traffic-class-statistics;
  }
  label-switched-path R1-R2 {
    to 20.0.0.1;
    oam mpls-tp-mode;
    ultimate-hop-popping;
    associate-lsp R2-R1;
  }
  interface ge-0/0/0.0;
  interface lo0.0;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface ge-0/0/0.0;
    interface lo0.0;
    interface fxp0.0 {
      disable;
    }
  }
}
```

## Verification

Confirm that the configuration is working properly.

- [Verifying the LSP Status on page 203](#)
- [Verifying Packet Loss Measurement on page 203](#)

- [Verifying Packet Delay Measurement on page 205](#)
- [Verifying Packet Loss-Delay Measurement on page 205](#)

### Verifying the LSP Status

**Purpose** Verify that the associated bidirectional LSP between Routers R1 and R2 is up.

**Action** From operational mode, run the **show mpls lsp** command.

```
user@R1> show mpls lsp

Ingress LSP: 1 sessions
To          From          State Rt P    ActivePath    LSPname
20.0.0.1    10.0.0.1    Up      0 *              R1-R2 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
10.0.0.1    20.0.0.1    Up      0  1 FF  299776      - R2-R1 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** The associated bidirectional LSP R1-R2 is up and active.

### Verifying Packet Loss Measurement

**Purpose** Verify the on-demand loss measurement result.

**Action** From operational mode, run the **monitor mpls loss rsvp R1-R2 count 2 detail** command.

```

user@R1> monitor mpls loss rsvp R1-R2 count 2 detail

(0)
Response code                : Success
Origin timestamp             : 1404129082 secs, 905571890 nsecs

## Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs

This example shows how to configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance.

- [Requirements on page 207](#)
- [Overview on page 208](#)
- [Configuration on page 208](#)
- [Verification on page 213](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series 5G Universal Routing Platforms that contain MPC/MICs only
- Junos OS Release 15.1 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - a. MPLS
  - b. OSPF
  - c. RSVP

## Overview

Starting with Junos OS Release 15.1, a pro-active tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate-hop popping point-to-point label-switched paths (LSPs) is introduced.

This feature provides the following performance metrics:

- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

## Topology

Figure 14 on page 199 illustrates the pro-active loss and delay measurements using a simple two-router topology.

*Figure 15: Configuring Pro-Active Loss and Delay Measurements*

In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics are measured.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

R1
set chassis network-services enhanced-ip
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set interfaces lo0 unit 0 family mpls
set protocols mpls interface ge-0/0/0.0
set protocols mpls interface lo0.0
set protocols mpls interface fxp0.0 disable
set protocols mpls label-switched-path R1-R2 associate-lsp R2-R1
set protocols mpls label-switched-path R1-R2 install 20.10.30.0/24 active

set routing-options router-id 20.0.0.1

```

### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R1:

1. Enable the enhanced IP network services configuration.

```

[edit chassis]
user@R1# set network-services enhanced-ip

```

2. Configure the interfaces for Router R1.

```

[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls

```

3. Configure the router ID for Router R1.

```

[edit routing-options]
user@R1# set router-id 10.0.0.1

```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```

[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable

```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```

[edit protocols]
user@R1# set mpls interface ge-0/0/0.0

```

```

user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable

```

6. Configure an associated bidirectional LSP to Router R2.

```

[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 install 20.10.30.0/24 active
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1

```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss and delay measurement.

```

[edit protocols]
user@R1# set mpls statistics traffic-class-statistics

```

8. Configure performance monitoring at the querier side.

```

[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
    delay traffic-class tc-0 query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
    loss traffic-class none query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
    loss-delay traffic-class tc-0 query-interval 1000

```

9. Configure performance monitoring at the responder side.

```

[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring
    responder delay min-query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring
    responder loss min-query-interval 1000

```

10. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```

[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable

```

## Results

---

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
network-services enhanced-ip;
```

```
user@R1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 1.1.1.1/30;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.1/32;
    }
    family mpls;
  }
}
```

```
user@R1# show routing-options
router-id 10.0.0.1;
```

```
user@R1# show protocols
rsvp {
  interface ge-0/0/0.0;
  interface lo0.0;
  interface fxp0.0 {
    disable;
  }
}
mpls {
  label-switched-path R1-R2 {

## Verification

### Verifying Loss and Delay Measurement

**Purpose** Verify the loss and delay measurement.

**Action** From operational mode, run the **show performance-monitoring mpls lsp** command.

```
user@R1> show performance-monitoring mpls lsp

Session Total: 3 Up: 3 Down: 0
LSP name:R1-R2, PM State:Up
  Loss measurement Data:
    Duration: 00:04:43
    Traffic-class: None
    Queries sent: 282
    Responses received: 282
    Responses dropped due to errors: 0
    Queries timeout: 0
    Forward loss measurement:
      Average packet loss: 0
      Average packet throughput: 554338
    Reverse loss measurement:
      Average packet loss: 0
      Average packet throughput: 1352077
LSP name:R1-R2, PM State:Up
  Delay measurement Data:
    Duration: 00:04:43
    Traffic-class: 0
    Queries sent: 282
    Responses received: 282
    Responses dropped due to errors: 0
    Queries timeout: 0
    Best 2-way channel delay: 72 usecs
    Worst 2-way channel delay: 365 usecs
    Best round trip time: 843 usecs
    Worst round trip time: 105523 usecs
    Avg absolute fw delay variation: 1619 usecs
    Avg absolute rv delay variation: 1619 usecs
LSP name:R1-R2, PM State:Up

## Configuring On-Demand Loss and Delay Measurement

You can configure an on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance. The **monitor mpls loss rsvp**, **monitor mpls delay rsvp**, and **monitor mpls loss-delay rsvp** CLI commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID.
3. Configure the following protocols:
  - RSVP
  - OSPF

Enable traffic engineering capabilities.

  - MPLS

To configure the PE device:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```
[edit chassis]
user@R1# set fpc fpc-slot pic pic-slot tunnel-services bandwidth bandwidth
user@R1# set network-services enhanced-ip
```

2. Configure an associated bidirectional LSP to the remote router.

```
[edit protocols]
user@R1# set mpls label-switched-path lsp-name to remote-router-ip-address
user@R1# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@R1# set mpls label-switched-path lsp-name ultimate-hop-popping
user@R1# set mpls label-switched-path lsp-name associate-lsp lsp-name
```

3. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss measurement.

```
[edit protocols]
```

```
user@R1# set mpls statistics traffic-class-statistics
```

## Configuring Pro-Active Loss and Delay Measurements

---

You can configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance. The **show performance-monitoring mpls lsp** CLI command provides a summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

This feature provides the following performance metrics:

- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - MPLS
  - OSPF
  - RSVP

To configure pro-active loss and delay measurements on the PE device:

1. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
```

```

user@host# set mpls label-switched-path lsp-name to remote-router-ip-address
user@host# set mpls label-switched-path lsp-name install
destination-prefix/prefix-length active
user@host# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@host# set mpls label-switched-path lsp-name ultimate-hop-popping
user@host# set mpls label-switched-path lsp-name associate-lsp remote-lsp-name

```

2. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss and delay measurements.

```

[edit protocols]
user@host# set mpls statistics traffic-class-statistics

```

3. Configure performance monitoring at the querier side.

```

[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
querier delay traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
querier loss traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
querier loss-delay traffic-class tc-value query-interval milliseconds

```

4. Configure performance monitoring at the responder side.

```

[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
responder delay min-query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
responder loss min-query-interval milliseconds

```

## SRLG Overview

---

In MPLS traffic engineering, a Shared Risk Link Group (SRLG) is a set of links sharing a common resource, which affects all links in the set if the common resource fails. These links share the same risk of failure and are therefore considered to belong to the same SRLG. For example, links sharing a common fiber are said to be in the same SRLG because a fault with the fiber might cause all links in the group to fail.

An SRLG is represented by a 32-bit number unique within an IGP (OSPFv2 and IS-IS) domain. A link might belong to multiple SRLGs. The SRLG of a path in a label-switched path (LSP) is the set of SRLGs for all the links in the path. When computing the secondary path for an LSP, it is preferable to find a path such that the secondary and primary paths do not have any links in common in case the SRLGs for the primary and secondary paths are disjoint. This ensures that a single point of failure on a particular link does not bring down both the primary and secondary paths in the LSP.

When the SRLG is configured, the device uses the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive. If the primary path goes down, the CSPF algorithm computes the secondary path by trying to avoid links that share any SRLG with the primary path. In addition, when computing the path for a bypass LSP, CSPF tries to avoid links that share any SRLG with the protected links.

When the SRLG is not configured, CSPF only takes into account the costs of the links when computing the secondary path.

Any change in link SRLG information triggers the IGP to send LSP updates for the new link SRLG information. CSPF recomputes the paths during the next round of reoptimization.

Junos OS Release 11.4 and later supports SRLG based on the following RFCs:

- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.
- RFC 5307, *IS-IS Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.

**NOTE:** Currently, the “Fate Sharing” feature continues to be supported with the SRLG feature.

## Example: Configuring SRLG

This example shows how to configure Shared Risk Link Groups (SRLGs) on a device.

- [Requirements on page 220](#)
- [Overview on page 220](#)
- [Configuration on page 221](#)
- [Verification on page 227](#)

### Requirements

This example uses the following hardware and software components:

- Seven routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 11.4 or later running on all the devices

### Overview

Junos OS Release 11.4 and later support SRLG configuration in an IGP (OSPFv2 and IS-IS) domain. In this example, you configure SRLG and associate it with the MPLS interface on a device.

The device uses the SRLG cost parameter for the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive by avoiding links that share any SRLG with the primary path.

To configure the SRLG, you first define the SRLG parameters at the **[edit routing-options srlg srlg-name]** hierarchy level and then associate the SRLG with an MPLS interface at the **[edit mpls interface interface-name]** hierarchy level.

The **srlg srlg-name** statement has the following options:

- **srlg-cost**—Include a cost for the SRLG ranging from 1 through 65535. The cost of the SRLG determines the level of impact this SRLG has on the CSPF algorithm for path computations. The higher the cost, the less likely it is for a secondary path to share the same SRLG as the primary path. By default, the **srlg-cost** is 1.
- **srlg-value**—Include a group ID for the SRLG ranging from 1 through 4294967295.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. The effective link metric, with the added **srlg-cost** of 10, becomes 11. Therefore, the computed secondary path is PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.

## Configuration

### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

**Step-by-Step  
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.12.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.13.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/3 {
    unit 0 {
      family inet {

        }
    }
}
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

**NOTE:** Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

## Verification

Confirm that the configuration is working properly.

- [Verifying SRLG Definitions on page 227](#)
- [Verify TE-Link SRLG on page 227](#)
- [Verify Standby Secondary Path on page 228](#)

### Verifying SRLG Definitions

**Purpose** Verify SRLG-to-value mappings and SRLG cost.

**Action** user@PE1> show mpls srlg

SRLG	Value	Cost
srlg-a	101	10

### Verify TE-Link SRLG

**Purpose** Verify the traffic engineering link SRLG association.

**Action** user@PE1> show ted link detail

```
...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 1, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
  Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps [1] 0bps [2] 0bps [3] 0bps
  localBW [4] 0bps [5] 0bps [6] 0bps [7] 0bps

## Example: Excluding SRLG Links Completely for the Secondary LSP

---

This example shows how to configure the **exclude-srlg** option to exclude Shared Risk Link Group (SRLG) links for the secondary label-switched path (LSP).

- [Requirements on page 230](#)
- [Overview on page 230](#)
- [Configuration on page 231](#)
- [Verification on page 234](#)

### Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

### Overview

For critical links where it is imperative to keep the secondary and primary paths completely disjoint from any common SRLG, you can optionally configure the **exclude-srlg** statement at the **[edit protocols mpls]** or **[edit protocols mpls label-switched-path *path-name*]** hierarchy levels. For logical systems, you configure the **exclude-srlg** statement at the **edit logical-systems protocols mpls[edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]** hierarchy level.

If **exclude-srlg** is configured, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. If **exclude-srlg** is not configured, and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. Because

**exclude-srlg** is configured, CSPF rejects link P2>PE2 as the link belongs to the SRLG **srlg-a**. Therefore, the computed standby secondary path is PE1>P3>P4>P5>PE2.

## Configuration

## CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

## Router PE1

```
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces ge-0/0/2 unit 0 family inet address 192.168.13.1/24
set interfaces ge-0/0/2 unit 0 family mpls
set interfaces ge-0/0/3 unit 0 family inet address 192.168.14.1/24
set interfaces ge-0/0/3 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.1/32
set routing-options srlg srlg-a srlg-value 101
set protocols rsvp interface ge-0/0/1.0

set protocols mpls label-switched-path pe1-pe2 primary via-p1
set protocols mpls label-switched-path pe1-pe2 secondary path2 standby
set protocols mpls path via-p1 10.255.0.2 strict
set protocols mpls path path2
set protocols mpls interface ge-0/0/1.0
set protocols mpls interface ge-0/0/2.0
```

```

set protocols mpls interface ge-0/0/3.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface lo0.0

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

1. Configure the device interfaces.

```

[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@PE1# set routing-options srlg srlg-a srlg-value 101

```

4. Configure MPLS and the LSPs.

```

[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set exclude-srlg
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2

```

5. Configure the **exclude-srlg** statement to forcibly keep the links for the secondary path completely disjoint from the primary LSP path.

```
user@PE1 set protocols mpls exclude-srlg
```

6. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.12.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.13.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/3 {
    unit 0 {
      family inet {
        address 192.168.14.1/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.0.1/32;
      }
    }
  }
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
  to 10.255.0.7;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
path via-p1 {
  10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options
routing-options {
  srlg {
    srlg-a srlg-value 101;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

**NOTE:** Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

## Verification

Confirm that the configuration is working properly.

### Verifying the Secondary Path Link for the LSP

**Purpose** Verify that the link for the secondary path is completely disjoint from the primary path.

**Action** user@PE1> show mpls lsp detail

```
Ingress LSP: 1 sessions

- [Example: Configuring SRLG on page 220](#)
- [exclude-srlg on page 2095](#)

## Example: Configuring SRLG with Link Protection

---

This example shows how to configure SRLG with link protection without the **exclude-srlg** option.

- [Requirements on page 236](#)
- [Overview on page 236](#)
- [Configuration on page 237](#)
- [Verification on page 256](#)

### Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

### Overview

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG srlg-a.

You configure link protection for the interface P1>PE2 by including the **link-protection** statement.

When SRLG srlg-a is configured on the link P1>PE2 and P2>PE2, the bypass takes the longer path P1>P4>P5>PE2, not selecting the link P2>PE2 because of the added SRLG cost for srlg-a.

## Configuration

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

## Configuring Device PE1

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

**[edit interfaces]**

```

user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32

```

2. Configure OSPF on the interfaces.

**[edit protocols ospf]**

```

user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0

```

```
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs and configure link protection for the **pe1-pe2** LSP.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.1/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.13.1/24;
```

```
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.14.1/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.1/32;
    }
  }
}
}
```

```
user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}
```

```
user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
  to 10.255.0.7;
  link-protection;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
path via-p1 {
  10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```

user@PE1# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure device P1:

1. Configure the device interfaces.

```

[edit interfaces]
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P1# set srlg srlg-a srlg-value 101
user@P1# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces and associate the SRLG **srlg-a** with interface **ge-0/0/2.0** for the P1>PE2 link.

```

[edit protocols mpls]

```

```
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and configure **link-protection** for interface **ge-0/0/2.0**.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.27.2/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.23.2/24;
    }
    family mpls;
  }
}
ge-0/0/4 {
  unit 0 {
    family inet {
      address 192.168.25.2/24;
    }
    family mpls;
  }
}
```

```

lo0 {
  unit 0 {
    family inet {
      address 10.255.0.2/32;
    }
  }
}

```

```

user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface ge-0/0/4.0;
  interface lo0.0;
}

```

```

user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;

```

```

user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  link-protection;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;

```

```

user@P1# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device P2

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P2:

1. Configure the device interfaces.

**[edit interfaces]**

```

user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32

```

2. Configure OSPF on the interfaces.

**[edit protocols ospf]**

```

user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

**[edit routing-options]**

```

user@P2# set srlg srlg-a srlg-value 101
user@P2# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces and associate the SRLG **srlg-a** with interface **ge-0/0/2.0** for the P2>PE2 link.

**[edit protocols mpls]**

```

user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0

```

5. Enable RSVP on the interfaces.

**[edit protocols rsvp]**

```

user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@P2# show interfaces
ge-0/0/1 {
  unit 0 {

```

```

    family inet {
        address 192.168.13.3/24;
    }
    family mpls;
}
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.37.3/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            address 192.168.23.3/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.3/32;
        }
    }
}
}
}

```

```

user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}
}

```

```

user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
}

```

```

user@P2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

```

```

user@P2# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P3

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P3:

1. Configure the device interfaces.

```

[edit interfaces]
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P3# set srlg srlg-a srlg-value 101
user@P3# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0

```

5. Enable RSVP on the interfaces.

```

[edit protocols rsvp]

```

```

user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@P3# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.14.4/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.45.4/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.0.4/32;
      }
    }
  }
}

```

```

user@P3# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface lo0.0;
}

```

```

user@P3# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;

```

```

user@P3# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;

```

```

user@P3# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P4

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P4:

1. Configure the device interfaces.

```

[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P4# set srlg srlg-a srlg-value 101
user@P4# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0

```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.45.5/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.56.5/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.25.5/24;
    }

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P5

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P5:

1. Configure the device interfaces.

```
[edit interfaces]
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P5# set srlg srlg-a srlg-value 101
```

```
user@P5# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P5# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.56.6/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.67.6/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.6/32;
    }
  }
}
```

```
user@P5# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
```

```
interface lo0.0;
}
```

```
user@P5# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device PE2

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set srlg srlg-a srlg-value 101
user@PE2# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.27.7/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.37.7/24;
      }
      family mpls;
    }
  }
  ge-0/0/3 {
    unit 0 {
      family inet {
        address 192.168.67.7/24;
      }
      family mpls;
    }
  }
  lo0 {
```

```
unit 0 {  
    family inet {  
        address 10.255.0.7/32;  
    }  
}  
}
```

```
user@PE2# show protocols ospf  
traffic-engineering;  
area 0.0.0.0 {  
    interface ge-0/0/1.0;  
    interface ge-0/0/2.0;  
    interface ge-0/0/3.0;  
    interface lo0.0;  
}
```

```
user@PE2# show protocols mpls  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;  
interface ge-0/0/3.0;
```

```
user@PE2# show protocols rsvp  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;  
interface ge-0/0/3.0;
```

```
user@PE2# show routing-options  
srlg {  
    srlg-a {  
        srlg-value 101;  
        srlg-cost 10;  
    }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying the SRLG Cost Is Added to the TE Link

**Purpose** Verify that the SRLG cost is added to the TE link if it belongs to the SRLG of the protected link. Issue the **show ted link detail** and **show rsvp session extensive bypass** commands on device P1.

**Action** user@P1> show ted link detail

```
...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0

Total 1 displayed, Up 1, Down 0
```

**Meaning** The shortest path for the bypass protecting the link P1->PE2 would have been P1->P2->PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG **srlg-a**, the SRLG cost of 10 for **srlg-a** is added to the metric for the link P2>PE2. This makes the metric for the link P2>PE2 too high to be selected for the shortest path. Therefore, the CSPF result for the computed path for the bypass becomes P1>P4>P5>PE2.

- Related Documentation**

## Example: Configuring SRLG with Link Protection with the exclude-srlg Option

---

This example shows how to configure SRLG with link protection with the **exclude-srlg** option.

- [Requirements on page 258](#)
- [Overview on page 258](#)
- [Configuration on page 259](#)
- [Verification on page 278](#)

### Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

### Overview

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG **srlg-a**.

You configure link protection for the interface P1>PE2 by including the **link-protection** statement along with the **exclude-srlg** option. This makes the bypass LSP and the protected link completely disjoint in any SRLG.

When SRLG **srlg-a** is configured on the link P1>PE2 and P2>PE2, the link P2>PE2 is rejected for CSPF consideration due to the **exclude-srlg** configuration. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

## Configuration

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
Router PE1

### Configuring Device PE1

---

**Step-by-Step Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

**[edit interfaces]**

```

user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32

```

2. Configure OSPF on the interfaces.

**[edit protocols ospf]**

```

user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

**[edit routing-options]**

```

user@PE1# set routing-options srlg srlg-a srlg-value 101
user@PE1# set routing-options srlg srlg-a srlg-cost 10

```

4. Configure MPLS and the LSPs and configure link protection for the **pe1-pe2** LSP.

```

[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2

```

5. Enable RSVP on the interfaces.

```

[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.1/24;
    }
    family mpls;
  }
}
ge-0/0/2 {

  primary via-p1;  
  secondary path2 {  
    standby;  
  }  
}  
path via-p1 {  
  10.255.0.2 strict;  
}  
path path2;  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;  
interface ge-0/0/3.0;
```

```
user@PE1# show protocols rsvp  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;  
interface ge-0/0/3.0;
```

```
user@PE1# show routing-options  
srlg {  
  srlg-a {  
    srlg-value 101;  
    srlg-cost 10;  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure device P1:

1. Configure the device interfaces.

```
[edit interfaces]
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P1# set routing-options srlg srlg-a srlg-value 101
user@P1# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P1>PE2 link.

```
[edit protocols mpls]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and include the **link-protection** statement with the **exclude-srlg** option for interface **ge-0/0/2.0**.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection exclude-srlg
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.27.2/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.23.2/24;
    }
    family mpls;
  }
}
ge-0/0/4 {
  unit 0 {
    family inet {
      address 192.168.25.2/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.2/32;
    }
  }
}
```

```

user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface ge-0/0/4.0;
  interface lo0.0;
}

```

```

user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;

```

```

user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  link-protection {
    exclude-srlg;
  }
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;
}

```

```

user@P1# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device P2

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P2:

1. Configure the device interfaces.

#### [edit interfaces]

```

user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls

```

```

user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P2# set routing-options srlg srlg-a srlg-value 101
user@P2# set routing-options srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P2>PE2 link.

```

[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0

```

5. Enable RSVP on the interfaces.

```

[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@P2# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.13.3/24;
    }
    family mpls;
  }
}

```

```

}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.37.3/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.23.3/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.3/32;
    }
  }
}
}
}

```

```

user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}

```

```

user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  srlg srlg-a;
}
interface ge-0/0/3.0;
}

```

```

user@P2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

```

```

user@P2# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

```
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P3

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P3:

1. Configure the device interfaces.

```
[edit interfaces]
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P3# set routing-options srlg srlg-a srlg-value 101
user@P3# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.14.4/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.45.4/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.0.4/32;
      }
    }
  }
}
```

```
user@P3# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface lo0.0;
}
```

```
user@P3# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P3# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
```

```

    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P4

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P4:

1. Configure the device interfaces.

```

[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P4# set routing-options srlg srlg-a srlg-value 101
user@P4# set routing-options srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0

```

5. Enable RSVP on the interfaces.

```

[edit protocols rsvp]

```

```

user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsdp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@P4# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.45.5/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.56.5/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.25.5/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.5/32;
    }
  }
}
}

```

```

user@P4# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}

```

```
user@P4# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@P4# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device P5

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P5:

1. Configure the device interfaces.

#### [edit interfaces]

```
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

#### [edit protocols ospf]

```
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

#### [edit routing-options]

```
user@P5# set routing-options srlg srlg-a srlg-value 101
user@P5# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P5# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.56.6/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.67.6/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.6/32;
    }
  }
}
```

```
user@P5# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface lo0.0;
}
```

```
user@P5# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
```

```
user@P5# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device PE2

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set routing-options srlg srlg-a srlg-value 101
user@PE2# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.27.7/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.37.7/24;
      }
      family mpls;
    }
  }

```

**Meaning** The shortest path for the bypass protecting the link P1>PE2 would have been P1>P2>PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG **srlg-a**, the link P2>PE2 is rejected for CSPF consideration due to the **exclude-srlg** constraint. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

### Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

---

This example shows how to configure the Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

- [Requirements on page 281](#)
- [Overview on page 281](#)
- [Configuration on page 284](#)
- [Verification on page 290](#)

### Requirements

No special configuration beyond device initialization is required before you configure this example.

### Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at <http://www.ietf.org/>.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In [Figure 16 on page 282](#), Routers PE1 and PE2 are dual-stack BGP routers, meaning they have both IPv4 and IPv6 stacks. The PE routers link the IPv6 networks through the customer edge (CE) routers to the IPv4 core network. The CE routers and the PE routers connect through a link layer that can carry IPv6 traffic. The PE routers use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

**Figure 16: IPv6 Networks Linked by MPLS IPv4 Tunnels**

The two PE routers are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE routers can learn the IPv6 routes from the CE routers connected to them using routing protocols Routing Information Protocol next generation (RIPng) or MP-BGP, or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE router and CE router could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGP, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of either LDP or RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE routers always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE router is not a Juniper Networks routing platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE routers to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 router in [Figure 16 on page 282](#) receives an IPv6 packet from the CE1 router, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 router, then no labels need to be pushed and the packet is simply sent to the CE2 router. If the destination matches a prefix that was learned from the PE2 router, then the PE1 router pushes two labels onto the packet and sends it to the provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the **family inet6** statement on all the CE router-facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.
- You enable IPv6 tunneling by including the **ipv6-tunneling** statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

**NOTE:** BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the `labeled-unicast` statement at the `[edit protocols bgp family inet]` hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the `inet6.3` routing table.

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the **explicit-null** statement in the BGP configuration.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

### Configuring Device PE1

**Step-by-Step  
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```

[edit interfaces]
user@PE1# set fe-1/2/0 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set fe-1/2/0 unit 2 family mpls
user@PE1# set fe-1/2/1 unit 5 family inet address 10.1.1.5/30
user@PE1# set fe-1/2/1 unit 5 family inet6
user@PE1# set fe-1/2/1 unit 5 family mpls
user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32

```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface fe-1/2/0.2
user@PE1# set interface fe-1/2/1.5
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1
user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6
user@PE1# set group toPE2 neighbor 1.1.1.4
```

4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface fe-1/2/1.5
user@PE1# set interface lo0.2 passive
```

5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set ldp interface fe-1/2/1.5
```

6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self
user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept
user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```

7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
```

```
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
  unit 2 {
    family inet6 {
      address ::10.1.1.2/126;
    }
    family mpls;
  }
}
fe-1/2/1 {
  unit 5 {
    family inet {
      address 10.1.1.5/30;
    }
    family inet6;
    family mpls;
  }
}
lo0 {
  unit 2 {
    family inet {
      address 1.1.1.2/32;
    }
  }
}
```

```
user@R1# show policy-options
policy-statement next-hop-self {
  then {
    next-hop self;
  }
}
policy-statement send-bgp6 {
  from {
    family inet6;
    protocol bgp;
  }
  then accept;
}
policy-statement send-v6 {
  from {
    family inet6;
    protocol [ bgp direct ];
  }
}
```

```

    }
    then accept;
  }

```

```

user@R1# show protocols
mpls {
  ipv6-tunneling;
  interface fe-1/2/0.2;
  interface fe-1/2/1.5;
}
bgp {
  group toCE1 {
    type external;
    local-address ::10.1.1.2;
    family inet6 {
      unicast;
    }
    export send-bgp6;
    peer-as 1;
    neighbor ::10.1.1.1;
  }
  group toPE2 {
    type internal;
    local-address 1.1.1.2;
    family inet6 {
      labeled-unicast {
        explicit-null;
      }
    }
    export [ next-hop-self send-v6 ];
    neighbor 1.1.1.4;
  }
}
ospf {
  area 0.0.0.0 {
    interface fe-1/2/1.5;
    interface lo0.2 {
      passive;
    }
  }
}
ldp {
  interface fe-1/2/1.5;
}

```

```

user@R1# show routing-options
router-id 1.1.1.2;
autonomous-system 2;

```

If you are done configuring the device, enter **commit** from configuration mode. Configure the other devices in the topology, as shown in [“CLI Quick Configuration” on page 284](#).

## Verification

Confirm that the configuration is working properly.

### Verifying That the CE Devices Have Connectivity

---

**Purpose** Make sure that the tunnel is operating.

**Action** From operational mode, enter the **ping** command.

```
user@CE1> ping ::10.1.1.14
PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms
```

```
user@CE3> ping ::10.1.1.1
PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

**Meaning** The IPv6 CE devices can communicate over the core IPv4 network.

## Configuring IPv6 Tunneling for MPLS (CLI Procedure)

---

You can configure the IPv6 tunneling for MPLS to tunnel IPv6 traffic over an MPLS-based IPv4 network. This configuration allows you to interconnect a number of smaller IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the switches in your core network. BGP is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

To configure IPv6 tunneling for MPLS on your EX Series switch:

1. Configure IPv4 and IPv6 IP addresses for all the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

2. Configure the number assigned to you by the Network Information Center (NIC) as the autonomous system (AS) number

```
[edit routing-options]
user@switch# set autonomous-system number
```

3. Advertise label 0 to the egress router of the LSP:

```
[edit protocols]
user@switch# set mpls explicit-null
```

4. Configure the LSP to allow IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table:

```
[edit protocols]
user@switch# set mpls ipv6-tunneling
```

5. Set the local AS number:

```
[edit protocols bgp]
user@switch# set local-as local-autonomous-system-number
```

6. Configure the default import and export policies:

```
[edit protocols bgp]
user@switch# set local-address address
user@switch# set import default-import
user@switch# set family inet6 labeled-unicast explicit-null
user@switch# set export default-export
```

7. Configure a BGP group that recognizes only the specified BGP systems as peers. Define a group name, group type, local end of a BGP session, and a neighbor (peer). To configure multiple BGP peers, include multiple neighbor statements:

```
[edit protocols bgp]
user@switch# set group group-name type internal
user@switch# set group group-name local-address address-of-the-local-end-of-a-bgp-session
user@switch# set group group-name family inet6 labeled-unicast explicit-null
user@switch# set group group-name peer-as peer-autonomous-system-number
user@switch# set group group-name neighbor address family inet6 labeled-unicast explicit-null
```

8. Configure routing options to accept the default import and export policies:

```
[edit policy-options]
user@switch# set policy-statement default-import then accept
user@switch# set policy-statement default-export then accept
```

## Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels

This example shows how to configure a dynamic MPLS-over-UDP tunnel that includes a tunnel composite next hop. The MPLS-over-UDP feature provides a scaling advantage on the number of IP tunnels supported on a device.

Starting in Junos OS Release 18.3R1, MPLS-over-UDP tunnels are supported on PTX Series routers and QFX Series switches. For every dynamic tunnel configured on a PTX router or a QFX switch, a tunnel composite next hop, an indirect next hop, and a forwarding next hop is created to resolve the tunnel destination route. You can also use policy control to resolve the dynamic tunnel over select prefixes by including the [forwarding-rib](#) configuration statement at the `[edit routing-options dynamic-tunnels]` hierarchy level.

- [Requirements on page 292](#)
- [Overview on page 292](#)
- [Configuration on page 294](#)
- [Verification on page 300](#)
- [Troubleshooting on page 304](#)

## Requirements

This example uses the following hardware and software components:

- Five MX Series routers with MPCs and MICs.
- Junos OS Release 16.2 or later running on the PE routers.

Before you begin:

1. Configure the device interfaces, including the loopback interface.
2. Configure the router ID and autonomous system number for the device.
3. Establish an internal BGP (IBGP) session with the remote PE device.
4. Establish OSPF peering among the devices.

## Overview

Starting with Junos OS Release 16.2, a dynamic UDP tunnel supports the creation of a tunnel composite next hop for every UDP tunnel configured. These next-hop-based dynamic UDP tunnels are referred to as MPLS-over-UDP tunnels. The tunnel composite next hop are enabled by default for the MPLS-over-UDP tunnels.

Starting in Junos OS Release 17.1, on MX Series routers with MPCs and MICs, the scaling limit of MPLS-over-UDP tunnels is increased.

**NOTE:** For the same tunnel destination, the next-hop-based dynamic tunnel encapsulation can either be GRE or UDP. Having both tunnel encapsulations for the same tunnel destination causes a commit error under the dynamic-tunnel configuration.

---

The existing dynamic tunnel feature requires complete static configuration. Currently, the tunnel information received from peer devices in advertised routes is ignored. Starting in Junos OS Release 17.4R1, on MX Series routers, the next-hop-based dynamic MPLS-over-UDP tunnels are signaled using BGP encapsulation extended community.

BGP export policy is used to specify the tunnel types, advertise the sender side tunnel information, and parse and convey the receiver side tunnel information. A tunnel is created according to the received type tunnel community.

Multiple tunnel encapsulations are supported by BGP. On receiving multiple capability, the next-hop-based dynamic tunnel is created based on the configured BGP policy and tunnel preference. The tunnel preference should be consistent across both the tunnel ends for the tunnel to be set up. By default, MPLS-over-UDP (MPLSoUDP) tunnel is preferred over GRE tunnels. If dynamic tunnel configuration exists, it takes precedence over received tunnel community.

When configuring a next-hop-based dynamic MPLS-over-UDP tunnel, be aware of the following considerations:

- An IBGP session must be configured between the PE devices.
- A switchover between the next-hop-based dynamic tunnel encapsulations (UDP and GRE) is allowed, and this can impact network performance in terms of the supported IP tunnel scaling values in each mode.
- Having both GRE and UDP next-hop-based dynamic tunnel encapsulation types for the same tunnel destination leads to a commit failure.
- Graceful Routing Engine switchover (GRES) is supported with MPLS-over-UDP, and the MPLS-over-UDP tunnel type flags are unified ISSU and NSR compliant.
- MPLS-over-UDP tunnels are supported on virtual MX (vMX).
- MPLS-over-UDP tunnels support dynamic GRE tunnel creation based upon new IPv4-mapped-IPv6 next hops.
- MPLS-over-UDP tunnel are supported in interoperability with contrail, wherein the MPLS-over-UDP tunnels are created from the contrail vRouter to an MX gateway. To enable this, the following community is required to be advertised in the route from the MX Series router to the contrail vRouter:

```
[edit policy-options community]
udp members 0x030c:64512:13;
```

At a given point in time, only one tunnel type is supported on the contrail vRouter—next-hop-based dynamic GRE tunnels, MPLS-over-UDP tunnels, or VXLAN.

- The following features are not supported with the next-hop-based dynamic MPLS-over-UDP tunnel configuration:
  - RSVP automatic mesh
  - Plain IPV6 GRE and UDP tunnel configuration
  - Logical systems

## Topology

Figure 17 on page 294 illustrates a Layer 3 VPN scenario over dynamic MPLS-over-UDP tunnels. The customer edge (CE) devices, CE1 and CE2, connect to provider edge (PE)

devices, PE1 and PE2, respectively. The PE devices are connected to a provider device (Device P1), and an internal BGP (IBGP) session interconnects the two PE devices. Two dynamic next-hop-based MPL-over-UDP tunnels are configured between the PE devices.

**Figure 17: Dynamic MPLS-over-UDP Tunnels**

The MPLS-over-UDP tunnel is handled as follows:

1. After a MPLS-over-UDP tunnel is configured, a tunnel destination mask route with a tunnel composite next hop is created for the tunnel in the inet.3 routing table. This IP tunnel route is withdrawn only when the dynamic tunnel configuration is deleted.

The tunnel composite next-hop attributes include the following:

- When Layer 3 VPN composite next hop is disabled—Source and destination address, encapsulation string, and VPN label.
  - When Layer 3 VPN composite next hop and per-prefix VPN label allocation are enabled—Source address, destination address, and encapsulation string.
  - When Layer 3 VPN composite next hop is enabled and per-prefix VPN label allocation is disabled—Source address, destination address, and encapsulation string. The route in this case is added to the other virtual routing and forwarding instance table with a secondary route.
2. The PE devices are interconnected using an IBGP session. The IBGP route next hop to a remote BGP neighbor is the protocol next hop, which is resolved using the tunnel mask route with the tunnel next hop.
  3. After the protocol next hop is resolved over the tunnel composite next hop, indirect next hops with forwarding next hops are created.
  4. The tunnel composite next hop is used to forward the next hops of the indirect next hops.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

CE1
set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.1/8
set interfaces lo0 unit 0 family inet address 127.0.0.1/8

```

#### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the device interfaces including the loopback interface of the device.

```
[edit interfaces]
```

```

user@PE1# set ge-0/0/0 unit 0 family inet address 10.0.0.2/8
user@PE1# set ge-0/0/1 unit 0 family inet address 192.0.2.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.2/8

```

2. Configure a static route for routes from Device PE1 with Device P1 as the next-hop destination.

```

[edit routing-options]
user@PE1# set static route 33.0.0.0/8 next-hop 192.0.2.2

```

3. Configure the router-ID and autonomous system number for Device PE1.

```

[edit routing-options]
user@PE1# set router-id 127.0.0.2
user@PE1# set autonomous-system 100

```

4. (PTX Series only) Configure policy control to resolve the MPLS-over-UDP dynamic tunnel route over select prefixes.

```

[edit routing-options dynamic-tunnels]
user@PTX-PE1# set forwarding-rib inet.0 inet-import
dynamic-tunnel-fwd-route-import

```

5. (PTX Series only) Configure the inet-import policy for resolving dynamic tunnel destination routes over .

```

[edit policy-options]
user@PTX-PE1# set policy-statement dynamic-tunnel-fwd-route-import term 1
from route-filter 127.0.0.0/8 exact
user@PTX-PE1# set policy-statement dynamic-tunnel-fwd-route-import term 1
then accept
user@PTX-PE1# set policy-options policy-statement
dynamic-tunnel-fwd-route-import then reject

```

6. Configure IBGP peering between the PE devices.

```

[edit protocols]
user@PE1# set bgp group IBGP type internal
user@PE1# set bgp group IBGP local-address 127.0.0.2
user@PE1# set bgp group IBGP family inet-vpn unicast
user@PE1# set bgp group IBGP neighbor 127.0.0.4

```

7. Configure OSPF on all the interfaces of Device PE1, excluding the management interface.

```

[edit protocols]

```

```
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Enable next-hop-based dynamic GRE tunnel configuration on Device PE1.

**NOTE:** This step is required only for illustrating the implementation difference between next-hop-based dynamic GRE tunnels and MPLS-over-UDP tunnels.

```
[edit routing-options]
user@PE1# set dynamic-tunnels gre next-hop-based-tunnel
```

9. Configure the MPLS-over-UDP tunnel parameters from Device PE1 to Device PE2.

```
[edit routing-options]
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 source-address 127.0.0.2
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 udp
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 destination-networks
127.0.0.0/8
```

10. Configure a VRF routing instance on Device PE1 and other routing instance parameters.

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 instance-type vrf
user@PE1# set MPLS-over-UDP-PE1 interface ge-0/0/0.0
user@PE1# set MPLS-over-UDP-PE1 route-distinguisher 127.0.0.2:1
user@PE1# set MPLS-over-UDP-PE1 vrf-target target:600:1
```

11. Enable BGP in the routing instance configuration for peering with Device CE1.

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 peer-as 200
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 neighbor 10.0.0.1
as-override
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
```

```
ge-0/0/0 {
  unit 0 {
    family inet {
      address 10.0.0.2/8;
    }
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.0.2.1/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 127.0.0.2/8;
    }
  }
}
```

```
user@PE1# show routing-options
static {
  route 33.0.0.0/8 next-hop 192.0.2.2;
}
router-id 127.0.0.2;
autonomous-system 100;
forwarding-table {
  export pplb;
}
dynamic-tunnels {
  gre next-hop-based-tunnel;
  udp-dyn-tunnel-to-pe2 {
    source-address 127.0.0.2;
    udp;
    destination-networks {
      127.0.0.0/8;
    }
  }
}
```

```
user@PE1# show protocols
bgp {
  group IBGP {
    type internal;
    local-address 127.0.0.2;
    family inet-vpn {
      unicast;
    }
    neighbor 127.0.0.4;
  }
}
```

```
ospf {  
  area 0.0.0.0 {  
    interface ge-0/0/1.0;  
    interface lo0.0 {  
      passive;  
    }  
  }  
}
```

```
user@PE1# show routing-instances  
MPLS-over-UDP-PE1 {  
  instance-type vrf;  
  interface ge-0/0/0.0;  
  route-distinguisher 127.0.0.2:1;  
  vrf-target target:600:1;  
  protocols {  
    bgp {  
      group pe1-cel {  
        peer-as 200;  
        neighbor 10.0.0.1 {  
          as-override;  
        }  
      }  
    }  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Connection Between PE Devices on page 300](#)
- [Verify the Dynamic Tunnel Routes on Device PE1 on page 301](#)
- [Verify the Dynamic Tunnel Routes on Device PE2 on page 303](#)
- [Verifying That the Routes Have the Expected Indirect-Next-Hop Flag on page 303](#)

### Verifying the Connection Between PE Devices

**Purpose** Verify the BGP peering status between Device PE1 and Device PE2, and the BGP routes received from Device PE2.

**Action** From operational mode, run the **show bgp summary** and **show route receive-protocol bgp ip-address table bgp.l3vpn.0** commands.

```
user@PE1> show bgp summary
```

```
Groups: 2 Peers: 2 Down peers: 0
Table      Tot Paths  Act Paths Suppressed  History  Damp State   Pending
bgp.l3vpn.0
          2         2         0         0         0         0
Peer      AS      InPkt   OutPkt   OutQ   Flaps  Last Up/Dwn
State|#Active/Received/Accepted/Damped...
127.0.0.4    100     139     136      0      0      58:23 Establ

  bgp.l3vpn.0: 2/2/2/0
  MPLS-over-UDP-PE1.inet.0: 2/2/2/0
10.0.0.1     200     135     136      0      0      58:53
Establ
  MPLS-over-UDP-PE1.inet.0: 1/1/1/0
```

```
user@PE1> show route receive-protocol bgp 127.0.0.4 table bgp.l3vpn.0
```

```
bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
Prefix      Nexthop      MED      Lc1pref    AS path
127.0.0.4:1:127.0.0.5/8
*           127.0.0.4      100      200 I
  127.0.0.4:1:200.1.1.0/24
*           127.0.0.4      100      I
```

- Meaning**
- In the first output, the BGP session state is **Establ**, which means that the session is up and the PE devices are peered.
  - In the second output, Device PE1 has learned two BGP routes from Device PE2.

### Verify the Dynamic Tunnel Routes on Device PE1

- Purpose** Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE1.

**Action** From operational mode, run the **show route table inet.3**, **show dynamic-tunnels database terse**, **show dynamic-tunnels database**, and **show dynamic-tunnels database summary** commands.

```
user@PE1> show route table inet.3
```

```
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
127.0.0.0/8      *[Tunnel/300] 00:21:18
                  Tunnel
127.0.0.4/8      *[Tunnel/300] 00:21:18
                  Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
```

```
Table: inet.3
```

Destination-network: 127.0.0.0/8	Destination	Source	Next-hop		Type	Status
	127.0.0.4/8	127.0.0.2	0xb395b10 nhid 613	udp	Up	

```
user@PE1> show dynamic-tunnels database
```

```
Table: inet.3
```

```
Destination-network: 55.0.0.0/8
```

```
Destination-network: 55.66.0.0/16
```

```

```

```
Tunnel to: 127.0.0.4/8
```

```
Reference count: 2
```

```
Next-hop type: UDP
```

```
Source address: 127.0.0.2 Tunnel Id: 2
```

```
Next hop: tunnel-composite, 0xb395b10, nhid 613
```

```
VPN Label: Push 299776 Reference count: 3
```

```
Traffic Statistics: Packets 0, Bytes 0
```

```
State: Up
```

```
user@PE1> show dynamic-tunnels database summary
```

```
Dynamic Tunnels, Total 1 displayed
```

```
GRE Tunnel:
```

```
Active Tunnel Mode, Next Hop Base
```

```
IFL Based, Total 0 displayed, Up 0, Down 0
```

```
Nexthop Based, Total 0 displayed, Up 0, Down 0
```

```
RSVP Tunnel:
```

```
Total 0 displayed
```

```
UDP Tunnel:
```

```
Total 1 displayed, Up 1, Down 0
```

**Meaning**

- In the first output, because Device PE1 is configured with the MPLS-over-UDP tunnel, a tunnel composite route is created for the inet.3 routing table route entry.

- In the remaining outputs, the MPLS-over-UDP tunnel is displayed with the tunnel encapsulation type, tunnel next hop parameters, and tunnel status.

### Verify the Dynamic Tunnel Routes on Device PE2

**Purpose** Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE2.

**Action** From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@PE2> show route table inet.3
```

```
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
127.0.0.0/8      *[Tunnel/300] 00:39:31
                  Tunnel
127.0.0.2/8      *[Tunnel/300] 00:24:53
                  Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
```

```
Table: inet.3
```

```
Destination-network: 127.0.0.0/8
```

Destination	Source	Next-hop	Type	Status
127.0.0.2/8	127.0.0.4	0xb395450 nhid 615	udp Up	

**Meaning** The outputs show the MPLS-over-UDP tunnel creation and the next-hop ID assigned as the next-hop interface, similar to Device PE1.

### Verifying That the Routes Have the Expected Indirect-Next-Hop Flag

**Purpose** Verify that Device PE1 and Device PE2 are configured to maintain the indirect next hop to forwarding next-hop binding on the Packet Forwarding Engine forwarding table.

**Action** From operational mode, run the **show krt indirect-next-hop** command on Device PE1 and Device PE2.

```
user@PE1> show krt indirect-next-hop
```

```
Indirect Nexthop:
```

```
Index: 1048574 Protocol next-hop address: 127.0.0.4

```

**Meaning** The outputs show that a next-hop-based dynamic MPLS-over-UDP tunnel is created between the PE devices.

## Troubleshooting

To troubleshoot the next-hop-based dynamic tunnels, see:

- [Troubleshooting Commands on page 304](#)

### Troubleshooting Commands

**Problem** The next-hop-based dynamic MPLS-over-UDP tunnel configuration is not taking effect.

**Solution** To troubleshoot the next-hop-based MPLS-over-UDP tunnel configuration, use the following **traceroute** commands at the **[edit routing-options dynamic-tunnels]** statement hierarchy:

- **traceoptions file *file-name***
- **traceoptions file size *file-size***
- **traceoptions flag all**

For example:

```
[edit routing-options dynamic-tunnels]
traceoptions {
  file udp_dyn_pe1.wri size 4294967295;
  flag all;
}
```

**Release History Table**

Release	Description
18.3R1	Starting in Junos OS Release 18.3R1, MPLS-over-UDP tunnels are supported on PTX Series routers and QFX Series switches.
17.4R1	Starting in Junos OS Release 17.4R1, on MX Series routers, the next-hop-based dynamic MPLS-over-UDP tunnels are signaled using BGP encapsulation extended community.
17.1R1	Starting in Junos OS Release 17.1, on MX Series routers with MPCs and MICs, the scaling limit of MPLS-over-UDP tunnels is increased.

## Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels Overview

With the rise in deployment of high-scale IP tunnels in data centers, there is a need to add security measures that allow users to limit malicious traffic from compromised virtual machines (VMs). One possible attack is the injecting of traffic into an arbitrary customer VPN from a compromised server through the gateway router. In such cases, anti-spoofing checks on IP tunnels ensure that only legitimate sources are injecting traffic into data centers from their designated IP tunnels.

Next-hop-based dynamic IP tunnels create a tunnel composite next hop for every dynamic tunnel created on the device. Because next-hop-based dynamic tunnels remove the dependency on physical interfaces for every new dynamic tunnel configured, configuring next-hop-based dynamic tunnels provides a scaling advantage over the number of dynamic tunnels that can be created on a device. Starting in Junos OS Release 17.1, anti-spoofing capabilities for next-hop-based dynamic IP tunnels is provided for

next-hop-based dynamic tunnels. With this enhancement, a security measure is implemented to prevent injecting of traffic into an arbitrary customer VPN from a compromised server through the gateway router.

Anti-spoofing is implemented using reverse path forwarding checks in the Packet Forwarding Engine. The checks are implemented for the traffic coming through the tunnel to the routing instance. Currently, when the gateway router receives traffic from a tunnel, only the destination lookup is done and the packet is forwarded accordingly. When anti-spoofing protection is enabled, the gateway router also does a source address lookup of the encapsulation packet IP header in the VPN, in addition to the tunnel destination lookup. This ensures that legitimate sources are injecting traffic through their designated IP tunnels. As a result, anti-spoofing protection ensures that the tunnel traffic is received from a legitimate source on the designated tunnels.

Figure 18 on page 306 illustrates a sample topology with the requirements for anti-spoofing protection.

**Figure 18: Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels**

In this example, the gateway router is Router G. Router G has two VPNs—Green and Blue. The two servers, Server A and Server B, can reach the Green and Blue VPNs on Router G through the next-hop-based dynamic tunnels T1 and T2, respectively. Several hosts and virtual machines (P, Q, R, S, and T) connected to the servers can reach the VPNs through the gateway router, Router G. Router G has the virtual routing and forwarding (VRF) tables for Green and Blue VPNs, each populated with the reachability information for the virtual machines in those VPNs.

For example, in VPN Green, Router G uses tunnel T1 to reach host P, tunnel T2 to reach hosts R and S, and load balancing is done between tunnels T1 and T2 to reach the multihomed host Q. In VPN Blue, Router G uses tunnel T1 to reach hosts P and R, and tunnel T2 to reach hosts Q and T.

The check passes for reverse path forwarding when:

- A packet comes from a legitimate source on its designated tunnel.

Host P in VPN Green sends a packet to host X using tunnel T1. Because Router G can reach host P through tunnel T1, it allows the packet to pass and forwards the packet to host X.

- A packet comes from a multihomed source on its designated tunnels.

Host Q in VPN Green is multihomed on servers A and B, and can reach Router G through tunnels T1 and T2. Host Q sends a packet to host Y using tunnel T1, and a packet to host X using tunnel T2. Because Router G can reach host Q through tunnels T1 and T2, it allows the packets to pass and forwards them to hosts Y and X, respectively.

Layer 3 VPNs do not have anti-spoofing protection enabled by default. To enable anti-spoofing for next-hop-based dynamic tunnels, include the **ip-tunnel-rpf-check** statement at the **[edit routing-instances routing-instance-name routing-options forwarding-table]** hierarchy level. The reverse path forwarding check is applied to the VRF routing instance only. The default mode is set to **strict**, where the packet that comes from a source on a nondesignated tunnel does not pass the check. The **ip-tunnel-rpf-check** mode can be set as **loose**, where the reverse path forwarding check fails when the packet comes from a nonexistent source. An optional firewall filter can be configured under the **ip-tunnel-rpf-check** statement to count and log the packets that failed the reverse path forwarding check.

The following sample output shows an anti-spoofing configuration:

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
ip-tunnel-rpf-check {
  mode loose;
  fail-filter filter-name;
}
```

Take the following guidelines under consideration when configuring anti-spoofing protection for next-hop-based dynamic tunnels:

- Anti-spoofing protection can be enabled for IPv4 tunnels and IPv4 data traffic only. The anti-spoofing capabilities are not supported on IPv6 tunnels and IPv6 data traffic.
- Anti-spoofing for next-hop-based dynamic tunnels can detect and prevent a compromised virtual machine (inner source reverse path forwarding check) but not a compromised server that is label-spoofing.
- The next-hop-based IP tunnels can originate and terminate on an inet.0 routing table.
- Anti-spoofing protection is effective when the VRF routing instance has label-switched interfaces (LSIs) (using the **vrf-table-label**), or virtual tunnel (VT) interfaces. With **per-next-hop** label on the VRF routing instance, anti-spoofing protection is not supported.
- The **rpf fail-filter** is applicable only to the inner IP packet.
- Enabling anti-spoofing checks does not affect the scaling limit of the next-hop-based dynamic tunnels on a device.

- The system resource utilization with anti-spoofing protection enabled for the VRF routing instance is slightly higher than the utilization of next-hop-based dynamic tunnels without the anti-spoofing protection enabled.
- Anti-spoofing protection requires additional source IP address checks, which has minimal impact on network performance.
- Graceful Routing Engine switchover (GRES) and in-service software upgrade (ISSU) are supported with anti-spoofing protection.

## Example: Configuring Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels

This example shows how to configure reverse path forwarding checks for the virtual routing and forwarding (VRF) routing instance to enable anti-spoofing protection for next-hop-based dynamic tunnels. The checks ensure that legitimate sources are injecting traffic through their designated IP tunnels.

- [Requirements on page 308](#)
- [Overview on page 309](#)
- [Configuration on page 310](#)
- [Verification on page 316](#)

### Requirements

This example uses the following hardware and software components:

- Three MX Series Routers with MICs, each connected to a host device.
- Junos OS Release 17.1 or later running on one or all the routers.

Before you begin:

- Enable tunnel services configuration on the Flexible PIC Concentrator.
- Configure the router interfaces.
- Configure the router-ID and assign an autonomous system number for the router.
- Establish an internal BGP (IBGP) session with the tunnel endpoints.
- Configure RSVP on all the routers.
- Configure OSPF or any other interior gateway protocol on all the routers.
- Configure two dynamic next-hop-based IP tunnels between the two routers.
- Configure a VRF routing instance for every router-to-host connection.

## Overview

Starting in Junos OS Release 17.1, anti-spoofing capabilities are added to next-hop-based dynamic IP tunnels, where checks are implemented for the traffic coming through the tunnel to the routing instance using reverse path forwarding in the Packet Forwarding Engine.

Currently, when the gateway router receives traffic from a tunnel, only the destination address lookup is done before forwarding. With anti-spoofing protection, the gateway router does a source address lookup of the encapsulation packet IP header in the VPN to ensure that legitimate sources are injecting traffic through their designated IP tunnels. This is called the strict mode and is the default behavior of anti-spoofing protection. To pass traffic from nondesignated tunnels, the reverse path forwarding check is enabled in the loose mode. For traffic received from nonexistent sources, the reverse path forwarding check fails for both the strict and loose modes.

Anti-spoofing is supported on VRF routing instances. To enable anti-spoofing for dynamic tunnels, include the `ip-tunnel-rpf-check` statement at the `[edit routing-instances routing-instance-name routing-options forwarding-table]` hierarchy level.

## Topology

Figure 19 on page 309 illustrates a sample network topology enabled with anti-spoofing protection. Routers R0, R1 and R2 are each connected to hosts Host0, Host1, and Host2, respectively. Two generic routing encapsulation (GRE) next-hop-based dynamic tunnels, Tunnel 1 and Tunnel 2 – connect Router R0 with Routers R1 and R2, respectively. The VRF routing instance is running between each router and its connected host devices.

**Figure 19: Anti-Spoofing Protection for Next-Hop-Based Dynamic Tunnels**

Taking as an example, three packets (Packets A, B, and C) are received on Router 0 from Router R2 through the next-hop-based dynamic GRE tunnel (Tunnel 2). The source IP address of these packets are 172.17.0.2 (Packet A), 172.18.0.2 (Packet B), and 172.20.0.2 (Packet C).

The source IP address of Packets A and B belong to Host 2 and Host 1, respectively. Packet C is a nonexistent source tunnel. The designated tunnel in this example is Tunnel 2, and the nondesignated tunnel is Tunnel 1. Therefore, the packets are processed as follows:

- **Packet A**—Because the source is coming from a designated tunnel (Tunnel 2), Packet A passes the reverse path forwarding check and is processed for forwarding through Tunnel 2.
- **Packet B**—Because the source is coming from Tunnel 1, which is a nondesignated tunnel, by default, Packet B fails the reverse path forwarding check in the strict mode. If loose mode is enabled, Packet B is allowed for forwarding.
- **Packet C**—Because the source is a nonexistent tunnel source, Packet C fails the reverse path forwarding check, and the packet is not forwarded.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R0:

1. Configure Router R0's interfaces, including the loopback interface.

```

[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 192.0.2.1/24
user@R0# set ge-0/0/1 unit 0 family inet address 198.51.100.1/24
user@R0# set ge-0/0/2 vlan-tagging
user@R0# set ge-0/0/2 unit 0 vlan-id 1
user@R0# set ge-0/0/2 unit 0 family inet address 172.16.0.1/16
user@R0# set lo0 unit 0 family inet address 10.1.1.1/32

```

2. Assign the router ID and autonomous system number for Router R0.

```

[edit routing-options]
user@R0# set router-id 10.1.1.1
user@R0# set autonomous-system 100

```

3. Configure IBGP peering between the routers.

```

[edit protocols]
user@R0# set bgp group IBGP type internal
user@R0# set bgp group IBGP local-address 10.1.1.1
user@R0# set bgp group IBGP family inet-vpn unicast
user@R0# set bgp group IBGP neighbor 20.1.1.1
user@R0# set bgp group IBGP neighbor 30.1.1.1

```

4. Configure OSPF on all the interfaces of Router R0, excluding the management interface.

```

[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface lo0.0 passive

```

```
user@R0# set ospf area 0.0.0.0 interface all
```

5. Configure RSVP on all the interfaces of Router R0, excluding the management interface.

```
[edit protocols]
user@R0# set rsvp interface all
user@R0# set rsvp interface fxp0.0 disable
```

6. Enable next-hop-based dynamic GRE tunnel configuration on Router R0.

```
[edit routing-options]
user@R0# set dynamic-tunnels gre next-hop-based-tunnel
```

7. Configure the dynamic GRE tunnel parameters from Router R0 to Router R1.

```
[edit routing-options]
user@R0# set dynamic-tunnels T1 source-address 192.0.2.1
user@R0# set dynamic-tunnels T1 gre
user@R0# set dynamic-tunnels T1 destination-networks 192.0.2.0/24
```

8. Configure the dynamic GRE tunnel parameters from Router R0 to Router R2.

```
[edit routing-options]
user@R0# set dynamic-tunnels T2 source-address 198.51.100.1
user@R0# set dynamic-tunnels T2 gre
user@R0# set dynamic-tunnels T2 destination-networks 198.51.100.0/24
```

9. Configure a virtual routing and forwarding (VRF) routing instance on Router R0, and assign the interface connecting to Host 1 to the VRF instance.

```
[edit routing-instances]
user@R0# set VPN1 instance-type vrf
user@R0# set VPN1 route-distinguisher 100:100
user@R0# set VPN1 vrf-target target:100:1
user@R0# set VPN1 vrf-table-label
user@R0# set VPN1 interface ge-0/0/2.0
```

10. Configure an external BGP session with Host 1 for the VRF routing instance.

```
[edit routing-instances]
user@R0# set VPN1 protocols bgp group External type external
user@R0# set VPN1 protocols bgp group External family inet unicast
user@R0# set VPN1 protocols bgp group External peer-as 200
user@R0# set VPN1 protocols bgp group External neighbor 172.16.0.1
```

11. Configure anti-spoofing protection for the VRF routing instance on Router R0. This enables reverse path forwarding check for the next-hop-based dynamic tunnels, T1 and T2, on Router 0.

```
[edit routing-instances]
user@R0# set VPN1 routing-options forwarding-table ip-tunnel-rpf-check mode
strict
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 192.0.2.1/24;
    }
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 198.51.100.1/24;
    }
  }
}
ge-0/0/2 {
  vlan-tagging;
  unit 0 {
    vlan-id 1;
    family inet {
      address 172.16.0.1/16;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.1.1.1/32;
    }
  }
}
```

```

## Verification

Confirm that the configuration is working properly.

- [Verifying Basic Configuration on page 316](#)
- [Verifying Dynamic Tunnel Configuration on page 317](#)
- [Verifying Anti-Spoofing Protection Configuration on page 318](#)

### Verifying Basic Configuration

**Purpose** Verify the OSPF and BGP peering status between the Router R0 and Routers R1 and R2.

**Action** From operational mode, run the **show ospf neighbor** and **show bgp summary** commands.

```
user@R0> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
192.0.2.2	ge-0/0/0.0	Full	20.1.1.1	128	32
198.51.100.2	ge-0/0/1.0	Full	30.1.1.1	128	32

```
user@R0> show bgp summary
```

Groups: 2 Peers: 3 Down peers: 1								
Table	Tot Paths	Act	Paths	Suppressed	History	Damp	State	Pending
bgp.13vpn.0	0	0	0	0	0	0	0	0
Peer	AS	InPkt	OutPkt	OutQ	Flaps	Last	Up/Dwn	
State #Active/Received/Accepted/Damped...								
20.1.1.1	100	182	178	0	0	1:20:27		
Establ								
bgp.13vpn.0: 0/0/0/0								
30.1.1.1	100	230	225	0	0	1:41:51		
Establ								
bgp.13vpn.0: 0/0/0/0								
172.16.0.1	200	0	0	0	0	1:42:08		
Establ								

**Meaning** The OSPF and BGP sessions are up and running between the Routers R0, R1, and R2.

### Verifying Dynamic Tunnel Configuration

**Purpose** Verify the status of the next-hop-based dynamic GRE tunnels between the Router R0 and Routers R1 and R2.

**Action** From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@R0> show route table inet.3
```

```
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
192.0.2.0/24      *[Tunnel/300] 01:47:57
                  Tunnel
```

```
192.0.2.2/24      *[Tunnel/300] 01:47:57
                  Tunnel Composite
```

```
198.51.100.0/24   *[Tunnel/300] 01:47:57
                  Tunnel
```

```
198.51.100.2/24   *[Tunnel/300] 01:47:57
                  Tunnel Composite
```

```
user@R0> show dynamic-tunnels database terse
```

```
Table: inet.3
```

```
Destination-network: 192.0.2.0/24
```

Destination	Source	Next-hop	Type	Status
192.0.2.2/24	192.0.2.1	0xb395e70	nhid 612	gre Up

```
Destination-network: 198.51.100.0/24
```

Destination	Source	Next-hop	Type	Status
198.51.100.2	198.51.100.1	0xb395e70	nhid 612	gre Up

**Meaning** The two next-hop-based dynamic GRE tunnels, Tunnel 1 and Tunnel 2, are up.

### Verifying Anti-Spoofing Protection Configuration

**Purpose** Verify that the reverse path forwarding check has been enabled on the VRF routing instance on Router R0.

**Action** From the operational mode, run the **show krt table VPN1.inet.0 detail**.

```
user@R0> show krt table VPN1.inet.0 detail

KRT tables:
VPN1.inet.0          : GF: 1 krt-index: 8      ID: 0 kernel-id: 8
  flags: (null)
  tunnel rpf config data : enable, strict, filter [0], 0x2
  tunnel rpf tlv data : enable, strict, filter [0], 0x4
  unicast reverse path: disabled
  fast-reroute-priority: 0
  Permanent NextHops
    Multicast      : 0 Broadcast : 0
    Receive       : 0 Discard   : 0
    Multicast Discard: 0 Reject   : 0
    Local         : 0 Deny      : 0
    Table         : 0
```

**Meaning** The configured reverse path forwarding check is enabled on the VRF routing instance in the strict mode.

## Next-Hop-Based Dynamic Tunnel Localization Overview

Next-hop-based dynamic tunnels includes generic routing encapsulation (GRE) tunnels and MPLS-over-UDP tunnels. These tunnels provide a scaling advantage over the interface-based tunnels, however, unlike the interface-based tunnels, the next-hop-based dynamic tunnels are anchorless in nature, where the forwarding information of the tunnels is distributed to the Packet Forwarding Engines (PFEs) on every line card on the device. This limits the maximum number of tunnels supported on the device to the tunnel capacity of a single line card. With the support for localization, you can configure next-hop-based dynamic tunnel localization to create the forwarding information only on the PFE of a line card that is designated as the anchor PFE. The PFEs on the other line cards on the device have state forwarding information to steer the packets to the anchor PFE. This provides a scaling advantage by increasing the maximum number of tunnels supported on a device.

## Benefits of Next-Hop-Based Dynamic Tunnel Localization

Provides a scaling advantage by increasing the maximum number of tunnels supported on a device.

## Use Cases for Next-Hop-Based Dynamic Tunnel Localization

- The IPsec gateway devices that host a number of MS-MPC are used to terminate IPsec tunnels and are required to support moderate load. This support is affected with the use of next-hop-based dynamic tunnels when the scaling limit of the device is reached. With the localization of next-hop-based dynamic tunnels, the maximum number of the tunnels supported is increased, allowing the device to accommodate more tunnels at the cost of an extra fabric hop.
- For Internet or VPN gateway devices, such as a virtual public cloud data center, there is a need for the gateway devices to communicate with a large number of servers. The data center servers are reachable through next-hop-based dynamic tunnels. The anchorless property of the dynamic tunnels limits the overall scaling numbers of the device. The gateway devices host multiple MPCs, with increased traffic demands. With the localization of the next-hop-based dynamic tunnels, the tunnels can be spread across the MPCs, thereby facilitating an increase in the tunnel scaling numbers.

## Traffic Handling with Localization of Next-Hop-Based Dynamic Tunnels

With support for localization, the next-hop-based dynamic tunnel state is localized to an anchor Packet Forwarding Engine, and the other Packet Forwarding Engine has the tunnel state for steering traffic to the tunnel anchor.

Figure 20 on page 320 illustrates the forwarding path of next-hop-based dynamic tunnels without localization.

*Figure 20: Forwarding Path of Next-Hop-Based Dynamic Tunnels Without Localization*

Figure 21 on page 321 illustrates the forwarding path of next-hop-based dynamic tunnels with localization.

Figure 21: Forwarding Path of Next-Hop-Based Dynamic Tunnels With Localization

## Configuring Next-Hop-Based Dynamic Tunnels Localization

Localization support can be configured for newly created next-hop-based dynamic tunnels, or for existing non-local dynamic tunnels.

- [Configuring Localization for New Next-Hop-Based Dynamic Tunnels on page 321](#)
- [Configuring Localization for Existing Next-Hop-Based Dynamic Tunnels on page 322](#)

### Configuring Localization for New Next-Hop-Based Dynamic Tunnels

The localization of next-hop-based dynamic tunnels uses a policy-based approach to specify prefix groups. In other words, route policies are used to apply the localization properties to the next-hop-based dynamic tunnels. Dynamic tunnel attribute profiles are created and configured under routing options for association with the prefix group using the policy.

#### 1. Creating dynamic tunnel profiles.

The dynamic tunnel profile specifies the tunnel type and the anchor Packet Forwarding Engine information. Multiple dynamic tunnel profiles can be created for localization of the dynamic tunnels.

The values for the dynamic tunnel type can be GRE, UDP, or BGP-SIGNAL. Although BGP-SIGNAL is not a valid tunnel type, on assigning BGP-SIGNAL as the tunnel type, the tunnels created from the BGP-signalled attributes are localized. BGP-SIGNAL avoids the need of changing the tunnel attributes based on BGP advertisement of tunnel type.

The anchor Packet Forwarding Engine value is the line card of the anchor Packet Forwarding Engine, for example, pfe-x/y/0. This information can be viewed from the **show interfaces terse pfe\*** command output.

#### Sample Configuration:

```
[edit routing-options]
dynamic-tunnels {
  dynamic-tunnel-attributes attribute-1 {
    dynamic-tunnel-type <GRE | UDP | BGP-SIGNAL>;
    dynamic-tunnel-anchor-pfe pfe-1/0/0;
  }
}
```

## 2. Associating dynamic tunnel profile to prefix list.

Configuring a policy with **dynamic-tunnel-attributes** as the action associates the dynamic tunnel to the prefix list. The policy **from** action allows the creation of tunnel with specified attributes for any matching condition, such as a prefix range, community, or source address of BGP routes, and so on.

### Sample configuration:

```
[edit policy-options]
policy-statement policy-name {
  term term {
    from {
      <route-filter | next-hop | community>;
    }
    then {
      dynamic-tunnel-attributes <attribute-name>;
    }
  }
}
```

## 3. Including the tunnel policy under the forwarding table export policy.

After the policy is configured, it is included in the forwarding table export policy for the parsing of the policy.

Using the export-policy, the tunnel attributes get associated with the route. Whenever a route from BGP is queued for resolution, the forwarding table export policy is evaluated, and the tunnel attributes are obtained from the policy module based on the applied filters. The obtained tunnel attributes are then attached to the next hop in form of a tunnel composite next hop. The corresponding anchor forwarding structures, based on the Packet Forwarding Engine name and tunnel type, are created and sent to the forwarding table before a tunnel composite next hop is sent. However, if none of the attributes map to the tunnel composite next hop, then the forwarding structure is created on every Packet Forwarding Engine, similar to the non-localized dynamic tunnels.

### Sample configuration:

```
[edit routing-options]
forwarding-table {
  export dynamic-tunnel;
}
```

## Configuring Localization for Existing Next-Hop-Based Dynamic Tunnels

**CAUTION:** Making on the fly changes to dynamic tunnel attributes can result in an FPC crash due to high memory utilization. Hence, we recommend deactivating the dynamic-tunnels configuration before configuring localization.

To update tunnel attributes for existing next-hop-based dynamic tunnels, the following should be performed:

1. Deactivate **dynamic-tunnels** configuration under the **[edit routing-options]** hierarchy level.

**Sample configuration:**

```
[edit routing-options]
user@host# deactivate dynamic-tunnels
user@host# commit
```

2. Change tunnel attributes as required.
3. Activate **dynamic-tunnels** configuration under the **[edit routing-options]** hierarchy level.

**Sample configuration:**

```
[edit routing-options]
user@host# activate dynamic-tunnels
user@host# commit
```

To configure localization for existing non-local next-hop-based dynamic tunnels:

**CAUTION:** Making on the fly changes to configure localization for existing non-local next-hop-based dynamic tunnels can result in an FPC crash due to high memory utilization. Hence, we recommend deactivating the **dynamic-tunnels** configuration before configuring localization.

1. Deactivate the **dynamic-tunnels** configuration at the **[edit routing-options]** hierarchy level.
2. Create tunnel-attributes profile and add policy for localizing the dynamic tunnels, similar to new next-hop-based dynamic tunnels.
3. Activate the **dynamic-tunnels** configuration.

## Troubleshooting Localized Next-Hop-Based Dynamic Tunnels

With localization of next-hop-based dynamic tunnels, the tunnel composite next hops are associated with anchor Packet Forwarding Engine IDs. The following traceroute configuration statements at the **[edit routing-options]** hierarchy level help in troubleshooting the localized dynamic tunnels:

- **dynamic-tunnels traceoptions flag all**—Tracking creation and deletion of tunnel in DTM.
- **resolution traceoptions flag tunnel**—Tracking resolver operations on BGP route.

- **forwarding-table traceoptions flag all**—Tracking tunnels sent to the kernel.
- **traceoptions flag all**—Tracking of route learning process.

The following commands can be used to check if a route is using a localized next-hop-based dynamic tunnel:

1. **show route *prefix* extensive**—To obtain the indirect next hop.

For example:

```
user@host> show route 1.2.3.4 extensive
MPLS-over-UDP-PE1.inet.0: 24 destinations, 26 routes (24 active, 0 holddown,
0 hidden)
1.2.3.4/32 (1 entry, 1 announced)
TSI:
KRT in-kernel 1.2.3.4/32 -> {indirect(1048577)}
Page 0 idx 1, (group pe1-ce1 type External) Type 1 val 0xb209a78 (adv_entry)
  Advertised metrics:
    Nexthop: Self
    AS path: [100] I
    Communities: target:600:1 encapsulation:mpls-in-udp(0xd)
```

2. **show krt indirect-next-hop index *indirect-next-hop* detail**—To check for anchor Packet Forwarding Engine field in the detailed output of the indirect next hop.

For example:

```
user@host> show krt indirect-next-hop index 1048577 detail
Indirect Nexthop detail:
Index: 1048577 Protocol next-hop address: 1.1.1.6
  RIB Table: bgp.l3vpn.0          Label: Push 299808
  Policy Version: 2              References: 11
  Locks: 3                      0xb227980
  Flags: 0x0
  INH Session ID: 0x0
  Ref RIB Table: unknown
  Export policy detail:
    (Dynamic tunnel hash : 309985522)
    Tunnel type: UDP, Reference count: 4, nhid: 1016
    Destination address: 1.1.1.6, Source address: 1.1.1.2
    Anchored-PFE: pfe-1/0/0
    VPN Label: Push 299808, TTL action: prop-ttl
  IGP FRR Interesting proto count : 11

  IGP Actual Route handle(hex)    : 0x0          IGP Actual rt_entry protocol
: Any
```

## Unsupported Features for Next-Hop-Based Dynamic Tunnels Localization

Junos OS does not support the following functionality with localization for next-hop-based dynamic tunnels:

- Chained composite next hops at the **[edit routing-options forwarding-table chained-composite-next-hop ingress {vpn}]** hierarchy level.
- Anchor Packet Forwarding Engine resiliency.

There is no resiliency support for next-hop-based dynamic tunnels with localization. After localization of the next-hop-based dynamic tunnels, the anchor Packet Forwarding Engine becomes the single entity for processing any given tunnel on the device. Although anchor Packet Forwarding Engine resiliency is not supported, for gateway devices, redundancy at the gateway device ensures that when the Packet Forwarding Engine to which the tunnel composite next hop is delegated goes down, the traffic must be rerouted to the redundant gateway device. The routing protocol process monitors the state of the Packet Forwarding Engine, and withdraws BGP advertisement of all the routes pointing to the tunnel composite next hops anchored on that Packet Forwarding Engine.

Only the anchored Packet Forwarding Engine has the full-fledged tunnel composite next hop and all the other Packet Forwarding Engines have only steering entries to forward traffic to the anchor Packet Forwarding Engine. These steering entries are not withdrawn, when an anchor FPC goes down.

- Localization of next-hop-based dynamic tunnels is not supported on logical systems.
- IPv6 is not supported with localization of next-hop-based dynamic tunnels.
- With localization, the **show dynamic-tunnels database summary** command does not display accurate tunnels summary when the state of the anchor Packet Forwarding Engine line card is not up. As a workaround, use the **show dynamic-tunnels database** and **show dynamic-tunnels database terse** command output.

### MPLS Label Overview

---

Packets traveling along an LSP are identified by a label—a 20-bit, unsigned integer in the range 0 through 1,048,575. For push labels on ingress routers, no labels in this range are restricted. For incoming labels on the transit static LSP, the label value is restricted to 1,000,000 through 1,048,575.

On MX Series, PTX Series, and T Series routers, the value for entropy and flow labels is restricted to 16 through 1,048,575.

### MPLS Label Allocation

---

In the Junos OS, label values are allocated per router or switch—the rest of this explanation uses router to cover both. The display output shows only the label (for example, **01024**).

Labels for multicast packets are independent of those for unicast packets. Currently, the Junos OS does not support multicast labels.

Labels are assigned by downstream routers relative to the flow of packets. A router receiving labeled packets (the next-hop router) is responsible for assigning incoming labels. A received packet containing a label that is unrecognized (unassigned) is dropped. For unrecognized labels, the router does not attempt to unwrap the label to analyze the network layer header, nor does it generate an Internet Control Message Protocol (ICMP) destination unreachable message.

A packet can carry a number of labels, organized as a last-in, first-out stack. This is referred to as a *label stack*. At a particular router, the decision about how to forward a labeled packet is based exclusively on the label at the top of the stack.

[Figure 22 on page 330](#) shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

**Figure 22: Label Encoding**

[Figure 23 on page 331](#) illustrates the purpose of the class-of-service bits (also known as the EXP or experimental bits). Bits 20 and 21 specify the queue number. Bit 22 is the packet loss priority (PLP) bit used to specify the random early detection (RED) drop profile. For more information about class of service and the class-of-service bits, see [“Configuring Class of Service for MPLS LSPs” on page 1067](#).

Figure 23: Class-of-Service Bits

Related Documentation • [per-prefix-label on page 2190](#)

## Operations on MPLS Labels

The router supports the following label operations:

- **Push**—Add a new label to the top of the packet. For IPv4 packets, the new label is the first label. The time-to-live (TTL) and s bits are derived from the IP packet header. The MPLS class of service (CoS) is derived from the queue number. If the push operation is performed on an existing MPLS packet, you will have a packet with two or more labels. This is called label stacking. The top label must have its s bit set to 0, and might derive CoS and TTL from lower levels. The new top label in a label stack always initializes its TTL to 255, regardless of the TTL value of lower labels.
- **Pop**—Remove the label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet. In the case of multiple labels in a packet (label stacking), removal of the top label yields another MPLS packet. The new top label might derive CoS and TTL from a previous top label. The popped TTL value from the previous top label is not written back to the new top label.
- **Swap**—Replace the label at the top of the label stack with a new label. The S and CoS bits are copied from the previous label, and the TTL value is copied and decremented (unless the **no-decrement-ttl** or **no-propagate-ttl** statement is configured). A transit router supports a label stack of any depth.
- **Multiple Push**—Add multiple labels (up to three) on top of existing packets. This operation is equivalent to pushing multiple times.
- **Swap and Push**—Replace the existing top of the label stack with a new label, and then push another new label on top.

## Understanding MPLS Label Operations

---

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is forwarded based on its IP routing information.

This topic describes:

- [MPLS Label-Switched Paths and MPLS Labels on page 332](#)
- [Reserved Labels on page 333](#)
- [MPLS Label Operations on page 333](#)
- [Penultimate-Hop Popping and Ultimate-Hop Popping on page 335](#)

### MPLS Label-Switched Paths and MPLS Labels

When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

[Figure 22 on page 330](#) shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 24: Label Encoding

## Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings.

The following reserved labels are used by QFX Series and EX4600 devices:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

## MPLS Label Operations

QFX Series and EX4600 devices support the following MPLS label operations:

- Push
- Pop
- Swap

**NOTE:** There is a limit with regard to the number of labels that QFX and EX4600 devices can affix (push operations) to the label stack or remove (pop operations) from the label stack.

- For Push operations—As many as three labels are supported.
- For Pop operations—As many as three labels are supported.

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet.

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 25 on page 334 shows an IP packet without a label arriving on the customer edge interface (ge-0/0/1) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (ge-0/0/5). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface ge-0/0/5 with label 100. The provider switch swaps label 100 with label 200 and forwards the MPLS packet through its core interface (ge-0/0/7) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch receives the MPLS packet through its core interface (ge-0/0/7), removes the MPLS label, and sends the IP packet out of its customer edge interface (ge-0/0/1) to a destination that is beyond the tunnel.

**Figure 25: MPLS Label Swapping**

Figure 25 on page 334 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

## Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

## Understanding MPLS Label Manager

MPLS label manager is used to manage different label types such as LSI, dynamic, block, and static, which are supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. These line cards provide more flexibility and scalability, when the **enhanced-ip** command is configured on the device.

The existing behavior of **label-space** command is retained, which is *not recommended*. To provide additional functionality such as multiple ranges for each type of label, **label-range** command is introduced under the **[edit protocols mpls label usage]** hierarchy, which is independent of **label-space** configuration. You can choose either style if only one range is needed for each type of label.

The following features are optimized with the **enhanced-ip** command configured on the device:

- Allows you to define the system wide global label pool to be used by segment-routing global block (SRGB) through IS-IS routing protocol.
- Increases the **vrf-table-label** space to at least 16,000, if the platform can support the scale.
- Allows you to specify the label value to be used by static VRF table label.
- Allows you to specify the label value range to be used by supported label application types.
- Allows you to change dynamically the SRGB and label type ranges.

## Understanding MPLS Label Operations on EX Series Switches

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

This topic describes:

- [MPLS Label-Switched Paths and MPLS Labels on the Switches on page 336](#)
- [Reserved Labels on page 337](#)
- [MPLS Label Operations on the Switches on page 337](#)
- [Penultimate-Hop Popping and Ultimate-Hop Popping on page 338](#)

### MPLS Label-Switched Paths and MPLS Labels on the Switches

When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

**NOTE:** The implementation of MPLS on Juniper Networks EX3200 and EX4200 Ethernet Switches supports only single-label packets. However, MPLS on Juniper Networks EX8200 Ethernet Switches supports packets with as many as three labels.

---

Figure 22 on page 330 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 26: Label Encoding

g040575

## Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings. The following reserved labels are used by the switches:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 2, IPv6 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

## MPLS Label Operations on the Switches

EX Series switches support the following label operations:

- Push
- Pop
- Swap

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet.

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 25 on page 334 shows an IP packet without a label arriving on the customer edge interface (**ge-0/0/1**) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (**ge-0/0/5**). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface **ge-0/0/5** with label 100. The provider switch swaps label 100 to label 200 and forwards the MPLS packet through its core interface (**ge-0/0/7**) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch receives the MPLS packet through its core interface (**ge-0/0/7**), removes the MPLS label, and sends the IP packet out of its customer edge interface (**ge-0/0/1**) to a destination that is beyond the tunnel.

Figure 27: MPLS Label Swapping

Figure 25 on page 334 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

## Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

On EX8200 switches, you can choose to use either the default, PHP, or to configure ultimate-hop popping.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

## How a Packet Travels Along an LSP

When an IP packet enters an LSP, the ingress router examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label.

The packet is then forwarded to the next router in the LSP. This router and all subsequent routers in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next router in the path.

When the packet reaches the egress router, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

## Types of LSPs

There are three types of LSPs:

- **Static LSPs**—For static paths, you must manually assign labels on all routers involved (ingress, transit, and egress). No signaling protocol is needed. This procedure is similar to configuring static routes on individual routers. Like static routes, there is no error reporting, liveliness detection, or statistics reporting.
- **LDP-signaled LSPs**—See [“LDP Introduction” on page 726](#).

- **RSVP-signaled LSPs**—For signaled paths, RSVP is used to set up the path and dynamically assign labels. (RSVP signaling messages are used to set up signaled paths.) You configure only the ingress router. The transit and egress routers accept signaling information from the ingress router, and they set up and maintain the LSP cooperatively. Any errors encountered while establishing an LSP are reported to the ingress router for diagnostics. For signaled LSPs to work, a version of RSVP that supports tunnel extensions must be enabled on all routers.

There are two types of RSVP-signaled LSPs:

- **Explicit-path LSPs**—All intermediate hops of the LSP are manually configured. The intermediate hops can be strict, loose, or any combination of the two. Explicit path LSPs provide you with complete control over how the path is set up. They are similar to static LSPs but require much less configuration.
- **Constrained-path LSPs**—The intermediate hops of the LSP are automatically computed by the software. The computation takes into account information provided by the topology information from the IS-IS or OSPF link-state routing protocol, the current network resource utilization determined by RSVP, and the resource requirements and constraints of the LSP. For signaled constrained-path LSPs to work, either the IS-IS or OSPF protocol and the IS-IS or OSPF traffic engineering extensions must be enabled on all routers.

---

## Scope of LSPs

For constrained-path LSPs, the LSP computation is confined to one IGP domain, and cannot cross any AS boundary. This prevents an AS from extending its IGP into another AS.

Explicit-path LSPs, however, can cross as many AS boundaries as necessary. Because intermediate hops are manually specified, the LSP does not depend on the IGP topology or a local forwarding table.

---

## Special MPLS Labels

Some of the reserved labels (in the 0 through 15 range) have well-defined meanings. For more complete details, see RFC 3032, *MPLS Label Stack Encoding*.

- **0, IPv4 Explicit Null label**—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped upon receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- **1, Router Alert label**—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- **2, IPv6 Explicit Null label**—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 6 (IPv6) packet.
- **3, Implicit Null label**—This label is used in the control protocol (LDP or RSVP) only to request label popping by the downstream router. It never actually appears in the

encapsulation. Labels with a value of 3 should not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

- 4 through 6—Unassigned.
- 7, Entropy label indicator—This label is used when an Entropy label is in the label stack and precedes the Entropy label.
- 8 through 15—Unassigned.

Special labels are commonly used between the egress and penultimate routers of an LSP. If the LSP is configured to carry IPv4 packets only, the egress router might signal the penultimate router to use 0 as a final-hop label. If the LSP is configured to carry IPv6 packets only, the egress router might signal the penultimate router to use 2 as a final-hop label.

The egress router might simply signal the penultimate router to use 3 as the final label, which is a request to perform penultimate-hop label popping. The egress router will not process a labeled packet; rather, it receives the payload (IPv4, IPv6, or others) directly, reducing one MPLS lookup at egress.

For label-stacked packets, the egress router receives an MPLS label packet with its top label already popped by the penultimate router. The egress router cannot receive label-stacked packets that use label 0 or 2. It typically requests label 3 from the penultimate router.

## Entropy Label Support in Mixed Mode Overview

Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration. The entropy label helps transit routers load-balance MPLS traffic across ECMP paths or link aggregation groups. The entropy label introduces a load-balancing label to be used by routers to load balance traffic rather than relying on deep packet inspection, reducing the packet processing requirements in the forwarding plane at the expense of increased label stack depth. Junos OS supports the entropy label only for MX Series routers with MPCs or MICs and can be enabled with enhanced-ip mode. But, this leads to a packet drop if the core-facing interface has an entropy label configured on the MPC or MIC and the other end of this core-facing connection has a DPC line card. In order to avoid this, the entropy label is now supported in mixed mode where the entropy label can be configured without enhanced-ip configuration. This allows MX Series router DPCs to support a pop out entropy label. However, this does not support a flow label.

### Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration.

## Abstract Hops for MPLS LSPs Overview

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), which results in a user-defined group or cluster of routers that can be sequenced and used as constraints for setting up an MPLS label-switched path (LSP). Abstract hops overcome the limitations of existing path constraint specifications and provide several benefits to the traffic engineering capabilities of MPLS.

- [Understanding Abstract Hops on page 342](#)
- [Benefits of Using Abstract Hops on page 343](#)
- [Junos OS Implementation of Abstract Hops on page 345](#)

### Understanding Abstract Hops

The path constraint for setting up of an MPLS LSP can be specified as either individual routers in the form of real hops or as a set of routers by way of administrative group or color specification. When a path constraint uses real hops (strict or loose), the LSP is set up along a specified sequence of routers (for example, R1, R2, ... Rn). When a path constraint uses an administrative group or color specification, a group of routers that meet the specified criteria is used to set up the LSP without picking a specific router, and unlike real-hop constraint, there is no sequence among the different groups of routers used in the constraint.

The drawback of real-hop constraint is that in a failure scenario, if any of the router hops goes down or the bandwidth utilization of the attached interface gets saturated, the path

goes down (or relies on local or end-to-end protection). Although other alternative routers might be available to recover or set up the LSP, the LSP remains down until the operator configures another router hop sequence as the path constraint to bring the path up again or to disengage the protection path.

The administrative group or color specification constraint overcomes this limitation of a real-hop constraint to a certain extent. Here, when one of the routers in the group goes down or has its link capacity saturated, setting up of the LSP is not affected. This is because the next hop router to be used in the path constraint is not picked beforehand, and the LSP is set up along other routers that have the same administrative group or color without operator intervention. However, the drawback with router group constraints is that a sequence cannot be specified among the hop constraints.

Abstract hops overcome these drawbacks by creating user-defined router groups, where each member router meets a user-defined constraint. The user-defined constraint is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs). Ordering is achieved among the router groups by specifying a sequence of abstract hops used in a path constraint. As a result, abstract hops combine the ordering property of real-hop constraint specification and the resilience that comes with the other traffic engineering constraints.

A path can use a combination of real and abstract hops as constraints. When using abstract hops, instead of specifying a sequence of routers ( $R_1, R_2, \dots, R_n$ ) as with real hops, you specify an ordered set of router groups or abstract hops ( $G_1, G_2, \dots, G_n$ ) as the path constraint. Each specified router group,  $G_i$  for example, consists of some user-defined set of routers— $R_1, R_2, R_j, \dots, R_n$ . When one of the routers in the group goes down, say Router  $R_j$  in group  $G_i$ , another router, say Router  $R_k$ , from the same group  $G_i$  is picked up by path computation to replace the router that went down (that is, Router  $R_j$ ). This is because the path constraint is sequenced and has to go through a sequence of abstract hops, instead of a sequence of individual routers.

## Benefits of Using Abstract Hops

Abstract hops are user-defined router groups. Similar to real-hop constraints that use a sequence of individual routers, a sequence of abstract hops can be used for setting up a label-switched path (LSP). The use of abstract hops provides resiliency to sequenced path constraints. The other benefits of using abstract hops include:

- [Specifying a Sequence of Constraint Combinations on page 343](#)
- [Avoiding New Network Configuration on Transit Nodes on page 344](#)
- [Combining Centralized and Distributed Path Computation Paradigms on page 344](#)

### Specifying a Sequence of Constraint Combinations

Currently, it is possible to specify a path that can go through links that satisfy multiple attributes. Such a path constraint is called a compound constraint combination; for example, a constraint ( $C_i$ ) that includes low latency links of green color and also excludes SRLG north.

However, there is no support for specifying a path with a sequence of compound constraint combinations. For example, a sequenced constraint (C1, C2, Ci, ...Cn) that includes low latency green links, no latency blue links, and then low latency red links.

The need for such a sequenced compound constraint combination arises when there is a requirement to establish paths through a sequence of geographical regions with a different link affinity (attributes) requirement in each region. Abstract hops meet this requirement by allowing computing nodes to map each constraint combination (Ci, for example) with the user-defined group of routers—that is, the abstract hops.

### Avoiding New Network Configuration on Transit Nodes

With current path constraint specification capabilities, it is possible to include or exclude links of certain attributes along an entire path; for example, excluding SRLG west from a path. However, there is no support to either conditionally exclude or include attributes, or to apply different exclude or include attributes in different parts of the path; for example, excluding SRLG west only when traversing red links.

As a workaround, a new administrative group can be created to identify all such red links that do not have SRLG west, and configure all the relevant links appropriately with that administrative group. The drawback of this approach is that configuration changes are required throughout the network to reflect the new administrative group membership.

Instead, by using abstract hops, the configuration changes can be contained on the ingress router only. At the ingress router, the constraint combination is mapped to the abstract hop, thereby meeting the aforementioned requirement without the need for any new configuration on the transit nodes.

### Combining Centralized and Distributed Path Computation Paradigms

Traffic engineering of MPLS paths can be achieved by distributed computing or with a centralized controller for computing paths. A combination of both the computation types is called the hybrid computation paradigm. The key feature of the hybrid computation approach is the ability of the centralized controller—referred to as a Path Computation Element (PCE)—to loosely specify the path computation directives, per path, to the ingress router—referred to as a Path Computation Client (PCC)—and the ability of the ingress router to use it as input for path computation.

A sequence of abstract hops serves the purpose of acting as the guideline from the centralized controller. Abstract hops provide the flexibility to the controller to weave into the path constraint and attributes. This also enables the controller to build in the element of sequence in the constraint. The controller does not have to specify each hop the path needs to take, leaving room for the ingress router to act within the limits of the guideline or directive.

[Table 12 on page 344](#) lists the key features of the hybrid computation paradigm and provides a comparison of this approach with the current path computation methods.

**Table 12: Hybrid Computation for Abstract Hops**

Features	Distributed Constrained Shortest Path First	Centralized Constrained Shortest Path First	Hybrid Constrained Shortest Path First
----------	---	---	--

*Table 12: Hybrid Computation for Abstract Hops (continued)*

React to frequent changes in a large network	Yes	Yes
Sophisticated path computation with global view	Yes	Yes
Incorporation of business logic in path computation	Yes	Yes
Resilience (no single point of failure)	Yes	Yes
Predictability	Yes	Yes
React to network load in (close to) real time	Yes	Yes
Field tested (versus early adoption)	Yes	Yes

## Junos OS Implementation of Abstract Hops

The order-aware abstract hops feature is introduced in Junos OS Release 17.1. The following sections describe the implementation of abstract hops in Junos OS:

- [Defining Abstract Hops on page 345](#)
- [Using Abstract Hops in Path Constraint on page 348](#)
- [Path Computation and Backtracking on page 352](#)
- [Sample Backtracking on page 352](#)

### Defining Abstract Hops

An abstract hop is a group of routers that users can define to be used in setting up a label-switched path (LSP). The user can control which routers to include in the group by defining a logical combination of heterogeneous link attributes or constraints called constituent attributes. The routers with links that satisfy the defined constituent attributes make it to the group of routers representing the abstract hop.

The mapping of constituent attributes with the abstract hop is local to the computing node or the ingress of the LSP being setup. As a result, abstract hops do not have associated interior gateway protocol updates or signaling protocol extensions, and implementing abstract hops in a network does not require new configuration on the transit nodes.

A constituent list enables defining of a set of constituent traffic engineering attributes, that is identified by a user-defined name. Constituent lists are used in an abstract hop definition by using any of the following configuration statements:

- **include-any-list**—Link satisfies the constituent-list if any of the specified constituent attributes are true for the link.
- **include-all-list**—Link satisfies the constituent-list if all the specified constituent attributes are true for the link.

- **exclude-all-list**—Link satisfies the constituent-list if none of the specified constituent attributes are true for the link.
- **exclude-any-list**—Link satisfies the constituent-list if at least one of the specified constituent attributes is not true for the link.

An abstract hop is defined as a logical combination of constituent-list references that can belong to any of the aforementioned categories. To achieve this, logical operators **AND** and **OR** are included in the abstract hop definition, and applied to the constituent list.

- **OR**—At least one of the constituent-list references in the abstract hop definition must be satisfied by a link for the attached node to be part of the abstract hop.
- **AND**—All of the constituent-list references in the abstract hop definition must be satisfied by a link for the attached node to be part of the abstract hop.

### ***Sample Abstract Hop Definition***

Taking as an example, the definition of abstract hops hopA is as follows:

Abstract hops hopA must include all routers whose emanating links satisfy the logical combination of the following link attributes, respectively:

- **hopA**—((administrative group red && Srlg south) || (administrative group green || Srlg north)), where:
  - *administrative group red* and *Srlg south* belong to include-all constituent list (listA1, in this example).
  - *administrative group green* and *Srlg north* belong to include-any constituent list (listA2, in this example).
  - || is the OR operator.

The configuration for abstract hops hopA is as follows:

- **hopA configuration**

```
[edit protocols mpls]
Constituent-list listA1 {
  administrative-group red;
  Srlg south;
}
Constituent-list listA2 {
  administrative-group green;
  Srlg north;
}
Abstract-hop hopA{
  Operator OR;
  Constituent-list listA1 include-all-list;
  Constituent-list listA2 include-any-list;
}
```

### **Verifying Abstract Hop Configuration**

The **show mpls abstract hop membership <abstract hop name>** command is used to view members of an abstract hop. The command output provides the abstract hop to traffic engineering database node mapping.

```
user@host> show mpls abstract-hop-membership
```

```
Abstract hop: hop1A
  Credibility: 0
Address: 128.102.165.105
Address: 128.102.166.237
Address: 128.102.168.0
Address: 128.102.173.123
```

```
Abstract hop: hopB
  Credibility: 0
Address: 128.102.160.211
Address: 128.102.165.5
Address: 128.102.166.237
Address: 128.102.172.157
Address: 128.102.172.196
```

Here, the output field **Credibility** indicates the credibility associated with interior gateway protocol in use.

The output of the **show ted database extensive local** command provides the view captured in traffic engineering database. A keyword **local** is added to indicate that the output would include any local instrumentation. The command output shows the abstract hop as an attribute of links that satisfy the associated logical combination of link attributes.

```
user@host> show ted database extensive local
```

```

Abstract hop hopA is for low latency AND SRLG west, and abstract hop hopB is for excluding SRLG west. [Figure 28 on page 348](#) displays the ingress view of these abstract hops.

*Figure 28: Ingress View of Abstract Hops*

### Using Abstract Hops in Path Constraint

The user associates a unique identifier with each abstract hop definition. This identifier is used for referring to the abstract hop in the path constraint. A sequence of abstract hops can be specified as the path constraint, similar to how real IP hops are used. The path constraint could also be a sequence of abstract hops interleaved by real IP hops.

Using abstract hops or real hops in a path constraint requires more than one Constrained Shortest Path First pass to the destination, typically one pass per hop. When real hops are provided as the path constraint, the constraint computation involves as many passes as the number of hops in the path constraint, where each pass ends on reaching a hop in the constraint list. The starting point for each pass is the destination of the previous pass, with the first pass using the ingress router as the start.

Alternatively, when path constraint uses strict or loose abstract hops, constraint computation comprises passes where each pass processes the subsequent abstract hop in the constraint list. In such a case, more than one node qualifies to be the destination for the pass. The set of nodes is called the viable router set for the pass.

An abstract hop traverses member nodes by using the following:

- Links that satisfy the logical combination of defined constituent attributes
- Any kind of links

The means of abstract hops traversing the member nodes is controlled by the use of the abstract hop qualifiers—strict, loose, and loose-link—in defining the path constraint. Taking for example, abstract hop hopA is processed differently with different qualifiers:

- **Strict**—After the last processed hop in the constraint list, the path traverses only links or nodes having membership of abstract hop hopA, before reaching a node with hopA's membership that is a feasible starting point for processing the next abstract hop.
- **Loose**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of hopA, before reaching a node with abstract hop membership hopA, which is a feasible starting point for processing the next abstract hop.
- **Loose-link**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of hopA, before reaching a node with abstract hop membership hopA, which is a feasible starting point for processing the next abstract hop. But the path should have traversed at least one link of abstract hop hopA membership in the course of the same.

In other words, the abstract hop of type loose-link is said to be processed only if any of the viable routers in the constraint is reachable through a link of associated abstract hop membership.

#### Sample Abstract Hops Specification

Table 13 on page 349 provides sample use case for using abstract hops in path constraints.

**Table 13: Using Abstract Hops in Path Constraints**

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity
Traverse nodes that are members of hopA taking only links that satisfy hopA.	Strict	<pre>[edit protocols mpls] Path path_hopA_s {   hopA abstract strict; }</pre>	All members of abstract hopA. That is, A1, A2...An.	hopA (pick only links that satisfy abstract hopA).
Traverse nodes that are members of hopA but not necessarily links that satisfy hopA	Loose	<pre>[edit protocols mpls] Path path_hopA_l {   hopA abstract loose; }</pre>	All members of abstract hopA. That is, A1, A2...An.	None (any kind of links).

Table 13: Using Abstract Hops in Path Constraints (continued)

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity
Traverse nodes that are members of hopA by taking at least one link that satisfies hopA.	Loose-link  <b>NOTE:</b> The loose-link qualifier is viewed as loose followed by strict for the same abstract hop. In other words, hopA loose-link is the same as hopA loose and hopA strict.	<pre>[edit protocols mpls] Path path_hopA_ll {   hopA abstract loose-link; }</pre>	In this case, there are two computation passes associated with hopA in the path constraint. The viable router set for both passes is:  All members of abstract hopA. That is, A1, A2...An.  <b>NOTE:</b> During path computation, a router is traversed only once.	In this case, there are two computation passes associated with hopA in the path constraint. The affinity for the two passes is:  <ul style="list-style-type: none"> <li>Pass 1—None (any kind of links).</li> <li>Pass 2—hopA (pick only links that satisfy abstract hopA).</li> </ul>
Traverse nodes that are members of hopA, taking only links that satisfy hopA, followed by nodes that are members of hopB taking only links that satisfy hopB.	Strict	<pre>[edit protocols mpls] Path path_hopA_hopB_s {   hopA abstract strict;   hopB abstract strict; }</pre>	<ul style="list-style-type: none"> <li>hopA—Intersection of member set of hopA and hopB.  <b>NOTE:</b> When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	<ul style="list-style-type: none"> <li>hopA—hopA (pick only links that satisfy abstract hopA).</li> <li>hopB—hopB (pick only links that satisfy abstract hopB).</li> </ul>
Traverse nodes that are members of hopA taking only links that satisfy hopA, followed by nodes that are members of hopB taking any kind of links.	Strict and loose	<pre>[edit protocols mpls] Path path_hopA_s_hopB_l {   hopA abstract strict;   hopB abstract loose; }</pre>	<ul style="list-style-type: none"> <li>hopA—All members of abstract hopA. That is, A1, A2...An.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	<ul style="list-style-type: none"> <li>hopA—hopA (pick only links that satisfy abstract hopA).</li> <li>hopB—None (pick any links).</li> </ul>
Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking any kind of links.	Loose	<pre>[edit protocols mpls] Path path_hopA_l_hopB_l {   hopA abstract loose;   hopB abstract loose; }</pre>	<ul style="list-style-type: none"> <li>hopA—All members of abstract hopA. That is, A1, A2...An.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	None (pick any links).

Table 13: Using Abstract Hops in Path Constraints (continued)

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity
Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking only links that satisfy hopB.	Loose and strict	<pre>[edit protocols mpls] Path path_hopA_to_hopB {   hopA abstract loose;   hopB abstract strict; }</pre>	<ul style="list-style-type: none"> <li>hopA—Intersection of the members of hopA and hopB. When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	<ul style="list-style-type: none"> <li>hopA—None (pick any links).</li> <li>hopB—hopB (pick only links that satisfy abstract hopB).</li> </ul>

Figure 29 on page 351 displays path constraints for abstract hops hopA, hopB, and hopC with loose, strict, and loose abstract hop qualifiers, respectively.

Figure 29: Sample Path Constraints for Abstract Hops

The Constrained Shortest Path First passes for the abstract hops are as follows:

- Pass 1 associated with hopA
  - Viable routers—Routers R1 and R2 (intersection of hopA and hopB, as hopB is a strict abstract hop).
  - Affinity—None (as hopA is loose).
- Pass 2 associated with hopB
  - Viable routers—Routers R1, R2, R3, and R4
  - Affinity—Pick only hopB-compliant links (as hopB is a strict abstract hop).
- Pass 3 associated with hopC
  - Viable routers—Routers R5, R6, R7, and the egress router.
  - Affinity—None (as hopC is a loose abstract hop).

## Path Computation and Backtracking

In each Constrained Shortest Path First pass, when the nearest router from a viable router set is reached using links satisfying the affinity figured for the pass, the abstract hop associated with the pass is said to be processed. The viable router thus reached serves as the start for the next constraint pass. If any constraint pass fails, and it is not the one with the ingress router as start router, then the pass is backtracked to the previous pass and the process is repeated.

### Sample Backtracking

When a Constrained Shortest Path First pass  $p$  (other than the first one) fails, the exit router of the previous pass ( $p - 1$ ) that served as start for the current pass  $p$  is disqualified in the viable router set of the previous pass ( $p - 1$ ). Then the previous pass ( $p - 1$ ) is re-executed to find the next best exit router or destination for the pass  $p - 1$  from the viable router set.

The router thus determined serves as the new start router for the pass  $p$ . This procedure is repeated as long as there are failures and there are viable routers that are not explored.

The `show mpls lsp abstract-hop-computation name lsp-name` command provides the various computation passes involved per LSP and the qualifying exit routers for each pass. The command output also gives the affinity per pass, and shows the current start router chosen for the pass. For each viable router, the state of backtracking is displayed, where it can be either valid or disqualified.

```
user@host> show mpls lsp abstract-computation
```

```

## Example: Configuring Abstract Hops for MPLS LSPs

This example shows how to configure abstract hops for MPLS label-switched paths (LSPs). Abstract hops combine the key features of existing traffic engineering constraints that enables the user to specify an order-aware and resilient path constraint for MPLS LSPs.

- [Requirements on page 353](#)
- [Overview on page 353](#)
- [Configuration on page 355](#)
- [Verification on page 367](#)

### Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers.
- Junos OS Release 17.1 or later running on all the devices.

Before you begin:

- Configure the device interfaces.
- Configure the device router ID and assign an autonomous system (AS) number.
- Configure RSVP on all the devices.
- Configure OSPF or any other interior gateway protocol on all the devices.
- Configure administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs) on all the devices.

### Overview

Junos OS Release 17.1 introduces abstract hops, which are user-defined router clusters or groups. Similar to the sequence of real-hop constraints (strict or loose), a sequence of abstract hops can be used for setting up a label-switched path (LSP). A path can use a combination of real and abstract hops as constraints.

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes.

To configure abstract hops:

- Create constituent lists with constituent traffic engineering attributes by including the **constituent-list *list-name*** statement at the **[edit protocols mpls]** hierarchy level.
- Include the constituent lists in the abstract hop definition at the **[edit protocols mpls abstract-hop *abstract-hop-name*]** hierarchy level.
- Define path constraints that use abstract hops at the **[edit protocols mpls path *path-name*]** hierarchy level.

Take the following guidelines under consideration when configuring abstract hops for MPLS LSPs:

- Abstract hops are supported only in the master routing instance of a device.
- IPv6 destinations are not supported in abstract hop constraints (only IPv4 destinations work).
- Abstract hops can be strict or loose constraints.
- Abstract hops support in Junos OS Release 17.1 is provided only for intra-area MPLS LSPs and not for inter-domain, or inter-area LSPs.
- Abstract hop constraints is enabled for regular point-to-point LSPs only. Other types of MPLS LSPs, such as point-to-multipoint LSPs, externally controlled bidirectional LSPs, dynamic container LSPs, RSVP automesh LSPs, and inter-area LSPs are not supported with abstract hops configuration.
- Abstract hops do not enable computation of overall shortest path for LSPs.
- An abstract hop must not be referred to more than once in the same path constraint.
- Abstract hop constraint specifications do not affect the support for Graceful Routing Engine switchover (GRES), unified in-service software upgrade (ISSU), and nonstop routing (NSR).
- Abstract hop constraint specifications do not affect overall network performance. However, the time taken for constrained shortest path first computation increases with abstract hop configuration. The setup time for an abstract hop LSP is more than the time taken to set up an LSP without abstract hop configuration.

---

## Topology

Figure 30 on page 355 illustrates a sample network topology configured with abstract hops. Devices R0 and R3 are each connected to hosts (Host 1 and Host 2). Devices R4 and R5 are each connected to Devices R0, R1, R2, and R3. Devices R1 and R2 are also directly connected to each other.

Devices R0 and R3 are configured under the same autonomous system—AS 64496. An MPLS LSP is configured from Device R0 through Device R3 with one primary path and two secondary paths (standby and nonstandby secondary paths).

Four constituent lists—c1, c2, c3, and c4—are created using three SRLGs (g1, g2, and g3), three administrative groups (green, blue, and red), and one extended administrative group (gold). Three abstract hops (ah1, ah2, and ah3) are defined using the configured

constituent lists, and are specified as path constraints. Abstract hop ah1 is specified as constraint for the primary path, while abstract hops ah2 and ah3 are specified as constraints for the secondary standby path and the secondary nonstandby path, respectively.

Figure 30: Configuring Abstract Hop Path Constraint

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R0:

1. Enable enhanced IP network services on Device R0.

```

[edit chassis]
user@R0# set network-services ip

```

2. Configure the interfaces on Device R0, including the loopback interface.

```

[edit interfaces]
user@R0# set ge-0/0/0 unit 0 family inet address 172.16.0.1/16
user@R0# set ge-0/0/0 unit 0 family mpls
user@R0# set ge-0/0/1 unit 0 family inet address 172.18.0.1/16
user@R0# set ge-0/0/1 unit 0 family mpls
user@R0# set ge-0/0/2 unit 0 family inet address 172.17.0.1/16
user@R0# set ge-0/0/2 unit 0 family mpls
user@R0# set ge-0/0/3 unit 0 family inet address 172.30.0.1/16
user@R0# set lo0 unit 0 family inet address 127.0.0.6/8

```

3. Assign the router ID and autonomous system number for Device R0.

```
[edit routing-options]
user@R0# set router-id 127.0.0.6
user@R0# set autonomous-system 64496
```

4. Configure the SRLG definitions.

```
[edit routing-options]
user@R0# set srlg g1 srlg-value 100
user@R0# set srlg g1 srlg-cost 1000
user@R0# set srlg g2 srlg-value 200
user@R0# set srlg g2 srlg-cost 2000
user@R0# set srlg g3 srlg-value 300
user@R0# set srlg g3 srlg-cost 3000
```

5. Configure the extended administrative group definitions.

```
[edit routing-options]
user@R0# set administrative-groups-extended-range minimum 50000
user@R0# set administrative-groups-extended-range maximum 60000
user@R0# set administrative-groups-extended gold group-value 50000
```

6. Configure the administrative group definitions.

```
[edit protocols]
user@R0# set mpls administrative-groups green 0
user@R0# set mpls administrative-groups blue 1
user@R0# set mpls administrative-groups red 2
```

7. Configure MPLS on all the interfaces of Device R0, excluding the management interface.

```
[edit protocols]
user@R0# set mpls interface all
user@R0# set mpls interface fxp0.0 disable
```

8. Assign the interfaces of Device R0 with the configured traffic engineering attributes.

```
[edit protocols]
user@R0# set mpls interface ge-0/0/0.0 srlg g1
user@R0# set mpls interface ge-0/0/0.0 administrative-group green
user@R0# set mpls interface ge-0/0/0.0 administrative-group-extended gold
user@R0# set mpls interface ge-0/0/2.0 srlg g2
user@R0# set mpls interface ge-0/0/2.0 administrative-group red
user@R0# set mpls interface ge-0/0/2.0 administrative-group-extended gold
user@R0# set mpls interface ge-0/0/1.0 srlg g3
user@R0# set mpls interface ge-0/0/1.0 administrative-group blue
user@R0# set mpls interface ge-0/0/1.0 administrative-group-extended gold
```

9. Configure an LSP connecting Device R0 with Device R3, and assign primary and secondary path attributes to the LSP.

```
[edit protocols]
user@R0# set mpls label-switched-path R0-R31 to 127.0.0.3
user@R0# set mpls label-switched-path R0-R31 primary prim
user@R0# set mpls label-switched-path R0-R31 secondary stdby standby
user@R0# set mpls label-switched-path R0-R31 secondary nonstdby
```

10. Define the primary and secondary paths for the R0-R31 LSP.

```
[edit protocols]
user@R0# set mpls path path_primary 172.16.0.2 strict
user@R0# set mpls path path_primary 172.21.0.2 strict
user@R0# set mpls path path_primary 172.24.0.2 strict
user@R0# set mpls path path_ter_nonstdby 172.18.0.1 strict
user@R0# set mpls path path_ter_nonstdby 172.26.0.2 strict
user@R0# set mpls path path_sec_stdby 172.17.0.2 strict
user@R0# set mpls path path_sec_stdby 172.23.0.2 strict
```

11. Create constituent lists with constituent traffic engineering attributes for abstract-hop definitions.

```
[edit protocols]
user@R0# set mpls constituent-list c1 srlg g1
user@R0# set mpls constituent-list c1 administrative-group green
user@R0# set mpls constituent-list c2 administrative-group green
user@R0# set mpls constituent-list c2 administrative-group-extended gold
user@R0# set mpls constituent-list c3 srlg g2
user@R0# set mpls constituent-list c3 administrative-group red
user@R0# set mpls constituent-list c3 administrative-group-extended gold
user@R0# set mpls constituent-list c4 srlg g3
user@R0# set mpls constituent-list c4 administrative-group blue
user@R0# set mpls constituent-list c4 administrative-group-extended gold
```

12. Define abstract hops by assigning the configured constituent lists and respective operators.

```
[edit protocols]
user@R0# set mpls abstract-hop ah1 operator AND
user@R0# set mpls abstract-hop ah1 constituent-list c1 include-all-list
user@R0# set mpls abstract-hop ah1 constituent-list c2 include-all-list
user@R0# set mpls abstract-hop ah2 operator AND
user@R0# set mpls abstract-hop ah2 constituent-list c3 include-all-list
user@R0# set mpls abstract-hop ah3 operator AND
user@R0# set mpls abstract-hop ah3 constituent-list c4 include-all-list
```

13. Define constraints for the configured paths by including abstract hop definitions.

```
[edit protocols]
```

```

user@R0# set mpls path prim ah1 abstract
user@R0# set mpls path prim ah1 strict
user@R0# set mpls path stdby ah2 abstract
user@R0# set mpls path stdby ah2 strict
user@R0# set mpls path nonstdby ah3 abstract
user@R0# set mpls path nonstdby ah3 strict

```

14. Configure RSVP on Device R0. Enable RSVP on all the interfaces of Device R0, excluding the management interface and interface connecting to Host1, and assign bandwidth values.

```

[edit protocols]
user@R0# set rsvp interface all aggregate
user@R0# set rsvp interface fxp0.0 disable
user@R0# set rsvp interface ge-0/0/0.0 bandwidth 80m
user@R0# set rsvp interface ge-0/0/2.0 bandwidth 200m
user@R0# set rsvp interface ge-0/0/1.0 bandwidth 500m

```

15. Configure OSPF on all the interfaces of Device R0, excluding the management interface, and assign traffic engineering capabilities.

```

[edit protocols]
user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface all
user@R0# set ospf area 0.0.0.0 interface fxp0.0 disable

```

16. Configure a policy on Device R0 to enable load balancing on a per-packet basis.

```

[edit policy-options]
user@R0# set forwarding-table export test

```

17. Export the load-balancing policy to the forwarding table.

```

[edit policy-options]
user@R0# set policy-statement test then load-balance per-packet

```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R0# show chassis

## Verification

Confirm that the configuration is working properly.

- [Verifying Abstract Hop Configuration on page 367](#)
- [Verifying Abstract Hop Path Computation on page 368](#)

### Verifying Abstract Hop Configuration

**Purpose** Verify the members of the abstract hop definition on Device R0 by issuing the **show mpls abstract-hop-membership** command, which displays the abstract hop membership tables.

**Action** From operational mode, run the **show mpls abstract-hop-membership** command.

```
user@R0> show mpls abstract-hop-membership
```

**Abstract hop: ah1**

```
Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.1
Address: 127.0.0.2
Address: 127.0.0.3
```

**Abstract hop: ah2**

```
Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.3
Address: 127.0.0.4
```

**Abstract hop: ah3**

```
Credibility: 0
Address: 127.0.0.6
Address: 127.0.0.3
Address: 127.0.0.5
```

**Meaning** The **show mpls abstract-hop-membership** command output provides the abstract hop to traffic engineering database node mapping. The **Credibility** field displays the credibility value associated with the interior gateway protocol in use (OSPF).

---

### Verifying Abstract Hop Path Computation

---

**Purpose** Verify the abstract computation preprocessing for LSPs on Device R0 by issuing the **show mpls lsp abstract-computation** command.

**Action** From operational mode, run the **show mpls lsp abstract-computation** command.

```
user@R0> show mpls lsp abstract-computation

Path computation using abstract hops for LSP: R0-R31
  Path type: Primary, Path name: prim

  Credibility: 0, Total no of CSPF passes: 2
    CSPF pass no: 0
      Start address of the pass: 127.0.0.6
      Destination: 127.0.0.1, State: VALID
      Destination: 127.0.0.2, State: VALID
      Destination: 127.0.0.3, State: VALID
      Affinity: ah1
    CSPF pass no: 1
      Start address of the pass: 127.0.0.1
      Destination: 127.0.0.3, State: VALID
  Path type: Secondary, Path name: nonstdby
  Path type: Standby, Path name: stdby

  Credibility: 0, Total no of CSPF passes: 2
    CSPF pass no: 0
      Start address of the pass: 127.0.0.6
      Destination: 127.0.0.3, State: VALID
      Destination: 127.0.0.4, State: VALID
      Affinity: ah2
    CSPF pass no: 1
      Start address of the pass: 127.0.0.4
      Destination: 127.0.0.3, State: VALID
```

**Meaning** The **show mpls lsp abstract-hop-computation** command output provides the various computation passes involved per LSP, and the qualifying exit devices for each pass. The command output also gives the affinity per pass, and shows the current start device chosen for the pass. For each viable router (device), the state of backtracking is displayed, where it can either be valid or disqualified.

The **Credibility** field indicates the credibility value associated with the interior gateway protocol in use (OSPF).

## Configuring the Maximum Number of MPLS Labels

For interfaces that you configure for MPLS applications, you can set the maximum number of labels upon which MPLS can operate.

By default, the maximum number of labels is three. You can change the maximum to four labels or five labels for applications that require four or five labels.

**NOTE:** When the maximum number of MPLS labels of an interface is modified, the MPLS interface is bounced. All LDP and RSVP sessions on that interface are restarted, resulting in all LSPs over that interface to flap.

For example, suppose you configure a two-tier carrier-of-carriers VPN service for customers who provide VPN service. A carrier-of-carrier VPN is a two-tiered relationship between a provider carrier (Tier 1 ISP) and a customer carrier (Tier 2 ISP). In a carrier-of-carrier VPN, the provider carrier provides a VPN backbone network for the customer carrier. The customer carrier in turn provides Layer 3 VPN service to its end customers. The customer carrier sends labeled traffic to the provider carrier to deliver it to the next hop on the other side of the provider carrier's network. This scenario requires a three-label stack: one label for the provider carrier VPN, another label for the customer carrier VPN, and a third label for the transport route.

If you add fast reroute service, the PE routers in the provider carrier's network must be configured to support a fourth label (the reroute label). If the customer carrier is using LDP as its signaling protocol and the provider carrier is using RSVP, the provider carrier must support LDP over RSVP tunnel service. This additional service requires an additional label, for a total of five labels.

To the customer carrier, the router it uses to connect to the provider carrier's VPN is a PE router. However, the provider carrier views this device as a CE router.

Table 14 on page 370 summarizes the label requirements.

**Table 14: Sample Scenarios for Using 3, 4, or 5 MPLS Labels**

Number of Labels Required	Scenarios
3	Carrier-of-carriers VPN or a VPN with two labels and fast reroute
4	Combination of carrier-of-carriers and fast reroute
5	Carrier-of-carriers with fast reroute and the customer carrier running LDP, with the provider carrier running RSVP

The system reserves label space when you configure the maximum number of labels on the interface. When you configure features that require MPLS labels, the label push is automatic. You do not need to explicitly push the labels. The transport route can be a static, LDP-signaled, or RSVP-signaled LSP.

This feature is supported on the following devices:

- MX Series 5G Universal Routing Platform
- M120 Multiservice Edge Router
- M320 Multiservice Edge Router with Enhanced III FPCs
- M7i Multiservice Edge Router and M10i Multiservice Edge Router with Enhanced Compact Forwarding Engine Board (CFEB-E)
- T640, T1600, TX Matrix, and TX Matrix Plus routers with Enhanced Scaling FPC1, Enhanced Scaling FP2, Enhanced Scaling FPC3, and Enhanced Scaling FPC4.
- QFX10000 switches.

To configure and monitor the maximum number of labels:

1. Specify the maximum on the logical interface. Apply this configuration to the carrier's PE routers.

```
[edit interfaces ge-0/1/3 unit 0 family mpls]
user@switch# set maximum-labels 5
```

2. Verify the configuration.

```
[edit system]
user@switch# show interfaces ge-0/1/3.0

Logical interface ge-0/1/3.0 (Index 77) (SNMP ifIndex 507)
  Flags: SNMP-Traps Encapsulation: ENET2
  Input packets : 0
  Output packets: 0
  Protocol mpls, MTU: 1480, Maximum labels: 5
  Flags: Is-Primary
```

The command output includes the **Maximum labels: 5** field under the logical interface unit 0.

## Configuring MPLS to Pop the Label on the Ultimate-Hop Router

You can control the label value advertised on the egress router of a label-switched path (LSP). The default advertised label is label 3 (Implicit Null Label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. By enabling ultimate-hop popping, label 0 (IPv4 Explicit Null Label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure MPLS to pop the label on the ultimate-hop router, include the **explicit-null** statement:

```
explicit-null;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

#### Related Documentation

- [MPLS Label Overview on page 329](#)
- [MPLS Label Allocation on page 329](#)

## Advertising Explicit Null Labels to BGP Peers

For the IPv4 (**inet**) family only, BGP peers in a routing group can send an explicit NULL label for a set of connected routes (direct and loopback routes) for the inet labeled-unicast and inet6 labeled-unicast NLRI. By default, peers advertise label 3 (implicit NULL). If the **explicit-null** statement is enabled, peers advertise label 0 (explicit NULL). The explicit NULL labels ensures that labels are always present on packets traversing an MPLS network. If the implicit NULL label is used, the penultimate hop router removes the label and sends the packet as a plain IP packet to the egress router. This might cause issues in queuing the packet properly on the penultimate hop router if the penultimate hop is another vendor's router. Some other vendors queue packets based on the CoS bits in the outgoing label rather than the incoming label.

To advertise an explicit null label, include the following statements in the configuration:

```
family inet {
  labeled-unicast {
    aggregate-label {
      community community-name;
    }
    explicit-null {
      connected-only;
    }
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The **connected-only** statement is required to advertise explicit null labels.

To verify that the explicit NULL label is being advertised for connected routes, use the **show route advertising-protocol bgp *neighbor-address*** command.

## MPLS and Routing Tables

The IGPs and BGP store their routing information in the inet.0 routing table, the main IP routing table. If the **traffic-engineering bgp** command is configured, thereby allowing only BGP to use MPLS paths for forwarding traffic, MPLS path information is stored in a separate routing table, inet.3. Only BGP accesses the inet.3 routing table. BGP uses both inet.0 and inet.3 to resolve next-hop addresses. If the **traffic-engineering bgp-igp** command is configured, thereby allowing the IGPs to use MPLS paths for forwarding traffic, MPLS path information is stored in the inet.0 routing table. (Figure 31 on page 376 and Figure 32 on page 377 illustrate the routing tables in the two traffic engineering configurations.)

*Figure 31: Routing and Forwarding Tables, traffic-engineering bgp*

The inet.3 routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route packets to the destination egress router. BGP uses the inet.3 routing table on the ingress router to help in resolving next-hop addresses.

MPLS also maintains an MPLS path routing table (mpls.0), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Typically, the egress router in an LSP does not consult the mpls.0 routing table. (This router does not need to consult mpls.0 because the penultimate router in the LSP either

changes the packet's label to a value of 0 or pops the label.) In either case, the egress router forwards it as an IPv4 packet, consulting the IP routing table, inet.0, to determine how to forward the packet.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or to determine that this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the inet.0 and inet.3 routing tables, seeking the next hop with the lowest preference. If it finds a next-hop entry with an equal preference in both routing tables, BGP prefers the entry in the inet.3 routing table.

*Figure 32: Routing and Forwarding Tables, traffic-engineering bgp-igp*

Generally, BGP selects next-hop entries in the inet.3 routing table because their preferences are always lower than OSPF and IS-IS next-hop preferences. When you configure LSPs, you can override the default preference for MPLS LSPs, which might alter the next-hop selection process.

When BGP selects a next-hop entry from the inet.3 routing table, it installs that LSP into the forwarding table in the Packet Forwarding Engine, which causes packets destined for that next hop to enter and travel along the LSP. If the LSP is removed or fails, the path is removed from the inet.3 routing table and from the forwarding table, and BGP reverts to using a next hop from the inet.0 routing table.

## MPLS and Traffic Protection

---

Typically, when an LSP fails, the router immediately upstream from the failure signals the outage to the ingress router. The ingress router calculates a new path to the egress router, establishes the new LSP, and then directs the traffic from the failed path to the new path. This rerouting process can be time-consuming and prone to failure. For example, the outage signals to the ingress router might get lost, or the new path might take too long to come up, resulting in significant packet drops. The Junos OS provides several complementary mechanisms for protecting against LSP failures:

- Standby secondary paths—You can configure primary and secondary paths. You configure secondary paths with the **standby** statement. To activate traffic protection, you need to configure these standby paths only on the ingress router. If the primary path fails, the ingress router immediately reroutes traffic from the failed path to the standby path, thereby eliminating the need to calculate a new route and signal a new path. For information about configuring standby LSPs, see [“Configuring Hot Standby of Secondary Paths for LSPs” on page 462](#).
- Fast reroute—You configure fast reroute on an LSP to minimize the effect of a failure in the LSP. Fast reroute enables a router upstream from the failure to route around the failure quickly to the router downstream of the failure. The upstream router then signals the outage to the ingress router, thereby maintaining connectivity before a new LSP is established. For a detailed overview of fast reroute, see [“Fast Reroute Overview” on page 379](#). For information about configuring fast reroute, see [“Configuring Fast Reroute” on page 381](#).
- Link protection—You can configure link protection to help ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails. When link protection is configured for an interface and configured for an LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. For information about configuring link protection, see [“Configuring Link Protection on Interfaces Used by LSPs” on page 687](#).

When standby secondary path, and fast reroute or link protection are configured on an LSP, full traffic protection is enabled. When a failure occurs in an LSP, the router upstream from the failure routes traffic around the failure and notifies the ingress router of the failure. This rerouting keeps the traffic flowing while waiting for the notification to be processed at the ingress router. After receiving the failure notification, the ingress router immediately reroutes the traffic from the patched primary path to the more optimal standby path.

Fast reroute and link protection provide a similar type of traffic protection. Both features provide a quick transfer service and employ a similar design. Fast reroute and link protection are both described in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*. However, you need to configure only one or the other. Although you can configure both, there is little, if any, benefit in doing so.

## Fast Reroute Overview

Fast reroute provides redundancy for an LSP path. When you enable fast reroute, detours are precomputed and preestablished along the LSP. In case of a network failure on the current LSP path, traffic is quickly routed to one of the detours. [Figure 33 on page 379](#) illustrates an LSP from Router A to Router F, showing the established detours. Each detour is established by an upstream node to avoid the link toward the immediate downstream node and the immediate downstream node itself. Each detour might traverse through one or more label-switched routers (or switches) that are not shown in the figure.

Fast reroute protects traffic against any single point of failure between the ingress and egress routers (or switches). If there is a failure in a scaled fast reroute scenario, the devices lose reachability to all the peers that were connected through the failed link. This leads to traffic interruption, as the BGP session among the devices goes down. If there are multiple failures along an LSP, fast reroute itself might fail. Also, fast reroute does not protect against failure of the ingress or egress routers.

**Figure 33: Detours Established for an LSP Using Fast Reroute**

If a node detects that a downstream link has failed (using a link-layer-specific liveness detection mechanism) or that a downstream node has failed (for example, using the RSVP neighbor hello protocol), the node quickly switches the traffic to the detour and, at the same time, signals the ingress router about the link or node failure.

[Figure 34 on page 379](#) illustrates the detour taken when the link between Router B and Router C fails.

**Figure 34: Detour After the Link from Router B to Router C Fails**

If the network topology is not rich enough (there are not enough routers with sufficient links to other routers), some of the detours might not succeed. For example, the detour from Router A to Router C in [Figure 33 on page 379](#) cannot traverse link A-B and Router B. If such a path is not possible, the detour does not occur.

Note that after the node switches traffic to the detour, it might switch the traffic again to a newly calculated detour soon after. This is because the initial detour route might not be the best route. To make rerouting as fast as possible, the node switches traffic onto the initial detour without first verifying that the detour is valid. Once the switch is made, the node recomputes the detour. If the node determines that the initial detour is still valid, traffic continues to flow over this detour. If the node determines that the initial detour is no longer valid, it again switches the traffic to a newly computed detour.

**NOTE:** If you issue `show` commands after the node has switched traffic to the initial detour, the node might indicate that the traffic is still flowing over the original LSP. This situation is temporary and should correct itself quickly.

The time required for a fast-rerouting detour to take effect depends on two independent time intervals:

- Amount of time to detect that there is a link or node failure—This interval depends greatly on the link layer in use and the nature of the failure. For example, failure detection on an SONET/SDH link typically is much faster than on a Gigabit Ethernet link, and both are much faster than detection of a router failure.
- Amount of time required to splice the traffic onto the detour—This operation is performed by the Packet Forwarding Engine, which requires little time to splice traffic onto the detour. The time needed can vary depending on the number of LSPs being switched to detours.

Fast reroute is a short-term patch to reduce packet loss. Because detour computation might not reserve adequate bandwidth, the detours might introduce congestion on the alternate links. The ingress router is the only router that is fully aware of LSP policy constraints and, therefore, is the only router able to come up with adequate long-term alternate paths.

Detours are created by use of RSVP and, like all RSVP sessions, they require extra state and overhead in the network. For this reason, each node establishes at most one detour for each LSP that has fast reroute enabled. Creating more than one detour for each LSP increases the overhead, but serves no practical purpose.

To reduce network overhead further, each detour attempts to merge back into the LSP as soon as possible after the failed node or link. If you can consider an LSP that travels through  $n$  router nodes, it is possible to create  $n - 1$  detours. For instance, in [Figure 35 on page 381](#), the detour tries to merge back into the LSP at Router D instead of at Router E or Router F. Merging back into the LSP makes the detour scalability problem more manageable. If topology limitations prevent the detour from quickly merging back into the LSP, detours merge with other detours automatically.

## Configuring Fast Reroute

Fast reroute provides a mechanism for automatically rerouting traffic on an LSP if a node or link in an LSP fails, thus reducing the loss of packets traveling over the LSP.

To configure fast reroute on an LSP, include the **fast-reroute** statement on the ingress router (or switch):

```
fast-reroute {
  (bandwidth bps | bandwidth-percent percentage);
  (exclude [ group-names ] | no-exclude );
  hop-limit number;
  (include-all [ group-names ] | no-include-all);
  (include-any [ group-names ] | no-include-any);
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

You do not need to configure fast reroute on the LSP's transit and egress routers (or switches). Once fast reroute is enabled, the ingress router (or switch) signals all the downstream routers (or switches) that fast reroute is enabled on the LSP, and each downstream router does its best to set up detours for the LSP. If a downstream router does not support fast reroute, it ignores the request to set up detours and continues to support the LSP. A router that does not support fast reroute will cause some of the detours to fail, but otherwise has no impact on the LSP.

**NOTE:** To enable PFE fast reroute, configure a routing policy statement with the **load-balance per-packet** statement at the [edit policy-options policy-statement *policy-name* then] hierarchy level on each of the routers where traffic might be rerouted. See also [“Configuring Load Balancing Across RSVP LSPs” on page 668](#).

---

By default, no bandwidth is reserved for the rerouted path. To allocate bandwidth for the rerouted path, include either the **bandwidth** statement or the **bandwidth-percent** statement. You can only include one of these statements at a time. If you do not include either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path.

When you include the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. The bandwidth does not need to be identical to that allocated for the LSP.

When you specify a bandwidth percent using the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying the bandwidth percentage by the bandwidth configured for the main traffic-engineered LSP. For information about how to configure the bandwidth for a traffic-engineered LSP, see [“Configuring Traffic-Engineered LSPs” on page 977](#).

Hop-limit constraints define how many more routers a detour is allowed to traverse compared with the LSP itself. By default, the hop limit is set to 6. For example, if an LSP traverses 4 routers, any detour for the LSP can be up to 10 (that is, 4 + 6) router hops, including the ingress and egress routers.

By default, a detour inherits the same administrative (coloring) group constraints as its parent LSP when CSPF is determining the alternate path. Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. If you specify the **include-any** statement when configuring the parent LSP, all links traversed by the alternate session must have at least one color found in the list of groups. If you specify the **include-all** statement when configuring the parent LSP, all links traversed by the alternate session must have all of the colors found in the list of groups. If you specify the **exclude** statement when configuring the parent LSP, none of the links must have a color found in the list of groups. For more information about administrative group constraints, see [“Configuring Administrative Groups for LSPs” on page 429](#).

---

## Detour Merging Process

---

This section describes the process used by a router to determine which LSP to select when the router receives path messages from different interfaces with identical Session

and Sender Template objects. When this occurs, the router needs to merge the path states.

The router employs the following process to determine when and how to merge path states:

- When all the path messages do not include a fast reroute or a detour object, or when the router is the egress of the LSP, no merging is required. The messages are processed according to RSVP traffic engineering.
- Otherwise, the router *must* record the path state in addition to the incoming interface. If the path messages do not share the same outgoing interface and next-hop router, the router considers them to be independent LSPs and does not merge them.
- For all the path messages that share the same outgoing interface and next-hop router, the router uses the following process to select the final LSP:
  - If only one LSP originates from this node, select it as the final LSP.
  - If only one LSP contains a fast reroute object, select it as the final LSP.
  - If there are several LSPs and some of them have a detour object, eliminate those containing a detour object from the final LSP selection process.
  - If several final LSP candidates remain (that is, there are still both detour and protected LSPs), select the LSPs with fast reroute objects.
  - If none of the LSPs have fast reroute objects, select the ones without detour objects. If all the LSPs have detour objects, select them all.
  - Of the remaining LSP candidates, eliminate from consideration those that traverse nodes that other LSPs avoid.
  - If several candidate LSPs still remain, select the one with the shortest explicit route object (ERO) path length. If more than one LSP has the same path length, select one randomly.
- Once the final LSP has been identified, the router must transmit only the path messages that correspond to this LSP. All other LSPs are considered merged at this node.

## Detour Computations

Computing and setting up detours is done independently at each node. On a node, if an LSP has fast reroute enabled and if a downstream link or node can be identified, the router performs a Constrained Shortest Path First (CSPF) computation using the information in the local traffic engineering database. For this reason, detours rely on your IGP supporting traffic engineering extensions. Without the traffic engineering database, detours cannot be established.

CSPF initially attempts to find a path that skips the next downstream node. Attempting to find this path provides protection against downstream failures in either nodes or links. If a node-skipping path is not available, CSPF attempts to find a path on an alternate link to the next downstream node. Attempting to find an alternate link provides protection against downstream failures in links only. Detour computations might not succeed the

first time. If a computation fails, the router recomputes detours approximately once every refresh interval until the computation succeeds. The RSVP metric for each detour is set to a value in the range from 10,000 through 19,999.

## Fast Reroute Path Optimization

---

A fast reroute protection path is nondeterministic. The actual protection path of a particular node depends on the history of the LSP and the network topology when the fast reroute path was computed. The lack of deterministic behavior can lead to operational difficulties and poorly optimized paths after multiple link flaps in a network. Even in a small network, after a few link flaps fast reroute paths can traverse an arbitrarily large number of nodes and can remain in that state indefinitely. This is inefficient and makes the network less predictable.

Fast reroute optimization addresses this deficiency. It provides a global path optimization timer, allowing you to optimize all LSPs that have fast reroute enabled and a detour path up and running. The timer value can be varied depending on the expected RE processing load.

The fast reroute optimization algorithm is based on the IGP metric only. As long as the new path's IGP metric is lower than the old path's, the CSPF result is accepted, even if the new path might be more congested (higher bandwidth utilization) or traverses more hops.

In conformance with RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, when a new path is computed and accepted for fast reroute optimization, the existing detour is destroyed first and then the new detour is established. To prevent traffic loss, detours actively protecting traffic are not optimized.

## Configuring the Optimization Interval for Fast Reroute Paths

---

You can enable path optimization for fast reroute by configuring the fast reroute optimize timer. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

To enable fast reroute path optimization, specify the number of seconds using the `optimize-timer` option for the **fast-reroute** statement:

```
fast-reroute seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsdp]`
- `[edit logical-systems logical-system-name protocols rsdp]`

## Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table

---

By default, a host route toward the egress router is installed in the inet.3 or inet6.3 routing table. (The host route address is the one you configure in the **to** statement.) Installing the host route allows BGP to perform next-hop resolution. It also prevents the host route

from interfering with prefixes learned from dynamic routing protocols and stored in the inet.0 or inet6.0 routing table.

Unlike the routes in the inet.0 or inet6.0 table, routes in the inet.3 or inet6.3 table are not copied to the Packet Forwarding Engine, and hence they cause no changes in the system forwarding table directly. You cannot use the **ping** or **traceroute** command through these routes. The only use for inet.3 or inet6.3 is to permit BGP to perform next-hop resolution. To examine the inet.3 or inet6.3 table, use the **show route table inet.3** or **show route table inet6.3** command.

To inject additional routes into the inet.3 or inet6.3 routing table, include the **install** statement:

```
install {
  destination-prefix <active>;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

The specified routes are installed as aliases into the routing table when the LSP is established. Installing additional routes allows BGP to resolve next hops within the specified prefix and to direct additional traffic for these next hops to a particular LSP.

Including the **active** option with the **install** statement installs the specified prefix into the inet.0 or inet6.0 routing table, which is the primary forwarding table. The result is a route that is installed in the forwarding table any time the LSP is established, which means you can ping or trace the route. Use this option with care, because this type of prefix is very similar to a static route.

You use alias routes for routers that have multiple addresses being used as BGP next hops, or for routers that are not MPLS capable. In either of these cases, the LSP can be configured to another MPLS capable system within the local domain, which then acts as a “border” router. The LSP then terminates on the border router and, from that router, Layer 3 forwarding takes the packet to the true next-hop router.

In the case of an interconnect, the domain's border router can act as the proxy router and can advertise the prefix for the interconnect if the border router is not setting the BGP next hop to itself.

In the case of a point of presence (POP) that has routers that do not support MPLS, one router (for example, a core router) that supports MPLS can act as a proxy for the entire POP and can inject a set of prefixes that cover the POP. Thus, all routers within the POP can advertise themselves as interior BGP (IBGP) next hops, and traffic can follow the

LSP to reach the core router. This means that normal IGP routing would prevail within the POP.

You cannot use the **ping** or **traceroute** commands on routes in the inet.3 or inet6.3 routing table.

For BGP next-hop resolution, it makes no difference whether a route is in inet.0/inet6.0 or inet.3/inet6.3; the route with the best match (longest mask) is chosen. Among multiple best-match routes, the one with the highest preference value is chosen.

**NOTE:** The install *destination-prefix* active statement is not supported on static LSPs. When the install *destination-prefix* active statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

## Constrained-Path LSP Computation

---

The Constrained Shortest Path First (CSPF) algorithm is an advanced form of the shortest-path-first (SPF) algorithm used in OSPF and IS-IS route computations. CSPF is used in computing paths for LSPs that are subject to multiple constraints. When computing paths for LSPs, CSPF considers not only the topology of the network, but also the attributes of the LSP and the links, and it attempts to minimize congestion by intelligently balancing the network load.

The constraints that CSPF considers include:

- LSP attributes
  - Administrative groups (that is, link color requirements)
  - Bandwidth requirements
  - Explicit route (strict or loose)
  - Hop limitations
  - Priority (setup and hold)
- Link attributes
  - Administrative groups (that is, link colors assigned to the link)
  - Reservable bandwidth of the links (static bandwidth minus the currently reserved bandwidth)

The data that CSPF considers comes from the following sources:

- Traffic engineering database—Provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors. For the CSPF algorithm

to perform its computations, a link-state IGP (such as OSPF or IS-IS) with special extensions is needed. For CSPF to be effective, the link-state IGP on all routers must support the special extensions. While building the topology database, the extended IGP must take into consideration the current LSPs and must flood the route information everywhere. Because changes in the reserved link bandwidth and link color cause database updates, an extended IGP tends to flood more frequently than a normal IGP. See [Figure 36 on page 387](#) for a diagram of the relationships between these components.

- **Currently active LSPs**—Includes all the LSPs that should originate from the router and their current operational status (up, down, or timeout).

**Figure 36: CSPF Computation Process**

This section discusses the following topics:

- [How CSPF Selects a Path on page 387](#)
- [CSPF Path Selection Tie-Breaking on page 388](#)
- [Computing CSPF Paths Offline on page 389](#)

## How CSPF Selects a Path

To select a path, CSPF follows certain rules. The rules are as follows:

1. Computes LSPs one at a time, beginning with the highest priority LSP (the one with the lowest setup priority value). Among LSPs of equal priority, CSPF services the LSPs in alphabetical order of the LSP names.
2. Prunes the traffic engineering database of all the links that are not full duplex and do not have sufficient reservable bandwidth.
3. If the LSP configuration includes the **include** statement, prunes all links that do not share any included colors.
4. If the LSP configuration includes the **exclude** statement, prunes all links that contain excluded colors. If the link does not have a color, it is accepted.
5. If several paths have equal cost, chooses the one whose last-hop address is the same as the LSP's destination.

6. If several equal cost paths remain, selects the one with the fewest number of hops.
7. If several equal-cost paths remain, applies the CSPF load-balancing rule configured on the LSP (least fill, most fill, or random).

CSPF finds the shortest path toward the LSP's egress router, taking into account explicit-path constraints. For example, if the path must pass through Router A, two separate SPF computations are performed, one from the ingress router to Router A, the other from Router A to the egress router. All CSPF rules are applied to both computations.

- Related Documentation**
- [Configuring CSPF Tie Breaking on page 389](#)
  - [CSPF Path Selection Tie-Breaking on page 388](#)

---

## CSPF Path Selection Tie-Breaking

If more than one path is still available after the CSPF rules ([“How CSPF Selects a Path” on page 387](#)) have been applied, a tie-breaking rule is applied to choose the path for the LSP. The rule used depends on the configuration. There are three tie-breaking rules:

- **Random**—One of the remaining paths is picked at random. This rule tends to place an equal number of LSPs on each link, regardless of the available bandwidth ratio. This is the default behavior.
- **Least fill**—The path with the largest minimum available bandwidth ratio is preferred. This rule tries to equalize the reservation on each link.
- **Most fill**—The path with the smallest minimum available bandwidth ratio is preferred. This rule tries to fill a link before moving on to alternative links.

The following definitions describe how a figure for minimum available bandwidth ratio is derived for the least fill and most fill rules:

- Reservable bandwidth = bandwidth of link x subscription factor of link
- Available bandwidth = reservable bandwidth – (sum of the bandwidths of the LSPs traversing the link)
- Available bandwidth ratio = available bandwidth/reservable bandwidth
- Minimum available bandwidth ratio (for a path) = the smallest available bandwidth ratio of the links in a path

**NOTE:** For the least fill or most fill behaviors to be used, the paths must have their bandwidth (specified using the `bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level) or minimum bandwidth (specified using the `minimum-bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name auto-bandwidth]` hierarchy level) configured to a value greater than 0. If the bandwidth or minimum bandwidth for the paths is either not configured or configured as 0, the minimum available bandwidth cannot be calculated and the random path selection behavior is used instead.

## Computing CSPF Paths Offline

The Junos OS provides online, real-time CSPF computation only; each router performs CSPF calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status.

To optimize links globally across the network, you can use an offline tool to perform the CSPF calculations and determine the paths for the LSPs. You can create such a tool yourself, or you can modify an existing network design tool to perform these calculations. You should run the tool periodically (daily or weekly) and download the results into the router. An offline tool should take the following into account when performing the optimized calculations:

- All the LSP's requirements
- All link attributes
- Complete network topology

## Configuring CSPF Tie Breaking

When selecting a path for an LSP, CSPF uses a tie-breaking process if there are several equal-cost paths. For information about how CSPF selects a path, see [“How CSPF Selects a Path” on page 387](#).

You can configure one of the following statements (you can only configure one of these statements at a time) to alter the behavior of CSPF tie-breaking:

- By default, a random tie-breaking rule for CSPF is used to select a path from the set of equal-cost paths. However, you can also explicitly configure this behavior using the **random** statement:

```
random;
```

- To prefer the path with the least-utilized links, include the **least-fill** statement:

```
least-fill;
```

- To prefer the path with the most-utilized links, include the **most-fill** statement:

```
most-fill;
```

You can include each of these statements at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]

**Related  
Documentation**

- [How CSPF Selects a Path on page 387](#)

## Disabling Constrained-Path LSP Computation

---

If the IGP is a link-state protocol (such as IS-IS or OSPF) and supports extensions that allow the current bandwidth reservation on each router's link to be reported, constrained-path LSPs are computed by default.

The Junos implementations of IS-IS and OSPF include the extensions that support constrained-path LSP computation.

- IS-IS—These extensions are enabled by default. To disable this support, include the **disable** statement at the [edit protocols isis traffic-engineering] hierarchy level, as discussed in the *Junos OS Routing Protocols Library*.
- OSPF—These extensions are disabled by default. To enable this support, include the **traffic-engineering** statement in the configurations of all routers running OSPF, as described in the *Junos OS Routing Protocols Library*.

If IS-IS is enabled on a router or you enable OSPF traffic engineering extensions, MPLS performs the constrained-path LSP computation by default. For information about how constrained-path LSP computation works, see [“Constrained-Path LSP Computation” on page 386](#).

Constrained-path LSPs have a greater chance of being established quickly and successfully for the following reasons:

- The LSP computation takes into account the current bandwidth reservation.
- Constrained-path LSPs reroute themselves away from node failures and congestion.

When constrained-path LSP computation is enabled, you can configure the LSP so that it is periodically reoptimized, as described in [“Optimizing Signaled LSPs” on page 437](#).

When an LSP is being established or when an existing LSP fails, the constrained-path LSP computation is repeated periodically at the interval specified by the retry timer until the LSP is set up successfully. Once the LSP is set up, no recomputation is done. For more information about the retry timer, see [“Configuring the Connection Between Ingress and Egress Routers” on page 419](#).

By default, constrained-path LSP computation is enabled. You might want to disable constrained-path LSP computation when all nodes do not support the necessary traffic engineering extensions. To disable constrained-path LSP computation, include the **no-cspf** statement:

```
no-cspf;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you disable constrained-path LSP computation on LSPs by configuring the **no-cspf** statement and then attempt to advertise other LSPs with lower metrics than the IGPs from this router in either IS-IS or OSPF, new LSPs cannot be established.

## Configuring Load Balancing Based on MPLS Labels

Load balancing occurs on a per-packet basis for MPLS flows on supported platforms. Entropy, or random distribution, is essential for the uniform distribution of packets to their next hops. By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across a set of equal-cost label switched paths (LSPs).

To ensure entropy for VPLS & VPWS traffic, Junos OS can create a hash based on data from the IP header and as many as three MPLS labels (the so-called top labels).

In some cases, as the number of network feature that use labels grows (such as MPLS Fast Reroute, and RFC 3107, RSVP and VPN) data in the top three labels can become static and thus not a sufficient source for entropy. Load balancing can become skewed as a result, or the incidence of out-of-order packet delivery may rise. For these cases, labels from the bottom of the label stack can be used (see Table 1, below for qualifications). Top labels and bottom labels cannot be used at the same time.

**NOTE:** MPC cards do not support the regular hash key configuration. For the MPC-based hash key configuration to be effective, you need an **enhanced-hash-key** configuration.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

An LSP tends to load-balance its placement by randomly selecting one of the equal-cost next hops and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces as well as multiple equal-cost MPLS next hops. In addition, on the T Series, MX Series, M120, and M320 routers only, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

To load-balance based on the MPLS label information, configure the **family mpls** statement:

```
[edit forwarding-options hash-key]
family mpls {
  all-labels;
  bottom-label-1;
  bottom-label-2;
  bottom-label-3;
  label-1;
  label-2;
  label-3;
  no-labels;
  no-label-1-exp;
  payload {
    ether-pseudowire;
    ip {
      disable;
      layer-3-only;
      port-data {
        destination-lsb;
        destination-msb;
        source-lsb;
        source-msb;
      }
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit forwarding-options hash-key]

[Table 15 on page 393](#) provides detailed information about all of the possible MPLS LSP load-balancing options.

Table 15: MPLS LSP Load Balancing Options

Statement	Supported Platforms	MPLS LSP Load Balancing Options
<b>all-labels</b>	PTX Series	Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This value is set by default.
<b>bottom-label-1</b>	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the bottom-most label for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
<b>bottom-label-2</b>	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the second label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
<b>bottom-label-3</b>	MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120.	Uses the third label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.
<b>label-1</b>	M Series, MX Series, T Series	Include the first label in the hash key. Use this option for single label packets.
<b>label-2</b>	M Series, MX Series, T Series	Include the second label in the hash key. You must also configure the <b>label-1</b> option. The entire first label and the first 16 bits of the second label are used in the hash key.
<b>label-3</b>	M Series, MX Series, T Series	Include the third label in the hash key. You must also configure the <b>label-1</b> option and the <b>label-2</b> option.
<b>no-labels</b>	All	Excludes MPLS labels from the hash key.
<b>no-label-1-exp</b>	M Series, MX Series, T Series	Excludes the EXP bit of the top label from the hash key. You must also configure the <b>label-1</b> option.  For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem.
<b>payload</b>	All	Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Router, this value is set by default.
<b>disable</b>	PTX Series	Exclude IP payload from the hash key.
<b>ether-pseudowire</b>	M120, M320, MX Series, T Series	Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
<b>ip</b>	All	Include the IPv4 or IPv6 address in the hash key. You must also configure either <b>label-1</b> or <b>no-labels</b> .
<b>layer-3-only</b>	All	Include only the Layer 3 IP information in the hash key. Excludes all of the <b>port-data</b> bytes from the hash key.

Table 15: MPLS LSP Load Balancing Options (continued)

Statement	Supported Platforms	MPLS LSP Load Balancing Options
<b>port-data</b>	M Series, MX Series, T Series	Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the <b>source-msb</b> , <b>source-lsb</b> , <b>destination-msb</b> , and <b>destination-lsb</b> options at the <b>[edit forwarding-options hash-key family mpls payload ip port-data]</b> hierarchy level. To prevent all four bytes from being hashed, include the <b>layer-3-only</b> statement at the <b>[edit forwarding-options hash-key family mpls payload ip]</b> hierarchy level.
<b>destination-lsb</b>	M Series, MX Series, T Series	Include the least significant byte of the destination port in the hash key. Can be combined with any of the other <b>port-data</b> options.
<b>destination-msb</b>	M Series, MX Series, T Series	Include the most significant byte of the destination port in the hash key. Can be combined with any of the other <b>port-data</b> options.
<b>source-lsb</b>	M Series, MX Series, T Series	Include the least significant byte of the source port in the hash key. Can be combined with any of the other <b>port-data</b> options.
<b>source-msb</b>	M Series, MX Series, T Series	Include the most significant byte of the source port in the hash key. Can be combined with any of the other <b>port-data</b> options.

The following examples illustrate ways in which you can configure MPLS LSP load balancing:

- To include the IP address as well as the first label in the hash key:
  - For M Series, MX Series, and T Series routers, configure the **label-1** statement and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
payload {
  ip;
}
```

- For PTX Series Packet Transport Routers, the **all-labels** and **ip payload** options are configured by default, so no configuration is necessary.
- (M320 and T Series routers only) To include the IP address as well as both the first and second labels in the hash key, configure the **label-1** and **label-2** options and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
payload {
  ip;
}
```

**NOTE:** You can include this combination of statements on M320 and T Series routers only. If you include them on an M Series Multiservice Edge Router, only the first MPLS label and the IP payload are used in the hash key.

- For T Series routers, ensure proper load balancing by including the **label-1**, **label-2**, and **label-3** options at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

- (M Series, MX Series, and T Series routers only) For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem. To exclude the EXP bit of the first label from the hash calculations, include the **no-label-1-exp** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
no-label-1-exp;
payload {
  ip;
}
```

## Configuring Load Balancing Based on MPLS Labels on ACX Series Routers

ACX Series routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops. This feature is enabled on supported platforms by default and requires no configuration.

Load balancing is used to evenly distribute traffic when there is a single next hop over an aggregated interface or a LAG bundle. Load balancing using MPLS labels is supported only for LAG interfaces and not for equal-cost multipath (ECMP) links.

By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across interfaces in an aggregated Ethernet (ae) interface.

An LSP tends to load-balance its placement by randomly selecting one of the interfaces in an **ae-** interface bundle and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

To load-balance based on the MPLS label information, configure the **family mpls** statement:

```
[edit forwarding-options hash-key]
family mpls {
  all-labels;
  label-1;
  label-2;
  label-3;
  no-labels;
  payload {
    ether-pseudowire;
    ip {
      layer-3-only;
      port-data {
        destination-lsb;
        destination-msb;
        source-lsb;
        source-msb;
      }
    }
  }
}
```

You can include this statement at the **[edit forwarding-options hash-key]** hierarchy level.

**NOTE:** When you configure payload ip (**user@host# set forwarding-options hash-key family mpls payload ip**), configuring **layer-3-only** and **port-data** is mandatory.

Load balancing functionality, without proper hash-keys configuration, may result in an unpredictable behavior.

For Layer 2 VPN/pseudowire tunnel termination, upto two labels are used for hashing and payload MAC destination and source addresses can be optionally selected. These controls can be used to support ether-pseudowire knob in family mpls under hash-key configuration shown above. However, since ACX2000 and ACX4000 also support TDM pseudowires, the ether-pseudowire knobs needs to be used only when TDM pseudowires are not being used.

For Layer 3 VPN tunnel termination, upto two labels are used for hasing and payload IP source and destination addresses and Layer 4 source and destination ports can be optionally selected. These controls can be used for supporting ip port-data knobs in family mpls under hash-key configuration shown above. However, since Layer 4 port MSB and LSB cannot be individually selected, one of destination-lsb or destination-msb

knobs or one of source-lsb or source-msb knobs would select Layer 4 destination or source ports, respectively.

For LSR case, upto three labels are used for hashing. If a BOS is seen when parsing the first three labels, BCM examines the first nibble of payload – if the nibble is 4, the payload is treated as IPv4 and if the first nibble is 6, the payload is treated as IPv6 and in such cases payload source and destination IP addresses can be speculatively used for hashing. These controls can be used for supporting ip port-data knobs in family mpls under hash-key configuration. However, Layer 4 ports cannot be used for hashing in LSR case, and only layer-3-only knob is applicable. BCM does not claim support for hashing on fields beyond the three MPLS labels. Load Balancing for a single pseudowire session does not take place in case of LSR as all the traffic specific to that session will carry the same set of MPLS labels.

Load balancing on LSR AE interfaces can be achieved for a higher number of MPLS sessions, that is minimum of 10 sessions. This is applicable for CCC/VPLS/L3VPN. In case of Layer 3 VPN, the traffic may not be equally distributed across the member links as the layer 3 addresses also get accounted for (along with the labels) for the hash input function.

For LER scenarios, in case of ACX5048 and ACX5096, hashing based on Layer 3 and Layer 4 fields is possible by configuring the payload option under the “family mpls” hierarchy. Hashing on the LER is not be based on Labels. For Layer 3 service, it is mandatory to mention the payload as “layer-3-only” and specify “port-data” in case of Layer 4 service. You can also mention the label count while configuring hash-keys on LER routers.

**NOTE:** LER and LSR load balancing behavior is applicable for CCC/VPLS/Layer 3 VPN and other IP MPLS scenarios.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces. In addition, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

[Table 15 on page 393](#) provides detailed information about all of the possible MPLS LSP load-balancing options.

**Table 16: MPLS LSP Load Balancing Options**

Statement	MPLS LSP Load Balancing Options
<b>label-1</b>	Include the first label in the hash key. Use this option for single label packets.
<b>label-2</b>	Include the second label in the hash key. You must also configure the <b>label-1</b> option. The entire first label and the first 16 bits of the second label are used in the hash key.
<b>label-3</b>	Include the third label in the hash key. You must also configure the <b>label-1</b> option and the <b>label-2</b> option.
<b>no-labels</b>	Excludes MPLS labels from the hash key.

Table 16: MPLS LSP Load Balancing Options (continued)

Statement	MPLS LSP Load Balancing Options
<b>payload</b>	Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Switch, this value is set by default.
<b>disable</b>	Exclude IP payload from the hash key.
<b>ether-pseudowire</b>	Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
<b>ip</b>	Include the IPv4 or IPv6 address in the hash key. You must also configure either <b>label-1</b> or <b>no-labels</b> .
<b>layer-3-only</b>	Include only the Layer 3 IP information in the hash key. Excludes all of the <b>port-data</b> bytes from the hash key.
<b>port-data</b>	Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the <b>source-msb</b> , <b>source-lsb</b> , <b>destination-msb</b> , and <b>destination-lsb</b> options at the <b>[edit forwarding-options hash-key family mpls payload ip port-data]</b> hierarchy level. To prevent all four bytes from being hashed, include the <b>layer-3-only</b> statement at the <b>[edit forwarding-options hash-key family mpls payload ip]</b> hierarchy level.
<b>destination-lsb</b>	Include the least significant byte of the destination port in the hash key. Can be combined with any of the other <b>port-data</b> options.
<b>destination-msb</b>	Include the most significant byte of the destination port in the hash key. Can be combined with any of the other <b>port-data</b> options.
<b>source-lsb</b>	Include the least significant byte of the source port in the hash key. Can be combined with any of the other <b>port-data</b> options.
<b>source-msb</b>	Include the most significant byte of the source port in the hash key. Can be combined with any of the other <b>port-data</b> options.

To include the IP address as well as the first label in the hash key, configure the **label-1** statement and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
payload {
  ip;
}
```

To include the IP address as well as both the first and second labels in the hash key, configure the **label-1** and **label-2** options and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
payload {
```

```
ip;
}
```

Ensure proper load balancing by including the **label-1**, **label-2**, and **label-3** options at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

## Example: Configuring a Constrained-Path LSP for Which Junos OS Makes All Forwarding Decisions

On the ingress router, create a constrained-path LSP in which the Junos OS makes all the forwarding decisions. When the LSP is successfully set up, a route toward 10.1.1.1/32 is installed in the inet.3 table so that all BGP routes with matching BGP next-hop addresses can be forwarded through the LSP.

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  rsvp {
    interface so-0/0/0;
  }
  mpls {
    label-switched-path to-hastings {
      to 10.1.1.1;
    }
    interface so-0/0/0;
  }
}
```

## Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most Forwarding Decisions and Considers Hop Constraints

On the ingress router, create a constrained-path LSP in which the Junos OS makes most of the forwarding decisions, taking into account the hop constraints listed in the **path** statements. The LSP is adaptive so that no bandwidth double-counting occurs on links shared by primary and secondary paths. To acquire the necessary link bandwidth, this

LSP is allowed to preempt lower priority sessions. Finally, this path always keeps the secondary path in hot-standby state for quick failover.

```
[edit protocols]
mpls {
  path to-hastings {
    14.1.1.1 loose;
  }
  path alt-hastings {
    12.1.1.1 loose;
    11.1.1.1 strict;
  }
  label-switched-path hastings {
    to 11.1.1.1;
    bandwidth 10m; # Reserve 10 Mbps
    priority 0 0; # Preemptive, but not preemptable
    adaptive; # Set adaptivity
    primary to-hastings;
    secondary alt-hastings {
      standby;
      bandwidth 1m; # Reserve only 1 Mbps for the secondary path
    }
  }
}
interface all;
```

### Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most Forwarding Decisions and the Secondary Path Is Explicit

On the ingress router, create a constrained-path LSP in which the Junos OS makes most of the forwarding decisions for the primary path, subject to constraints of the path **to-hastings**, and in which the secondary path is an explicit path. The primary path must transit green or yellow links and must stay away from red links. The primary path is periodically recomputed and reoptimized. Finally, this path always keeps the secondary path in hot-standby state for quick failover.

When the LSP is up—either because the primary or secondary path is up, or because both paths are up—the prefix 16.0.0.0/8 is installed in the inet.3 table so that all BGP routes whose BGP next hop falls within that range can use the LSP. Also, the prefix 17.0.0.0/8 is installed in the inet.0 table so that BGP can resolve only its next hop through that prefix. The route also can be reached with the **traceroute** or **ping** command. These two routes are in addition to the 11.1.1.1/32 route.

```
[edit protocols]
mpls {
  admin-groups {
    green 1;
    yellow 2;
    red 3;
  }
  path to-hastings {
    14.1.1.1 loose;
```

```

}
path alt-hastings {
  14.1.1.1 strict;
  13.1.1.1 strict;
  12.1.1.1 strict;
  11.1.1.1 strict;
}
label-switched-path hastings {
  to 11.1.1.1;
  bandwidth 100m;
  install 16.0.0.0/8; # in inet.3; cannot use to traceroute or ping
  install 17.0.0.0/8 active; # installed in inet.0; can use to traceroute or ping
  primary to-hastings {
    admin-group { # further constraints for path computation
      include-all [ green yellow ];
      exclude red;
    }
    optimize-timer 3600; # reoptimize every hour
  }
  secondary alt-hastings {
    standby;
    no-cspf; # do not perform constrained-path computation
  }
}
interface all;

```

## Path Computation for LSPs on an Overloaded Router

Setting the overload bit in a router running IS-IS causes it to appear overloaded and prevents it from being used for transit traffic. Any new MPLS LSPs, including RSVP-signaled or LDP-signaled LSPs, are re-routed away from an overloaded router. In the case of RSVP, this behavior applies to both Constrained Shortest Path First (CSPF) and non-CSPF LSPs. However, this behavior does not apply to new or existing bypass LSPs. Bypass LSPs are recalculated only when a different event triggers a path recalculation. For example, if you set the smart optimize timer with the [smart-optimize-timer](#) statement, the bypass LSP is rerouted away from the overloaded router only after the specified time elapses. Otherwise, the bypass LSP continues to transit the overloaded router.

You cannot establish any new transit LSPs through an overloaded router. However, you can configure ingress and egress LSPs through an overloaded router.

**NOTE:** When you set the overload bit on an IS-IS router, any new LSPs transiting through it are recomputed and re-routed away from it. However, existing CSPF LSPs remain active and are not torn down.

An example of when you might want to establish transit LSPs through an overloaded router is illustrated in [Figure 37 on page 402](#), which shows an aggregation router (Router A) dual-homed on two core routers (Router B and Router C). You want to include the aggregation router in the LSP mesh, but transit LSPs should not pass through it,

because it is a less capable router with relatively low-bandwidth uplinks to the core. Certain failure and rerouting scenarios could make it impossible for the aggregation router to establish some of its LSPs. Consequently, you run the router in a steady state with the overload bit set, but you are still able to establish ingress and egress LSPs through it.

**Figure 37: Aggregation Router A Dual-Homed on Core Routers B and C**

## Computing Backup Paths for LSPs Using Fate Sharing

Fate sharing allows you to create a database of information that CSPF uses to compute one or more backup paths to use in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. You can specify one or more elements within a group.

Through fate sharing, you can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible, to ensure that if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path, ensuring that a single point of failure will not affect the primary and backup paths simultaneously.

## Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts

Link-state protocols, such as OSPF and IS-IS, use the shortest-path-first (SPF) algorithm to compute the shortest-path tree to all nodes in the network. The results of such computations can be represented by the destination node, next-hop address, and output interface, where the output interface is a physical interface. Label-switched paths (LSPs) can be used to augment the SPF algorithm.

IGP typically performs two independent computations. The first is performed without considering any LSP. The result of the computation is stored in the inet.0 table. This step is no different from traditional SPF computations and is always performed even if IGP shortcut is disabled.

The second computation is performed considering only LSPs as a logical interface. Each LSP's egress router is considered. The list of destinations whose shortest path traverses the egress router (established during the first computation) is placed in the inet.3 routing table. These destinations are given the egress router of the LSP as a next hop, enabling BGP on the local router to use these LSPs to access BGP next hops beyond the egress router. Normally, BGP can use only LSPs that terminate at the BGP next hop.

As an illustration, begin with a typical SPF tree (see [Figure 38 on page 403](#)).

*Figure 38: Typical SPF Tree, Sourced from Router A*

If an LSP connects Router A to Router D and if IGP shortcuts are enabled on Router A, you might have the SPF tree shown in [Figure 39 on page 403](#).

*Figure 39: Modified SPF Tree, Using LSP A–D as a Shortcut*

Note that Router D is now reachable through LSP A–D.

When computing the shortest path to reach Router D, Router A has two choices:

- Use IGP path A–B–D.
- Use LSP A–D.

Router A decides between the two choices by comparing the IGP metrics for path A–B–D with the LSP metrics for LSP A–D. If the IGP metric is lower, path A–B–D is chosen ([Figure 38 on page 403](#)). This path A–B–D is valid only when node D is not the tail-end of the LSP. If node D is the tail end of the LSP, even if the LSP metric is lower or both IGP and LSP metrics are equal, LSP A–D is used ([Figure 39 on page 403](#)).

Note that Router E is reachable through LSP A–D and Router F will take the IGP path.

- [IGP Shortcuts and Routing Tables on page 405](#)

## Enabling IGP Shortcuts

IGP shortcuts are supported for both IS-IS and OSPF. A link-state protocol is required for IGP shortcuts. Shortcuts are disabled by default. You can enable IGP shortcuts on a per-router basis; you do not need to enable shortcuts globally. A router's shortcut computation does not depend on another router performing similar computations, and shortcuts performed by other routers are irrelevant.

## LSPs Qualified in IGP Shortcut Computations

Not all LSPs are used in IGP shortcuts. Only those LSPs whose egress point (using the **to** statement) matches the router ID of the egress node are considered. Other LSPs, whose egress point matches the egress node interface address, are ignored in IGP shortcuts.

There are exceptions, however. If an LSP has an alias egress point (using the **install** statement) and it matches certain router IDs, it is included in the shortcut computation as well. If multiple equal metric LSPs destined to the same router ID exist, traffic can load-share among them.

## IGP Shortcut Applications

You can use shortcuts to engineer traffic traveling toward destination nodes that do not support MPLS LSPs. For example, in [Figure 39 on page 403](#), traffic traveling toward Router F enters LSP A–E. You can control traffic between Router A and Router F by manipulating LSP A–E; you do not need to explicitly set up an LSP between Router A and Router F.

In [Figure 40 on page 404](#), all traffic from Region 1 to Region 2 traverses LSP A–B if IGP shortcuts are enabled on the ingress router (Router A), permitting aggregation of interregional traffic into one LSP. To perform traffic engineering on the interregional traffic, you have to manipulate LSP A–B only, which avoids creating  $n^2$  LSPs from all routers in Region 1 to all routers in Region 2 and allows efficient resource controls on the backbone network.

**Figure 40: IGP Shortcuts**

Shortcuts allow you to deploy LSPs into a network in an incremental, hierarchical fashion. In [Figure 41 on page 405](#), each region can choose to implement traffic engineering LSPs independently, without requiring cooperation from other regions. Each region can choose to deploy intraregion LSPs to fit the region's bandwidth needs, at the pace appropriate for the region.

*Figure 41: IGP Shortcuts in a Bigger Network*

When intraregion LSPs are in place, interregional traffic automatically traverses the intraregion LSPs as needed, eliminating the need for a full mesh of LSPs between edge routers. For example, traffic from Router A to Router D traverses LSPs A–B, B–C, and C–D.

## IGP Shortcuts and Routing Tables

IGP typically performs two independent computations. The first is performed without considering any LSP. The result of the computation is stored in the `inet.0` table. This step is no different from traditional SPF computations and is always performed even if IGP shortcut is disabled.

The second computation is performed considering only LSPs as a logical interface. Each LSP's egress router is considered. The list of destinations whose shortest path traverses the egress router (established during the first computation) is placed in the `inet.3` routing table. These destinations are given the egress router of the LSP as a next hop, enabling BGP on the local router to use these LSPs to access BGP next hops beyond the egress router. Normally, BGP can use only LSPs that terminate at the BGP next hop. Note that BGP is the only protocol that uses the `inet.3` routing table. Other protocols will not route traffic through these LSPs.

If traffic engineering for IGP and BGP is enabled (see [“IGP and BGP Destinations” on page 18](#)), IGP moves all routes in `inet.3` into `inet.0`, merging all routes while emptying the `inet.3` table. The number of routes in `inet.0` will be exactly the same as before. Route next-hops can traverse a physical interface, an LSP, or the combination of the two if the metrics are equal.

IGP shortcuts are enabled on a per-node basis. You do not need to coordinate with other nodes.

## IGP Shortcuts and VPNs

You can configure IGP shortcuts for either IS-IS or OSPF. IGP shortcuts allow the IGP to use an LSP as the next hop instead of the IGP route. IGP shortcuts can also be enabled for VPNs by also specifying the `bgp-igp-both-ribs` or `mpls-forwarding` options for the `traffic-engineering` statement at the `[edit protocols mpls]` hierarchy level. VPNs are dependant on routes stored in the `inet.3` routing table. The `bgp-igp` option for the

**traffic-engineering** statement moves all routes from the inet.3 routing table to the inet.0 routing table and is therefore incompatible with VPNs.

  - *traffic-engineering*
  - *OSPF Support for Traffic Engineering*

## Advertising LSPs into IGPs

You can configure your IGP to treat an LSP as a link. IGP shortcuts allow only the ingress router of an LSP to use the LSP in its SPF computation. However, other routers on the network do not know of the existence of that LSP, so they cannot use it. This can lead to suboptimal traffic engineering. In addition, only BGP can use an IGP shortcut to an LSP. When you advertise an LSP as a link into the IGP, all traffic can traverse it, and all routers know about it.

As an example, consider the network shown in [Figure 42 on page 406](#).

**Figure 42: SPF Computations with Advertised LSPs**

Assume that Router A is computing a path to Router D. The link between Router E and Router F has a metric of 20; all other links have a metric of 10. Here, the path chosen by Router A is A–B–C–D, which has a metric of 30, instead of A–E–F–D, which has a metric of 40.

If Router E has an LSP to Router D with a metric of 15, you want traffic from Router A to Router D to use the path A–E–D, which has a metric of 25, instead of the path A–B–C–D. However, because Router A does not know about the LSP between Router E and Router D, it cannot route traffic through this path.

For all routers on the network to know about the LSP between Router E and Router D, you need to advertise it. This advertisement announces the LSP as a unidirectional, point-to-point link in the link-state database, and all routers can compute paths using the LSP. The link-state database maintains information about the AS topology and contains information about the router's local state (for example, the router's usable interfaces and reachable neighbors). In [Figure 42 on page 406](#), Router A will see the link from Router E to Router D and route traffic along this lower-metric path.

Because an LSP is announced as a unidirectional link, you might need to configure a reverse LSP (one that starts at the egress router and ends at the ingress router) so that

the SPF bidirectionality check succeeds. As a step in the SPF computation, IS-IS considers a link from Router E to Router D. Before IS-IS uses any link, it verifies that there is a link from Router D to Router E (there is bidirectional connectivity between router E and D). Otherwise, the SPF computation will not use an announced LSP.

When an LSP is advertised to the IGP, the advertising router uses the LSP as the forwarding path for regular routes after installing them in the inet.0 routing table. All packets traversing the router could be forwarded through the LSP. Conversely, IGP shortcuts are used only to forward packets that are following BGP routes.

**NOTE:** Do not configure IGP shortcuts and advertise LSPs to the IGP at the same time.

## Selecting a Forwarding LSP Next Hop

If more than one LSP tunnel to a BGP next hop exists, the prefixes learned from the BGP next hop are randomly divided among the LSP tunnels. To control which LSP BGP uses to forward data for a given prefix, use the **install-nexthop** statement in the export policy applied to the forwarding table.

## Example: Assigning Different Forwarding Next-Hop LSPs to Different Destination Prefixes

Assign different forwarding next-hop LSPs to different destination prefixes learned from BGP.

```
routing-options {
  router-id 10.10.20.101;
  autonomous-system 2;
  forwarding-table {
    export forwarding-policy;
  }
}
policy-options {
  policy-statement forwarding-policy {
    term one {
      from {
        protocol bgp;
        route-filter 10.1.0.0/16 orlonger;
      }
      then {
        install-nexthop lsp mc-c-lsp-1;
        accept;
      }
    }
  }
}
```

```

term two {
  from {
    protocol bgp;
    route-filter 10.2.0.0/16 orlonger;
  }
  then {
    install-nexthop lsp mc-c-lsp-2;
    accept;
  }
}
term three {
  from {
    protocol bgp;
    route-filter 10.3.0.0/16 orlonger;
  }
  then {
    install-nexthop lsp mc-c-lsp-3;
    accept;
  }
}
}
}
protocols {
  mpls {
    label-switched-path mc-c-lsp-1 {
      from 10.10.20.101;
      to 10.10.20.103;
    }
    label-switched-path mc-c-lsp-2 {
      from 10.10.20.101;
      to 10.10.20.103;
    }
    label-switched-path mc-c-lsp-3 {
      from 10.10.20.101;
      to 10.10.20.103;
    }
  }
}
}

```

## ECMP Flow-Based Forwarding on ACX Series Routers

An equal-cost multipath (ECMP) set is formed when the routing table contains multiple next-hop addresses for the same destination with equal cost. (Routes of equal cost have the same preference and metric values.) If there is an ECMP set for the active route, the Junos OS software uses a hash algorithm to choose *one* of the next-hop addresses in the ECMP set to install in the forwarding table.

You can configure the Junos OS so that multiple next-hop entries in an ECMP set are installed in the forwarding table. On ACX Series routers, per-flow load balancing can be performed to spread traffic across multiple paths between routing devices. ECMP flow-based forwarding is supported for IPv4, IPv6, and MPLS packets on aggregated Ethernet (ae) interfaces.

Load balancing is used to evenly distribute traffic when there are multiple equal-cost next hops over different interfaces or a single next hop over an aggregated interface. By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table.

If a next-hop address is no longer part of the ECMP set or if it is removed from the routing table because of a route change, a flow that uses the next hop is rerouted and the session is not affected. Rerouting of the flow also occurs if there is a configuration change that takes away the next-hop address or if an administrator takes down the next-hop interface without deleting it. If a next-hop address is removed from the routing table because the interface is deleted or the session is intentionally cleared, the session is killed without being rerouted.

To select which packet header data to use for per-flow load balancing, include the **hash-key** statement at the **[edit forwarding-options]** hierarchy level. To load-balance IPv4 traffic by using the port data into the hash key, include the **family-inet** statement at the **[edit forwarding-options hash-key]** hierarchy level. You can incorporate either the Layer 3 IP port data, or the Layer 4 TCP or UDP port data into the hash key. To load-balance based on the MPLS label information, configure the **family mpls** statement at the **[edit forwarding-options hash-key]** hierarchy level.

Forwarding of MPLS traffic by using penultimate-hop popping (PHP) and label-switched routing (LSR) is not supported on ACX Series routers. For ECMP flow-based forwarding over pseudowires, MPLS flows are assigned to one of the ECMP routes by using the hashing algorithm based on user-to-network interface (UNI) index.

To configure ECMP flow-based forwarding on ACX Series routers, first define a load-balancing routing policy by including one or more **policy-statement** configuration statements at the **[edit policy-options]** hierarchy level, with the action **load-balance per-packet**. Then apply the routing policy to routes exported from the routing table to the forwarding table. To do this, include the **forwarding-table** and **export** configuration statements at the **[edit routing-options]** hierarchy level.

To view the details of the ECMP next hops and to obtain information for debugging any problem with the ECMP functionality, issue the **show route** or the **show route summary** command.

The maximum number of next-hop addresses in an ECMP set that can be installed in the forwarding table of ACX Series routers is 16. A maximum of 2047 ECMP next-hops are supported.

## Routers in an LSP

---

Each router in an LSP performs one of the following functions:

- **Ingress router**—The router at the beginning of an LSP. This router encapsulates IP packets with an MPLS Layer 2 frame and forwards it to the next router in the path. Each LSP can have only one ingress router.
- **Egress router**—The router at the end of an LSP. This router removes the MPLS encapsulation, thus transforming it from an MPLS packet to an IP packet, and forwards the packet to its final destination using information in the IP forwarding table. Each LSP can have only one egress router. The ingress and egress routers in an LSP cannot be the same router.
- **Transit router**—Any intermediate router in the LSP between the ingress and egress routers. A transit router forwards received MPLS packets to the next router in the MPLS path. An LSP can contain zero or more transit routers, up to a maximum of 253 transit routers in a single LSP.

A single router can be part of multiple LSPs. It can be the ingress or egress router for one or more LSPs, and it also can be a transit router in one or more LSPs. The functions that each router supports depend on your network design.

## Configuring the Ingress and Egress Router Addresses for LSPs

---

The following sections describe how to specify the addresses of an LSP's ingress and egress routers:

- [Configuring the Ingress Router Address for LSPs on page 412](#)
- [Configuring the Egress Router Address for LSPs on page 412](#)
- [Preventing the Addition of Egress Router Addresses to Routing Tables on page 413](#)

### Configuring the Ingress Router Address for LSPs

The local router always is considered to be the ingress router, which is the beginning of the LSP. The software automatically determines the proper outgoing interface and IP address to use to reach the next router in an LSP.

By default, the router ID is chosen as the address of the ingress router. To override the automatic selection of the source address, specify a source address in the **from** statement:

```
from address;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

The outgoing interface used by the LSP is not affected by the source address that you configure.

### Configuring the Egress Router Address for LSPs

When configuring an LSP, you must specify the address of the egress router by including the **to** statement:

```
to address;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

When you are setting up a signaled LSP, the **to** statement is the only required statement. All other statements are optional.

After the LSP is established, the address of the egress router is installed as a host route in the routing table. This route can then be used by BGP to forward traffic.

To have the software send BGP traffic over an LSP, the address of the egress router is the same as the address of the BGP next hop. You can specify the egress router's address as any one of the router's interface addresses or as the BGP router ID. If you specify a different address, even if the address is on the same router, BGP traffic is not sent over the LSP.

To determine the address of the BGP next hop, use the **show route detail** command. To determine the destination address of an LSP, use the **show mpls lsp** command. To determine whether a route has gone through an LSP, use the **show route** or **show route forwarding-table** command. In the output of these last two commands, the **label-switched-path** or **push** keyword included with the route indicates it has passed through an LSP. Also, use the **traceroute** command to trace the actual path to which the route leads. This is another indication whether a route has passed through an LSP.

You also can manipulate the address of the BGP next hop by defining a BGP import policy filter that sets the route's next-hop address.

## Preventing the Addition of Egress Router Addresses to Routing Tables

You must configure an address using the **to** statement for all LSPs. This address is always installed as a /32 prefix in the inet.3 or inet.0 routing tables. You can prevent the egress router address configured using the **to** statement from being added to the inet.3 and inet.0 routing tables by including the **no-install-to-address** statement.

Some reasons not to install the **to** statement address in the inet.3 and inet.0 routing tables include the following:

- Allow Constrained Shortest Path First (CSPF) RSVP LSPs to be mapped to traffic intended for secondary loopback addresses. If you configure an RSVP tunnel, including the **no-install-to-address** statement, and then configure an **install pfx/ <active>** policy later, you can do the following:
  - Verify that the LSP was set up correctly without impacting traffic.
  - Map traffic to the LSP in incremental steps.
  - Map traffic to the destination loopback address (the BGP next hop) by removing the **no-install-to-address** statement once troubleshooting is complete.
- Prevent CCC connections from losing IP traffic. When an LSP determines that it does not belong to a connection, it installs the address specified with the **to** statement in the inet.3 routing table. IP traffic is then forwarded to the CCC remote endpoint, which can cause some types of PICs to fail.

To prevent the egress router address configured using the **to** statement from being added to the inet.3 and inet.0 routing tables, include the **no-install-to-address** statement:

```
no-install-to-address;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit protocols mpls [static-label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [static-label-switched-path](#) *lsp-name*]

## Configuring the Ingress Router for MPLS-Signaled LSPs

---

MPLS-signaled label-switched paths (LSPs) run from a specific ingress router to a specific egress router. For basic MPLS-signaled LSP function, you must configure the ingress router, but do not have to configure any other routers.

To configure signaled LSPs, perform the following tasks on the ingress router:

- [Creating Named Paths on page 414](#)
- [Configuring Alternate Backup Paths Using Fate Sharing on page 416](#)

### Creating Named Paths

To configure signaled LSPs, you must first create one or more named paths on the ingress router. For each path, you can specify some or all transit routers in the path, or you can leave it empty.

Each pathname can contain up to 32 characters and can include letters, digits, periods, and hyphens. The name must be unique within the ingress router. Once a named path is created, you can use the named path with the **primary** or **secondary** statement to configure LSPs at the [edit protocols mpls [label-switched-path](#) *label-path-name*] hierarchy level. You can specify the same named path on any number of LSPs.

To determine whether an LSP is associated with the primary or secondary path in an RSVP session, issue the [show rsvp session detail](#) command.

To create an empty path, create a named path by including the following form of the **path** statement. This form of the **path** statement is empty, which means that any path between the ingress and egress routers is accepted. In actuality, the path used tends to be the same path as is followed by destination-based, best-effort traffic.

```
path path-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

To create a path in which you specify some or all transit routers in the path, include the following form of the **path** statement, specifying one address for each transit router:

```
path path-name {
```

```
(address | hostname) <strict | loose>;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

In this form of the **path** statement, you specify one or more transit router addresses. Specifying the ingress or egress routers is optional. You can specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path up to the egress router (optional) or the router immediately before the egress router. You need to specify only one address per router hop. If you specify more than one address for the same router, only the first address is used; the additional addresses are ignored and truncated.

For each router address, you specify the type, which can be one of the following:

- **strict**—(Default) The route taken from the previous router to this router is a direct path and cannot include any other routers. If **address** is an interface address, this router also ensures that the incoming interface is the one specified. Ensuring that the incoming interface is the one specified is important when there are parallel links between the previous router and this router. It also ensures that routing can be enforced on a per-link basis.

For strict addresses, you must ensure that the router immediately preceding the router you are configuring has a direct connection to that router. The address can be a loopback interface address, in which case the incoming interface is not checked.

- **loose**—The route taken from the previous router to this router need not be a direct path, can include other routers, and can be received on any interface. The address can be any interface address or the address of the loopback interface.

### Examples: Creating Named Paths

Configure a path, **to-hastings**, to specify the complete strict path from the ingress to the egress routers through 14.1.1.1, 13.1.1.1, 12.1.1.1, and 11.1.1.1, in that order. There cannot be any intermediate routers except the ones specified. However, there can be intermediate routers between 11.1.1.1 and the egress router because the egress router is not specifically listed in the **path** statement. To prevent intermediate routers before egress, configure the egress router as the last router, with a **strict** type.

```
[edit protocols mpls]
path to-hastings {
  14.1.1.1 strict;
  13.1.1.1 strict;
  12.1.1.1 strict;
  11.1.1.1 strict;
}
```

Create a path, **alt-hastings**, to allow any number of intermediate routers between routers 14.1.1.1 and 11.1.1.1. In addition, intermediate routers are permitted between 11.1.1.1 and the egress router.

```
[edit protocols mpls]
path alt-hastings {
  14.1.1.1 strict;
  11.1.1.1 loose;
}
```

## Configuring Alternate Backup Paths Using Fate Sharing

You can create a database of information that Constrained Shortest Path First (CSPF) uses to compute one or more backup paths in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. Because these network elements share the same fate, this relationship is called fate sharing.

You can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible to ensure that, if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path. This ensures that a single point of failure will not affect the primary and backup paths at the same time.

The following sections describe how to configure fate sharing and how it affects CSPF, and provides a fate sharing configuration example:

- [Configuring Fate Sharing on page 416](#)
- [Implications for CSPF on page 417](#)
- [Implications for CSPF When Fate Sharing with Bypass LSPs on page 418](#)
- [Example: Configuring Fate Sharing on page 418](#)

### Configuring Fate Sharing

---

To configure fate sharing, include the **fate-sharing** statement:

```
fate-sharing {
  group group-name {
    cost value;
    from address <to address>;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Each fate-sharing group must have a name, which can be up to 32 characters long and can contain letters, digits, periods (.) and hyphens (-). You can define up to 512 groups.

Fate-sharing groups contain three types of objects:

- Point-to-point links—Identified by the IP addresses at each end of the link. Unnumbered point-to-point links are typically identified by borrowing IP addresses from other interfaces. Order is not important; **from 1.2.3.4 to 1.2.3.5** and **from 1.2.3.5 to 1.2.3.4** have the same meaning.
- Non-point-to-point links—Include links on a LAN interface (such as Gigabit Ethernet interfaces) or nonbroadcast multiaccess (NBMA) interfaces (such as Asynchronous Transfer Mode [ATM] or Frame Relay). You identify these links by their individual interface address. For example, if the LAN interface **192.168.200.0/24** has four routers attached to it, each router link is individually identified:

```
from 192.168.200.1; # LAN interface of router 1
from 192.168.200.2; # LAN interface of router 2
from 192.168.200.3; # LAN interface of router 3
from 192.168.200.4; # LAN interface of router 4
```

You can list the addresses in any order.

- A router node—Identified by its configured router ID.

All objects in a group share certain similarities. For example, you can define a group for all fibers that share the same fiber conduit, all optical channels that share the same fiber, all links that connect to the same LAN switch, all equipment that shares the same power source, and so on. All objects are treated as /32 host addresses.

For a group to be meaningful, it should contain at least two objects. You can configure groups with zero or one object; these groups are ignored during processing.

An object can be in any number of groups, and a group can contain any number of objects. Each group has a configurable cost attributed to it, which represents the level of impact this group has on CSPF computations. The higher the cost, the less likely a backup path will share with the primary path any objects in the group. The cost is directly comparable to traffic engineering metrics. By default, the cost is 1. Changing the fate-sharing database does not affect established LSPs until the next reoptimization of CSPF. The fate-sharing database does influence fast-reroute computations.

### Implications for CSPF

When CSPF computes the primary paths of an LSP (or secondary paths when the primary path is not active), it ignores the fate-sharing information. You always want to find the best possible path (least IGP cost) for the primary path.

When CSPF computes a secondary path while the primary path (of the same LSP) is active, the following occurs:

1. CSPF identifies all fate-sharing groups that are associated with the primary path. CSPF does this by identifying all links and nodes that the primary path traverses and compiling group lists that contain at least one of the links or nodes. CSPF ignores the ingress and egress nodes in the search.
2. CSPF checks each link in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group. If a link is a member of multiple groups, all group costs are added together.

3. CSPF performs the check for every node in the traffic engineering database, except the ingress and egress node. Again, a node can belong to multiple groups, so costs are additive.
4. The router performs regular CSPF computation with the adjusted topology.

---

### Implications for CSPF When Fate Sharing with Bypass LSPs

---

When fate sharing is enabled with link protection or link-node protection, CSPF operates as follows when calculating the bypass LSP path:

- CSPF identifies the fate-sharing groups that are associated with the primary LSP path. CSPF does this by identifying the immediate downstream link and immediate downstream nodes that the bypass is trying to protect. CSPF compiles group lists that contain the immediate downstream link and immediate downstream nodes.
- CSPF checks each link (from ingress to the immediate downstream node) in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group.
- CSPF identifies the downstream link that is not in the fate-shared path.

This calculation prevents bypasses from using the same physical link as the primary LSP path when viable alternatives are available.

---

### Example: Configuring Fate Sharing

---

Configure fate-sharing groups **east** and **west**. Because **west** has no objects, it is ignored during processing.

```
[edit routing-options]
fate-sharing {
  group east {
    cost 20; # Optional, default value is 1
    from 1.2.3.4 to 1.2.3.5; # A point-to-point link
    from 192.168.200.1; # LAN interface
    from 192.168.200.2; # LAN interface
    from 192.168.200.3; # LAN interface
    from 192.168.200.4; # LAN interface
    from 10.168.1.220; # Router ID of a router node
    from 10.168.1.221; # Router ID of a router node
  }
  group west {
    .....
  }
}
```

---

## Configuring the Intermediate and Egress Routers for MPLS-Signaled LSPs

---

To configure signaled LSPs on all MPLS routers that should participate in MPLS, you need to enable MPLS and RSVP on these routers.

- Related Documentation**
- [MPLS Configuration Overview on page 39](#)
  - [Minimum RSVP Configuration on page 649](#)

## Configuring the Connection Between Ingress and Egress Routers

The ingress router might make many attempts to connect and reconnect to the egress router using the primary path. You can control how often the ingress router tries to establish a connection using the primary path and how long it waits between retry attempts.

The retry timer configures how long the ingress router waits before trying to connect again to the egress router using the primary path. The default retry time is 30 seconds. The time can be from 1 through 600 seconds. To modify this value, include the **retry-timer** statement:

```
retry-timer seconds;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

By default, no limit is set to the number of times an ingress router attempts to establish or reestablish a connection to the egress router using the primary path. To limit the number of attempts, include the **retry-limit** statement:

```
retry-limit number;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

The limit can be a value up to 10,000. When the retry limit is exceeded, no more attempts are made to establish a path connection. At this point, intervention is required to restart the primary path.

If you set a retry limit, it is reset to 1 each time a successful primary path is created.

## Pinging LSPs

The following sections describe how to use the **ping mpls** command to confirm LSP functioning.

- [Pinging MPLS LSPs on page 420](#)
- [Pinging Point-to-Multipoint LSPs on page 420](#)
- [Pinging the Endpoint Address of MPLS LSPs on page 420](#)

- [Pinging CCC LSPs on page 421](#)
- [Pinging Layer 3 VPNs on page 421](#)
- [Support for LSP Ping and Traceroute Commands Based on RFC 4379 on page 421](#)

## Pinging MPLS LSPs

You can ping a specific LSP. Echo requests are sent over the LSP as MPLS packets. The payload is a User Datagram Protocol (UDP) packet forwarded to an address in the 127/8 range (127.0.0.1 by default, this address is configurable) and port 3503. The label and interface information for building and sending this information as an MPLS packet is the same as for standard LSP traffic.

When the echo request arrives at the egress node, the receiver checks the contents of the packet and sends a reply containing the correct return value, by using UDP. The router sending the echo request waits to receive an echo reply after a timeout of 2 seconds (you cannot configure this value).

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router to be able to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

To ping an MPLS LSP use the **ping mpls <count count> <ldp <fec>> <rsvp <exp forwarding-class> <lsp-name>>** command. To ping a secondary MPLS LSP, use the **ping mpls <count count> <rsvp <lsp-name>> standby path-name** command. For a detailed description of this command, see the [CLI Explorer](#).

**NOTE:** The **ping mpls** command is not supported within routing instances.

**NOTE:** Self-ping is supported for the master instance and not supported for VLAN-based LSPs or LSPs used in CCC. The message is displayed for each LSP and reduces the readability of the configuration.

## Pinging Point-to-Multipoint LSPs

To ping a point-to-multipoint LSP, use the **ping mpls rsvp lsp-name multipoint** or **ping mpls rsvp egress address** commands. The **ping mpls rsvp lsp-name multipoint** command returns a list of all of the egress router identifiers and the current status of the point-to-multipoint LSP egress routers. The **ping mpls rsvp lsp-name multipoint egress address** command returns the current status of the specified egress router.

## Pinging the Endpoint Address of MPLS LSPs

To determine whether an LSP between two provider edge (PE) routers is up and running, you can ping the endpoint address of the LSP. To ping an MPLS LSP endpoint, use the **ping mpls lsp-end-point address** command. This command tells you what type of LSP (RSVP or LDP) terminates at the address specified and whether that LSP is up or down.

For a detailed description of this command, see the [CLI Explorer](#).

## Pinging CCC LSPs

You can ping a specific CCC LSP. The CCC LSP ping command is identical to the one used for MPLS LSPs. The command you use is **ping mpls <count count> <rsvp <lsp-name>>**. You can also ping a secondary standby CCC LSP by using the **ping mpls <count count> <rsvp <lsp-name>> standby path-name** command.

For a detailed description of this command, see the [CLI Explorer](#).

## Pinging Layer 3 VPNs

You can use a similar command, **ping mpls l3vpn vpn-name prefix prefix <count count>**, to ping a Layer 3 VPN. For more information about this command, see the *Junos OS VPNs Library for Routing Devices* and the [CLI Explorer](#).

## Support for LSP Ping and Traceroute Commands Based on RFC 4379

The Junos OS supports LSP **ping** and **traceroute** commands based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

LSP **ping** and **traceroute** commands based on RFC 4379 attempt to trace the path taken by an LSP by relying on MPLS TTL expiration. An LSP can take multiple paths from ingress to egress. This occurs in particular with Equal Cost Multipath (ECMP). The LSP **traceroute** command can trace all possible paths to an LSP node.

## Configuring LSP Metrics

---

The LSP metric is used to indicate the ease or difficulty of sending traffic over a particular LSP. Lower LSP metric values (lower cost) increase the likelihood of an LSP being used. Conversely, high LSP metric values (higher cost) decrease the likelihood of an LSP being used.

The LSP metric can be specified dynamically by the router or explicitly by the user as described in the following sections:

- [Configuring Dynamic LSP Metrics on page 424](#)
- [Configuring Static LSP Metrics on page 424](#)

### Configuring Dynamic LSP Metrics

If no specific metric is configured, an LSP attempts to track the IGP metric toward the same destination (the **to** address of the LSP). IGP includes OSPF, IS-IS, Routing Information Protocol (RIP), and static routes. BGP and other RSVP or LDP routes are excluded.

For example, if the OSPF metric toward a router is 20, all LSPs toward that router automatically inherit metric 20. If the OSPF toward a router later changes to a different value, all LSP metrics change accordingly. If there are no IGP routes toward the router, the LSP raises its metric to 65,535.

Note that in this case, the LSP metric is completely determined by IGP; it bears no relationship to the actual path the LSP is currently traversing. If LSP reroutes (such as through reoptimization), its metric does not change, and thus it remains transparent to users. Dynamic metric is the default behavior; no configuration is required.

### Configuring Static LSP Metrics

You can manually assign a fixed metric value to an LSP. Once configured with the **metric** statement, the LSP metric is fixed and cannot change:

```
metric number;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**
- **[edit protocols mpls static-label-switched-path *lsp-name*]**

- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [static-label-switched-path](#) *lsp-name*]

The LSP metric has several uses:

- When there are parallel LSPs with the same egress router, the metrics are compared to determine which LSP has the lowest metric value (the lowest cost) and therefore the preferred path to the destination. If the metrics are the same, the traffic is shared.

Adjusting the metric values can force traffic to prefer some LSPs over others, regardless of the underlying IGP metric.

- When an IGP shortcut is enabled (see [“Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts” on page 402](#)), an IGP route might be installed in the routing table with an LSP as the next hop, if the LSP is on the shortest path to the destination. In this case, the LSP metric is added to the other IGP metrics to determine the total path metric. For example, if an LSP whose ingress router is X and egress router is Y is on the shortest path to destination Z, the LSP metric is added to the metric for the IGP route from Y to Z to determine the total cost of the path. If several LSPs are potential next hops, the total metrics of the paths are compared to determine which path is preferred (that is, has the lowest total metric). Or, IGP paths and LSPs leading to the same destination could be compared by means of the metric value to determine which path is preferred.

By adjusting the LSP metric, you can force traffic to prefer LSPs, prefer the IGP path, or share the load among them.

- If router X and Y are BGP peers and if there is an LSP between them, the LSP metric represents the total cost to reach Y from X. If for any reason the LSP reroutes, the underlying path cost might change significantly, but X’s cost to reach Y remains the same (the LSP metric), which allows X to report through a BGP multiple exit discriminator (MED) a stable metric to downstream neighbors. As long as Y remains reachable through the LSP, no changes are visible to downstream BGP neighbors.

It is possible to configure IS-IS to ignore the configured LSP metric by including the **ignore-lsp-metrics** statement at the [edit protocols isis traffic-engineering shortcuts] hierarchy level. This statement removes the mutual dependency between IS-IS and MPLS for path computation. For more information, see the *Junos OS Routing Protocols Library*.

## Configuring a Text Description for LSPs

You can provide a textual description for an LSP by enclosing any descriptive text that includes spaces within quotation marks (" "). The descriptive text you include is displayed in the detail output of the **show mpls lsp** or the **show mpls container-lsp** command.

Adding a text description for an LSP has no effect on the operation of the LSP. The LSP text description can be no more than 80 characters in length.

To provide a textual description for an LSP, include the **description** statement at any of the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **container-label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

Before you begin:

- Configure the device interfaces.
- Configure the device for network communication.
- Enable MPLS on the device interfaces.
- Configure an LSP in the MPLS domain.

To add a text description for an LSP:

1. Enter any text describing the LSP.

```
[edit protocols mpls lsp lsp-name]  
user@host# set description text
```

For example:

```
[edit protocols mpls lsp LSP1]  
user@host# set description "Connecting remote device"
```

2. Verify and commit the configuration.

For example:

```
[edit protocols mpls lsp]  
user@host# set protocols mpls label-switched-path LSP1 to 1.1.1.1  
user@host# set protocols mpls label-switched-path LSP1 description "Connecting  
remote device"  
user@host# set protocols mpls interface ge-1/0/8.0
```

```
[edit]  
user@host# commit  
commit complete
```

3. View the description of an LSP using the **show mpls lsp detail** or **show mpls container-lsp detail** command, depending on the type of LSP configured.

```
user@host> show mpls lsp detail
```

```

Ingress LSP: 1 sessions
1.1.1.1
  From: 0.0.0.0, State: Up, ActiveRoute: 1, LSPname: LSP1
  Description: Connecting remote device

  - [Configuring LSP Metrics on page 424](#)

## Configuring MPLS Soft Preemption

Soft preemption attempts to establish a new path for a preempted LSP before tearing down the original LSP. The default behavior is to tear down a preempted LSP first, signal a new path, and then reestablish the LSP over the new path. In the interval between when the path is taken down and the new LSP is established, any traffic attempting to use the LSP is lost. Soft preemption prevents this type of traffic loss. The trade-off is that during the time when an LSP is being soft preempted, two LSPs with their corresponding bandwidth requirements are used until the original path is torn down.

MPLS soft preemption is useful for network maintenance. For example, you can move all LSPs away from a particular interface, then take the interface down for maintenance without interrupting traffic. MPLS soft preemption is described in detail in RFC 5712, *MPLS Traffic Engineering Soft Preemption*.

Soft preemption is a property of the LSP and is disabled by default. You configure it at the ingress of an LSP by including the **soft-preemption** statement:

```
soft-preemption;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]

You can also configure a timer for soft preemption. The timer designates the length of time the router should wait before initiating a hard preemption of the LSP. At the end of the time specified, the LSP is torn down and resigaled. The soft-preemption cleanup timer has a default value of 30 seconds; the range of permissible values is 0 through 180 seconds. A value of 0 means that soft preemption is disabled. The soft-preemption cleanup timer is global for all LSPs.

Configure the timer by including the **cleanup-timer** statement:

```
cleanup-timer seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols **rsvp** **preemption soft-preemption**]
- [edit logical-systems *logical-system-name* protocols **rsvp** **preemption soft-preemption**]

**NOTE:** Soft preemption cannot be configured on LSPs for which secondary paths or fast reroute has been configured. The configuration fails to commit. However, you can enable soft preemption in conjunction with node and link protection.

**NOTE:** The counter value for *SoftPreemptionCnt* initializes with a value of 0 (zero), visible in the command **show rsvp interface detail** output.

---

## Configuring Priority and Preemption for LSPs

---

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to free the bandwidth. You do this by preempting the existing LSP.

Whether an LSP can be preempted is determined by two properties associated with the LSP:

- Setup priority—Determines whether a new LSP that preempts an existing LSP can be established. For preemption to occur, the setup priority of the new LSP must be higher than that of the existing LSP. Also, the act of preempting the existing LSP must produce sufficient bandwidth to support the new LSP. That is, preemption occurs only if the new LSP can be set up successfully.
- Reservation priority—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. When the reservation priority is high, the existing LSP is less likely to give up its reservation, and hence it is unlikely that the LSP can be preempted.

You cannot configure an LSP with a high setup priority and a low reservation priority, because permanent preemption loops might result if two LSPs are allowed to preempt

each other. You must configure the reservation priority to be higher than or equal to the setup priority.

The setup priority also defines the relative importance of LSPs on the same ingress router. When the software starts, when a new LSP is established, or during fault recovery, the setup priority determines the order in which LSPs are serviced. Higher-priority LSPs tend to be established first and hence enjoy more optimal path selection.

To configure the LSP's preemption properties, include the **priority** statement:

```
priority setup-priority reservation-priority;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Both **setup-priority** and **reservation-priority** can be a value from 0 through 7. The value 0 corresponds to the highest priority, and the value 7 to the lowest. By default, an LSP has a setup priority of 7 (that is, it cannot preempt any other LSPs) and a reservation priority of 0 (that is, other LSPs cannot preempt it). These defaults are such that preemption does not happen. When you are configuring these values, the setup priority should always be less than or equal to the hold priority.

## Configuring Administrative Groups for LSPs

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups.

Administrative groups are meaningful only when constrained-path LSP computation is enabled.

You can assign up to 32 names and values (in the range 0 through 31), which define a series of names and their corresponding values. The administrative names and values must be identical across all routers within a single domain.

**NOTE:** The administrative value is distinct from the priority. You configure the priority for an LSP using the **priority** statement. See “[Configuring Priority and Preemption for LSPs](#)” on page 428.

To configure administrative groups, follow these steps:

1. Define multiple levels of service quality by including the **admin-groups** statement:

```
admin-groups {  
  group-name group-value;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The following configuration example illustrates how you might configure a set of administrative names and values for a domain:

```
[edit protocols mpls]
admin-groups {
  gold 1;
  silver 2;
  copper 3;
  best-effort 4;
}
```

2. Define the administrative groups to which an interface belongs. You can assign multiple groups to an interface. Include the **interface** statement:

```
interface interface-name {
  admin-group [ group-names ];
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

If you do not include the **admin-group** statement, an interface does not belong to any group.

IGPs use the group information to build link-state packets, which are then flooded throughout the network, providing information to all nodes in the network. At any router, the IGP topology, as well as administrative groups of all the links, is available.

Changing the interface's administrative group affects only new LSPs. Existing LSPs on the interface are not preempted or recomputed to keep the network stable. If LSPs need to be removed because of a group change, issue the **clear RSVP session** command.

**NOTE:** When configuring administrative groups and extended administrative groups together for a link, both the types of administrative groups must be configured on the interface.

3. Configure an administrative group constraint for each LSP or for each primary or secondary LSP path. Include the **label-switched-path** statement:

```
label-switched-path lsp-name {
  to address;
  ...
  admin-group {
    exclude [ group-names ];
  }
}
```

```

include-all [ group-names ];
include-any [ group-names ];
}
primary path-name {
  admin-group {
    exclude [ group-names ];
    include-all [ group-names ];
    include-any [ group-names ];
  }
}
secondary path-name {
  admin-group {
    exclude [ group-names ];
    include-all [ group-names ];
    include-any [ group-names ];
  }
}
}

```

You can include the **label-switched-path** statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

If you omit the **include-all**, **include-any**, or **exclude** statements, the path computation proceeds unchanged. The path computation is based on the constrained-path LSP computation. For information about how the constrained-path LSP computation is calculated, see “How CSPF Selects a Path” on page 387.

**NOTE:** Changing the LSP's administrative group causes an immediate recomputation of the route; therefore, the LSP might be rerouted.

**Related Documentation**

- [Configuring Extended Administrative Groups for LSPs on page 431](#)

## Configuring Extended Administrative Groups for LSPs

In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in the interior gateway protocol (IGP) (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. Juniper Networks routers normally interpret this 32-bit value as a bit mask with each bit representing a group, limiting each network to a total of 32 distinct administrative groups (value range 0 through 31).

You configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. The original range of values available for administrative groups is still supported for backwards compatibility.

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by Constrained Shortest Path First (CSPF) for path computation.

The following procedure describes how to configure extended administrative groups:

1. Configure the **admin-groups-extended-range** statement:

```
admin-groups-extended-range {  
    maximum maximum-number;  
    minimum minimum-number;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

The **admin-groups-extended-range** statement includes the **minimum** and **maximum** options. The range maximum must be greater than the range minimum.

2. Configure the **admin-groups-extended** statement:

```
admin-groups-extended group-name {  
    group-value group-identifier;  
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

The **admin-groups-extended** statement enables you to configure a group name and group value for the administrative group. The group value must be within the range of values configured using the **admin-groups-extended-range** statement.

3. The extended administrative groups for an MPLS interface consist of the set of extended administrative group names assigned for the interface. The interface extended administrative group names must be configured for the global extended administrative groups.

To configure an extended administrative group for an MPLS interface, specify the administrative group name within the MPLS interface configuration using the **admin-groups-extended** statement:

```
admin-groups-extended group-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls interface *interface-name*]
  - [edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]
4. The LSP extended administrative groups define the set of include and exclude constraints for an LSP and for a path's primary and secondary paths. The extended administrative group names must be configured for the global extended administrative groups.

To configure extended administrative groups for an LSP, include the **admin-group-extended** statement at an LSP hierarchy level:

```
admin-group-extended {
  apply-groups group-value;
  apply-groups-except group-value;
  exclude group-value;
  include-all group-value;
  include-any group-value;
}
```

The **admin-group-extended** statement includes the following options: **apply-groups**, **apply-groups-except**, **exclude**, **include-all**, and **include-any**. Each option enables you to configure one or more extended administrative groups.

For the list of the hierarchy levels at which you can configure this statement, see the statement summary for this statement.

5. To display the currently configured extended administrative groups, issue the **show mpls admin-groups-extended** command.

**NOTE:** When configuring administrative groups and extended administrative groups together for a link, both the types of administrative groups must be configured on the interface.

## Configuring Preference Values for LSPs

As an option, you can configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for RSVP LSPs is 7 and for LDP LSPs is 9. These preference values are lower (more preferred) than all learned routes except direct interface routes.

To change the default preference value, include the **preference** statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Disabling Path Route Recording by LSPs

The Junos implementation of RSVP supports the Record Route object, which allows an LSP to actively record the routers through which it transits. You can use this information for troubleshooting and to prevent routing loops. By default, path route information is recorded. To disable recording, include the **no-record** statement:

```
no-record;
```

For a list of hierarchy levels at which you can include the **record** and **no-record** statements, see the statement summary section for the statement.

---

## Achieving a Make-Before-Break, Hitless Switchover for LSPs

Adaptive label-switched paths (LSPs) might need to establish a new LSP instance and transfer traffic from an old LSP instance onto the new LSP instance before tearing down the old one. This type of configuration is referred to as a *make before break* (MBB).

RSVP-TE is a protocol used to establish LSPs in MPLS networks. The Junos OS implementation of RSVP-TE to achieve a hitless (no traffic loss) MBB switchover has relied on configuring the timer values in the following configuration statements:

- **optimize-switchover-delay**—Amount of time to wait before switching to the new LSP instance.
- **optimize-hold-dead-delay**—Amount of time to wait after switchover and before deletion of the old LSP instance.

Both the **optimize-switchover-delay** and **optimize-hold-dead-delay** statements apply to all LSPs that use the make-before-break behavior for LSP setup and teardown, not just for LSPs for which the **optimize-timer** statement has also been configured. The following MPLS features cause LSPs to be set up and torn down using make-before-break behavior:

- Adaptive LSPs
- Automatic bandwidth allocation
- BFD for LSPs
- Graceful Routing Engine switchover
- Link and node protection
- Nonstop active routing
- Optimized LSPs
- Point-to-multipoint (P2MP) LSPs

- Soft preemption
- Standby secondary paths

Both the **optimize-switchover-delay** and **optimize-hold-dead-delay** statements when configured add an artificial delay to the MBB process. The value of the **optimize-switchover-delay** statement varies with the size of the Explicit Route Objects (EROs). An ERO is an extension to RSVP that allows an RSVP PATH message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The value of the **optimize-switchover-delay** statement also depends on the CPU load on each of the routers on the path. Customers set the **optimize-switchover-delay** statement by trial and error.

The value of the **optimize-hold-dead-delay** statement depends on how fast the ingress router moves all application prefixes to point to the new LSP. This is determined by the Packet Forwarding Engine load, which can vary from platform to platform. Customers have to set the **optimize-hold-dead-delay** statement by trial and error.

However, as of Release 15.1, Junos OS is able to achieve a hitless MBB switchover without configuring the artificial delays that such timer values introduce.

This topic summarizes the three methods of achieving a MBB switchover from an old LSP to a new LSP using Junos OS:

- [Specifying the Amount of Time the Router Waits to Switch Over to New Paths on page 435](#)
- [Specifying the Amount of Time to Delay the Tear Down of Old Paths on page 436](#)
- [Achieving a Hitless, MBB Switchover Without Artificial Delays on page 436](#)

## Specifying the Amount of Time the Router Waits to Switch Over to New Paths

To specify the amount of time the router waits to switch over LSP instances to newly optimized paths, use the **optimize-switchover-delay** statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that the new optimized paths have been established before traffic is switched over from the old paths. This timer can only be enabled or disabled for all of the LSPs configured on the router.

To configure the amount of time the router waits to switch over LSP instances to newly optimized paths, specify the time in seconds by using the **optimize-switchover-delay** statement:

```
optimize-switchover-delay seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

## Specifying the Amount of Time to Delay the Tear Down of Old Paths

To specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the **optimize-hold-dead-delay** statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths. This timer can be enabled for specific LSPs or for all of the LSPs configured on the router.

To configure the amount of time in seconds to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the **optimize-hold-dead-delay** statement:

```
optimize-hold-dead-delay seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Achieving a Hitless, MBB Switchover Without Artificial Delays

As of Junos OS Release 15.1, there is another way to relinquish the old LSP instances after MBB switchover without relying on the arbitrary time intervals set up by the **optimize-switchover-delay** or **optimize-hold-dead-delay** statement. For example, if you use the **optimize-hold-dead-delay** statement, you configure a time you think it is safe to wait before tearing down the old LSP instance after MBB. However, some routes might still be in the process of shifting to the new instance. Tearing down the old LSP instance prematurely results in one of the transit nodes dropping the traffic for those routes that have not shifted to the new LSP instance.

To avoid traffic loss, instead of using the **optimize-switchover-delay** statement, you can use MPLS-OAM (lsp ping), which confirms that the LSP data plane is established end-to-end. Instead of using the **optimize-hold-dead-delay** statement, you can use a feedback mechanism from the rpd infrastructure that confirms that all prefixes referring to the old LSP have been switched over. The feedback mechanism is sourced from the Tag library and relies on the routing protocol process (rpd) infrastructure to determine when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover.

The feedback mechanism is always in place, and it is optional. Configure the **optimize-adaptive-teardown** statement to have the feedback mechanism used during MBB switchover. This feature is not supported for RSVP point-to-multipoint (P2MP) LSP instances. Global configuration of the **optimize-adaptive-teardown** statement only affects the point-to-point LSPs that are configured in the system.

You only need to configure the **optimize-adaptive-teardown** statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). This feedback mechanism ensures that old paths are not torn down before all routes have been switched over to the new optimized paths. The global

configuration of this configuration statement affects only the point-to-point LSPs that are configured in the system.

```
optimize-adaptive-teardown {
  p2p:
}
```

You can include this statement at the **[edit protocols mpls]** hierarchy level.

## Optimizing Signaled LSPs

Once an LSP has been established, topology or resources changes might, over time, make the path suboptimal. A new path might have become available that is less congested, has a lower metric, and traverses fewer hops. You can configure the router to recompute paths periodically to determine whether a more optimal path has become available.

If reoptimization is enabled, an LSP can be rerouted through different paths by constrained-path recomputations. However, if reoptimization is disabled, the LSP has a fixed path and cannot take advantage of newly available network resources. The LSP is fixed until the next topology change breaks the LSP and forces a recomputation.

Reoptimization is not related to failover. A new path is always computed when topology failures occur that disrupt an established path.

Because of the potential system overhead involved, you need to carefully control the frequency of reoptimization. Network stability might suffer when reoptimization is enabled. By default, the **optimize-timer** statement is set to 0 (that is, it is disabled).

LSP optimization is meaningful only when constrained-path LSP computation is enabled, which is the default behavior. For more information about constrained-path LSP computation, see [“Disabling Constrained-Path LSP Computation” on page 390](#). Also, LSP optimization is only applicable to ingress LSPs, so it is only necessary to configure the **optimize-timer** statement on the ingress router. The transit and egress routers require no specific configuration to support LSP optimization (other than to have MPLS enabled).

To enable path reoptimization, include the **optimize-timer** statement:

```
optimize-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Once you have configured the **optimize-timer** statement, the reoptimization timer continues its countdown to the configured value even if you delete the **optimize-timer** statement from the configuration. The next optimization uses the new value. You can force the Junos OS to use a new value immediately by deleting the old value, committing the configuration, configuring the new value for the **optimize-timer** statement, and then committing the configuration again.

After reoptimization is run, the result is accepted only if it meets the following criteria:

1. The new path is not higher in IGP metric. (The metric for the old path is updated during computation, so if a recent link metric changed somewhere along the old path, it is accounted for.)
2. If the new path has the same IGP metric, it is not more hops away.
3. The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
4. The new path does not worsen congestion overall.

The relative congestion of the new path is determined as follows:

- a. The percentage of available bandwidth on each link traversed by the new path is compared to that for the old path, starting from the most congested links.
- b. For each current (old) path, the software stores the four smallest values for bandwidth availability for the links traversed in ascending order.
- c. The software also stores the four smallest bandwidth availability values for the new path, corresponding to the links traversed in ascending order.
- d. If any of the four new available bandwidth values are smaller than any of the corresponding old bandwidth availability values, the new path has at least one link that is more congested than the link used by the old path. Because using the link would cause more congestion, traffic is not switched to this new path.
- e. If none of the four new available bandwidth values is smaller than the corresponding old bandwidth availability values, the new path is less congested than the old path.

When all the above conditions are met, then:

5. If the new path has a lower IGP metric, it is accepted.
6. If the new path has an equal IGP metric and lower hop count, it is accepted.
7. If you choose **least-fill** as a load balancing algorithm, LSPs are load balanced as follows:
  - a. The LSP is moved to a new path that is utilized at least 10% less than the current path. This might reduce congestion on the current path by only a small amount.

For example, if an LSP with 1 MB of bandwidth is moved off a path carrying a minimum of 200 MB, congestion on the original path is reduced by less than 1%.

b. For **random** or **most-fill** algorithms, this rule does not apply.

The following example illustrates how the **least-fill** load balancing algorithm works.

**Figure 43: least-fill Load Balancing Algorithm Example**

As shown in [Figure 43 on page 439](#), there are two potential paths for an LSP to traverse from router A to router H, the odd links from L1 through L13 and the even links from L2 through L14. Currently, the router is using the even links as the active path for the LSP. Each link between the same two routers (for example, router A and router B) has the same bandwidth:

- L1, L2 = 10GE
- L3, L4 = 1GE
- L5, L6 = 1GE
- L7, L8 = 1GE
- L9, L10 = 1GE
- L11, L12 = 10GE
- L13, L14 = 10GE

The 1GE links are more likely to be congested. In this example, the odd 1GE links have the following available bandwidth:

- L3 = 41%
- L5 = 56%
- L7 = 66%
- L9 = 71%

The even 1GE links have the following available bandwidth:

- L4 = 37%
- L6 = 52%
- L8 = 61%
- L10 = 70%

Based on this information, the router would calculate the difference in available bandwidth between the odd links and the even links as follows:

- $L4 - L3 = 41\% - 37\% = 4\%$
- $L6 - L5 = 56\% - 52\% = 4\%$

- $L8 - L7 = 66\% - 61\% = 5\%$
- $L10 - L9 = 71\% - 70\% = 1\%$

The total additional bandwidth available over the odd links is 14% (4% + 4% + 5% + 1%). Since 14% is greater than 10% (the least-fill algorithm minimum threshold), the LSP is moved to the new path over the odd links from the original path using the even links.

8. Otherwise, the new path is rejected.

You can disable the following reoptimization criteria (a subset of the criteria listed previously):

- If the new path has the same IGP metric, it is not more hops away.
- The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
- The new path does not worsen congestion overall.
- If the new path has an equal IGP metric and lower hop count, it is accepted.

To disable them, either issue the **clear mpls lsp optimize-aggressive** command or include the **optimize-aggressive** statement:

```
optimize-aggressive;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Including the **optimize-aggressive** statement in the configuration causes the reoptimization procedure to be triggered more often. Paths are rerouted more frequently. It also limits the reoptimization algorithm to the IGP metric only.

---

## Configuring the Smart Optimize Timer for LSPs

Because of network and router resource constraints, it is typically inadvisable to configure a short interval for the optimize timer. However, under certain circumstances, it might be

desirable to reoptimize a path sooner than would normally be provided by the optimize timer.

For example, an LSP is traversing a preferred path that subsequently fails. The LSP is then switched to a less desirable path to reach the same destination. Even if the original path is quickly restored, it could take an excessively long time for the LSP to use it again, because it has to wait for the optimize timer to reoptimize the network paths. For such situations, you might want to configure the smart optimize timer.

When you enable the smart optimize timer, an LSP is switched back to its original path so long as the original path has been restored within 3 minutes of going down. Also, if the original path goes down again within 60 minutes, the smart optimize timer is disabled, and path optimization behaves as it normally does when the optimize timer alone is enabled. This prevents the router from using a flapping link.

The smart optimize timer is dependant on other MPLS features to function properly. For the scenario described here in which an LSP is switched to an alternate path in the event of a failure on the original path, it is assumed that you have configured one or more of the MPLS traffic protection features, including fast reroute, link protection, and standby secondary paths. These features help to ensure that traffic can reach its destination in the event of a failure.

At the least, you must configure a standby secondary path for the smart optimize timer feature to work properly. Fast reroute and link protection are more temporary solutions to a network outage. A secondary path ensures that there is a stable alternate path in the event the primary path fails. If you have not configured any sort of traffic protection for an LSP, the smart optimize timer by itself does not ensure that traffic can reach its destination. For more information about MPLS traffic protection, see [“MPLS and Traffic Protection” on page 378](#).

When a primary path fails and the smart optimize timer switches traffic to the secondary path, the router might continue to use the secondary path even after the primary path has been restored. If the ingress router completes a CSPF calculation, it might determine that the secondary path is the better path.

This might be undesirable if the primary path should be the active path and the secondary path should be used as a backup only. Also, if the secondary path is being used as the active path (even though the primary path has been reestablished) and the secondary path fails, the smart optimize timer feature will not automatically switch traffic back to the primary path. However, you can enable protection for the secondary path by configuring node and link protection or an additional standby secondary path, in which case, the smart optimize timer can be effective.

Specify the time in seconds for the smart optimize timer using the **smart-optimize-timer** statement:

```
smart-optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**

- [\[edit logical-systems \*logical-system-name\* protocols mpls\]](#)

**Related  
Documentation**

- [MPLS and Traffic Protection on page 378](#)
- [Optimizing Signaled LSPs on page 437](#)

---

## Limiting the Number of Hops in LSPs

By default, each LSP can traverse a maximum of 255 hops, including the ingress and egress routers. To modify this value, include the **hop-limit** statement:

```
hop-limit number;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The number of hops can be from 2 through 255. (A path with two hops consists of the ingress and egress routers only.)

---

## Configuring the Bandwidth Value for LSPs

Each LSP has a bandwidth value. This value is included in the sender's Tspec field in RSVP path setup messages. You can specify a bandwidth value in bits per second. If you configure more bandwidth for an LSP, it should be able to carry a greater volume of traffic. The default bandwidth is 0 bits per second.

A nonzero bandwidth requires that transit and egress routers reserve capacity along the outbound links for the path. The RSVP reservation scheme is used to reserve this capacity. Any failure in bandwidth reservation (such as failures at RSVP policy control or admission control) might cause the LSP setup to fail. If there is insufficient bandwidth on the interfaces for the transit or egress routers, the LSP is not established.

To specify a bandwidth value for a signaled LSP, include the **bandwidth** statement:

```
bandwidth bps;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth; this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

You set a sampling interval on an LSP configured with automatic bandwidth allocation. The average bandwidth is monitored during this interval. At the end of the interval, an attempt is made to signal a new path for the LSP with the bandwidth allocation set to

the maximum average value for the preceding sampling interval. If the new path is successfully established and the original path is removed, the LSP is switched over to the new path. If a new path is not created, the LSP continues to use its current path until the end of the next sampling interval, when another attempt is made to establish a new path. Note that you can set minimum and maximum bandwidth values for the LSP.

During the automatic bandwidth allocation interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

## Configuring Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth, and this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

At the end of the automatic bandwidth allocation time interval, the current maximum average bandwidth usage is compared with the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

**NOTE:** In calculating the value for Max AvgBW (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

If you have configured link and node protection for the LSP and traffic has been switched to the bypass LSP, the automatic bandwidth allocation feature continues to operate and take bandwidth samples from the bypass LSP. For the first bandwidth adjustment cycle, the maximum average bandwidth usage taken from the original link and node-protected LSP is used to resignal the bypass LSP if more bandwidth is needed. (Link and node protection are not supported on QFX Series switches.)

If you have configured fast-reroute for the LSP, you might not be able to use this feature to adjust the bandwidth. Because the LSPs use a fixed filter (FF) reservation style, when a new path is signaled, the bandwidth might be double-counted. Double-counting can prevent a fast-reroute LSP from ever adjusting its bandwidth when automatic bandwidth allocation is enabled. (Fast reroute is not supported on QFX Series switches.)

To configure automatic bandwidth allocation, complete the steps in the following sections:

- [Configuring Automatic Bandwidth Allocation on LSPs on page 444](#)
- [Requesting Automatic Bandwidth Allocation Adjustment on page 450](#)

**NOTE:** On the QFX10000 switches, you can only configure automatic bandwidth allocation at the `edit protocols mpls` hierarchy level. Logical systems are not supported.

## Configuring Automatic Bandwidth Allocation on LSPs

To enable automatic bandwidth allocation on an LSP, include the **auto-bandwidth** statement:

```
auto-bandwidth (MPLS Tunnel) {
  adjust-interval seconds;
  adjust-threshold percent;
  adjust-threshold-overflow-limit number;
  adjust-threshold-underflow-limit number;
  maximum-bandwidth bps;
  minimum-bandwidth bps;
  minimum-bandwidth-adjust-interval
  minimum-bandwidth-adjust-threshold-change
  minimum-bandwidth-adjust-threshold-value
  monitor-bandwidth;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

If an LSP has an automatic bandwidth configuration, you can disable automatic bandwidth adjustments on a particular path (either primary or secondary) by configuring a static bandwidth value and by disabling the CSPF computation (using the **no-cspf** statement).

For example:

```
user@host> show protocols mpls
label-switched-path primary-path {
  to 192.168.0.1;
  ldp-tunneling;
  optimize-timer 3571;
  least-fill;
  link-protection;
  adaptive;
  auto-bandwidth {
    adjust-interval 7177;
    adjust-threshold 5;
    minimum-bandwidth 1m;
```

```

maximum-bandwidth 2500000000;
adjust-threshold-overflow-limit 2;
resignal-minimum-bandwidth;
}
primary primary-path;
secondary secondary-path {
    bandwidth 0;
    no-cspf;
    priority 0 0;
}
}

```

The statements configured at the `[edit protocols mpls label-switched-path label-switched-path-name auto-bandwidth]` hierarchy level are optional and explained in the following sections:

- [Configuring the Automatic Bandwidth Allocation Interval on page 445](#)
- [Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 446](#)
- [Configuring the Automatic Bandwidth Adjustment Threshold on page 447](#)
- [Configuring a Limit on Bandwidth Overflow and Underflow Samples on page 447](#)
- [Configuring Passive Bandwidth Utilization Monitoring on page 449](#)

### Configuring the Automatic Bandwidth Allocation Interval

At the end of the automatic bandwidth allocation interval, the automatic bandwidth computation and new path setup process is triggered.

**NOTE:** To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (interval statement at the `[edit protocols mpls statistics]` hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (adjust-interval statement at the `[edit protocols mpls label-switched-path label-switched-path-name auto-bandwidth]` hierarchy level). See also “[Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs](#)” on page 451.

To specify the bandwidth reallocation interval in seconds for a specific LSP, include the `adjust-interval` statement:

```
adjust-interval seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name auto-bandwidth (MPLS Tunnel)]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth (MPLS Tunnel)]`

### Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth

You can maintain the LSP's bandwidth between minimum and maximum bounds by specifying values for the **minimum-bandwidth** and **maximum-bandwidth** statements.

**NOTE:** For a label-switched path (LSP) that has both bandwidth and minimum-bandwidth for autobandwidth configured under the [edit protocols mpls label-switched-path lsp-name] hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the [edit protocols mpls label-switched-path lsp-name] hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the [edit protocols mpls label-switched-path lsp-name autobandwidth] hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the [edit protocols mpls label-switched-path lsp-name autobandwidth] hierarchy level, then the LSP is signaled only using the maximum bandwidth.

To specify the minimum amount of bandwidth allocated for a specific LSP, include the **minimum-bandwidth** statement:

```
minimum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

To specify the maximum amount of bandwidth allocated for a specific LSP, include the **maximum-bandwidth** statement:

```
maximum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

### Configuring the Automatic Bandwidth Adjustment Threshold

Use the **adjust-threshold** statement to specify the sensitivity of the automatic bandwidth adjustment of an LSP to changes in bandwidth utilization. You can set the threshold for when to trigger automatic bandwidth adjustments. When configured, bandwidth demand for the current interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the specified **adjust-threshold** percentage, the LSP's bandwidth is adjusted to the current bandwidth demand.

For example, assume that the current bandwidth allocation is 100 megabits per second (Mbps) and that the percentage configured for the **adjust-threshold** statement is 15 percent. If the bandwidth demand increases to 110 Mbps, the bandwidth allocation is not adjusted. However, if the bandwidth demand increases to 120 Mbps (20 percent over the current allocation) or decreases to 80 Mbps (20 percent under the current allocation), the bandwidth allocation is increased to 120 Mbps or decreased to 80 Mbps, respectively.

To configure the threshold for automatic bandwidth adjustment, include the **adjust-threshold** statement:

```
adjust-threshold percent;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]

### Configuring a Limit on Bandwidth Overflow and Underflow Samples

The automatic bandwidth adjustment timer is a periodic timer which is triggered every adjust interval to determine whether any bandwidth adjustments are required on the LSP's active path. This interval is typically configured as a long period of time, usually hours. If, at the end of adjust interval, the change in bandwidth is above a certain adjust threshold, the LSP is resigaled with the new bandwidth.

During the automatic bandwidth adjustment interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Every statistics interval, the router samples the average bandwidth utilization of an LSP and if this has exceeded the current maximum average bandwidth utilization, the maximum average bandwidth utilization is updated.

During each sample period, the following conditions are also checked:

- Is the current average bandwidth utilization above the active bandwidth of the path?

- Has the difference between the average bandwidth utilization and the active bandwidth exceeded the adjust threshold (bandwidth utilization has changed significantly) ?

If these conditions are true, it is considered to be one bandwidth overflow sample. Using the **adjust-threshold-overflow-limit** statement, you can define a limit on the number of bandwidth overflow samples such that when the limit is reached, the current automatic bandwidth adjustment timer is expired and a bandwidth adjustment is triggered. Once this adjustment is complete, the normal automatic bandwidth adjustment timer is reset to expire after the periodic adjustment interval.

To specify a limit on the number of bandwidth overflow samples before triggering an automatic bandwidth allocation adjustment, configure the **adjust-threshold-overflow-limit** statement:

```
adjust-threshold-overflow-limit number;
```

Similarly, if the current average bandwidth utilization is below the active bandwidth of the path by the configured adjusted threshold (meaning that bandwidth utilization has gone down significantly), the sample is considered to be an underflow sample. The adjusted (new signaling) bandwidth after an adjustment due to underflow is the maximum average bandwidth among the underflow samples. Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

You can specify a limit on the number of bandwidth underflow samples before triggering an automatic bandwidth allocation adjustment by configuring the **adjust-threshold-underflow-limit** statement:

```
adjust-threshold-underflow-limit number;
```

These statements can be configured at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

You must configure the **adjust-threshold** and **minimum-bandwidth** statements whenever you configure the **adjust-threshold-underflow-limit** statement. You must configure the **adjust-threshold** and **maximum-bandwidth** statements whenever you configure the **adjust-threshold-overflow-limit** statement

- You must configure a nonzero value for the **adjust-threshold** statement if you configure the **adjust-threshold-overflow-limit** or **adjust-threshold-underflow-limit** statement.
- Any bandwidth increase or decrease below the value configured for the **adjust-threshold** statement does not constitute an overflow or underflow condition.

- To prevent unlimited increases in LSP bandwidth (to limit overflow beyond a certain bandwidth), you must also configure the **maximum-bandwidth** statement when you configure the **adjust-threshold-overflow-limit** statement.

The following describes the other aspects of the **adjust-threshold-overflow-limit** statement:

- It only applies to bandwidth overflows. If the bandwidth is decreasing, the normal automatic bandwidth adjustment interval is used.
- It does not affect manually triggered automatic bandwidth adjustment.
- It applies to single-class DiffServ-TE LSPs.
- Because the **adjust-threshold-overflow-limit** statement can trigger a bandwidth adjustment, it cannot be enabled at the same time as the **monitor-bandwidth** statement (for information about that statement, see [“Configuring Passive Bandwidth Utilization Monitoring” on page 449](#)).
- You cannot configure automatic bandwidth adjustments to occur more often than every 300 seconds. The **adjust-threshold-overflow-limit** statement is subject to the same minimum value with regard to the minimum frequency of adjustment allowed. Overflow condition based adjustments can occur no sooner than 300 seconds from the start of the overflow condition. Therefore it is required that:

**sample interval x adjust-threshold-overflow-limit >= 300s**

These values are checked during the commit operation. An error is returned if the value is less than 300 seconds.

- If you change the value of the **adjust-threshold-overflow-limit** statement on a working router, you can expect the following behavior:
  - If you increase the current value of the **adjust-threshold-overflow-limit** statement, the old value is replaced with the new one.
  - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is less than the new value, the old value is replaced with the new one.
  - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is greater than the new value, the adjustment timer is immediately expired and a bandwidth adjustment is initiated.

### Configuring Passive Bandwidth Utilization Monitoring

Use the **monitor-bandwidth** statement to switch to a passive bandwidth utilization monitoring mode. In this mode, no automatic bandwidth adjustments are made, but the maximum average bandwidth utilization is continuously monitored and recorded.

To configure passive bandwidth utilization monitoring, include the **monitor-bandwidth** statement:

```
monitor-bandwidth;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]

If you have configured an LSP with primary and secondary paths, the automatic bandwidth allocation statistics are carried over to the secondary path if the primary path fails. For example, consider a primary path whose adjustment interval is half complete and whose maximum average bandwidth usage is currently calculated as 50 Mbps. If the primary path suddenly fails, the time remaining for the next adjustment and the maximum average bandwidth usage are carried over to the secondary path.

## Requesting Automatic Bandwidth Allocation Adjustment

For MPLS LSP automatic bandwidth allocation adjustment, the minimum value for the adjustment interval is 5 minutes (300 seconds). You might find it necessary to trigger a bandwidth allocation adjustment manually, for example in the following circumstances:

- When you are testing automatic bandwidth allocation in a network lab.
- When the LSP is configured for automatic bandwidth allocation in monitor mode (the **monitor-bandwidth** statement is included in the configuration as described in [“Configuring Passive Bandwidth Utilization Monitoring” on page 449](#)), and want to initiate an immediate bandwidth adjustment.

To use the **request mpls lsp adjust-autobandwidth** command, the following must be true:

- Automatic bandwidth allocation must be enabled on the LSP.
- The criteria required to trigger a bandwidth adjustment have been met (the difference between the adjust bandwidth and the current LSP path bandwidth is greater than the threshold limit).

A manually triggered bandwidth adjustment operates only on the active LSP path. Also, if you have enabled periodic automatic bandwidth adjustment, the periodic automatic bandwidth adjustment parameters (the adjustment interval and the maximum average bandwidth) are not reset after a manual adjustment.

For example, suppose the periodic adjust interval is 10 hours and there are currently 5 hours remaining before an automatic bandwidth adjustment is triggered. If you initiate a manual adjustment with the **request mpls lsp adjust-autobandwidth** command, the adjust timer is not reset and still has 5 hours remaining.

To manually trigger a bandwidth allocation adjustment, you need to use the **request mpls lsp adjust-autobandwidth** command. You can trigger the command for all affected LSPs on the router, or you can specify a particular LSP:

```
user@host> request mpls lsp adjust-autobandwidth
```

Once you execute this command, the automatic bandwidth adjustment validation process is triggered. If all the criteria for adjustment are met, the LSP's active path bandwidth is adjusted to the adjusted bandwidth value determined during the validation process.

Release History Table

Release	Description
14.1R9	Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

## Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure the device to collect statistics related to automatic bandwidth allocation by completing the following steps:

1. To collect statistics related to automatic bandwidth allocation, configure the **auto-bandwidth** option for the **statistics** statement at the **[edit protocols mpls]** hierarchy level. These settings apply to all LSPs configured on the router on which you have also configured the **auto-bandwidth** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level.

```
statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
  transit-statistics-polling;
}
```

2. Specify the ***filename*** for the files used to store the MPLS trace operation output using the **file** option. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.
3. Specify the maximum number of trace files using the **files number** option. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file.0***, then

**trace-file** 1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

4. Specify the interval for calculating the average bandwidth usage by configuring a time in seconds using the **interval** option. You can also set the adjustment interval on a specific LSP by configuring the **interval** option at the **[edit protocols mpls label-switch-path label-switched-path-name statistics]** hierarchy level.

**NOTE:** To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (**interval** statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (**adjust-interval** statement at the **[edit protocols mpls label-switched-path label-switched-path-name auto-bandwidth]** hierarchy level).

5. To trace automatic bandwidth allocation, include the **autobw-state** flag for the MPLS **traceoptions** statement at the **[edit protocols mpls]** hierarchy level.

The following configuration enables the MPLS traceoptions for automatic bandwidth allocation. The trace records are stored in a file called **auto-band-trace** (the filename is user configurable):

```
[edit protocols mpls]
traceoptions {
  file auto-band-trace size 10k files 10 world-readable;
  flag autobw-state;
}
```

6. Using the **show log** command, you can display the automatic bandwidth allocation statistics file generated when you configure the **auto-bandwidth (MPLS Statistics)** statement. The following shows sample log file output taken from an MPLS statistics file named **auto-band-stats** on a router configured with an LSP named **E-D**. The log file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. Before **Oct 30 17:14:57**, the router triggered an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:16:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```

- Issue the `show mpls lsp autobandwidth` command to display current information about automatic bandwidth allocation. The following shows sample output from the `show mpls lsp autobandwidth` command taken at about the same time as the log file shown previously:

```

user@host> show mpls lsp autobandwidth
Lspname      Last      Requested      Reserved      Highwater      AdjustTime LastAdjust
BW           BW           BW           mark           Left (sec)
E-D          300bps      812.005bps    812bps        1.56801kbps 294 sec      Wed Oct 30 17:15:26 2013

```

- Issue the `file show` command to display the MPLS trace file. You need to specify the file location and file name (the file is located in `/var/log/`). The following shows sample trace file output is taken from an MPLS trace file named `auto-band-trace.0.gz` on a router configured with an LSP named **E-D**. The trace file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. At **Oct 30 17:15:26**, the router triggers an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:15:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```

## Configuring an LSP Across ASs

You can configure an LSP to traverse multiple areas in a network by including the **inter-domain** statement as a part of the LSP configuration. This statement allows the router to search for routes in the IGP database. You need to configure this statement on routers that might be unable to locate a path using intra-domain CSPF (by looking in the traffic engineering database (TED)). When you configure inter-area LSPs, the **inter-domain** statement is required.

Before you begin:

- Configure the device interfaces with family MPLS.
- Configure the device router ID and autonomous system number.
- Enable MPLS and RSVP on the router and transit interfaces.
- Configure your IGP to support traffic engineering.
- Set up an LSP from the ingress to the egress router.

To configure an LSP across multiple ASs on the ingress label-switched router (LER):

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set mpls interface all
user@LER# set mpls interface fxp0.0 disable
```

2. Enable RSVP on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set rsvp interface all
user@LER# set rsvp interface fxp0.0 disable
```

3. Configure the inter-area LSP.

```
[edit protocols]
user@LER# set mpls label-switched-path inter-area-LSP-name to
  egress-LER-ip-address
user@LER# set mpls label-switched-path inter-area-LSP-name inter-domain
```

4. Verify and commit the configuration.

```
[edit protocols]
user@LER# set rsvp interface ge-0/0/0.0
user@LER# set rsvp interface lo0.0
```

```
user@LER# set rsvp interface fxp0.0 disable
user@LER# set mpls statistics traffic-class-statistics
user@LER# set mpls label-switched-path R1-R2 to 20.0.0.1
user@LER# set mpls label-switched-path R1-R2 inter-domain
user@LER# set mpls interface ge-0/0/0.0
user@LER# set mpls interface lo0.0
user@LER# set mpls interface fxp0.0 disable
user@LER# set ospf traffic-engineering
user@LER# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@LER# set ospf area 0.0.0.0 interface lo0.0
```

## Disabling Normal TTL Decrementing

---

By default, the time-to-live (TTL) field value in the packet header is decremented by 1 for every hop the packet traverses in the LSP, thereby preventing loops. If the TTL field value reaches 0, packets are dropped, and an Internet Control Message Protocol (ICMP) error packet is sent to the originating router.

If the normal TTL decrement is disabled, the TTL field of IP packets entering LSPs are decremented by only 1 on transiting the LSP, making the LSP appear as a one-hop router to diagnostic tools, such as **traceroute**. Decrementing the TTL field by 1 is done by the ingress router, which pushes a label on IP packets with the TTL field in the label initialized to 255. The label's TTL field value is decremented by 1 for every hop the MPLS packet traverses in the LSP. On the penultimate hop of the LSP, the router pops the label but does not write the label's TTL field value to the IP packet's TTL field. Instead, when the IP packet reaches the egress router, the IP packet's TTL field value is decremented by 1.

When you use **traceroute** to diagnose problems with an LSP from outside that LSP, **traceroute** sees the ingress router, even though the egress router performs the TTL decrement. The behavior of **traceroute** is different if it is initiated from the ingress router of the LSP. In this case, the egress router would be the first router to respond to **traceroute**.

You can disable normal TTL decrementing in an LSP so that the TTL field value does not reach 0 before the packet reaches its destination, thus preventing the packet from being dropped. You can also disable normal TTL decrementing to make the MPLS cloud appear as a single hop, thereby hiding the network topology.

There are two ways to disable TTL decrementing:

- On the ingress of the LSP, if you include the **no-decrement-ttl** statement, the ingress router negotiates with all downstream routers using a proprietary RSVP object, to ensure all routers are in agreement. If negotiation succeeds, the whole LSP behaves as one hop to transit IP traffic.

```
no-decrement-ttl;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** The RSVP object is proprietary to the Junos OS and might not work with other software. This potential incompatibility applies only to RSVP-signaled LSPs. When you include the **no-decrement-ttl** statement, TTL hiding can be enforced on a per-LSP basis.

- On the ingress router, you can include the **no-propagate-ttl** statement. The **no-propagate-ttl** statement applies to all LSPs, regardless of whether they are RSVP-signaled or LDP-signaled. Once set, all future LSPs traversing through this router behave as a single hop to IP packets. LSPs established before you configure this statement are not affected.

```
no-propagate-ttl;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The operation of the **no-propagate-ttl** statement is interoperable with other vendors' equipment. However, you must ensure that all routers are configured identically.

To configure the TTL behavior for a single VRF routing instance, include the **no-vrf-propagate-ttl** or the **vrf-propagate-ttl** statement in the routing instance configuration at the **[edit routing-instances *instance-name*]** hierarchy level. The **no-vrf-propagate-ttl** or the **vrf-propagate-ttl** statement overrides the behavior configured globally for the router. If the router is operating in default mode with normal TTL decrementing, the **no-vrf-propagate-ttl** overrides the global behavior for the routing instance on which the **no-vrf-propagate-ttl** statement is configured.

## Configuring Adaptive LSPs

An LSP occasionally might need to reroute itself for these reasons:

- The continuous reoptimization process is configured with the **optimize-timer** statement.
- The current path has connectivity problems.
- The LSP is preempted by another LSP configured with the **priority** statement and is forced to reroute.
- The explicit-path information for an active LSP is modified, or the LSP's bandwidth is increased.

You can configure an LSP to be *adaptive* when it is attempting to reroute itself. When it is adaptive, the LSP holds onto existing resources until the new path is successfully established and traffic has been cut over to the new LSP. To retain its resources, an adaptive LSP does the following:

- Maintains existing paths and allocated bandwidths—This ensures that the existing path is not torn down prematurely and allows the current traffic to continue flowing while the new path is being set up.
- Avoids double-counting for links that share the new and old paths—Double-counting occurs when an intermediate router does not recognize that the new and old paths belong to the same LSP and counts them as two separate LSPs, requiring separate bandwidth allocations. If some links are close to saturation, double-counting might cause the setup of the new path to fail.

By default, adaptive behavior is disabled. You can include the **adaptive** statement in two different hierarchy levels.

If you specify the **adaptive** statement at the LSP hierarchy levels, the adaptive behavior is enabled on all primary/secondary paths of the LSP. This means both the primary and secondary paths share the same bandwidth on common links.

To configure adaptive behavior for all LSP paths, include the **adaptive** statement in the LSP configuration:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

If you specify the **adaptive** statement at the [edit protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*] hierarchy level, adaptive behavior is enabled only on the path on which it is specified. Bandwidth double-counting occurs between different paths. However, if you also have the **adaptive** statement configured at the [edit protocols mpls **label-switched-path** *lsp-name*] hierarchy level, it overrides the adaptive behavior of each individual path.

To configure adaptive behavior for either the primary or secondary level, include the **adaptive** statement:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]

## Damping Advertisement of LSP State Changes

When an LSP changes from being up to being down, or from down to up, this transition takes effect immediately in the router software and hardware. However, when advertising LSPs into IS-IS and OSPF, you may want to damp LSP transitions, thereby not advertising the transition until a certain period of time has transpired (known as the hold time). In this case, if the LSP goes from up to down, the LSP is not advertised as being down until it has remained down for the hold-time period. Transitions from down to up are advertised into IS-IS and OSPF immediately. Note that LSP damping affects only the IS-IS and OSPF advertisements of the LSP; other routing software and hardware react immediately to LSP transitions.

To damp LSP transitions, include the **advertisement-hold-time** statement:

```
advertisement-hold-time seconds;
```

**seconds** can be a value from 0 through 65,535 seconds. The default is 5 seconds.

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

## Configuring Primary and Secondary LSPs

By default, an LSP routes itself hop-by-hop toward the egress router. The LSP tends to follow the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are “soft” in nature because they automatically re-route themselves whenever a change occurs in a routing table or in the status of a node or link.

To configure the path so that it follows a particular route, create a named path using the **path** statement, as described in [“Creating Named Paths” on page 414](#). Then apply the named path by including the **primary** or **secondary** statement. A named path can be referenced by any number of LSPs.

To configure primary and secondary paths for an LSP, complete the steps in the following sections:

- [Configuring Primary and Secondary Paths for an LSP on page 459](#)
- [Configuring the Revert Timer for LSPs on page 460](#)
- [Specifying the Conditions for Path Selection on page 461](#)

## Configuring Primary and Secondary Paths for an LSP

The **primary** statement creates the primary path, which is the LSP’s preferred path. The **secondary** statement creates an alternative path. If the primary path can no longer reach the egress router, the alternative path is used.

To configure primary and secondary paths, include the **primary** and **secondary** statements:

```
primary path-name {  
  ...  
}  
secondary path-name {  
  ...  
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

When the software switches from the primary to a secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable, but no sooner than the retry time specified in the **retry-timer** statement. (For more information, see [“Configuring the Connection Between Ingress and Egress Routers” on page 419.](#))

You can configure zero or one primary path. If you do not configure a primary path, the first secondary path that is established is selected as the path.

You can configure zero or more secondary paths. All secondary paths are equal. The software does not attempt to switch among secondary paths. If the current secondary path is not available, the next one is tried in no particular order. To create a set of equal paths, specify secondary paths without specifying a primary path.

If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress router.

## Configuring the Revert Timer for LSPs

For LSPs configured with both primary and secondary paths, it is possible to configure the revert timer. If a primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to a primary path. If during this time, the primary path experiences any connectivity problems or stability problems, the timer is restarted. You can configure the revert timer for both static and dynamic LSPs.

The Junos OS also makes a determination as to which path is the preferred path. The preferred path is the path that has not encountered any difficulty in the last revert timer period. If both the primary and secondary paths have encountered difficulty, neither path is considered preferred. However, if one of the paths is dynamic and the other static, the dynamic path is selected as the preferred path.

If you have configured BFD on the LSP, Junos OS waits until the BFD session comes up on the primary path before starting the revert timer counter.

The range of values you can configure for the revert timer is 0 through 65,535 seconds. The default value is 60 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the primary path to the secondary path, remains on the secondary path permanently (until the network operator intervenes or until the secondary path goes down).

You can configure the revert timer for all LSPs on the router at the `[edit protocols mpls]` hierarchy level or for a specific LSP at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level.

To configure the revert timer, include the **revert-timer** statement:

```
revert-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

## Specifying the Conditions for Path Selection

When you have configured both primary and secondary paths for an LSP, you may need to ensure that only a specific path is used.

The **select** statement is optional. If you do not include it, MPLS uses an automatic path selection algorithm.

The **manual** and **unconditional** options do the following:

- **manual**—The path is immediately selected for carrying traffic as long as it is up and stable. Traffic is sent to other working paths if the current path is down or degraded (receiving errors). This parameter overrides all other path attributes except the **select unconditional** statement.
- **unconditional**—The path is selected for carrying traffic unconditionally, regardless of whether the path is currently down or degraded (receiving errors). This parameter overrides all other path attributes.

Because the **unconditional** option switches to a path without regard to its current status, be aware of the following potential consequences of specifying it:

- If a path is not currently up when you enable the **unconditional** option, traffic can be disrupted. Ensure that the path is functional before specifying the **unconditional** option.
- Once a path is selected because it has the **unconditional** option enabled, all other paths for the LSP are gradually cleared, including the primary and standby paths. No path can act as a standby to an unconditional path, so signaling those paths serves no purpose.

For a specific path, the **manual** and **unconditional** options are mutually exclusive. You can include the **select** statement with the **manual** option in the configuration of only one of an LSP's paths, and the **select** statement with the **unconditional** option in the configuration of only one other of its paths.

Enabling or disabling the **manual** and **unconditional** options for the **select** statement while LSPs and their paths are up does not disrupt traffic.

To specify that a path be selected for carrying traffic if it is up and stable for at least the revert timer window, include the **select** statement with the **manual** option:

```
select manual;
```

To specify that a path should always be selected for carrying traffic, even if it is currently down or degraded, include the **select** statement with the **unconditional** option:

```
select unconditional;
```

You can include the **select** statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]

---

## Configuring Hot Standby of Secondary Paths for LSPs

By default, secondary paths are set up only as needed. To have the system maintain a secondary path in a hot-standby state indefinitely, include the **standby** statement:

```
standby;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **secondary**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **secondary**]

The hot-standby state is meaningful only on secondary paths. Maintaining a path in a hot-standby state enables swift cutover to the secondary path when downstream routers on the current active path indicate connectivity problems. Although it is possible to configure the **standby** statement at the [edit protocols mpls **label-switched-path** *lsp-name* **primary** *path-name*] hierarchy level, it has no effect on router behavior.

If you configure the **standby** statement at the following hierarchy levels, the hot-standby state is activated on all secondary paths configured beneath that hierarchy level:

- [edit protocols mpls]
- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

The hot-standby state has two advantages:

- It eliminates the call-setup delay during network topology changes. Call setup can suffer from significant delays when network failures trigger large numbers of LSP reroutes at the same time.

- A cutover to the secondary path can be made before RSVP learns that an LSP is down. There can be significant delays between the time the first failure is detected by protocol machinery (which can be an interface down, a neighbor becoming unreachable, a route becoming unreachable, or a transient routing loop being detected) and the time an LSP actually fails (which requires a timeout of soft state information between adjacent RSVP routers). When topology failures occur, hot-standby secondary paths can usually achieve the smallest cutover delays with minimal disruptions to user traffic.

When the primary path is considered to be stable again, traffic is automatically switched from the standby secondary path back to the primary path. The switch is performed no faster than twice the retry-timer interval and only if the primary path exhibits stability throughout the entire switch interval.

The drawback of the hot-standby state is that more state information must be maintained by all the routers along the path, which requires overhead from each of the routers.

**NOTE:** When viewed with `inet.3`, the same LSP may appear to be shown twice as the active route (both primary and secondary), even though traffic actually is being forwarded over the primary path LSP only. This is normal output, and reflects only that the secondary standby path is available.

## Configuring Corouted Bidirectional LSPs

A corouted bidirectional packet LSP is a combination of two LSPs sharing the same path between a pair of ingress and egress nodes, as shown in [Figure 44 on page 463](#). It is established using the GMPLS extensions to RSVP-TE. This type of LSP can be used to carry any of the standard types of MPLS-based traffic, including Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. You can configure a single BFD session for the bidirectional LSP (you do not need to configure a BFD session for each LSP in each direction). You can also configure a single standby bidirectional LSP to provide a backup for the primary bidirectional LSP. Corouted bidirectional LSPs are supported for both penultimate hop popping (PHP) and ultimate hop popping (UHP).

High availability is available for bidirectional LSPs. You can enable graceful restart and nonstop active routing. Graceful restart and nonstop active routing are supported when the restarting router is the ingress, egress, or transit router for the bidirectional LSP.

**Figure 44: Corouted Bidirectional LSP**

To configure a corouted bidirectional LSP:

1. In configuration mode, configure the ingress router for the LSP and include the **corouted-bidirectional** statement to specify that the LSP be established as a corouted bidirectional LSP.

The path is computed using CSPF and initiated using RSVP signaling (just like a unidirectional RSVP signaled LSP). Both the path to the egress router and the reverse path from the egress router are created when this configuration is committed.

```
[edit protocols mpls]
user@PE1# set label-switched-path sample-lsp corouted-bidirectional
```

2. (Optional) For a reverse path, configure an LSP on the egress router and include the **corouted-bidirectional-passive** statement to associate the LSP with another LSP.

No path computation or signaling is used for this LSP since it relies on the path computation and signaling provided by the ingress LSP. You cannot configure both the **corouted-bidirectional** statement and the **corouted-bidirectional-passive** statement on the same LSP.

```
[edit protocols mpls]
user@PE1# set label-switched-path sample-lsp-reverse-path
corouted-bidirectional-passive
```

This statement also makes it easier to debug corouted bidirectional LSPs. If you configure the **corouted-bidirectional-passive** statement (again, on the egress router), you can issue **ping mpls lsp-end-point**, **ping mpls ldp**, **ping mpls rsvp**, **traceroute mpls ldp**, and **traceroute mpls rsvp** commands to test the corouted bidirectional LSP from the egress router.

3. Use the **show mpls lsp extensive** and the **show rsvp session extensive** commands to display information about the bidirectional LSP.

The following shows output for the **show rsvp session extensive** command when run on an ingress router with a bidirectional LSP configured:

```
user@PE1> show rsvp session extensive
```

```
Ingress RSVP: 2 sessions
```

```

## Configuring the Entropy Label for LSPs

The insertion of entropy labels for an LSP enables transit routers to load-balance MPLS traffic across ECMP paths or Link Aggregation groups using just the MPLS label stack as a hash input without having to rely on deep packet inspection. Deep packet inspection requires more of the router's processing power and different routers have differing deep-packet inspection capabilities.

To configure the entropy label for an LSP, complete the following steps:

1. On the ingress router, include the **entropy-label** statement at the **[edit protocols mpls labeled-switched-path *labeled-switched-path-name*]** hierarchy level or at the **[edit protocols mpls static-labeled-switched-path *labeled-switched-path-name* ingress]** hierarchy level. The entropy label is added to the MPLS label stack and can be processed in the forwarding plane.

```
entropy-label;
```

**NOTE:** This is only applicable for RSVP and static LSPs.

2. On the ingress router, you can configure an ingress policy for LDP-signaled LSPs:

```
entropy-label {
  ingress-policy policy-name;
}
```

Configure the ingress policy at the **[edit policy-options]** hierarchy level:

```
policy-options {
  policy-statement policy-name {
    term term-name {
      from {
        prefix-list prefix-list-name;
      }
      then actions;
    }
  }
}
```

The following shows an example of an entropy label ingress policy.

```
policy-options {
  policy-statement entropy-policy {
    term no-insert-entropy-label {
      from {
        prefix-list no-entropy-label-fec;
      }
      then accept;
    }
  }
}
```

```
}
}
```

3. (Optional) By default, routers that support the pushing and popping of entropy labels are configured with the **load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the provider edge (PE) router from signaling the entropy label capability by configuring the **no-load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level.

```
[edit forwarding-options]
user@PE no-load-balance-label-capability;
```

Transit routers require no configuration. The presence of the entropy label indicates to the transit router to load balance based solely on the MPLS label stack.

Penultimate hop routers pop the entropy label by default.

## Example: Configuring an Entropy Label for a BGP Labeled Unicast LSP

This example shows how to configure an entropy label for a BGP labeled unicast to achieve end-to-end load balancing using entropy labels. When an IP packet has multiple paths to reach its destination, Junos OS uses certain fields of the packet headers to hash the packet to a deterministic path. This requires an entropy label, a special load-balancing label that can carry the flow information. LSRs in the core simply use the entropy label as the key to hash the packet to the correct path. An entropy label can be any label value between 16 to 1048575 (regular 20-bit label range). Since this range overlaps with the existing regular label range, a special label called entropy label indicator (ELI) is inserted before the entropy label. ELI is a special label assigned by IANA with the value of 7.

BGP labeled unicasts generally concatenate RSVP or LDP LSPs across multiple IGP areas or multiple autonomous systems. RSVP or LDP entropy labels are popped at the penultimate hop node, together with the RSVP or LDP label. This feature enables the use of entropy labels at the stitching points to bridge the gap between the penultimate hop node and the stitching point, in order to achieve end-to-end entropy label load balancing for BGP traffic.

- [Requirements on page 468](#)
- [Overview on page 468](#)
- [Configuration on page 469](#)
- [Verification on page 484](#)

## Requirements

This example uses the following hardware and software components:

- Seven MX Series routers with MPCs
- Junos OS Release 15.1 or later running on all the devices

Before you configure an entropy label for BGP labeled unicast, make sure you:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure RSVP.
5. Configure MPLS.

## Overview

When BGP labeled unicasts concatenate RSVP or LDP LSPs across multiple IGP areas or multiple autonomous systems, RSVP or LDP entropy labels are popped at the penultimate hop node, together with the RSVP or LDP label. However, there are no entropy labels at the stitching points, that is, the routers between two areas. Therefore, the routers at the stitching points used the BGP labels to forward packets.

Beginning with Junos OS Release 15.1, you can configure an entropy label for BGP labeled unicast to achieve end-to-end entropy label load balancing. This feature enables the use of an entropy label at the stitching points in order to achieve end-to-end entropy label load balancing for BGP traffic. Junos OS allows the insertion of entropy labels at the BGP labeled unicast LSP ingress.

By default, routers that support entropy labels are configured with the **load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the signaling of entropy label capability by configuring the **no-load-balance-label-capability** at the **[edit forwarding-options]** hierarchy level.

```
[edit forwarding-options]
user@PE# no-load-balance-label-capability
```

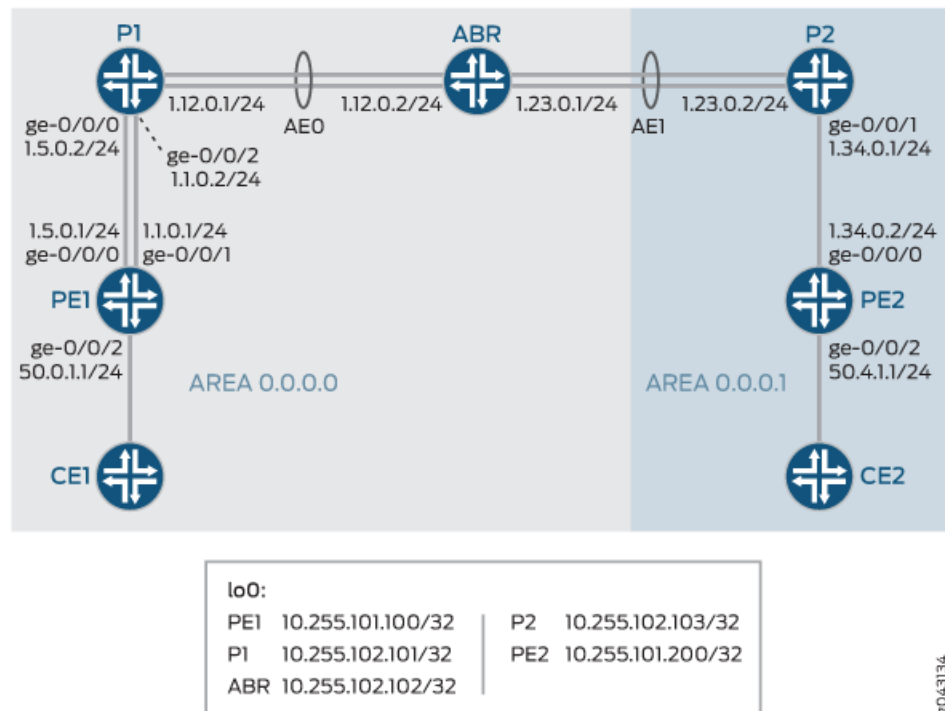

**NOTE:** You can explicitly disable advertising entropy label capability at egress for routes specified in the policy with the `no-entropy-label-capability` option at the `[edit policy-options policy-statement policy-name then]` hierarchy level.

```
[edit policy-options policy-statement policy-name then]
user@PE# no-entropy-label-capability
```

## Topology

In Figure 45 on page 469, Router PE1 is the ingress router and Router PE2 is the egress router. Routers P1 and P2 are the transit routers. Router ABR is the area bridge router between Area 0 and Area 1. LAG is configured on the provider routers for load balancing the traffic. Entropy label capability for BGP labeled unicast is enabled on the ingress Router PE1.

Figure 45: Configuring an Entropy Label for BGP Labeled Unicast

## Configuration

- Configuring Router PE1 on page 474
- Configuring Router P1 on page 477
- Configuring Router ABR on page 479
- Results on page 481

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
Router PE1
set interfaces ge-0/0/0 unit 0 family inet address 1.5.0.1/24
set interfaces ge-0/0/0 unit 0 family iso
set interfaces ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:1/120
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces ge-0/0/1 unit 0 family inet address 1.1.0.1/24
set interfaces ge-0/0/1 unit 0 family iso
set interfaces ge-0/0/1 unit 0 family inet6 address 2000::1:1:0:1/120
set interfaces ge-0/0/1 unit 0 family mpls

## Configuring Router PE1

### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

**NOTE:** Repeat this procedure for Router PE2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.5.0.1/24
user@PE1# set ge-0/0/0 unit 0 family iso
user@PE1# set ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:1/120
user@PE1# set ge-0/0/0 unit 0 family mpls

user@PE1# set ge-0/0/1 unit 0 family inet address 1.1.0.1/24
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6 address 2000::1:1:0:1/120
user@PE1# set ge-0/0/1 unit 0 family mpls

user@PE1# set ge-0/0/2 unit 0 family inet address 50.0.1.1/24
user@PE1# set ge-0/0/2 unit 0 family inet6 address 2000::1:34:0:2/120

user@PE1# set ge-0/0/3 vlan-tagging
user@PE1# set ge-0/0/3 unit 0 vlan-id 520
user@PE1# set ge-0/0/3 unit 0 family inet address 1.0.0.2/16
```

2. Configure the loopback interface.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.101.100/32 primary
```

3. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@PE1# set router-id 10.255.101.100
user@PE1# set autonomous-system 1
```

4. Configure RSVP protocol for all interfaces.

```
[edit protocols]
user@PE1# set protocols rsvp interface all
```

5. Enable MPLS on all the interfaces of Router PE1 and specify the LSP.

```
[edit protocols]
user@PE1# set mpls icmp-tunneling
user@PE1# set mpls no-cspf
user@PE1# set mpls label-switched-path r0-r2 to 10.255.102.102
user@PE1# set mpls label-switched-path r0-r2 entropy-label
user@PE1# set mpls interface all
```

6. Configure IBGP on the internal routers.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
user@PE1# set bgp group ibgp local-address 10.255.101.100
```

7. Enable entropy label capability for BGP labeled unicast for internal BGP group ibgp.

```
user@PE1# set bgp group ibgp family inet labeled-unicast entropy-label
user@PE1# set bgp group ibgp neighbor 10.255.102.102 family inet labeled-unicast
rib inet.3
user@PE1# set bgp group ibgp neighbor 10.255.101.200 family inet-vpn unicast
```

8. Enable the OSPF protocol on all the interfaces of the area border router (ABR).

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

9. Define prefix lists to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-options prefix-list el-fec 10.255.101.200/32
user@PE1# set policy-options prefix-list el-fec-2 10.255.102.102/32
```

10. Define a policy EL to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-statement EL from prefix-list el-fec
user@PE1# set policy-statement EL then accept
```

11. Define another policy EL-2 to specify the routes with entropy label capability.

```
[edit policy-options ]
user@PE1# set policy-statement EL-2 from prefix-list el-fec-2
user@PE1# set policy-statement EL-2 then accept
```

12. Define a policy to export BGP routes to the OSPF routing table.

```
[edit policy-options ]
user@PE1# set policy-statement bgp-to-ospf from protocol bgp
user@PE1# set policy-statement bgp-to-ospf then accept
```

13. Define a policy to export OSPF routes to the BGP routing table.

```
[edit policy-options ]
user@PE1# set policy-statement ospf-to-bgp from protocol ospf
user@PE1# set policy-statement ospf-to-bgp then accept
```

14. Define a policy to export static routes to the BGP routing table.

```
[edit policy-options ]
user@PE1# set policy-statement stat-to-bgp from protocol static
user@PE1# set policy-statement stat-to-bgp then accept
```

15. Configure a VPN target for the VPN community.

```
[edit policy-options ]
user@PE1# set community VPN members target:100:1
```

16. Configure the Layer 3 VPN routing instance VPN-l3vpn.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn instance-type vrf
```

17. Assign the interfaces for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn interface ge-0/0/2.0
user@PE1# set VPN-l3vpn interface ge-0/0/3.0
```

18. Configure the route distinguisher for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn route-distinguisher 100.100.100.100:100
```

19. Configure a VPN routing and forwarding (VRF) target for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn vrf-target target:100:1
```

20. Configure a static route to Device CE1 using the Layer 3 VPN protocol for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn routing-options static route 5.0.0.0/16 next-hop 1.0.0.1
```

21. Export the BGP routes to the OSPF routing table for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn protocols ospf export bgp-to-ospf
```

22. Assign the OSPF interface for the VPN-l3vpn routing instance.

```
[edit routing-instances]
user@PE1# set VPN-l3vpn protocols ospf area 0.0.0.0 interface ge-0/0/2.0
```

### Configuring Router P1

#### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router P1:

**NOTE:** Repeat this procedure for Router P2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the interfaces with IPv4 and IPv6 addresses.

```
[edit interfaces]
user@P1# set ge-0/0/0 unit 0 family inet address 1.5.0.2/24
user@P1# set ge-0/0/0 unit 0 family iso
user@P1# set ge-0/0/0 unit 0 family inet6 address 2000::1:5:0:2/120
user@P1# set ge-0/0/0 unit 0 family mpls

user@P1# set ge-0/0/2 unit 0 family inet address 1.1.0.2/24
user@P1# set ge-0/0/2 unit 0 family iso
user@P1# set ge-0/0/2 unit 0 family inet6 address 2000::1:1:0:2/120
user@P1# set ge-0/0/2 unit 0 family mpls

user@P1# set ge-0/0/1 gigether-options 802.3ad ae0

user@P1# set ge-0/0/3 gigether-options 802.3ad ae0
```

2. Configure link aggregation on the interfaces.

```
user@P1# set ae0 unit 0 family inet address 1.12.0.1/24
user@P1# set ae0 unit 0 family mpls
```

3. Configure the loopback interface.

```
[edit interfaces]
user@P1# set lo0 unit 0 family inet address 10.255.102.101/32 primary
```

4. Configure MPLS labels that the router uses for hashing the packets to its destination for load balancing.

```
[edit forwarding-options]
user@P1# set hash-key family mpls label-1
user@P1# set hash-key family mpls label-2
user@P1# set hash-key family mpls label-3
user@P1# set enhanced-hash-key family mpls no-payload
```

5. Set the router ID and the autonomous system number.

```
[edit routing-options]
user@P1# set router-id 10.255.102.101
user@P1# set autonomous-system 1
```

6. Enable per packet load balancing.

```
[edit routing-options]
user@P1# set forwarding-table export pplb
```

7. Configure the RSVP protocol for all interfaces.

```
[edit protocols]
user@P1# set protocols rsvp interface all
```

8. Enable MPLS on all the interfaces of Router P1 and specify the LSP.

```
[edit protocols]
user@P1# set protocols mpls icmp-tunneling
user@P1# set protocols mpls interface all
```

9. Enable the OSPF protocol on all the interfaces of Router P1 excluding the management interface.

```
[edit protocols]
user@P1# set protocols ospf traffic-engineering
user@P1# set protocols ospf area 0.0.0.0 interface lo0.0 passive
user@P1# set protocols ospf area 0.0.0.0 interface fxp0.0 disable
```

```

user@P1# set protocols ospf area 0.0.0.0 interface all
user@P1# set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
user@P1# set protocols ospf area 0.0.0.0 interface ge-0/0/1.0

```

10. Define a policy for per packet load balancing.

```

[edit policy-options]]
user@P1# set policy-statement pplb then load-balance per-packet

```

### Configuring Router ABR

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router ABR:

1. Configure the interfaces with IPv4 and IPv6 addresses.

```

[edit interfaces]
user@ABR# set ge-0/0/0 gigether-options 802.3ad ae0

user@ABR# set ge-0/0/1 gigether-options 802.3ad ae1

user@ABR# set ge-0/0/2 gigether-options 802.3ad ae0

user@ABR# set ge-0/0/3 gigether-options 802.3ad ae1

```

2. Configure the loopback interface.

```

[edit interfaces]
user@ABR# set lo0 unit 0 family inet address 10.255.102.102/32 primary

```

3. Configure link aggregation on the interfaces.

```

[edit interfaces]
user@ABR# set ae0 unit 0 family inet address 1.12.0.2/24
user@ABR# set ae0 unit 0 family mpls
user@ABR# set ae1 unit 0 family inet address 1.23.0.1/24
user@ABR# set ae1 unit 0 family mpls

```

4. Configure MPLS labels that the router uses for hashing the packets to its destination for load balancing.

```

[edit forwarding-options]

```

```

user@ABR# set hash-key family mpls label-1
user@ABR# set hash-key family mpls label-2
user@ABR# set hash-key family mpls label-3
user@ABR# set enhanced-hash-key family mpls no-payload

```

5. Set the router ID and the autonomous system number.

```

[edit routing-options]
user@ABR# set router-id 10.255.102.102
user@ABR# set autonomous-system 1

```

6. Enable per packet load balancing.

```

[edit routing-options]
user@ABR# set forwarding-table export pplib

```

7. Configure the RSVP protocol for all interfaces.

```

[edit protocols]
user@ABR# set protocols rsvp interface all

```

8. Enable MPLS on all the interfaces of Router P1 and specify the LSP.

```

[edit protocols]
user@ABR# set mpls icmp-tunneling
user@ABR# set mpls label-switched-path r2-r0 to 10.255.101.100
user@ABR# set mpls label-switched-path r2-r0 entropy-label
user@ABR# set mpls label-switched-path r2-r4 to 10.255.101.200
user@ABR# set mpls label-switched-path r2-r4 entropy-label
user@ABR# set mpls interface all

```

9. Configure IBGP on the internal routers.

```

[edit protocols ]
user@ABR# set bgp group ibgp type internal
user@ABR# set bgp group ibgp local-address 10.255.102.102
user@ABR# set bgp group ibgp family inet labeled-unicast rib inet.3
user@ABR# set bgp group ibgp neighbor 10.255.101.100 export send-inet3-R4
user@ABR# set bgp group ibgp neighbor 10.255.101.200 export send-inet3-R0

```

10. Enable the OSPF protocol on all the interfaces of ABR.

```

[edit protocols ]
user@ABR# set ospf traffic-engineering
user@ABR# set ospf area 0.0.0.0 interface lo0.0 passive
user@ABR# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@ABR# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@ABR# set ospf area 0.0.0.0 interface ae0.0

```

```

user@ABR# set ospf area 0.0.0.0 interface fxp0.0 disable
user@ABR# set ospf area 0.0.0.1 interface ge-0/0/3.0
user@ABR# set ospf area 0.0.0.1 interface ge-0/0/1.0
user@ABR# set ospf area 0.0.0.1 interface ae1.0

```

11. Define a policy to specify the routes with entropy label capability.

```

[edit policy-options ]
user@ABR# set policy-statement pplb then load-balance per-packet
user@ABR# set policy-statement send-inet3-R0 from route-filter 10.255.101.100/32
exact
user@ABR# set policy-statement send-inet3-R0 then accept
user@ABR# set policy-statement send-inet3-R4 from route-filter 10.255.101.200/32
exact
user@ABR# set policy-statement send-inet3-R4 then accept

```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, **show forwarding options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

## Verification

Confirm that the configuration is working properly.

- [Verifying That the Entropy Label Capability Is Being Advertised from Router PE2 on page 484](#)
- [Verifying That Router ABR Receives the Entropy Label Advertisement on page 485](#)
- [Verifying That the Entropy Label Flag Is Set on page 486](#)

### Verifying That the Entropy Label Capability Is Being Advertised from Router PE2

**Purpose** Verify that the entropy label capability path attribute is being advertised from the upstream Router PE2 at egress.

**Action** From operational mode, run the **show route 10.255.101.200 advertising-protocol bgp 10.255.102.102** command on Router PE2.

```
user@PE2> show route 10.255.101.200 advertising-protocol bgp 10.255.102.102
```

```

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
* 10.255.101.200/32 (1 entry, 1 announced)
  BGP group ibgp type Internal
    Route Label: 299920
    Nexthop: Self
    Flags: Nexthop Change
    MED: 2
    Localpref: 4294967294
    AS path: [1] I
    Entropy label capable

```

**Meaning** The output shows that the host PE2 with the IP address of 10.255.101.200 has the entropy label capability. The host is advertising the entropy label capability to its BGP neighbors.

### Verifying That Router ABR Receives the Entropy Label Advertisement

**Purpose** Verify that Router ABR receives the entropy label advertisement at ingress from Router PE2.

**Action** From operational mode, run the **show route 10.255.101.200 receiving-protocol bgp 10.255.101.200** command on Router ABR.

```

user@ABR> show route 10.255.101.200 receiving-protocol bgp 10.255.101.200
inet.0: 63 destinations, 63 routes (63 active, 0 holddown, 0 hidden)

## Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (PHP).

[Figure 46 on page 487](#) illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

**Figure 46: Penultimate-Hop Popping for an LSP**

You can also configure ultimate-hop popping (UHP) (as shown in [Figure 47 on page 488](#)) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate-hop popping LSP, the penultimate router (Router P2 in [Figure 47 on page 488](#)) performs the standard

MPLS label swapping operation (in this example, label 2 for label 3 ) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

Figure 47: Ultimate-Hop Popping for an LSP

The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band OAM
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs
- Point-to-multipoint LSPs
- CCC
- **traceroute** command

For more information about UHP behavior, see Internet draft [draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt](#), *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a VT interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- **Layer 2 VPNs and Layer 2 circuits**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the VC label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- **Layer 3 VPN**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward the CE router. However, if you have configured the **vrf-table-label** statement for the Layer 3 VPN routing instance, the inner LSI label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

**NOTE:** UHP for Layer 3 VPNs configured with the **vrf-table-label** statement is supported on MX Series 5G Universal Routing Platforms only.

- **VPLS**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

**NOTE:** UHP for VPLS configured with the **no-tunnel-service** statement is supported on MX 3D Series routers only.

- **IPv4 over MPLS**—A packet arrives at the PE router (egress of the UHP LSP) with one label (S=1). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route (S=1) points to the inet.0 routing table.
- **IPv6 over MPLS**—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the

inner label in the mpls.0 routing table redirects back to the mpls.0 routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the inet6.0 routing table.

- Enabling both PHP and UHP LSPs—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the **install-nexthop** statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the **ultimate-hop-popping** statement:

```
ultimate-hop-popping;
```

Include this statement at the **[edit protocols mpls label-switched-path label-switched-path-name]** hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the **[edit protocols mpls]** hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the router. You can also configure the **ultimate-hop-popping** statement under the equivalent **[edit logical-routers]** hierarchy levels.

**NOTE:** When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a PathTear message along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).

If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the **enhanced-ip** option for the **network-services** statement:

```
network-services enhanced-ip;
```

You configure this statement at the **[edit chassis]** hierarchy level. Once you have configured the **network-services** statement, you need to reboot the router to enable UHP behavior.

## Configuring Static LSPs

To configure static LSPs, configure the ingress router and each router along the path up to and including the egress router.

To configure static MPLS, perform the following tasks:

- [Configuring the Ingress Router for Static LSPs on page 491](#)
- [Configuring the Intermediate \(Transit\) and Egress Routers for Static LSPs on page 494](#)
- [Configuring a Bypass LSP for the Static LSP on page 497](#)
- [Configuring the Protection Revert Timer for Static LSPs on page 497](#)
- [Configuring Static Unicast Routes for Point-to-Multipoint LSPs on page 497](#)

### Configuring the Ingress Router for Static LSPs

The ingress router checks the IP address in the incoming packet's destination address field and, if it finds a match in the routing table, applies the label associated with that address to the packets. The label has forwarding information associated with it, including the address of the next-hop router, and the route preference and CoS values.

To configure static LSPs on the ingress router, include the **ingress** statement:

```
ingress {
  bandwidth bps;
  class-of-service cos-value;
  description string;
  install {
    destination-prefix <active>;
  }
  link-protection bypass-name name;
  metric metric;
  next-hop (address | interface-name | address/interface-name);
  no-install-to-address;
  node-protection bypass-name name next-next-label label;
  policing {
    filter filter-name;
    no-auto-policing;
  }
  preference preference;
  push out-label;
  to address;
}
```

You can include these statements at the following hierarchy levels:

- `[edit protocols mpls static-label-switched-path static-lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls static-label-switched-path static-lsp-name]`

When you configure a static LSP on the ingress router, the **next-hop**, **push**, and **to** statements are required; the other statements are optional.

The configuration for a static LSP on the ingress router requires you to configure the following parts:

- Criteria for analyzing an incoming packet:
  - The **install** statement creates an LSP that handles IPv4 packets. All static MPLS routes created using the **install** statement are installed in inet.3 routing table, and the creating protocol is identified as static. This process is no different from creating static IPv4 routes at the **[edit routing-options static]** hierarchy level.
  - In the **to** statement, you configure the IP destination address to check when incoming packets are analyzed. If the address matches, the specified outgoing label (**push out-label**) is assigned to the packet, and the packet enters an LSP. Manually assigned outgoing labels can have values from 0 through 1,048,575. Each prefix that you specify is installed as a static route in the routing table.
- The **next-hop** statement, which supplies the IP address of the next hop to the destination. You can specify this as the IP address of the next hop, the interface name (for point-to-point interfaces only), or as **address/interface-name** to specify an IP address on an operational interface. When the next hop is on a directly attached interface, the route is installed in the routing table. You cannot configure a LAN or nonbroadcast multiaccess (NBMA) interface as a next-hop interface.
- Properties to apply to the LSP (all are optional):
  - Bandwidth reserved for this LSP (**bandwidth bps**)
  - Link protection and node protection to apply to the LSP (**bypass bypass-name, link-protection bypass-name name, node-protection bypass-name next-next-label label**)
  - Metric value to apply to the LSP (**metric**)
  - Class-of-service value to apply to the LSP (**class-of-service**)
  - Preference value to apply to the LSP (**preference**)
  - Traffic policing to apply to the LSP (**policing**)
  - Text description to apply to the LSP (**description**)
  - Install or no-install policy (**install** or **no-install-to-address**)

To determine whether a static ingress route is installed, use the command **show route table inet.3 protocol static**. Sample output follows. The **push** keyword denotes that a label is to be added in front of an IP packet.

```
10.0.0.0      *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0, push 1000123
```

### Example: Configuring the Ingress Router

Configure the ingress router for a static LSP that consists of three routers (see Figure 48 on page 493).

Figure 48: Static MPLS Configuration

For packets addressed to 10.0.0.0, assign label 1000123 and transmit them to the next-hop router at 11.1.1.1:

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  mpls {
    static-label-switched-path path1 {
      ingress {
        next-hop 11.1.1.1;
        to 10.0.0.0;
        push 1000123;
      }
    }
  }
  interface so-0/0/0.0;
}
routing-options {
  static {
    route 10.0.0.0/8 {
      static-lsp-next-hop path1;
    }
  }
}
```

To determine whether the static ingress route is installed, use the following command:

```
user@host> show route table inet.0 protocol static
```

Sample output follows. The **push 1000123** keyword identifies the route.

```
10.0.0.0/8          *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0.0, push 1000123
```

## Configuring the Intermediate (Transit) and Egress Routers for Static LSPs

Intermediate (transit) and egress routers perform similar functions—they modify the label that has been applied to a packet. An intermediate router can change the label. An egress router removes the label (if the packet still contains a label) and continues forwarding the packet to its destination.

To configure static LSPs on intermediate and egress routers, include the **transit** statement:

```
static-label-switched-path lsp-name {
  transit incoming-label {
    bandwidth bps;
    description string;
    link-protection bypass-name name;
    next-hop (address | interface-name | address/interface-name);
    node-protection bypass-name name next-next-label label;
    pop;
    swap out-label;
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls static-label-switched-path *static-lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]

For the **transit** statement configuration, the **next-hop** and **pop** | **swap** statements are required. The remaining statements are optional.

Each statement within the **transit** statement consists of the following parts:

- Packet label (specified in the **transit** statement)
- The **next-hop** statement, which supplies the IP address of the next hop to the destination. The address is specified as the IP address of the next hop, or the interface name (for point-to-point interfaces only), or **address** and **interface-name** to specify an IP address on an operational interface. When the specified next hop is on a directly attached interface, this route is installed in the routing table. You cannot configure a LAN or NBMA interface as a next-hop interface.
- Operation to perform on the labeled packet:
  - For egress routers, you generally just remove the packet's label altogether (**pop**) and continue forwarding the packet to the next hop. However, if the previous router removed the label, the egress router examines the packet's IP header and forwards the packet toward its IP destination.

- For intermediate (transit) routers only, exchange the label for another label (**swap out-label**). Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. Manually assigned outgoing labels can have values from 0 through 1,048,575.
- Label properties to apply to the packet (all are optional):
  - Bandwidth reserved for this route (**bandwidth bps**).
  - Link-protection and node-protection to apply to the LSP (**bypass bypass-name, link-protection bypass-name name, node-protection bypass-name next-next-label label**).
  - Text description to apply to the LSP (specified in the **description** statement).

The static routes are installed in the default MPLS routing table, `mpls.0`, and the creating protocol is identified as static. To verify that a static route is properly installed, use the command **show route table mpls.0 protocol static**. Sample output follows:

```
1000123      *[Static/5] 00:00:38
> to 12.2.2.2 via so-5/0/0.0, swap 1000456
```

You can configure a revert timer for a static LSP transiting an intermediate router. After traffic has been switched to a bypass static LSP, it is typically switched back to the primary static LSP when it comes back up. There is a configurable delay in the time (called the revert timer) between when the primary static LSP comes up and when traffic is reverted back to it from the bypass static LSP. This delay is needed because when the primary LSP comes back up, it is not certain whether all of the interfaces on the downstream node of the primary path have come up yet. You can display the revert timer value for an interface using the **show mpls interface detail** command. For more information, see [“Configuring the Revert Timer for LSPs” on page 460](#).

### Example: Configuring an Intermediate Router

For packets labeled **1000123** arriving on interface **so-0/0/0**, assign the label **1000456**, and transmit them to the next-hop router at **12.2.2.2**:

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  mpls {
    static-label-switched-path path1 {
      transit 1000123 {
        next-hop 12.2.2.2;
        swap 1000456;
      }
    }
  }
}
```

```

    }
    interface so-0/0/0.0;
  }
}

```

To determine whether the static intermediate route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The **swap 1000456** keyword identifies the route.

```

1000123      *[Static/5] 00:01:48
> to 12.2.2.2 via so-0/0/0, swap 1000456

```

### Example: Configuring an Egress Router

For packets labeled **1000456** arriving on interface **so-0/0/0**, remove the label and transmit the packets to the next-hop router at **13.3.3.3**:

```

[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  mpls {
    static-label-switched-path path1 {
      transit 1000456 {
        next-hop 13.3.3.3;
        pop;
      }
    }
    interface so-0/0/0.0;
  }
}

```

To determine whether the static egress route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The **pop** keyword identifies the egress route.

```

1000456      *[Static/5] 00:01:48
> to 13.3.3.3 via so-0/0/0, pop

```

## Configuring a Bypass LSP for the Static LSP

To enable a bypass LSP for the static LSP, configure the **bypass** statement:

```
bypass bypass-name {
    bandwidth bps;
    description string;
    next-hop (address | interface-name | address/interface-name);
    push out-label;
    to address;
}
```

## Configuring the Protection Revert Timer for Static LSPs

For static LSPs configured with a bypass static LSP, it is possible to configure the protection revert timer. If a static LSP goes down and traffic is switched to the bypass LSP, the protection revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert back to the original static LSP.

The range of values you can configure for the protection revert timer is 0 through 65,535 seconds. The default value is 5 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the original static LSP to the bypass static LSP, remains on the bypass LSP permanently (until the network operator intervenes or until the bypass LSP goes down).

You can configure the protection revert timer for all LSPs on the router at the **[edit protocols mpls]** hierarchy level or for a specific LSP at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level.

To configure the protection revert timer for static LSPs include the **protection-revert-time** statement:

```
protection-revert-time seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

## Configuring Static Unicast Routes for Point-to-Multipoint LSPs

You can configure a static unicast IP route with a point-to-multipoint LSP as the next hop. For more information about point-to-multipoint LSPs, see [“Point-to-Multipoint LSPs Overview” on page 527](#), [“Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs” on page 551](#), and [“Configuring CCC Switching for Point-to-Multipoint LSPs” on page 1374](#).

To configure a static unicast route for a point-to-multipoint LSP, complete the following steps:

1. On the ingress PE router, configure a static IP unicast route with the point-to-multipoint LSP name as the next hop by including the **p2mp-lsp-next-hop** statement:

```
p2mp-lsp-next-hop point-to-multipoint-lsp-next-hop;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options static route *route-name*]
  - [edit logical-systems *logical-system-name* routing-options static route *route-name*]
2. On the egress PE router, configure a static IP unicast route with the same destination address configured in Step 1 (the address configured at the [edit routing-options static route] hierarchy level) by including the **next-hop** statement:

```
next-hop address;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options static route *route-name*]
- [edit logical-systems *logical-system-name* routing-options static route *route-name*]

**NOTE:** CCC and static routes cannot use the same point-to-multipoint LSP.

For more information on static routes, see the *Junos OS Routing Protocols Library*.

The following **show route** command output displays a unicast static route pointing to a point-to-multipoint LSP on the ingress PE router where the LSP has two branch next hops:

```
user@host> show route 5.5.5.5 detail
```

```
inet.0: 29 destinations, 30 routes (28 active, 0 holddown, 1 hidden)
5.5.5.5/32 (1 entry, 1 announced)
  *Static Preference: 5
    Next hop type: Flood
    Next hop: via so-0/3/2.0 weight 1
    Label operation: Push 100000
    Next hop: via t1-0/1/1.0 weight 1
    Label operation: Push 100064
    State: <Active Int Ext>
    Local AS: 10458
    Age: 2:41:15
    Task: RT
    Announcement bits (2): 0-KRT 3-BGP.0.0.0.0+179
    AS path: I
```

## Configuring Static Label Switched Paths for MPLS (CLI Procedure)

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress switch and each provider switch along the path up to and including the egress switch.

For the ingress switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575. Optionally, you can apply preference, class-of-service (CoS) values, node protection, and link protection to the packets.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575. Optionally, you can apply node protection and link protection to the packets.

For the egress switch, you generally just remove the label and continue forwarding the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure an LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\)” on page 77](#).
- Configure one or more provider switches. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 81](#).

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

1. [Configuring the Ingress PE Switch on page 499](#)
2. [Configuring the Provider and the Egress PE Switch on page 500](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
user@switch# set interfaces interface-name unit logical-unit-number family inet address
address
```

2. Configure the name and the traffic rate associated with the LSP:

```
[edit]
user@switch# set protocols mpls static-label-switched-path lsp-name ingress bandwidth
rate
```

3. Configure the next hop switch for the LSP:

```
[edit]
```

```
user@switch# set protocols mpls static-label-switched-path lsp-name ingress next-hop  
address-of-next-hop
```

4. Enable link protection on the specified static LSP:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path lsp-name ingress link-protection  
bypass-name name
```

5. Specify the address of the egress switch for the LSP:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path path1 ingress to  
address-of-egress-switch
```

6. Configure the new label that you want to add to the top of the label stack:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path path1 ingress push out-label
```

7. Optionally, configure the next hop address and the egress router address that you want to bypass, for the static LSP:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path lsp-name by bypass next-hop  
address-of-next-hop  
user@switch# set protocols mpls static-label-switched-path lsp-name by bypass to  
address-of-the-egress-switch  
user@switch# set protocols mpls static-label-switched-path lsp-name bypass push out-label
```

## Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress provider edge switch:

1. Configure a transit static LSP:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path path1 transit incoming-label
```

2. Configure the next hop switch for the LSP:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label  
next-hop address-of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit]  
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label  
swap out-label
```

4. Only for the egress provider edge switch, remove the label at the top of the label stack:

**NOTE:** If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

[edit]

```
user@switch# set protocols mpls static-label-switched-path lsp-name transit incoming-label
pop
```

## Configuring Static Label Switched Paths for MPLS

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress PE switch and each provider switch along the path up to and including the egress PE switch.

For the ingress PE switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575.

The egress PE switch removes the label and forwards the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure a static LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge Switches” on page 67](#).

**NOTE:** Do not configure LSPs at the [edit protocols mpls label-switched-path] hierarchy level on the PE switches.

- Configure one or more provider switches. See [“Configuring MPLS on Provider Switches” on page 71](#).

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

1. [Configuring the Ingress PE Switch on page 502](#)
2. [Configuring the Provider and the Egress PE Switch on page 502](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for every core interface:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family inet address address
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure the name associated with the static LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name
```

3. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress next-hop address-of-next-hop
```

4. Specify the address of the egress switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress to address-of-egress-switch
```

5. Configure the new label that you want to add to the top of the label stack:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress push out-label
```

## Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress PE switch:

1. Configure a transit static LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label
```

2. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label next-hop
address-of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label swap out-label
```

4. Only for the egress PE switch, remove the label at the top of the label stack:

**NOTE:** If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name transit incoming-label pop
```

## Static Segment Routing Label Switched Path

You can create static segment routing label switched paths (LSPs) for MPLS networks. For more information, see the following topics:

- [Understanding Static Segment Routing LSP in MPLS Networks on page 503](#)
- [Example: Configuring Static Segment Routing Label Switched Path on page 507](#)

### Understanding Static Segment Routing LSP in MPLS Networks

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Essentially, segments are provisioned on transit routers using the following two methods:

- First, by configuring static segment MPLS label switched paths (LSPs) at **[edit protocols mpls static-label-switched-path]** hierarchy level.
- Second, by using IGPs like ISIS and OSPF to manage segments and advertise segment labels.

The non-colored static segment routing LSPs are then configured on ingress routers at the **[edit protocols source-packet-routing sourc-routing-path]** hierarchy level. These

non-colored static segment routing LSPs refer to segment-lists which consists of the labels of the segments provisioned on the transit routers.

Segment routing leverages the source routing paradigm. A node steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress node to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack. Segment routing can be applied to the IPv6 architecture, with a new type of routing extension header. A segment is encoded as an IPv6 address. An ordered list of segments is encoded as an ordered list of IPv6 addresses in the routing extension header. The segment to process is indicated by a pointer in the routing extension header. Upon completion of a segment, the pointer is incremented. Static segment routing provisioning in MPLS networks supports static adjacency segments, prefix segment, and non-colored segment routing label switched paths. Static segment routing provisioning in an MPLS network involves segment provisioning, segment information distribution, and segment routing LSP provisioning.

- [Static Segment Routing Provisioning on page 504](#)
- [Benefits of using Static Segment Routing of Label Switched Path on page 505](#)
- [Non-Colored Static Segment Routing LSP on page 505](#)
- [Static Segment Routing LSP Provisioning on page 506](#)
- [Limitations on page 506](#)

---

### Static Segment Routing Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique segment identifier(SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. A route for the SID label is then installed in the mpls.0 table. The next-hop of the route is obtained either through pops-and-forwards for an adjacency SID label, or through swaps-and-forwards for a prefix SID label or node SID label.

Junos OS allows static segment routing LSPs by configuring the **segment** statement at the **[edit protocols mpls static-label-switched-path static-label-switched-path]** hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the **static-label-range static-label-range** statement at the **[edit protocols mpls label-range]** hierarchy level. The default range of static label pool is 100000 through 1048575. The static segment LSP performs pop-and-forward label operation for adjacency segment or swap-and-forward label operation for prefix or node segment. For both the types of label operation, the static segment LSP has a next hop operation that specifies the remote IP address or the name of an outgoing interface. The interface name is only acceptable for point-to-point interface. For each static segment LSP, the SID label route

is installed in the `mpls.0` table with the next hop as per the label operation and the outgoing interface. For an adjacency segment that uses pop-and-forward label operation, a clone route is installed in the `mpls.0` table as well. The adjacency segment, prefix segment, and node segment are locally unprotected static segments.

### Benefits of using Static Segment Routing of Label Switched Path

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

### Non-Colored Static Segment Routing LSP

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

#### *Segment List*

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. For a segment routing LSP to be considered as non-colored static LSP, the first hop of the segment list has to be an IP address of an outgoing interface and the second to Nth hops can be SID labels. The number of SID labels in the segment list should not exceed the maximum segment list limit. By default, the maximum segment list limit is 5. You can configure the maximum segment list limit at the **[edit protocols source-packet-routing]** hierarchy level with a range of 2 through 5 SID labels.

#### *Non-colored Segment Routing LSP*

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the `inet.3` routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1. A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may

specify a metric and a preference at **[edit protocols source-packet-routing source-routing-path *lsp-name*]** for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

### Static Segment Routing LSP Provisioning

---

Junos OS currently has a limitation that the next hop cannot be built to push more than 5 labels. So, a segment list with more than 5 SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than 5, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed 5. You can configure the maximum segment list limit at **[edit protocols source-packet-routing]** hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to 5 SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label. The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring **no-ingress** statement at **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session. These non-colored segment routing LSPs may have binding segment ID (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

### Limitations

---

- A segment-list is usable for non-colored static segment routing LSPs only if the first hop specifies an IP address. If the first hop specifies only as SID label, it cannot be used to resolve an outgoing interface, and a log message is displayed. If the first hop specifies both an IP address and a SID label, the SID label is simply ignored.
- A maximum of 8 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- The maximum depth of label stack that a next hop can push is 5. If any segment-list is configured with more labels then the configuration commit check fails with an error.

## Example: Configuring Static Segment Routing Label Switched Path

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

- [Requirements on page 507](#)
- [Overview on page 507](#)
- [Configuration on page 508](#)
- [Verification on page 518](#)

### Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

### Overview

Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the **segment-list** statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure segment routing tunnel by configuring the **source-routing-path** statement at **[edit protocols source-packet-routing]** hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

### Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5. Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

**Figure 49: Static Segment Routing Label Switched Path**

## Configuration

- [Configuring Device PE2 on page 516](#)
- [Results on page 517](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

PE1 set interfaces ge-0/0/0 unit 0 family inet address 10.10.12.1/24

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5

set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5

set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRIs in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
```

```
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

```

### Configuring Device PE2

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls

set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

## Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 55.1.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 55.1.23.2/24;
    }
    family mpls;
  }
}
```

```
user@PE2# show protocols
mpls {
  static-label-switched-path adj-23 {
    segment {
      1000123;
      next-hop 55.1.23.3;
      pop;
    }
  }
  static-label-switched-path adj-21 {
    segment {
      1000221;
      next-hop 55.1.12.1;
      pop;
    }
  }
  interface ge-0/0/0.0;
  interface ge-0/0/1.0;
  label-range {
    static-label-range 1000000 1000999;
  }
}
ospf {

- [Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2 on page 520](#)
- [Verifying the Status of Static MPLS LSP Segments of Router PE2 on page 521](#)

### ***Verifying Route Entry of Routing Table inet.3 of Router PE1***

**Purpose** Verify the route entry of routing table inet.3 of router PE1.

**Action** From operational mode, enter the **show route table inet.3** command.

```
user@PE1> show route table inet.3

inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32    *[SPRING-TE/8] 03:09:26, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)
                    to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134,
                    Push 1000123(top)
```

**Meaning** The output displays the ingress routes of segment routing tunnels.

### ***Verifying Route Table Entries of Routing Table mpls.0 of Router PE1***

**Purpose** Verify the route entries of routing table mpls.0

**Action** From operational mode, enter the **show route table mpls.0** command.

```
user@PE1> show route table mpls.0

mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 03:25:52, metric 1
            Receive
1          *[MPLS/0] 03:25:52, metric 1
            Receive
2          *[MPLS/0] 03:25:52, metric 1
            Receive
13         *[MPLS/0] 03:25:52, metric 1
            Receive
16         *[VPN/0] 03:25:52
            > via lsi.0 (VRF1), Pop
1000999    *[SPRING-TE/8] 03:04:03, metric 1
            > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)

            to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134,
            Push 1000123(top)
```

**Meaning** The output displays the SID labels of segment routing tunnels.

#### *Verifying SPRING Traffic Engineered LSP of Router PE1*

**Purpose** Verify SPRING traffic engineered LSPs on the ingress routers.

**Action** From operational mode, enter the **show spring-traffic-engineering overview** command.

```
user@PE1> show spring-traffic-engineering overview

Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
    < Not configured >
```

**Meaning** The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

#### *Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1*

**Purpose** Verify SPRING traffic engineered LSPs on the ingress router.

**Action** From operational mode, enter the **show spring-traffic-engineering lsp detail** command.

```

user@PE1# show spring-traffic-engineering lsp detail

Name: lsp-15
To: 192.168.146.181
State: Up
  Path: sl-15-primary
  Outgoing interface: ge-0/0/1.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 3

            > to 10.10.12.1 via ge-0/0/0.0, Pop
```

#### *Verifying the Status of Static MPLS LSP Segments of Router PE2*

**Purpose** Verify the status of MPLS LSP segments of router PE2.

**Action** From operational mode, enter the **show mpls static-lsp** command.

```
user@PE2> show mpls static-lsp

Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname          SID-label      State
adj-21           1000221        Up
adj-23           1000123        Up
Total 2, displayed 2, Up 2, Down 0
```

**Meaning** The output displays the status of static MPLS LSP segments of router PE2.

## Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.

## Related Documentation

## Configuring Explicit-Path LSPs

If you disable constrained-path label-switched path (LSP) computation, as described in [“Disabling Constrained-Path LSP Computation” on page 390](#), you can configure LSPs manually or allow the LSPs to follow the IGP path.

When explicit-path LSPs are configured, the LSP is established along the path you specified. If the path is topologically not feasible, either because the network is partitioned or insufficient resources are available along some parts of the path, the LSP will fail. No alternative paths can be used. If the setup succeeds, the LSP stays on the defined path indefinitely.

To configure an explicit-path LSP, follow these steps:

1. Configure the path information in a named path, as described in [“Creating Named Paths” on page 414](#). To configure complete path information, specify every router hop between the ingress and egress routers, preferably using the **strict** attribute. To configure incomplete path information, specify only a subset of router hops, using the **loose** attribute in places where the path is incomplete.

For incomplete paths, the MPLS routers complete the path by querying the local routing table. This query is done on a hop-by-hop basis, and each router can figure out only enough information to reach the next explicit hop. It might be necessary to traverse a number of routers to reach the next (loose) explicit hop.

Configuring incomplete path information creates portions of the path that depend on the current routing table, and this portion of the path can reroute itself as the topology changes. Therefore, an explicit-path LSP that contains incomplete path information is not completely fixed. These types of LSPs have only a limited ability to repair themselves, and they tend to create loops or flaps depending on the contents of the local routing table.

2. To configure the LSP and point it to the named path, use either the **primary** or **secondary** statement, as described in [“Configuring Primary and Secondary LSPs” on page 459](#).

3. Disable constrained-path LSP computation by including the **no-cspf** statement either as part of the LSP or as part of a **primary** or **secondary** statement. For more information, see [“Disabling Constrained-Path LSP Computation” on page 390](#).
4. Configure any other LSP properties.

Using explicit-path LSPs has the following drawbacks:

- More configuration effort is required.
- Configured path information cannot take into account dynamic network bandwidth reservation, so the LSPs tend to fail when resources become depleted.
- When an explicit-path LSP fails, you might need to manually repair it.

Because of these limitations, we recommend that you use explicit-path LSPs only in controlled situations, such as to enforce an optimized LSP placement strategy resulting from computations with an offline simulation software package.

### Example: Configuring an Explicit-Path LSP

On the ingress router, create an explicit-path LSP, and specify the transit routers between the ingress and egress routers. In this configuration, no constrained-path computation is performed. For the primary path, all intermediate hops are strictly specified so that its route cannot change. The secondary path must travel through router 14.1.1.1 first, then take whatever route is available to reach the destination. The remaining route taken by the secondary path is typically the shortest path computed by the IGP.

```

## Configuring Static Adjacency Segment Identifier for Aggregate Ethernet Member Links Using Single-hop Static LSP

---

In a network where aggregate Ethernet (AE) bundles are in use, an aggregate link could be bundle of 'N' number of physical link. The traffic sent over these AE bundle interfaces are forwarded on any of the member links of an AE interface. The traffic can take any physical link based on the hash defined for load-balancing the traffic, which makes it difficult to isolate which link have gone bad or dropping the traffic.

One way to test the forwarding path available in the network, including member links of an AE interface, is by adding a single-hop static LSP with the next-hop pointing to specific member link of AE interface. The default label-operation for these static LSP must be pop and forward. When a packet hits these labeled routes, the packet is forwarded on to a specific member-link. A unique label is used to identify the member link thus these labels are referred as adjacency SID and these are statically provisioned.

You can control the flow of the packets in the network by constructing a label stack in controller, which includes the labels allocated by all transit static LSP. The OAM packets are crafted and injected into the network with entire label-stack.

When a packet hits this label route the label is popped and traffic is forwarded on the member link specified in the configuration. A destination MAC is chosen while forwarding the packet, the destination Mac is the aggregate interface MAC address (selected based on nexthop address configured).

When the member link goes down and aggregate interface is up then the route corresponding to that member link is deleted. When an aggregate interface goes down then all the routes corresponding to member links of the aggregate interface is deleted. When the child physical interface is LACP detached but the child physical interface is up, the labeled route for the child link is deleted. In the case of LACP detach, the member link is up and invalid forwarding state then the OAM packets is dropped in PFE when child physical interface is detached.

The static LSP configuration is extended to accommodate the member-link name. A new CLI statement **member-interface** is added under the transit configuration.

A static LSP label should be configured from a defined static label range. The following is a sample configuration of static LSP label:

```
user@host# show protocols mpls label-range static-label-range 1000000 1048575;
```

**NOTE:** The recommendation is to configure the default static label range (1000000-1048575) of Junos for the static LSP. If you wish to configure label-range other than the default static label range, then it can be done as multiple ranges can be configured.

The following is an example to configure single-hop static LSP for AE member link:

1. Define a static label range.

```
user@host# set protocols mpls label-range static-label-range 1000000 1048575;
```

2. Create a static LSP for AE member link from the static label range.

```
user@host# set protocols mpls static-label-switched-path static-lsp transit 100001 pop
next-hop 10.1.1.1 member-interface interface-name
```

In this configuration, a transit labelled router is installed in mpls.0 and pops the label and forwards the packet down the next-hop. The next-hop address is mandatory for broadcast interfaces (such as ge-, xe-, ae-) and the if-name is be used for p2p interfaces (such as so-). The address is required for broadcast interfaces because the next-hop IP address is needed to pick the destination MAC address. The source MAC address for the packet is the AE's MAC address.

The following are sample outputs to view the member link name in the next-hop output:

#### show mpls static-lsp extensive

```
user@host> show mpls static-lsp extensive
```

## Point-to-Multipoint LSPs Overview

---

A point-to-multipoint MPLS LSP is an LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in [Figure 50 on page 528](#). Router PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Router PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Router P1 replicates the packet and forwards it to Routers PE2 and PE3. Router P2 sends the packet to Router PE4.

This feature is described in detail in the Internet drafts [draft-raggarwa-mpls-p2mp-te-02.txt](#) (expired February 2004), *Establishing Point to Multipoint MPLS TE LSPs*, [draft-ietf-mpls-rsvp-te-p2mp-02.txt](#), *Extensions to Resource Reservation Protocol-Traffic Engineering (RSVP-TE) for Point-to-Multipoint TE Label-Switched Paths (LSPs)*, and RFC 6388, *Label Distribution Protocol Extensions for*

*Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths (only point-to-multipoint LSPs are supported).*

**Figure 50: Point-to-Multipoint LSPs**

The following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP enables you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an egress router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any of the primary paths fail, traffic can be quickly switched to the bypass.
- You can configure branch LSPs either statically, dynamically, or as a combination of static and dynamic LSPs.
- You can enable graceful Routing Engine switchover (GRES) and graceful restart for point-to-multipoint LSPs at ingress and egress routers. The point-to-multipoint LSPs must be configured using either static routes or circuit cross-connect (CCC). GRES and graceful restart allow the traffic to be forwarded at the Packet Forwarding Engine based on the old state while the control plane recovers. Feature parity for GRES and

graceful restart for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

## Understanding Point-to-Multipoint LSPs

A point-to-multipoint MPLS label-switched path (LSP) is an LDP-signaled or RSVP-signaled LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the inbound (ingress) router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in [Figure 51 on page 529](#). Device PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Device PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Device P1 replicates the packet and forwards it to Routers PE2 and PE3. Device P2 sends the packet to Device PE4.

**Figure 51: Point-to-Multipoint LSPs**

Following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP allows you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an outbound (egress) router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any primary paths fail, traffic can be quickly switched to the bypass.
- You can configure subpaths either statically or dynamically.
- You can enable graceful restart on point-to-multipoint LSPs.

- [Point-to-Multipoint LSP Configuration Overview on page 530](#)

---

## Point-to-Multipoint LSP Configuration Overview

---

To set up a point-to-multipoint LSP:

1. Configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers.
2. Specify a pathname on the primary LSP and this same path name on each branch LSP.

.....

**NOTE:** By default, the branch LSPs are dynamically signaled by means of Constrained Shortest Path First (CSPF) and require no configuration. You can alternatively configure the branch LSPs as static paths.

.....

## Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP

---

This example shows how to configure a collection of paths to create an RSVP-signaled point-to-multipoint label-switched path (LSP).

- [Requirements on page 531](#)
- [Overview on page 531](#)
- [Configuration on page 532](#)
- [Verification on page 549](#)

### Requirements

In this example, no special configuration beyond device initialization is required.

### Overview

In this example, multiple routing devices serve as the transit, branch, and leaf nodes of a single point-to-multipoint LSP. On the provider edge (PE), Device PE1 is the ingress node. The branches go from PE1 to PE2, PE1 to PE3, and PE1 to PE4. Static unicast routes on the ingress node (PE1) point to the egress nodes.

This example also demonstrates static routes with a next hop that is a point-to-multipoint LSP, using the `p2mp-lsp-next-hop` statement. This is useful when implementing filter-based forwarding.

**NOTE:** Another option is to use the `lsp-next-hop` statement to configure a regular point-to-point LSP to be the next hop. Though not shown in this example, you can optionally assign an independent preference and metric to the next hop.

---

### Topology Diagram

[Figure 52 on page 532](#) shows the topology used in this example.

set routing-options static route 10.0.244.8/30 next-hop 10.0.104.9

```

### Configuring the Ingress Label-Switched Router (LSR) (Device PE1)

#### Step-by-Step Procedure

To configure Device PE1:

1. Configure the interfaces, interface encapsulation, and protocol families.

```

[edit interfaces]
user@PE1# set ge-2/0/2 unit 0 description PE1-to-CE1
user@PE1# set ge-2/0/2 unit 0 family inet address 10.0.244.10/30
user@PE1# set fe-2/0/10 unit 1 description PE1-to-P2
user@PE1# set fe-2/0/10 unit 1 family inet address 2.2.2.1/24
user@PE1# set fe-2/0/10 unit 1 family mpls

```

```

user@PE1# set fe-2/0/9 unit 8 description PE1-to-P3
user@PE1# set fe-2/0/9 unit 8 family inet address 6.6.6.1/24
user@PE1# set fe-2/0/9 unit 8 family mpls
user@PE1# set fe-2/0/8 unit 9 description PE1-to-P4
user@PE1# set fe-2/0/8 unit 9 family inet address 3.3.3.1/24
user@PE1# set fe-2/0/8 unit 9 family mpls
user@PE1# set lo0 unit 1 family inet address 100.10.10.10/32

```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```

[edit protocols]
user@PE1# set rsvp interface fe-2/0/10.1
user@PE1# set rsvp interface fe-2/0/9.8
user@PE1# set rsvp interface fe-2/0/8.9
user@PE1# set rsvp interface lo0.1
user@PE1# set mpls interface fe-2/0/10.1
user@PE1# set mpls interface fe-2/0/9.8
user@PE1# set mpls interface fe-2/0/8.9
user@PE1# set mpls interface lo0.1
user@PE1# set ospf area 0.0.0.0 interface ge-2/0/2.0
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/10.1
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/9.8
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/8.9
user@PE1# set ospf area 0.0.0.0 interface lo0.1

```

3. Configure the MPLS point-to-multipoint LSPs.

```

[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 to 100.50.50.50
user@PE1# set mpls label-switched-path PE1-PE2 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE3 to 100.70.70.70
user@PE1# set mpls label-switched-path PE1-PE3 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE4 to 100.40.40.40
user@PE1# set mpls label-switched-path PE1-PE4 p2mp p2mp1

```

4. (Optional) Enable link protection on the LSPs.

Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

```

[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 link-protection
user@PE1# set mpls label-switched-path PE1-PE3 link-protection
user@PE1# set mpls label-switched-path PE1-PE4 link-protection

```

5. Enable MPLS to perform traffic engineering for OSPF.

```

[edit protocols]
user@PE1# set mpls traffic-engineering bgp-igp

```

This causes the ingress routes to be installed in the inet.0 routing table. By default, MPLS performs traffic engineering for BGP only. You need to enable MPLS traffic engineering on the ingress LSR only.

6. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

7. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 100.10.10.10
```

8. Configure static IP unicast routes with the point-to-multipoint LSP name as the next hop for each route.

```
[edit routing-options]
user@PE1# set static route 5.5.5.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 7.7.7.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 4.4.4.0/24 p2mp-lsp-next-hop p2mp1
```

9. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

### Configuring the Transit and Egress LSRs (Devices P2, P3, P4, PE2, PE3, and PE4)

#### Step-by-Step Procedure

To configure the transit and egress LSRs:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit]
user@P2# set interfaces fe-2/0/10 unit 2 description P2-to-PE1
user@P2# set interfaces fe-2/0/10 unit 2 family inet address 2.2.2.2/24
user@P2# set interfaces fe-2/0/10 unit 2 family mpls
user@P2# set interfaces fe-2/0/9 unit 10 description P2-to-PE2
user@P2# set interfaces fe-2/0/9 unit 10 family inet address 5.5.5.1/24
user@P2# set interfaces fe-2/0/9 unit 10 family mpls
user@P2# set interfaces lo0 unit 2 family inet address 100.20.20.20/32
user@PE2# set interfaces ge-2/0/3 unit 0 description PE2-to-CE2
user@PE2# set interfaces ge-2/0/3 unit 0 family inet address 10.0.224.10/30
user@PE2# set interfaces fe-2/0/10 unit 5 description PE2-to-P2
user@PE2# set interfaces fe-2/0/10 unit 5 family inet address 5.5.5.2/24
```

```

user@PE2# set interfaces fe-2/0/10 unit 5 family mpls
user@PE2# set interfaces lo0 unit 5 family inet address 100.50.50.50/32
user@P3# set interfaces fe-2/0/10 unit 6 description P3-to-PE1
user@P3# set interfaces fe-2/0/10 unit 6 family inet address 6.6.6.2/24
user@P3# set interfaces fe-2/0/10 unit 6 family mpls
user@P3# set interfaces fe-2/0/9 unit 11 description P3-to-PE3
user@P3# set interfaces fe-2/0/9 unit 11 family inet address 7.7.7.1/24
user@P3# set interfaces fe-2/0/9 unit 11 family mpls
user@P3# set interfaces lo0 unit 6 family inet address 100.60.60.60/32
user@PE3# set interfaces ge-2/0/1 unit 0 description PE3-to-CE3
user@PE3# set interfaces ge-2/0/1 unit 0 family inet address 10.0.134.10/30
user@PE3# set interfaces fe-2/0/10 unit 7 description PE3-to-P3
user@PE3# set interfaces fe-2/0/10 unit 7 family inet address 7.7.2.2/24
user@PE3# set interfaces fe-2/0/10 unit 7 family mpls
user@PE3# set interfaces lo0 unit 7 family inet address 100.70.70.70/32
user@P4# set interfaces fe-2/0/10 unit 3 description P4-to-PE1
user@P4# set interfaces fe-2/0/10 unit 3 family inet address 3.3.3.2/24
user@P4# set interfaces fe-2/0/10 unit 3 family mpls
user@P4# set interfaces fe-2/0/9 unit 12 description P4-to-PE4
user@P4# set interfaces fe-2/0/9 unit 12 family inet address 4.4.4.1/24
user@P4# set interfaces fe-2/0/9 unit 12 family mpls
user@P4# set interfaces lo0 unit 3 family inet address 100.30.30.30/32
user@PE4# set interfaces ge-2/0/0 unit 0 description PE4-to-CE4
user@PE4# set interfaces ge-2/0/0 unit 0 family inet address 10.0.104.9/30
user@PE4# set interfaces fe-2/0/10 unit 4 description PE4-to-P4
user@PE4# set interfaces fe-2/0/10 unit 4 family inet address 4.4.4.2/24
user@PE4# set interfaces fe-2/0/10 unit 4 family mpls
user@PE4# set interfaces lo0 unit 4 family inet address 100.40.40.40/32

```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```

[edit]
user@P2# set protocols rsvp interface fe-2/0/10.2
user@P2# set protocols rsvp interface fe-2/0/9.10

user@PE4# set protocols ospf area 0.0.0.0 interface ge-2/0/0.0
user@PE4# set protocols ospf area 0.0.0.0 interface fe-2/0/10.4
user@PE4# set protocols ospf area 0.0.0.0 interface lo0.4

```

3. Enable traffic engineering for OSPF.

```

[edit]
user@P2# set protocols ospf traffic-engineering
user@P3# set protocols ospf traffic-engineering
user@P4# set protocols ospf traffic-engineering
user@PE2# set protocols ospf traffic-engineering
user@PE3# set protocols ospf traffic-engineering
user@PE4# set protocols ospf traffic-engineering

```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

4. Configure the router IDs.

```

[edit]
user@P2# set routing-options router-id 100.20.20.20
user@P3# set routing-options router-id 100.60.60.60
user@P4# set routing-options router-id 100.30.30.30
user@PE2# set routing-options router-id 100.50.50.50
user@PE3# set routing-options router-id 100.70.70.70
user@PE4# set routing-options router-id 100.40.40.40

```

5. If you are done configuring the devices, commit the configuration.

```
[edit]
user@host# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

**Device PE1**

## Configuring Device CE1

### Step-by-Step Procedure

To configure Device CE1:

1. Configure an interface to Device PE1.

```

[edit interfaces]
user@CE1# set ge-1/3/2 unit 0 family inet address 10.0.244.9/30
user@CE1# set ge-1/3/2 unit 0 description CE1-to-PE1

```

2. Configure static routes from Device CE1 to the three other customer networks, with Device PE1 as the next hop.

```

[edit routing-options]
user@CE1# set static route 10.0.104.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.134.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.224.8/30 next-hop 10.0.244.10

```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE1# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-1/3/2 {
  unit 0 {
    family inet {
      address 10.0.244.9/30;
      description CE1-to-PE1;
    }
  }
}
```

```
user@CE1# show routing-options
static {
  route 10.0.104.8/30 next-hop 10.0.244.10;
  route 10.0.134.8/30 next-hop 10.0.244.10;
  route 10.0.224.8/30 next-hop 10.0.244.10;
}
```

---

### Configuring Device CE2

---

**Step-by-Step Procedure** To configure Device CE2:

1. Configure an interface to Device PE2.

```
[edit interfaces]
user@CE2# set ge-1/3/3 unit 0 family inet address 10.0.224.9/30
user@CE2# set ge-1/3/3 unit 0 description CE2-to-PE2
```

2. Configure a static route from Device CE2 to CE1, with Device PE2 as the next hop.

```
[edit routing-options]
user@CE2# set static route 10.0.244.8/30 next-hop 10.0.224.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE2# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show interfaces
ge-1/3/3 {
  unit 0 {
    family inet {
      address 10.0.224.9/30;
      description CE2-to-PE2;
    }
  }
}
```

```
user@CE2# show routing-options
static {
  route 10.0.244.8/30 next-hop 10.0.224.10;
}
```

### Configuring Device CE3

#### Step-by-Step Procedure

To configure Device CE3:

1. Configure an interface to Device PE3.

```
[edit interfaces]
user@CE3# set ge-2/0/1 unit 0 family inet address 10.0.134.9/30
user@CE3# set ge-2/0/1 unit 0 description CE3-to-PE3
```

2. Configure a static route from Device CE3 to CE1, with Device PE3 as the next hop.

```
[edit routing-options]
user@CE3# set static route 10.0.244.8/30 next-hop 10.0.134.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE3# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE3# show interfaces
ge-2/0/1 {
  unit 0 {
    family inet {
```

```

        address 10.0.134.9/30;
        description CE3-to-PE3;
    }
}

```

```

user@CE3# show routing-options
static {
    route 10.0.244.8/30 next-hop 10.0.134.10;
}

```

### Configuring Device CE4

#### Step-by-Step Procedure

To configure Device CE4:

1. Configure an interface to Device PE4.

```

[edit interfaces]
user@CE4# set ge-3/1/3 unit 0 family inet address 10.0.104.10/30
user@CE4# set ge-3/1/3 unit 0 description CE4-to-PE4

```

2. Configure a static route from Device CE4 to CE1, with Device PE4 as the next hop.

```

[edit routing-options]
user@CE4# set static route 10.0.244.8/30 next-hop 10.0.104.9

```

3. If you are done configuring the device, commit the configuration.

```

[edit]
user@CE4# commit

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@CE4# show interfaces
ge-3/1/3 {
    unit 0 {
        family inet {
            address 10.0.104.10/30;
            description CE4-to-PE4;
        }
    }
}

```

```

user@CE4# show routing-options
static {

```

```
route 10.0.244.8/30 next-hop 10.0.104.9;  
}
```

## Verification

Confirm that the configuration is working properly.

- [Verifying Connectivity on page 549](#)
- [Verifying the State of the Point-to-Multipoint LSP on page 550](#)
- [Checking the Forwarding Table on page 551](#)

### Verifying Connectivity

**Purpose** Make sure that the devices can ping each other.

**Action** Run the **ping** command from CE1 to the interface on CE2 connecting to PE2.

```
user@CE1> ping 10.0.224.9

PING 10.0.224.9 (10.0.224.9): 56 data bytes
64 bytes from 10.0.224.9: icmp_seq=0 ttl=61 time=1.387 ms
64 bytes from 10.0.224.9: icmp_seq=1 ttl=61 time=1.394 ms
64 bytes from 10.0.224.9: icmp_seq=2 ttl=61 time=1.506 ms
^C
--- 10.0.224.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.387/1.429/1.506/0.055 ms
```

Run the **ping** command from CE1 to the interface on CE3 connecting to PE3.

```
user@CE1> ping 10.0.134.9

PING 10.0.134.9 (10.0.134.9): 56 data bytes
64 bytes from 10.0.134.9: icmp_seq=0 ttl=61 time=1.068 ms
64 bytes from 10.0.134.9: icmp_seq=1 ttl=61 time=1.062 ms
64 bytes from 10.0.134.9: icmp_seq=2 ttl=61 time=1.053 ms
^C
--- 10.0.134.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.053/1.061/1.068/0.006 ms
```

Run the **ping** command from CE1 to the interface on CE4 connecting to PE4.

```
user@CE1> ping 10.0.104.10

PING 10.0.104.10 (10.0.104.10): 56 data bytes
64 bytes from 10.0.104.10: icmp_seq=0 ttl=61 time=1.079 ms
64 bytes from 10.0.104.10: icmp_seq=1 ttl=61 time=1.048 ms
64 bytes from 10.0.104.10: icmp_seq=2 ttl=61 time=1.070 ms
^C
--- 10.0.104.10 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.048/1.066/1.079/0.013 ms
```

---

### Verifying the State of the Point-to-Multipoint LSP

---

**Purpose** Make sure that the ingress, transit, and egress LSRs are in the Up state.

**Action** Run the `show mpls lsp p2mp` command on all of the LSRs. Only the ingress LSR is shown here.

```
user@PE1> show mpls lsp p2mp

Ingress LSP: 1 sessions
P2MP name: p2mp1, P2MP branch count: 3
To          From          State Rt P    ActivePath    LSPname
100.40.40.40 100.10.10.10 Up    0 *              PE1-PE4
100.70.70.70 100.10.10.10 Up    0 *              PE1-PE3
100.50.50.50 100.10.10.10 Up    0 *              PE1-PE2
Total 3 displayed, Up 3, Down 0
...
```

### Checking the Forwarding Table

**Purpose** Make sure that the routes are set up as expected by running the `show route forwarding-table` command. Only the routes to the remote customer networks are shown here.

**Action** user@PE1> show route forwarding-table

```
Routing table: default.inet
Internet:
Destination      Type RtRef Next hop          Type Index NhRef Netif
...
10.0.104.8/30     user    0 3.3.3.2          ucst 1006   6 fe-2/0/8.9
10.0.134.8/30     user    0 6.6.6.2          ucst 1010   6 fe-2/0/9.8
10.0.224.8/30     user    0 2.2.2.2          ucst 1008   6 fe-2/0/10.1
...
```

## Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs

A point-to-multipoint MPLS label-switched path (LSP) is an RSVP LSP with multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. For more information about point-to-multipoint LSPs, see “[Point-to-Multipoint LSPs Overview](#)” on page 527.

To configure a point-to-multipoint LSP, you need to configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers, as described in the following sections:

- [Configuring the Primary Point-to-Multipoint LSP on page 552](#)
- [Configuring a Branch LSP for Point-to-Multipoint LSPs on page 552](#)

## Configuring the Primary Point-to-Multipoint LSP

A point-to-multipoint LSP must have a configured primary point-to-multipoint LSP to carry traffic from the ingress router. The configuration of the primary point-to-multipoint LSP is similar to a signaled LSP. See [“Configuring the Ingress Router for MPLS-Signaled LSPs” on page 414](#) for more information. In addition to the conventional LSP configuration, you need to specify a path name for the primary point-to-multipoint LSP by including the **p2mp** statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path lsp-name](#)]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path lsp-name](#)]

You can enable the optimization timer for point-to-multipoint LSPs. See [“Optimizing Signaled LSPs” on page 437](#) for more information.

## Configuring a Branch LSP for Point-to-Multipoint LSPs

The primary point-to-multipoint LSP sends traffic to two or more branch LSPs carrying traffic to each of the egress provider edge (PE) routers. In the configuration for each of these branch LSPs, the point-to-multipoint LSP path name you specify must be identical to the path name configured for the primary point-to-multipoint LSP. See [“Configuring the Primary Point-to-Multipoint LSP” on page 552](#) for more information.

To associate a branch LSP with the primary point-to-multipoint LSP, specify the point-to-multipoint LSP name by including the **p2mp** statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path lsp-name](#)]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path lsp-name](#)]

**NOTE:** Any change in any of the branch LSPs of a point-to-multipoint LSP, either due to a user action or an automatic adjustment made by the router, causes the primary and branch LSPs to be resigaled. The new point-to-multipoint LSP is signaled first before the old path is taken down.

The following sections describe how you can configure the branch LSP as a dynamically signaled path using Constrained Shortest Path First (CSPF), as a static path, or as a combination of dynamic and static paths:

- [Configuring the Branch LSP as a Dynamic Path on page 553](#)
- [Configuring the Branch LSP as a Static Path on page 553](#)

### Configuring the Branch LSP as a Dynamic Path

By default, the branch LSP for a point-to-multipoint LSP is signaled dynamically using CSPF and requires no configuration.

When a point-to-multipoint LSP is changed, either by the addition or deletion of new destinations or by the recalculation of the path to existing destinations, certain nodes in the tree might receive data from more than one incoming interface. This can happen under the following conditions:

- Some of the branch LSPs to destinations are statically configured and might intersect with statically or dynamically calculated paths to other destinations.
- When a dynamically calculated path for a branch LSP results in a change of incoming interface for one of the nodes in the network, the older path is not immediately torn down after the new one has been signaled. This ensures that any data in transit relying on the older path can reach its destination. However, network traffic can potentially use either path to reach the destination.
- A faulty router at the ingress calculates the paths to two different branch destinations such that a different incoming interface is chosen for these branch LSPs on a router node common to these branch LSPs.

### Configuring the Branch LSP as a Static Path

You can configure the branch LSP for a point-to-multipoint LSP as a static path. See [“Configuring Static LSPs” on page 491](#) for more information.

## Configuring Inter-Domain Point-to-Multipoint LSPs

An inter-domain P2MP LSP is a P2MP LSP that has one or more sub-LSPs (branches) that span multiple domains in a network. Examples of such domains include IGP areas and autonomous systems (ASs). A sub-LSP of an inter-domain P2MP LSP may be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source).

On the ingress node, a name is assigned to the inter-domain P2MP LSP and shared by all constituent sub-LSPs. Each sub-LSP is configured separately, with its own egress node and optionally an explicit path. The location of the egress node of the sub-LSP with respect to the ingress node determines whether the sub-LSP is intra-area, inter-area, or inter-AS.

Inter-domain P2MP LSPs can be used to transport traffic in the following applications in a multi-area or multi-AS network:

- Layer 2 broadcast and multicast over MPLS
- Layer 3 BGP/MPLS VPN
- VPLS

On each domain boundary node (ABR or ASBR) along the path of the P2MP LSP, the **expand-loose-hop** statement must be configured at the **[edit protocols mpls]** hierarchy

level so that CSPF can extend a loose-hop ERO (usually the first entry of the ERO list carried by RSVP Path message) towards the egress node or the next domain boundary node.

CSPF path computation for inter-domain P2MP LSPs:

- CSPF path computation is supported on each sub-LSP for inter-domain P2MP LSPs. A sub-LSP may be intra-area, inter-area, or inter-AS. CSPF treats an inter-area or inter-AS sub-LSP in the same manner as an inter-domain P2P LSP.
- On an ingress node or a domain boundary node (ABR or ASBR), CSPF can perform an Explicit Route Object (ERO) expansion per-RSVP query. The destination queried could be an egress node or a received loose-hop ERO. If the destination resides in a neighboring domain that the node is connected to, CSPF generates either a sequence of strict-hop EROs towards it or a sequence of strict-hop EROs towards another domain boundary node that can reach the destination.
- If RSVP fails to signal a path through a previously selected domain boundary node, RSVP attempts to signal a path through other available domain boundary nodes in a round-robin fashion.
- When a sub-LSP is added or removed to or from an inter-domain P2MP LSP, causing its path (branch) to be merged or pruned with or from the current P2MP tree, the paths being taken by the other sub-LSPs should not be affected, helping to prevent traffic disruption on those sub-LSPs.

Be aware of the following when deploying inter-domain P2MP LSPs in your network:

- Periodic path re-optimization is supported for inter-domain P2MP LSPs on ingress nodes. It can be turned on for an inter-domain P2MP LSP by configuring the **optimize-timer** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level with the same interval for every sub-LSP.
- Only link protection bypass LSPs are supported for inter-domain P2MP LSPs. To enable it for an inter-domain P2MP LSP, link-protection must be configured for all sub-LSPs and on all of the RSVP interfaces that the P2MP LSP might travel through.
- Only OSPF areas are supported for inter-domain P2MP LSPs. IS-IS levels are not supported.

---

## Configuring Link Protection for Point-to-Multipoint LSPs

---

Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. When link protection is configured for an interface and a point-to-multipoint LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination.

To extend link protection to all of the paths used by a point-to-multipoint LSP, link protection must be configured on each router that each branch LSP traverses. If you enable link protection on a point-to-multipoint LSP, you must enable link protection on all of the branch LSPs.

The Internet draft `draft-ietf-mpls-rsvp-te-p2mp-01.txt`, *Extensions to RSVP-TE for Point to Multipoint TE LSPs*, describes link protection for point-to-multipoint LSPs.

To enable link protection on point-to-multipoint LSPs, complete the following steps:

1. Configure link protection on each branch LSP. To configure link protection, include the **link-protection** statement:

```
link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *branch-lsp-name*]
  - [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *branch-lsp-name*]
2. Configure link protection for each RSVP interface on each router that the branch LSP traverses. For information about how to configure link protection on RSVP interfaces, see [“Configuring Link Protection on Interfaces Used by LSPs” on page 687](#).

For more information on how to configure link protection, see [“Configuring Node Protection or Link Protection for LSPs” on page 695](#).

## Configuring Graceful Restart for Point-to-Multipoint LSPs

You can configure graceful restart on point-to-multipoint LSPs. Graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not apparent to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers.

To enable graceful restart on a router handling point-to-multipoint LSP traffic, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

The graceful restart configuration for point-to-multipoint LSPs is identical to that of point-to-point LSPs. For more information on how to configure graceful restart, see [“Configuring RSVP Graceful Restart” on page 699](#).

## Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs

You can control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to PIM islands situated downstream from the egress routers of the point-to-multipoint LSPs.

By configuring the **rpf-check-policy** statement, you can disable RPF checks for a source and group pair. You would typically configure this statement on the egress routers of a point-to-multipoint LSP, because the interface receiving the multicast traffic on a point-to-multipoint LSP egress router might not always be the RPF interface.

You can also configure a routing policy to act upon a source and group pair. This policy behaves like an import policy, so if no policy term matches the input data, the default policy action is “acceptance.” An accept policy action enables RPF checks. A reject policy action (applied to all source and group pairs that are not accepted) disables RPF checks for the pair.

To configure a multicast RPF check policy for a point-to-multipoint LSP, specify the RPF check policy using the **rpf-check-policy** statement:

```
rpf-check-policy policy;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options multicast]**
- **[edit logical-systems *logical-system-name* routing-options multicast]**

You also must configure a policy for the multicast RPF check. You configure policies at the **[edit policy-options]** hierarchy level. For more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

**NOTE:** When you configure the **rpf-check-policy** statement, the Junos OS cannot perform RPF checks on incoming traffic and therefore cannot detect traffic arriving on the wrong interface. This might cause routing loops to form.

### Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP

Configure a policy to ensure that an RPF check is not performed for sources with prefix **128.83/16** or longer that belong to groups having a prefix of **228/8** or longer:

```
[edit]
policy-options {
  policy-statement rpf-sg-policy {
    from {
      route-filter 228.0.0.0/8 orlonger;
      source-address-filter 128.83.0.0/16 orlonger;
    }
  }
}
```

```

    then {
      reject;
    }
  }
}

```

## Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs

You can configure one or more PE routers as part of a backup PE router group to enable ingress PE router redundancy. You accomplish this by configuring the IP addresses of the backup PE routers (at least one backup PE router is required) and the local IP address used by the local PE router.

You must also configure a full mesh of point-to-point LSPs between the primary and backup PE routers. You also need to configure BFD on these LSPs. See [“Configuring BFD for RSVP-Signaled LSPs” on page 90](#) and [“Configuring BFD for LDP LSPs” on page 773](#) for more information.

To configure ingress PE router redundancy for point-to-multipoint LSPs, include the **backup-pe-group** statement:

```

backup-pe-group pe-group-name {
  backups [addresses];
  local-address address;
}

```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

After you configure the ingress PE router redundancy backup group, you must also apply the group to a static route on the PE router. This ensures that the static route is active (installed in the forwarding table) when the local PE router is the designated forwarder for the backup PE group. You can only associate a backup PE router group with a static route that also has the **p2mp-lsp-next-hop** statement configured. For more information, see [“Configuring Static Unicast Routes for Point-to-Multipoint LSPs” on page 497](#).

## Enabling Point-to-Point LSPs to Monitor Egress PE Routers

Configuring an LSP with the **associate-backup-pe-groups** statement enables it to monitor the status of the PE router to which it is configured. You can configure multiple backup PE router groups using the same router's address. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. The **associate-backup-pe-groups** statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to that address.

To allow an LSP to monitor the status of the egress PE router, include the **associate-backup-pe-groups** statement:

```

associate-backup-pe-groups;

```

This statement can be configured at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

If you configure the **associate-backup-pe-groups** statement, you must configure BFD for the point-to-point LSP. For information about how to configure BFD for an LSP, see [“Configuring BFD for MPLS IPv4 LSPs” on page 89](#) and [“Configuring BFD for LDP LSPs” on page 773](#).

You also must configure a full mesh of point-to-point LSPs between the PE routers in the backup PE router group. A full mesh is required so that each PE router within the group can independently determine the status of the other PE routers, allowing each router to independently determine which PE router is currently the designated forwarder for the backup PE router group.

If you configure multiple LSPs with the **associate-backup-pe-groups** statement to the same destination PE router, the first LSP configured is used to monitor the forwarding state to that PE router. If you configure multiple LSPs to the same destination, make sure to configure similar parameters for the LSPs. With this configuration scenario, a failure notification might be triggered even though the remote PE router is still up.

---

## Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases

---

In Junos OS Release 9.1 and earlier, Resv messages that include the S2L\_SUB\_LSP object are rejected by default. In Junos OS Release 9.2 and later, such messages are accepted by default. To ensure proper functioning of point-to-multipoint LSPs in a network that includes both devices running Junos OS Release 9.1 and earlier and devices running Junos 9.2 and later, you must include the **no-p2mp-sublsp** statement in the configuration of the devices running Junos 9.2 and later:

```
no-p2mp-sublsp;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

## CHAPTER 16

# Configuring Container LSPs

- [Dynamic Bandwidth Management Using Container LSP Overview on page 559](#)
- [Example: Configuring Dynamic Bandwidth Management Using Container LSP on page 587](#)
- [Configuring Dynamic Bandwidth Management Using Container LSP on page 615](#)

### **Dynamic Bandwidth Management Using Container LSP Overview**

---

RSVP LSPs with the autobandwidth feature are increasingly deployed in networks to meet traffic engineering needs. However, the current traffic engineering solutions for point-to-point LSPs are inefficient in terms of network bandwidth utilization, mainly because the ingress routers originating the RSVP LSPs either try to fit the LSPs along a particular path without creating parallel LSPs, or do not interact with the other routers in the network and probe for additional available bandwidth.

This feature provides an ingress router with the capability of acquiring as much network bandwidth as possible by creating parallel LSPs dynamically.

- [Understanding RSVP Multipath Extensions on page 559](#)
- [Junos OS RSVP Multipath Implementation on page 560](#)
- [Current Traffic Engineering Challenges on page 560](#)
- [Using Container LSP as a Solution on page 564](#)

- [Configuration Statements Supported for Container LSPs on page 581](#)
- [Impact of Configuring Container LSPs on Network Performance on page 585](#)
- [Supported and Unsupported Features on page 586](#)

### **Understanding RSVP Multipath Extensions**

The RSVP multipath extensions proposed in the IETF [KOMPELLA-MLSP] allow the setup of traffic engineered multipath label-switched paths (container LSPs). The container LSPs, in addition to conforming to traffic engineering constraints, use multiple independent paths from a source to a destination, thereby facilitating load balancing of traffic. The multipath extensions require changes to the RSVP-TE protocol and allow for merging of labels at the downstream nodes (similar to LDP), which also helps in preserving forwarding resources.

The multipath extensions to RSVP provide the following benefits:

- Ease of configuration. Typically, multiple RSVP LSPs are configured for either load balancing or bin packing. With a container LSP, there is a single entity to provision, manage, and monitor LSPs. Changes in topology are handled easily and autonomously by the ingress LSP, by adding, changing, or removing member LSPs to rebalance traffic, while maintaining the same traffic engineering constraints.
- RSVP equal-cost multipath (ECMP) inherits the standard benefits of ECMP by absorbing traffic surges.
- Multipath traffic engineering allows for better and complete usage of network resources.
- Knowing the relationship among LSPs helps in computing diverse paths with constraint-based routing. It allows adjustment of member LSPs while other member LSPs continue to carry traffic.
- The intermediate routers have an opportunity to merge the labels of member LSPs. This reduces the number of labels that need to get added to the forwarding plane and in turn reduces the convergence time.

If the number of independent ECMP paths is huge, label merging overcomes the platform limitations on maximum (ECMP) next hops. With point-to-point RSVP LSPs that require link or node protection, the next hops are doubled as each LSP is programmed with both primary and backup next hops. RSVP multipath (or ECMP) obviates the need for backup next hops.

- When there is a link failure, the router upstream to the link failure can distribute traffic from the failed link to the remaining ECMP branches, obviating the need for bypass LSPs. The bypass LSP approach not only requires more state when signaling backup LSPs, but also suffers from scaling issues that result in merge-point timing out a protected path state block (PSB) before point of local repair (PLR) gets a chance to signal the backup LSP.

## Junos OS RSVP Multipath Implementation

In order to deploy RSVP multipath (ECMP) in a network, all the nodes through which ECMP LSPs pass must understand RSVP ECMP protocol extensions. This can be a challenge, especially in a multivendor networks.

Junos OS implements the RSVP multipath extensions without the need for protocol extensions. A single container LSP, which has the characteristics of ECMP and RSVP TE, is provisioned. A container LSP consists of several member LSPs and is set up between the ingress and egress routing device. Each member LSP takes a different path to the same destination. The ingress routing device is configured with all the required parameters to compute the RSVP ECMP LSP. The parameters configured to compute a set of RSVP point-to-point LSPs can be used by the ingress routing device to compute the container LSP as well.

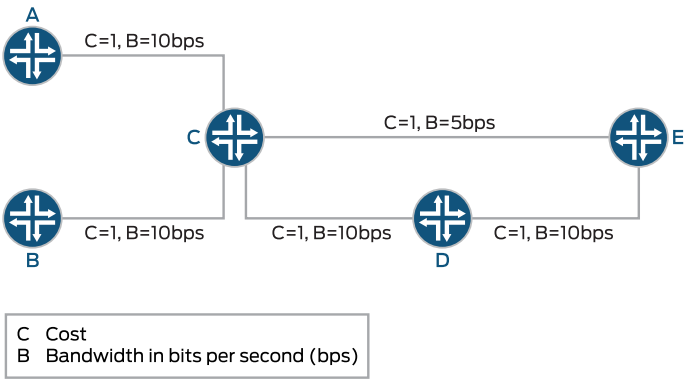

## Current Traffic Engineering Challenges

The main challenge for traffic engineering is to cope with the dynamics of both topology and traffic demands. Mechanisms are needed that can handle traffic load dynamics in

scenarios with sudden changes in traffic demand and dynamically distribute traffic to benefit from available resources.

Figure 53 on page 561 illustrates a sample network topology with all the LSPs having the same hold and setup priorities, and admission control restricted on the ingress router. All the links are annotated with a tuple (cost and capacity).

Figure 53: Sample Topology

8042458

Some of the traffic engineering problems seen in [Figure 53 on page 561](#) are listed here:

- **Bin Packing**

This problem arises because of a particular order in which LSPs are signaled. The ingress routers might not be able to signal some LSPs with required demands although bandwidth is available in the network, leading to under-utilization of link capacity.

For example, the following LSPs arrive in the sequence mentioned in [Table 17 on page 562](#).

**Table 17: LSP Sequence Order for Bin Packing**

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	10	No ERO

The LSP originating at Router B is not routable as constraint-based routing fails to find a feasible path. However, if Router B is signaled first, both the LSPs are routable. Bin packing happens because of lack of visibility of individual per-LSP, per-device bandwidth demands at the ingress routing device.

Bin packing can also happen when there is no requirement for ordering of LSPs. For example, if there is an LSP with demand X and there are two different paths to the destination from the ingress router with available bandwidths Y1 and Y2, such that Y1 is less than X, Y2 is less than X, and Y1 plus Y2 is greater than or equal to X.

In this case, even though there are enough network resources in terms of available bandwidth to satisfy the aggregate LSP demand X, the LSP might not be signaled or re-optimized with the new demand. In [Figure 53 on page 561](#), with container LSP support, the ingress B creates two LSPs each of size 5 when demand 10 is posed. One LSP is routed along B-C-E and another one along B-C-D-E.

- **Deadlock**

Considering [Figure 53 on page 561](#), the LSPs follow the sequence mentioned in [Table 18 on page 562](#).

**Table 18: LSP Sequence Order for Deadlock**

Time	Source	Destination	Demand	ERO	Event
1	A	E	2	A-C-D-E	Constraint-based routing with RSVP signaling
2	B	E	2	B-C-D-E	Constraint-based routing with RSVP signaling
3	A	E	2 to 20	A-C-D-E	Constraint-based routing fails, no RSVP signaling

At time 3, the demand on LSP from A to E increases from 2 to 20. If autobandwidth is configured, the change does not get detected until the adjustment timer expires. In

the absence of admission control at A, the increased traffic demand might cause traffic to drop on other LSPs that share common links with the mis-behaving LSP.

This happens due to the following reasons:

- Lack of global state at all the ingress routers
- Signaling of mis-behaving demands
- Tearing down of mis-behaving demands

With container LSP configured, ingress A has more chances of splitting the load (even incrementally if not fully) across multiple LSPs. So, LSP from A is less likely to see prolonged traffic loss.

- **Latency Inflation**

Latency inflation is caused by the autobandwidth and other LSPs parameters. Some of the other factors that contribute to latency inflation include:

- LSP priority

LSPs choose longer paths because shorter paths between data centers located in the same city can be congested. The bandwidth on the shorter paths can get exhausted by equal or higher priority LSPs. Due to periodic LSP optimization by autobandwidth, LSP can get rerouted to a higher delay path. When many LSPs undergo less than optimal path selection, they can potentially form a chain of dependencies. Modifying the LSP priorities dynamically is a workaround to the issue; however, dynamically adjusting LSP priorities to find shorter paths is a challenging task.

- All or Nothing policy

When the demand on an LSP increases and at least one of the links along the shorter path is close to its reservation limit, LSP optimization can force the LSP to move to a longer latency path. LSP has to traverse a long path even though the short path is capable of carrying most of the traffic.

- Minimum and maximum bandwidth

Minimum and maximum bandwidth specify the boundaries for LSP sizes. If minimum bandwidth is small, an LSP is more prone to autobandwidth adjustment because a small change in bandwidth is enough to cross the threshold limits. LSPs might reroute although bandwidth is available. On the other hand, if the minimum bandwidth is large, network bandwidth might be wasted. If the maximum bandwidth value is small, a large number of LSPs might be needed at the ingress router to accommodate the application demand. If the maximum bandwidth is large, the LSPs can grow larger in size. Such LSPs can suffer because of an all or nothing policy.

- Autobandwidth adjustment threshold

Bandwidth threshold dictates if LSPs need to be re-optimized and resized. If the value is small, LSPs are frequently re-optimized and rerouted. That might cause CPU spike because applications or protocols, such as BGP resolving over the LSPs, might keep the Routing Engine busy doing next-hop resolution. A large value might make an LSP immobile. With container LSP configured, an LSP is less likely to get subjected

to one or no policy. An ingress router originates multiple LSPs, although not all LSPs potentially traverse high latency paths.

- **Predictability**

Service providers often want predictable behavior in terms of how LSPs get signaled and routed. Currently, without any global coordination, it is difficult to set up the same set of LSPs in a predictable way. Consider the two different orderings in [Table 19 on page 564](#) and [Table 20 on page 564](#). The ERO that an LSP uses depends on its signaling time.

**Table 19: LSP Sequence Order for Predictability**

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	5	B-C-E

**Table 20: LSP Sequence Order for Predictability**

Time	Source	Destination	Demand	ERO
1	B	E	5	B-C-E
2	A	E	5	A-C-D-E

Container LSP does not directly help LSPs find predictable EROs. If LSPs are getting rerouted because of an all or no policy without container LSP configured, such LSPs might see less churn if container LSPs are configured, because smaller LSPs have better chances of finding a shorter or same path.

## Using Container LSP as a Solution

A container LSP can be used as a solution to the challenges faced by the current traffic engineering features. Considering [Figure 53 on page 561](#), when the demand X on a container LSP increases with the network capacity (max-flow) being more than the demand, the following approaches come into effect with a container LSP:

- [Accommodating the New Demand X on page 564](#)
- [Creating New LSPs to Meet Demand X on page 565](#)
- [Assigning Bandwidth to the New LSPs on page 565](#)
- [Controlling the LSP Paths on page 565](#)

### Accommodating the New Demand X

In the current implementation, autobandwidth attempts to re-signal an LSP with the new demand X and follows the all or nothing policy as mentioned earlier.

The container LSP approach computes several small (smaller than demand X) bandwidth LSPs such that the aggregate bandwidth is not less than X, and the ingress router performs

this adjustment periodically. One of the triggers to create new LSPs or to delete old LSPs can be changed in aggregate bandwidth. The ingress router then load-balances the incoming traffic across the newly created LSPs.

### Creating New LSPs to Meet Demand X

---

Although the number of new LSPs created can be a maximum of the allowed configurable limit, there is not much benefit from these LSPs once the number of LSPs exceeds the number of possible diverse paths or equal-cost multipaths (ECMPs). The benefit of creating the smaller LSPs is seen when an ingress router uses the newly created LSPs for load-balancing traffic. This, however, depends on the network topology and state.

Creating multiple parallel LSPs by all the ingress routers in the network can lead to scaling issues at the transit routers. Thus, the number of new LSPs to be created depends on the size of the individual LSPs and the given aggregate demand, X in this case.

### Assigning Bandwidth to the New LSPs

---

In general, there can be a number of heuristics to allocate bandwidths to the newly created LSPs. An ingress router can solve an optimization problem in which it can maximize a given utility function. The output of an optimization problem is assigning optimal bandwidth values. However, to solve an optimization problem, the number of newly created LSPs has to be fixed. Therefore, it is complex to optimize the number and size of each LSP. Thus, to simplify the problem, the same amount of bandwidth is assumed for all the newly created LSPs, and then the number of required LSPs is computed.

### Controlling the LSP Paths

---

The flexibility to control the LSP paths is expressed in terms of the configuration for point-to-point LSPs and container LSPs. Controlling the LSP paths using the configuration parameters can be applied under two different aspects:

- **Topology**—There are no topology constraints with this feature. Each member LSP is treated like a point-to-point LSP and is re-optimized individually. An ingress router does not try to compute equal IGP cost paths for all its LSPs, but instead it computes paths for all the LSPs using current traffic engineering database information. While computing a path, constraint-based routing adheres to any constraints specified through the configuration, although there is no change in the constraint-based routing method for path computation.
- **When to create a new LSP**—When to create a new LSP can be explicitly specified. By default, an ingress router periodically computes the aggregate traffic rate by adding up the traffic rate of all the individual LSPs. Looking at the aggregate bandwidth and configuration, the ingress router recomputes the number of LSPs and the bandwidths of the LSPs. The new LSPs are then signaled or the existing LSPs are re-signaled with the updated bandwidth. Instead of looking at the instantaneous aggregate rate, the ingress routers can compute an average (of aggregates) over some duration by removing outlier samples (of aggregates). Managing the LSPs that remain outstanding and active by considering aggregate bandwidth is more scalable than creating the new LSPs based on the usage of a particular LSP. The intervals and thresholds can be configured to track the aggregate traffic and trigger adjustment. These dynamic LSPs co-exist and interoperate with per-LSP autobandwidth configuration.

## Junos OS Container LSP Implementation

A container LSP is an ECMP TE LSP that acts like a container LSP consisting of one or more member LSPs. A point-to-point TE LSP is equivalent to a container LSP with a single member LSP. Member LSPs are added to the container LSP through a process called splitting, and removed from the container LSP through a process called merging.

- [Container LSP Terminology on page 566](#)
- [LSP Splitting on page 567](#)
- [LSP Merging on page 569](#)
- [Node and Link Protection on page 571](#)
- [Naming Convention on page 571](#)
- [Normalization on page 572](#)
- [Constraint-Based Routing Path Computation on page 577](#)
- [Sampling on page 578](#)
- [Support for NSR, IPG-FA, and Static Routes on page 578](#)

---

### Container LSP Terminology

The following terms are defined in the context of a container LSP:

- **Normalization**—An event occurring periodically when an action is taken to adjust the member LSPs, either to adjust their bandwidths, their number, or both. A normalization process is associated with a sampling process and periodically estimates aggregate utilization of a container LSP.
- **Nominal LSP**—The instance of a container LSP that is always present.
- **Supplementary LSP**—The instances or sub-LSPs of a container LSP, which are dynamically created or removed.

Autobandwidth is run over each of the member LSPs, and each LSP is resized according to the traffic it carries and the autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by adding up the bandwidth across all the member LSPs.

- **Minimum signaling-bandwidth**—The minimum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the minimum-bandwidth defined under autobandwidth.
- **Maximum signaling-bandwidth**—The maximum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the maximum-bandwidth defined under autobandwidth.
- **Merging-bandwidth**—Specifies the lower bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage falls below this value, the ingress router merges the member LSPs at the time of normalization.
- **Splitting-bandwidth**—Specifies the upper bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage exceeds this value, the ingress router splits the member LSPs at the time of normalization.

- **Aggregate minimum-bandwidth**—Sum of merging-bandwidth of the current active member LSPs. This minimum bandwidth is different from the autobandwidth minimum-bandwidth.
- **Aggregate maximum-bandwidth**—Sum of the splitting-bandwidth of the current active member LSPs. This maximum bandwidth is different from the autobandwidth maximum-bandwidth.

## LSP Splitting

- [Operational Overview on page 567](#)
- [Operational Constraints on page 568](#)
- [Supported Criteria on page 568](#)
- [Splitting Triggers on page 569](#)

### Operational Overview

The LSP splitting mechanism enables an ingress router to create new member LSPs or to re-signal existing LSPs with different bandwidths within a container LSP when a demand X is placed on the container LSP. With LSP splitting enabled, an ingress router periodically creates a number of LSPs (by signaling new ones or re-signaling existing ones) to accommodate a new aggregate demand X. In the current implementation, an ingress router tries to find an LSP path satisfying a demand X and other constraints. If no path is found, either the LSP is not signaled or it remains up, but with the old reserved bandwidth.

Between two normalization events (splitting or merging), individual LSPs might get re-sigaled with different bandwidths due to the autobandwidth adjustments. If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. There is no dynamic splitting in this case, as there is no dynamic estimation of aggregate bandwidth. The splitting adjustments with a specific bandwidth value can be manually triggered.

#### NOTE:

Be aware of the following considerations for LSP splitting:

- After LSP splitting, the ingress router continues to inject one forwarding adjacency. Forwarding adjacencies are not supported in IGP for this feature.
- Between two normalization events, two LSPs might have different bandwidths subjected to autobandwidth constraints.
- After LSPs are split (or merged), make-before-break uses the fixed filter (FF) style sharing unless the adaptive option is configured. However, two different LSPs do not do the shared explicit (SE) style sharing for this feature.
- When LSPs are re-sigaled with modified bandwidths, some of the LSPs might not get signaled successfully, leading to failover options.

### ***Operational Constraints***

LSP splitting has the following operational constraints:

- LSP bandwidth—Although there are a number of ways to allocate bandwidth values to the LSPs, the Junos OS implementation supports only an equal-bandwidth allocation policy when normalization is done, wherein all the member LSPs are signaled or re-signaled with equal bandwidth.
- Number of LSPs—If an ingress router is configured to have a minimum number of LSPs, it maintains the minimum number of LSPs even if the demand can be satisfied with less than the minimum number of LSPs. In case the ingress router is unable to do constraint-based routing for computations on the sufficient number of LSPs or signal sufficient number of LSPs, the ingress router resorts to a number of fallback options.

By default, an incremental approach is supported as a fallback option (unless configured differently), where an ingress router makes attempts to bring up the sufficient number of LSPs, such that the new aggregate bandwidth exceeds the old aggregate bandwidth (and is as close to the desired demand as possible). The ingress router then load-balances traffic using the LSPs. The LSPs that could not be brought up are removed by the ingress router.

### ***Supported Criteria***

When a container LSP signals a member LSP, the member LSP gets signaled with minimum-signaling-bandwidth. Since each member LSP is configured with autobandwidth, between two normalization events, each LSP can undergo autobandwidth adjustment multiple times. As the traffic demand increases, the ingress router creates additional supplementary LSPs. All member LSPs are used for ECMP, so they should roughly have the same reserved bandwidth after normalization.

For example, if there are K LSPs signaled after normalization, each LSP is signaled with equal bandwidth B. The total aggregate bandwidth reserved is B.K, where B satisfies the following condition:

- Minimum signaling-bandwidth is less than or equal to B, which in turn is less than or equal to the maximum signaling-bandwidth  
(minimum-signaling-bandwidth  $\leq$  B  $\leq$  maximum-signaling-bandwidth)

Until the next normalization event, each member LSP undergoes several autobandwidth adjustments. After any autobandwidth adjustment, if there are N LSPs with reserved bandwidths  $b_i$ , where  $i=1,2,\dots, N$ , each  $b_i$  should satisfy the following condition:

- Minimum bandwidth is less than or equal to  $b_i$ , which in turn is less than or equal to the maximum bandwidth  
(minimum-bandwidth  $\leq b_i \leq$  maximum-bandwidth)

Both the above-mentioned conditions are applicable for per member LSP (nominal and supplementary), and essentially have the reserved bandwidth to exist within a range.

### Splitting Triggers

Every time the normalization timer expires, the ingress router decides if LSP splitting is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

Taking for example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP splitting are as follows:

- Absolute trigger—LSP splitting is performed when **New-Aggr-Bw** is greater than **Aggregate-maximum-bandwidth**.

(**New-Aggr-Bw** > **Aggregate-maximum-bandwidth**)

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP splitting is performed when the difference in the bandwidth amount is off by a threshold.

$([1-a] \times \text{Current-Aggr-Bw} < \text{New-Aggr-Bw} < [1+a] \times \text{Current-Aggr-Bw})$ , where  $0 \leq a \leq 1$

When **New-Aggr-Bw** is greater than or equal to  $[1+a]$  multiplied by **Current-Aggr-Bw**, the ingress routing device does not perform normalization, but instead LSP splitting is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

### LSP Merging

- [Operational Overview on page 569](#)
- [Operational Constraints on page 570](#)
- [Merging Triggers on page 570](#)

#### Operational Overview

Junos OS supports two kinds of LSPs – CLI-configured LSPs and dynamically created LSPs. The CLI-configured LSPs are created manually and remain in the system until the configuration is modified. The dynamic LSPs are created dynamically by next generation MVPN, BGP virtual private LAN service (VPLS), or LDP, based on a template configuration, and are removed from the system when not used by any application for a certain duration. LSP merging follows a similar approach as dynamic LSPs.

LSP merging enables an ingress routing device to dynamically eliminate some member LSPs of the container LSP so less state information is maintained in the network. If an ingress router provisions several member LSPs between the ingress and egress routers, and there is an overall reduction in aggregate bandwidth (resulting in some LSPs being under-utilized), the ingress router distributes the new traffic load among fewer LSPs.

Although there are a number of ways to merge the member LSPs, Junos OS supports only overall-merge when normalization is being performed. An ingress router considers the aggregate demand and the minimum (or maximum) number of LSPs and revises the number of LSPs that should be active at an ingress routing device. As a result, the following can take place periodically as the normalization timer fires:

- Re-signaling some of the existing LSPs with updated bandwidth
- Creating new LSPs
- Removing some of the existing LSPs

### ***Operational Constraints***

If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. LSP merging does not happen because there is no dynamic estimation of aggregate bandwidth. However, a manual trigger for splitting and adjusting with a specific bandwidth value can be configured.

#### **NOTE:**

- Nominal LSPs are never deleted as part of LSP merging.
  - Before deleting an LSP, the LSP is made inactive, so that traffic shifts to other LSPs before removing the LSP. This is because RSVP sends PathTear before deleting routes and next hops from the Packet Forwarding Engine.
  - When member LSPs are re-signaled with modified bandwidth, it might happen that some LSPs do not get signaled successfully.
- 

### ***Merging Triggers***

Every time the normalization timer expires, the ingress router decides if LSP merging is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

For example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP merging are as follows:

- Absolute trigger—LSP merging is performed when **New-Aggr-Bw** is less than **Aggregate-minimum-bandwidth**.

(**New-Aggr-Bw** < **Aggregate-maximum-bandwidth**)

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP merging is performed when the difference in the bandwidth amount is off by a threshold.

$$([1-a] \times \text{Current-Aggr-Bw} < \text{New-Aggr-Bw} < [1+a] \times \text{Current-Aggr-Bw}, \text{ where } 0 \leq a \leq 1)$$

When the **New-Aggr-Bw** value is less than or equal to  $[1+a]$  multiplied by the **Current-Aggr-Bw** value, the ingress routing device does not perform normalization, but instead LSP merging is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

### Node and Link Protection

Junos OS supports the following mechanisms for node and link protection:

- Fast-reroute
- Link protection
- Node-link protection

Only one of the above-mentioned modes of protection can be configured on an ingress routing device at any given time. All member LSPs (nominal and supplementary) use the same mode of protection that is configured.

### Naming Convention

While configuring a container LSP, a name is assigned to the LSP. The name of a nominal and a supplementary LSP is formed by adding the configured-name suffix and an auto-generated suffix to the name of the container LSP. The name of the container LSP is unique and is checked for accuracy during the configuration parsing. The container LSP name should uniquely identify parameters, such as the ingress and egress router names.

**NOTE:** A container LSP member LSP and a point-to-point LSP on an ingress routing device cannot have the same LSP name.

The container LSPs follow a number-based LSP naming convention. For example, if the nominal LSP's configured name is **bob** and the number of member LSPs is  $N$ , the member LSPs are named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-N***.

After a normalization event, the number of member LSPs can change. For example, if the number of member LSPs increases from six to eight, then the ingress routing device keeps the first six LSPs named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-6***. The two additional LSPs are named **bob-7** and **bob-8**. The original LSPs might need to be re-optimized if their signaled bandwidth changes.

Similarly, if the number of member LSPs reduces from eight to six, the ingress routing device re-signals the member LSPs in such a way that the remaining active LSPs in the system are named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-6***.

In the process of creating new LSPs, an RSVP LSP named **bob-*<configured-suffix>-7*** can be configured.

## Normalization

---

- [Operational Overview on page 572](#)
- [Operational Constraints on page 572](#)
- [Inter-Operation with Autobandwidth on page 573](#)

### **Operational Overview**

Normalization is an event that happens periodically. When it happens, a decision is made on the number of member LSPs that should remain active and their respective bandwidths in a container LSP. More specifically, the decision is made on whether new supplementary LSPs are to be created, or any existing LSPs are required to be re-signaled or deleted during the normalization event.

Between two normalization events, a member LSP can undergo several autobandwidth adjustments. A normalization timer, similar to re-optimization timer, is configured. The normalization timer interval should be no less than the adjustment interval or optimization timer.

**NOTE:** Normalization is not triggered based on network events, such as topology changes.

---

### **Operational Constraints**

Normalization has the following operational constraints:

- Normalization happens only when none of the member LSPs are undergoing re-optimization or make-before-break. Normalization starts when all the member LSPs complete their ongoing make-before-break. If normalization is pending, new optimization should not be attempted until the normalization is complete.
- After normalization, an ingress routing device first computes a set of bandwidth-feasible paths using constraint-based routing computations. If enough constraint-based routing computed paths are not brought up with an aggregate bandwidth value that exceeds the desired bandwidth, several failover actions are taken.
- After a set of bandwidth-feasible paths are available, the ingress routing device signals those paths while keeping the original set of paths up with the old bandwidth values. The make-before-break is done with shared explicit (SE) sharing style, and when some of the LSPs do not get successfully re-signaled, a bounded number of retries is attempted for a specified duration. Only when all the LSPs are successfully signaled does the ingress router switch from the old instance of the container LSP to the newer instance. If all LSPs could not be successfully signaled, the ingress router keeps those instances of members that are up with higher bandwidth values.

For example, if the bandwidth of an old instance of a member LSP (LSP-1) is 1G, the LSP is split into LSP-1 with bandwidth 2G and LSP-2 with bandwidth 2G. If the signaling of LSP-1 with bandwidth 2G fails, the ingress router keeps LSP-1 with bandwidth 1G and LSP-2 with bandwidth 2G.

When there is a signaling failure, the ingress routing device stays in the error state, where some LSPs have updated bandwidth values only if the aggregate bandwidth has increased. The ingress router makes an attempt to bring up those LSPs that could not be successfully signaled, resulting in minimum traffic loss.

- If an LSP goes down between two normalization events, it can increase the load on other LSPs that are up. In order to prevent overuse of other LSPs, premature normalization can be configured in case of LSP failure. LSPs can go down because of pre-emption or lack of node or link protection. It might not be necessary to bring up the LSPs that are down because the normalization process re-runs the constraint-based routing path computations.

### ***Inter-Operation with Autobandwidth***

Taking as an example, there is one nominal LSP named LSP-1 configured with the following parameters:

- Splitting-bandwidth and maximum-signaling-bandwidth of 1G
- Merging-bandwidth and minimum-signaling-bandwidth of 0.8G
- Autobandwidth

Normalization is performed differently in the following scenarios:

- [Changes in Per-LSP Autobandwidth Adjustments on page 573](#)
- [Changes in Traffic Growth on page 575](#)
- [Computed Range and Configured Feasible Ranges on page 575](#)

### ***Changes in Per-LSP Autobandwidth Adjustments***

[Table 21 on page 573](#) illustrates how normalization splits and merges member LSPs as autobandwidth adjustments change per-LSP bandwidth with unconditional normalization.

***Table 21: Normalization with Per-LSP Autobandwidth Adjustment Changes***

Normalization Time	Current State	Events	Adjusted State
T0	No state.	Initialization	LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increases to 1.5G	<ul style="list-style-type: none"> <li>• Multiple autobandwidth adjustments since T0 is possible.</li> <li>• The ingress router decides to split LSP-1 into two LSPs, and creates LSP-2.</li> </ul>	LSP-1 = 0.8G LSP-2 = 0.8G
T2	LSP-1 usage increase to 2G LSP-2 usage increases to 0.9G (within limits)	<ul style="list-style-type: none"> <li>• Aggregate bandwidth is 2.9G, which exceeds aggregate splitting maximum of 2G.</li> <li>• The ingress router decides to split LSP-1 into three LSPs, and creates LSP-3.</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

*Table 21: Normalization with Per-LSP Autobandwidth Adjustment Changes (continued)*

Normalization Time	Current State	Events	Adjusted State
T3	LSP-3 usage increases to 1.5G	<ul style="list-style-type: none"> <li>Aggregate bandwidth is 3.5G with a maximum aggregate splitting of 3G.</li> <li>The ingress router decides to split LSP-1 into four LSPs, and creates LSP-4.</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G LSP-4 = 1G
T4	LSP-2 usage drops to 0.5G	<ul style="list-style-type: none"> <li>Aggregate bandwidth is 3G.</li> <li>The ingress router decides to merge LSP-1 and removes LSP-4.</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Because autobandwidth is configured on a per-LSP basis, every time there is an autobandwidth adjustment, the ingress router re-signals each LSP with **Max Avg Bw**.

Another approach to handling the changes in per-LSP autobandwidth adjustments is to not allow individual LSPs to run autobandwidth on the ingress router, but to run autobandwidth in passive (monitor) mode. This way, sampling is done at every statistics interval for member LSPs only, and normalization is performed for the container LSP alone instead of acting on individual LSPs adjustment timer expiry.

As a result, the number of re-signaling attempts and bandwidth fluctuations for a given member LSP is reduced. Only the computed bandwidth-values per-member LSP is used by the ingress router to find an aggregate bandwidth to be used during normalization. Configuring autobandwidth adjustment followed by normalization (adjustments and normalization intervals are comparable) can lead to considerable overhead because of re-signaling.

Taking the same example, and applying the second approach, LSP-1 goes from 0.8G to 1.5G and then back to 0.8G. If the normalization timer is of the same order as the adjustment interval, the ingress router leaves LSP-1 alone with its original 0.8G and only signals LSP-2 with 0.8G. This helps achieve the final result of normalization, thus avoiding the extra signaling attempt on LSP-1 with 1.5G at adjustment timer expiry.

Because member LSPs always use equal bandwidth, any adjustment done on member LSPs is undone. The member LSPs are re-signaled with reduced bandwidth when compared to the reserved capacity in adjustment trigger with normalization trigger. Therefore, avoiding adjustment trigger for member LSPs might be useful assuming that normalization and adjustment intervals are of the same order.

**NOTE:** We recommend that the normalization timer be higher than the autobandwidth adjustment interval and regular optimization duration, as the traffic trends are observed at a longer time scale and normalization is performed one-to-three times per day. An LSP can undergo optimization for the following reasons:

- Normal optimization
- Autobandwidth adjustment
- Normalization

**Changes in Traffic Growth**

Table 22 on page 575 illustrates how normalization is performed when traffic grows in large factor.

Table 22: Normalization with Traffic Growth

Normalization Time	Current State	Events	Adjusted State
T0	No state		LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increase to 3G	<ul style="list-style-type: none"><li>• Aggregate usage exceeds maximum splitting bandwidth</li><li>• The ingress router decides to split LSP-1, and creates two more supplementary LSPs</li></ul>	<div>LSP-1 = 1G</div> <div>LSP-2 = 1G</div> <div>LSP-3 = 1G</div>

Having fewer LSPs is preferred over signaling four LSPs each with 0.8G bandwidth, unless there is a constraint on the minimum number of LSPs.

**Computed Range and Configured Feasible Ranges**

When an ingress router is configured with the minimum and maximum number of LSPs, and per LSP splitting-bandwidth and merging-bandwidth values, the bandwidth thresholds are used for splitting and merging. For this, the number of LSPs (N) should satisfy the following constraints:

$$\text{minimum-member-lsps} \leq N \leq \text{maximum-member-lsps}$$

At the time of normalization, based on the aggregate demand X:

$$\lceil X/\text{splitting-bandwidth} \rceil \leq N \leq \lfloor X/\text{merging-bandwidth} \rfloor$$

The above-mentioned constraints provide two ranges for N to work from. If the two ranges for N are overlapping, N will be selected from the overlapping interval (lowest possible N) to keep the number of LSPs small in the network.

Otherwise, if maximum-member-lsps is less than  $\lceil X/\text{splitting-bandwidth} \rceil$ , the ingress router keeps (at maximum) the maximum-member-lsps in the system, and the bandwidth of each LSP is  $\lceil X/\text{maximum-member-lsps} \rceil$  or the maximum-signaling-bandwidth, whichever is less. It is possible that some LSPs might not get signaled successfully.

Similarly, if minimum-member-lsps is greater than  $\lceil X/\text{merging-bandwidth} \rceil$ , the ingress router keeps (at minimum) the minimum-member-lsps in the system, and the bandwidth of each LSP is  $\lceil X/\text{minimum-member-lsps} \rceil$  or the minimum-signaling-bandwidth, whichever is less.

Taking as an example, normalization is performed as following in these cases:

- Case 1
  - minimum-member-lsps = 2
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 1G
  - splitting-bandwidth = 2.5G

In this case, the ingress routing device signals four member LSPs each with a bandwidth of 2G.

- Case 2
  - minimum-member-lsps = 5
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 2.5G
  - splitting-bandwidth = 10G

In this case, the ingress routing device signals five member LSPs each with a bandwidth of 2G. Here, the static configuration on the number of member LSPs takes precedence.

- Case 3
  - minimum-signaling-bandwidth = 5G
  - maximum-signaling-bandwidth = 40G
  - merging-bandwidth = 10G
  - splitting-bandwidth = 50G

When a container LSP comes up, the nominal LSP is signaled with minimum-signaling-bandwidth. At the time of normalization, the new-aggregate-bandwidth is 100G. To find N and the bandwidth of each LSP, N should satisfy the following constraint:

$$100/50 \leq N \leq 100/10, \text{ which gives } 2 \leq N \leq 10$$

Therefore, N is equal to:

- $N = 2$ , bandwidth =  $\min \{100/2G, 40G\} = 40G$

This option does not satisfy the new aggregate of 100G.

- $N = 3$ , bandwidth =  $\min \{100/3G, 40G\} = 33.3G$

This option makes the aggregate bandwidth equal to 100G.

In this case, the ingress routing device signals three LSPs each with a bandwidth of 33.3G.

**NOTE:** The ingress router does not signal an LSP smaller than the minimum-signaling-bandwidth.

### Constraint-Based Routing Path Computation

Although there are no changes in the general constraint-based routing path computation, with a container LSP, there is a separate module that oversees the normalization process, schedules constraint-based routing events, and schedules switchover from an old instance to a new instance, when appropriate. An ingress routing device has to handle the constraint-based routing path computation periodically. When normalization occurs, an ingress router has to compute constraint-based routing paths, if the number of LSPs or the bandwidth of the LSPs needs to be changed.

For example, there are K LSPs at the ingress router with bandwidth values X-1, X-2, ..., and X-K. The current aggregate bandwidth value is Y, which is the sum of X-1 plus X-2 plus X-K. If there is a new demand of W, the ingress router first computes how many LSPs are required. If the ingress router only needs N LSPs (LSP-1, LSP-2, ..., and LSP-N) each with bandwidth value B, the task of the constraint-based routing module is to provide a set of bandwidth-feasible LSPs that can accommodate the new aggregate demand which is not less than Y.

The ingress router then tries to see if the constraint-based routing paths can be computed successfully for all N LSPs. If the paths for all the LSPs are found successfully, the constraint-based routing module returns the set to the normalization module.

It is possible that the constraint-based routing computation is not successful for some LSPs. In this case, the ingress routing device takes the following action:

- If the configuration allows for incremental-normalization, implying if the ingress router has enough LSPs whose aggregate exceeds Y, the constraint-based routing module returns that set of paths.
- Whether increment-normalization is configured or not, if constraint-based routing paths could not be computed for a sufficient number of LSPs, the ingress router has to repeat the process of finding a new set of LSPs. Initially, the ingress router starts with the lowest value of N from the feasible region. Every time, the ingress router has to revise the number, it linearly increases it by 1. As a result, per LSP bandwidth becomes less and therefore, there is a greater chance of successful signaling. The process is

repeated for all feasible values of N (or some bounded number of times or duration as configured).

The ingress router signals the LSPs after successful computations of the constraint-based routing path computation. It might happen that when the LSPs are signaled, signaling of many LSPs fail. In addition to the constraint-based routing path computations to be successful, the RSVP signaling should also succeed, such that the new aggregate is not less than the old aggregate bandwidth.

### **Sampling**

---

Sampling is important for normalization to function. With sampling configured, an ingress routing device is able to make a statistical estimate of the aggregate traffic demands. Every time the sampling timer fires, the ingress routing device can consider traffic rates on different LSPs and compute an aggregate bandwidth sample. This sampling timer is different from the statistics sampling done periodically by RSVP on all LSPs. The aggregate bandwidth is a sample to be used at the time of normalization. An ingress routing device can save past samples to compute an average (or some other statistical measure) and use it the next time normalization happens.

To remove any outlier samples, a sampling token is configured. In other words, from all the aggregate samples collected during the configured time, the bottom and top outliers are ignored before computing a statistical measure from the remaining samples.

The following two methods of computing an aggregate bandwidth value are supported:

- **Average**—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The average bandwidth value is computed from the remaining samples to be used during normalization.
- **Max**—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The maximum bandwidth value is picked from the remaining samples to be used during normalization.

The time duration, the number of past aggregate samples to store, the percentile value to determine, and the ignore outliers are user-configurable parameters.

### **Support for NSR, IPG-FA, and Static Routes**

---

Starting with Junos OS Release 15.1, container label-switched paths (LSPs) provide support for nonstop active routing (NSR), IGP forwarding adjacency (FA), and static routes to address the requirements of wider business cases.

- [NSR Support on page 578](#)
- [IPG-FA Support on page 580](#)
- [Static Route Support on page 581](#)

#### **NSR Support**

A container LSP has the characteristics of ECMP and RSVP traffic engineering. Because a container LSP consists of several member LSPs between an ingress and an egress router, with each member LSP taking a different path to the same destination, the ingress router is configured with all the parameters necessary to compute an RSVP ECMP LSP.

These parameters along with the forwarding state information have to be synchronized between the master and backup Routing Engines to enable the support for nonstop active routing (NSR) for container LSPs. While some of the forwarding state information on the backup Routing Engine is locally built based on the configuration, most of it is built based on periodic updates from the master Routing Engine. The container LSPs are created dynamically using the replicated states on the backup Routing Engine.

By default, normalization occurs once in every 6 hours and during this time, a number of autobandwidth adjustments happen over each member LSP. A member LSP is resized according to the traffic it carries and the configured autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by summing up the bandwidth across all the member LSPs.

For RSVP point-to-point LSPs, a Routing Engine switchover can be under any one of the following:

- **Steady state**

In the steady state, the LSP state is up and forwards traffic; however, no other event, such as the make-before-break (MBB), occurs on the LSP. At this stage, the RPD runs on both the Routing Engines, and the switchover event toggles between the master and backup Routing Engine. The backup Routing Engine has the LSP information replicated already. After the switchover, the new master uses the information of the replicated structure to construct the container LSP and en-queues the path (ERO) of LSP in the retrace mode. RSVP signals and checks if the path mentioned in the ERO is reachable. If the RSVP checks fail, then the LSP is restarted. If the RSVP checks succeed, the LSP state remains up.

- **Action leading to make-before-break (MBB)**

A container LSP can be optimized with updated bandwidth, and this change is done in a MBB fashion. During an MBB process, there are two path instances for a given LSP, and the LSP switches from one instance to another. For every Routing Engine switchover, the path is checked to find out where in the MBB process the path is. If the path is in the middle of the MBB process, with the main instance being down and the re-optimized path being up, then MBB can switch over to the new instance. The **show mpls lsp extensive** command output, in this case, is as follows:

```
13 Dec 3 01:33:38.941 Make-before-break: Switched to new instance
12 Dec 3 01:33:37.943 Record Route: 10.1.1.1
11 Dec 3 01:33:37.942 Up
10 Dec 3 01:33:37.942 Automatic Autobw adjustment succeeded: BW changes
from 100 bps to 281669 bps
9 Dec 3 01:33:37.932 Originate make-before-break call
8 Dec 3 01:33:37.931 CSPF: computation result accepted 10.1.1.1
7 Dec 3 01:28:44.228 CSPF: ERO retrace was successful 10.1.1.1
6 Dec 3 01:19:39.931 10.1.1.2 Down: mbb/reopt
5 Dec 3 01:18:29.286 Up: mbb/reopt
4 Dec 3 01:14:47.119 10.1.1.2 Down: mbb/reopt
3 Dec 3 01:13:29.285 Up: mbb/reopt
2 Dec 3 01:10:59.755 Selected as active path: selected by master RE
```

A similar behavior is retained for member LSPs during bandwidth optimization.

A Routing Engine switchover under the steady state (when normalization is not in progress), keeps the container LSPs up and running without any traffic loss. Events, such as an MBB due to autobandwidth adjustments, link status being down, or double failure, in the steady state are similar to a normal RSVP point-to-point LSP.

If the container LSP is in the process of normalization, and the normalization event is triggered either manually or periodically, it goes through the computation and execution phase. In either of the cases, zero percent traffic loss is not guaranteed.

- Normalization in the computation phase

During the computation phase, the master Routing Engine calculates the targeted member LSP count and bandwidth with which each member LSP should be re-signaled. The backup Routing Engine has limited information about the container LSP, such as the LSP name, LSP ID, current bandwidth of its member LSP, member LSP count, and the normalization retry count. If the switchover happens during the computation phase, then the backup Routing Engine is not aware of the targeted member LSP count and the bandwidth to be signaled. Since traffic statistics are not copied to the backup Routing Engine, it cannot compute the targeted member count and bandwidth. In this case, the new master Routing Engine uses the old data stored in the targeted member LSP count and the targeted bandwidth to signal the LSPs.

- Normalization in the execution phase

During the execution phase, RSVP of the master Routing Engine tries to signal the LSPs with the newly calculated bandwidth. If the switchover occurs during the signaling of LSPs with greater bandwidth or during LSP splitting or merging, then the new master Routing Engine uses the information of the targeted member count and bandwidth value to be signaled with, to bring up the LSPs.

### ***IPG-FA Support***

A forwarding adjacency (FA) is a traffic engineering label-switched path (LSP) that is configured between two nodes and used by an interior gateway protocol (IGP) to forward traffic. By default, an IGP does not consider MPLS traffic-engineering tunnels between sites, for traffic forwarding. Forwarding adjacency treats a traffic engineering LSP tunnel as a link in an IGP topology, thus allowing the nodes in the network also to forward the IP traffic to reach the destination over this FA LSP. A forwarding adjacency can be created between routing devices regardless of their location in the network.

To advertise a container LSP as an IGP-FA, the LSP name needs to be configured either under IS-IS or OSPF. For example:

IS-IS	<pre>[edit] protocols {   isis {     label-switched-path <i>container-lsp-name</i>;   } }</pre>
-------	---

OSPF	<pre>[edit]</pre>
------	-------------------

```

protocols {
  ospf {
    area 0.0.0.0 {
      label-switched-path container-lsp-name;
    }
  }
}

```

**NOTE:** The IGP-FA is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for FA.

### Static Route Support

Static routes often include only one or very few paths to a destination and generally do not change. These routes are used for stitching services when policies and other protocols are not configured.

To advertise a container LSP as a static route, the LSP name needs to be configured under the static route configuration. For example:

#### Static Route

```

[edit]
routing-options {
  static {
    route destination {
      lsp-next-hop container-lsp-name;
    }
  }
}

```

**NOTE:** The static route support is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for static routing.

## Configuration Statements Supported for Container LSPs

Table 23 on page 582 lists the MPLS LSP configuration statements that apply to RSVP LSP and a container LSP (nominal and supplementary).

The configuration support is defined using the following terms:

- Yes—The configuration statement is supported for this type of LSP.
- No—The configuration statement is not supported for this type of LSP.
- N/A—The configuration statement is not applicable for this type of LSP.

**Table 23: Applicability of RSVP LSPs Configuration to a Container LSP**

Configuration Statement	RSVP LSP (Ingress)	Member LSP (Ingress)
adaptive (Default: non-adaptive)	Yes	Yes
admin-down	Yes	Yes
admin-group	Yes	Yes
admin-groups-except	Yes	Yes
apply-groups	Yes	Yes
apply-groups-except	Yes	Yes
associate-backup-pe-groups	Yes	No
associate-lsp (No bidirectional support)	Yes	No
auto-bandwidth	Yes	Yes
backup	Yes	No
bandwidth	Yes	Yes
class-of-service	Yes	Yes
corouted-bidirectional (No bidirectional support)	Yes	No
corouted-bidirectional-passive (No bidirectional support)	Yes	No
description	Yes	Yes
disable	Yes	Yes
egress-protection	Yes	No
exclude-srlg	Yes	Yes
fast-reroute (Same fast reroute for all member LSPs)	Yes	Yes

Table 23: Applicability of RSVP LSPs Configuration to a Container LSP (continued)

Configuration Statement	RSVP LSP (Ingress)	Member LSP (Ingress)
from	Yes	Yes
hop-limit	Yes	Yes
install	Yes	Yes
inter-domain (Same termination router)	Yes	Yes
secondary (All LSPs are primary)	Yes	No
ldp-tunneling (All LSPs do tunneling)	Yes	Yes
least-fill	Yes	Yes
link-protection (All LSPs share same link protection mechanism)	Yes	Yes
lsp-attributes	Yes	Yes
lsp-external-controller	Yes	No
metric (All LSPs are same)	Yes	Yes
most-fill	Yes	Yes
no-cspf (LSPs use IGP)	Yes	Yes
no-decrement-ttl (All LSPs share same TTL behavior)	Yes	Yes
no-install-to-address	Yes	Yes
no-record	Yes	Yes
node-link-protection (All LSPs share same node-link protection mechanism)	Yes	Yes

## Impact of Configuring Container LSPs on Network Performance

A container LSP is a container LSP that allows multiple member LSPs to co-exist and be managed as a bundle. The member LSPs are similar to independent point-to-point RSVP LSPs. As a result, resource consumption is similar to the sum of resources consumed by each point-to-point RSVP LSP. However, provisioning a container LSP is more efficient, as under-utilized member LSPs are dynamically removed, thus saving memory and CPU resources.

The container LSP features are dependent on the presence of a functional base MPLS RSVP implementation. As a result, a container LSP does not introduce any security considerations beyond the existing considerations for the base MPLS RSVP functionality. The categories of possible attacks and countermeasures are as follows:

- Interaction with processes and router configuration

No new communication mechanisms with external hosts are required for a container LSP. Data arrives at the RSVP module through local software processes and router configuration, other than RSVP neighbor adjacency. Junos OS provides security controls on access to the router and router configuration.

- Communication with external RSVP neighbors

RSVP signaled MPLS LSPs depend on the services of RSVP and IGP to communicate RSVP messages among neighboring routers across the network. Because the RSVP sessions involve communication outside of the local router, they are subject to many forms of attack, such as spoofing of peers, injection of falsified RSVP messages and route updates, and attacks on the underlying TCP/UDP transport for sessions. Junos OS provides countermeasures for such attack vectors.

- Resource limits and denial of service

Junos OS provides several mechanisms through policers and filters to protect against denial-of-service attacks based on injecting higher than the expected traffic demands. At the MPLS LSP level, Junos OS allows operators to configure limits on the LSP

bandwidth and the number of LSPs. However, like point-to-point RSVP LSPs, container LSPs do not enforce limits on the volume of traffic forwarded over these LSPs.

## Supported and Unsupported Features

Junos OS supports the following container LSP features:

- Equal-bandwidth-based LSP splitting mechanism
- Aggregate-bandwidth-based LSP splitting and merging in a make-before-break way
- LSP-number-based naming mechanism for dynamically created member LSPs
- Periodic sampling mechanisms to estimate aggregate bandwidth
- Interoperability with auto-bandwidth feature
- ECMP using the dynamically created LSPs
- LDP-tunneling on the dynamically created LSP
- Configuring container LSP using IGP shortcuts
- Aggregated Ethernet links
- Logical systems

Junos OS does **not** support the following container LSP functionality:

- Node and link disjoint paths for different LSPs between an ingress and an egress routing device
- Bandwidth allocation policy different from equal bandwidth policy at the normalization event
- Constraint-based routing path computation to find equal IGP cost paths for different LSPs
- RSVP objects, such as **MLSP\_TUNNEL Sender Template**, and **MLSP\_TUNNEL Filter Specification** defined in [KOMPELLA-MLSP]
- Change in topology as a trigger for LSP splitting and merging
- Change in topology and link failure as a trigger for normalization, unless member LSPs go down
- Egress protection on container LSP
- Container LSP as a backup LSP for IGP interface
- Container LSP as provider tunnel for multicast VPNs
- Dynamic LSPs for normalization
- CCC using container LSP
- Secondary paths for container LSP
- Bidirectional container LSP
- Policing

- Static routes using container LSPs as next hops on a best-effort basis
- External path computing entity, such as PCE
- Multichassis
- IPv6

## Example: Configuring Dynamic Bandwidth Management Using Container LSP

This example shows how to enable dynamic bandwidth management by configuring container label-switched paths (LSPs) that enable load balancing across multiple point-to-point member LSPs.

- [Requirements on page 587](#)
- [Overview on page 587](#)
- [Configuration on page 588](#)
- [Verification on page 597](#)

### Requirements

This example uses the following hardware and software components:

- Five routers that can be a combination of M Series, MX Series, or T Series routers, out of which two routers are provider edge (PE) routers and three routers are provider (P) routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - BGP
  - OSPF

### Overview

Starting with Junos OS Release 14.2, a new type of LSP, called a container LSP, is introduced to enable load balancing across multiple point-to-point LSPs. A container

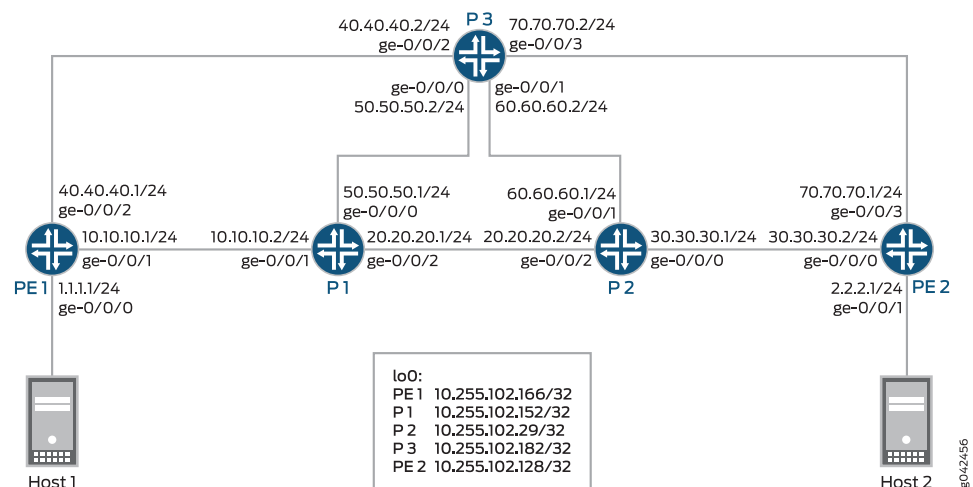

LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

## Topology

Figure 54 on page 588 is a sample topology configured with container LSPs.

Figure 54: Dynamic Bandwidth Management Using Container LSP

In this example, Routers PE1 and PE2 are the PE routers connected to hosts Host1 and Host2, respectively. The core routers, Routers P1, and P2, and P3 connect to the PE routers.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
PE1 set interfaces ge-0/0/0 unit 0 family inet address 1.1.1/24
PE1 set interfaces ge-0/0/1 unit 0 family inet address 10.10.10.1/24

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

1. Configure the Router PE1 interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/24
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 40.40.40.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.102.166/32
user@PE1# set lo0 unit 0 family mpls
```

2. Configure the router ID and autonomous system number for Router PE1.

```
[edit routing-options]
user@PE1# set router-id 10.255.102.166
user@PE1# set autonomous-system 1234
```

3. Enable the policy to load-balance traffic.

```
[edit routing-options]
user@PE1# set forwarding-table export pplb
```

4. Enable RSVP on all Router PE1 interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
```

5. Enable MPLS on all the interfaces of Router PE1 (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

6. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
```

```

user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth

```

7. Configure the label-switched path (LSP) template parameters.

```

[edit protocols]
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
adjust-interval 300
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
adjust-threshold 5
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
minimum-bandwidth 10m
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
maximum-bandwidth 10m

```

8. Configure a container LSP between Router PE1 and Router PE2, and assign the PE1-to-PE2-template1 LSP template.

```

[edit protocols]
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 to
10.255.102.128
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
label-switched-path-template PE1-to-PE2-template1

```

9. Configure the container LSP parameters.

```

[edit protocols]
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging maximum-member-lsps 20
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging minimum-member-lsps 2
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging splitting-bandwidth 40m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging merging-bandwidth 6m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging maximum-signaling-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging minimum-signaling-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization normalize-interval 400
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization failover-normalization
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization normalization-retry-duration 20
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization normalization-retry-limits 3

```

```

user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging sampling cut-off-threshold 1
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging sampling use-percentile 90

```

10. Configure the BGP group, and assign the local and neighbor IP addresses.

```

[edit protocols]
user@PE1# set bgp group to-PE2 type internal
user@PE1# set bgp group to-PE2 local-address 10.255.102.166
user@PE1# set bgp group to-PE2 neighbor 10.255.102.128
user@PE1# set bgp group to-PE2 family inet-vpn unicast
user@PE1# set bgp group to-PE2 export direct

```

11. Enable OSPF on all the interfaces of Router PE1 (excluding the management interface) along with traffic engineering capabilities.

```

[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/2.0 metric 100

```

12. Configure the policy statement to load-balance traffic.

```

[edit policy-options]
user@PE1# set policy-statement direct term 1 from protocol direct
user@PE1# set policy-statement direct term 1 then accept
user@PE1# set policy-statement pplb then load-balance per-packet

```

13. Configure a routing instance on Router PE1, and assign the routing instance interface.

```

[edit routing-instances]
user@PE1# set vpn1 instance-type vrf
user@PE1# set vpn1 interface ge-0/0/0.0

```

14. Configure the route distinguisher, vrf target, and vrf-table label values for the VRF routing instance.

```

[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 10.255.102.166:1
user@PE1# set vpn1 vrf-target target:1:1
user@PE1# set vpn1 vrf-table-label

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, **show policy-options**, and **show routing-options**

commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

### Verifying the Container LSP Status Without Bandwidth

---

**Purpose**    Verify the status of the container LSP.

**Action** From operational mode, run the **show mpls container-lsp extensive** command.

```

user@PE1> show mpls container-lsp extensive

Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
Normalization

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

**Meaning** At the expiry of the normalization timer, the container LSP is split into five member LSPs, each with 10 Mbps (minimum and maximum signaling bandwidth). As a result, the aggregate bandwidth is 50 Mbps.

#### Verifying the Container LSP Splitting Process

---

**Purpose** Verify the container LSP splitting process after normalization happens.

**Action** From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2

vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24          *[BGP/170] 00:12:14, localpref 100, from 10.255.102.128
                    AS path: I, validation-state: unverified
>to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-1
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-2
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-3
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-4
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-5
```

**Meaning** After LSP splitting, Router PE1 has injected the forwarding adjacency.

#### Verifying the Container LSP Statistics

---

**Purpose** Verify the container LSP statistics after normalization happens.

**Action** From operational mode, run the **show mpls container-lsp statistics** command.

```
user@PE1> show mpls container-lsp statistics
```

Ingress LSP: 1 sessions			State	Member LSP count
Container LSP name			Up	5
To	From	State	Packets	Bytes LSPname
10.255.102.128	10.255.102.166	Up	15166271	2062612856
PE1-PE2-container-100-1				
10.255.102.128	10.255.102.166	Up	12289912	1671428032
PE1-PE2-container-100-2				
10.255.102.128	10.255.102.166	Up	13866911	1885899896
PE1-PE2-container-100-3				
10.255.102.128	10.255.102.166	Up	12558707	1707984152
PE1-PE2-container-100-4				
10.255.102.128	10.255.102.166	Up	11512151	1565652536
PE1-PE2-container-100-5				

**Meaning** Traffic is load-balanced across the newly created member LSPs.

### Verifying the Container LSP Status with Decreased Bandwidth (Before Normalization)

**Purpose** Verify the status of the container LSP with decreased bandwidth before normalization happens.

**Action** From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
```

```
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 5
Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 50Mbps, Sampled Aggregate bandwidth: 2.0215Mbps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
  BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 384 second(s)
---Output truncated---
```

**Meaning** Because normalization has not happened, the member LSP count remains at 5.

### Verifying the Container LSP Status with Decreased Bandwidth (After Normalization)

---

**Purpose** Verify the status of the container LSP with decreased bandwidth after normalization happens.

**Action** From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 20Mbps, Sampled Aggregate bandwidth: 0bps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
  BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 397 second(s)
  22 Jun  5 22:30:37.094 Clear history and statistics: on container
  (PE1-PE2-container-100)
  21 Jun  5 22:30:37.094 Delete member LSPs: PE1-PE2-container-100-3 through
  PE1-PE2-container-100-5
  20 Jun  5 22:30:37.090 Normalize: container (PE1-PE2-container-100) into 2
  members - each with bandwidth 10000000 bps
  19 Jun  5 22:30:37.090 Normalize: normalization with aggregate bandwidth 2037595
  bps
  18 Jun  5 22:30:37.090 Normalize: normalization with 2037595 bps
---Output truncated---
```

**Meaning** At the expiry of the normalization timer, the container LSP merging takes place because there is an overall reduction in bandwidth. The member LSPs are merged, and the member LSP count is 2 after normalization.

### Verifying the Container LSP Merging Process

---

**Purpose** Verify the container LSP splitting process after normalization happens.

**Action** From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2
vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24          *[BGP/170] 01:09:45, localpref 100, from 10.255.102.128
                   AS path: I, validation-state: unverified
                   > to 10.10.10.2 via ge-0/0/1.0, label-switched-path
PE1-PE2-container-100-1
                   to 10.10.10.2 via ge-0/0/1.0, label-switched-path
PE1-PE2-container-100-2
```

**Meaning** After LSP merging, Router PE1 has deleted the merged member LSPs.

### Verifying Failover Normalization

**Purpose** Verify load redistribution when traffic is sent at 35 Mbps and the link between Routers P1 and P2 is disabled. Arrival of PathErr on link failure triggers immediate normalization.

To enable failover normalization, include the **failover-normalization** configuration statement at the **[edit protocols mpls container-label-switched-path container-lsp-name splitting-merging normalization]** hierarchy level.

**Action** From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp

Ingress LSP: 1 sessions
Container LSP name
PE1-PE2-container-100
To          From          State Rt P    State      Member LSP count
10.255.102.128 10.255.102.166 Up      0 *    Up        ActivePath      2
PE1-PE2-container-100-1
10.255.102.128 10.255.102.166 Up      0 *
PE1-PE2-container-100-2
Total 2 displayed, Up 2, Down 0
```

After the ge-0/0/2 link between Routers P1 and P2 goes down, normalization is immediately triggered.

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail

Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 4
Normalization
  Min LSPs: 2, Max LSPs: 20

  on member PE1-PE2-container-100-2[2 times]
    9 Jun 5 19:28:20.315 Normalize: container (PE1-PE2-container-100) received
  PathErr on member PE1-PE2-container-100-1[2 times]
    8 Jun 5 19:28:20.311 Clear history and statistics: on container
  (PE1-PE2-container-100)
    7 Jun 5 19:28:20.311 Normalize: container (PE1-PE2-container-100) into 4
  members - each with bandwidth 10000000 bps
    6 Jun 5 19:28:20.311 Normalize: normalization with aggregate bandwidth 33665020
  bps
    5 Jun 5 19:28:20.308 Normalize: container (PE1-PE2-container-100) received
  PathErr on member PE1-PE2-container-100-2
    4 Jun 5 19:28:20.308 Normalize: container (PE1-PE2-container-100) received
  PathErr on member PE1-PE2-container-100-1
    3 Jun 5 19:27:48.574 Normalization complete: container (PE1-PE2-container-100)
  with 2 members
    2 Jun 5 19:27:28.644 Normalize: container (PE1-PE2-container-100) create 2
  LSPs, min bw 10000000bps, member count 0
    1 Jun 5 19:27:28.644 Normalize: normalization with aggregate bandwidth 0 bps
  ----Output truncated----
```

**Meaning** Arrival of PathErr message on link failure triggers immediate normalization.

### Verifying Incremental Normalization

**Purpose** Verify incremental normalization when enough bandwidth is not available.  
On Router PE1, the RSVP interfaces static bandwidth is restricted to 22 Mbps each.

**Action** From operational mode, run the **show rsvp interface** command.

```
user@PE1> show rsvp interface
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
ge-0/0/2.0	Up	0	100%	22Mbps	22Mbps	0bps	21.4031Mbps
ge-0/0/1.0	Up	2	100%	22Mbps	12Mbps	10Mbps	21.7011Mbps

Before normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
```

Ingress LSP: 1 sessions				State	Member LSP count
Container LSP name				Up	2
PE1-PE2-container-100				ActivePath	LSPname
To	From	State	Rt P		
10.255.102.128	10.255.102.166	Up	0 *		
PE1-PE2-container-100-1					
10.255.102.128	10.255.102.166	Up	0 *		
PE1-PE2-container-100-2					

After normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
```

Ingress LSP: 1 sessions				State	Member LSP count
Container LSP name				Up	7
PE1-PE2-container-100				ActivePath	LSPname
To	From	State	Rt P		
10.255.102.128	10.255.102.166	Up	0 *	PE1-PE2-container-100-1	
10.255.102.128	10.255.102.166	Up	0 *	PE1-PE2-container-100-2	
10.255.102.128	10.255.102.166	Up	0 *	PE1-PE2-container-100-3	
10.255.102.128	10.255.102.166	Up	0 *	PE1-PE2-container-100-4	
10.255.102.128	10.255.102.166	Up	0 *	PE1-PE2-container-100-5	
10.255.102.128	10.255.102.166	Up	0 *	PE1-PE2-container-100-6	
10.255.102.128	0.0.0.0	Dn	0 -	PE1-PE2-container-100-7	
Total 7 displayed, Up 6, Down 1					

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
```

Ingress LSP: 1 sessions  
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 7  
Normalization  
Min LSPs: 2, Max LSPs: 10  
Aggregate bandwidth: 40.8326Mbps, Sampled Aggregate bandwidth: 50.129Mbps  
NormalizeTimer: 9000 secs, NormalizeThreshold: 10%  
Max Signaling BW: 10Mbps, Min Signaling BW: 5Mbps, Splitting BW: 40Mbps, Merging BW: 5Mbps

- [Dynamic Bandwidth Management Using Container LSP Overview on page 559](#)

## Configuring Dynamic Bandwidth Management Using Container LSP

You can configure a container LSP to enable load balancing across multiple point-to-point LSPs dynamically. A container LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID and autonomous system number.
3. Configure the following protocols:
  - RSVP
  - BGP

Configure a BGP group to peer device with remote provider edge (PE) device.

- OSPF

Enable traffic engineering capabilities.

4. Configure a VRF routing instance.

To configure the PE device:

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

2. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file file-name
user@PE1# set mpls statistics file size size
user@PE1# set mpls statistics interval seconds
user@PE1# set mpls statistics auto-bandwidth
```

3. Configure the label-switched path (LSP) template parameters.

```
[edit protocols]
user@PE1# set mpls label-switched-path template-name template
user@PE1# set mpls label-switched-path template-name optimize-timer seconds
user@PE1# set mpls label-switched-path template-name link-protection
user@PE1# set mpls label-switched-path template-name adaptive
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    adjust-interval seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    adjust-threshold seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    minimum-bandwidth mbps
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    maximum-bandwidth mbps
```

4. Configure a container LSP between the two PE routers, and assign the LSP template.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name to
    remote-PE-ip-address
user@PE1# set mpls container-label-switched-path container-lsp-name
    label-switched-path-template template-name
```

5. Configure the container LSP parameters.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging maximum-member-lsps number
```

```

user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging minimum-member-lsps number
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging splitting-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging merging-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging maximum-signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging minimum-signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging normalization normalize-interval seconds
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging normalization failover-normalization
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging normalization normalization-retry-duration seconds
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging normalization normalization-retry-limits number
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging sampling cut-off-threshold number
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging sampling use-percentile number

```

6. Configure the policy statement to load-balance traffic.

```

[edit policy-options]
user@PE1# set policy-statement first-policy-name term 1 from protocol direct
user@PE1# set policy-statement first-policy-name term 1 then accept
user@PE1# set policy-statement second-policy-name then load-balance per-packet

```

**NOTE:** The policy to load-balance traffic should be assigned to the forwarding table configuration under the [edit routing-options] hierarchy level.

```

user@PE1# set forwarding-table export pplb

```

7. Verify and commit the configuration.

For example:

```

[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth

```

```
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
adjust-interval 300

## RSVP-TE Pop-and-Forward LSP Tunnels Overview

---

Pop-and-forward LSPs introduces the notion of pre-installed per traffic engineering link pop labels that are shared by RSVP-TE LSPs that traverse these links and significantly reducing the required forwarding plane state . A transit label-switching router (LSR) allocates a unique pop label per traffic engineering link with a forwarding action to pop the label and forward the packet over that traffic engineering link should the label appear at the top of the packet. These pop labels are sent back in the RESV message of the LSP at each LSR and further recorded in the record route object (RRO). The label stack is constructed from the recorded labels in the RRO and pushed by the ingress label edge router (LER), as each transit hop performs a pop-and-forward action on its label. The pop-and-forward tunnels enhances the RSVP-TE control plane feature benefits with the simplicity of the shared MPLS forwarding plane.

- [Benefits of RSVP-TE Pop-and-Forward LSP Tunnels on page 621](#)

- [RSVP-TE Pop-and-Forward LSP Tunnel Supported and Unsupported Features on page 626](#)

## Benefits of RSVP-TE Pop-and-Forward LSP Tunnels

- **Scaling advantage of RSVP-TE**—Any platform-specific label space limit on an LSR is prevented from being a constraint to the control plane scaling on that interface.
- **Reduced forwarding plane state**—The transit labels on a traffic engineering link are shared across RSVP-TE tunnels traversing the link, and are used independent of the ingress and egress devices of the LSPs, thereby significantly reducing the required forwarding plane state.
- **Reduced transit data plane state**—Because the pop labels are allocated per traffic engineering link and shared across LSPs, the total label state in the forwarding plane is reduced to a function of the number of RSVP neighbors on that interface.

- **Faster LSP setup time**—The forwarding plane state is not programmed during the LSP setup and teardown. As a result, the control plane need not wait sequentially at each hop for the forwarding plane to be programmed prior to sending the label upstream in the RESV message, resulting in reduced LSP setup time.
- **Backward compatibility**—This allows backward compatibility with transit LSRs that provide regular labels in RESV messages. Labels can be mixed across transit hops in a single MPLS RSVP-TE LSP. Certain LSRs can use traffic engineering link labels and others can use regular labels. The ingress can construct a label stack appropriately based on what type of label is recorded from every transit LSR.

## Pop-and-Forward LSP Tunnel Terminology

The following terminology is used in the implementation of RSVP-TE pop-and-forward LSP tunnels:

- **Pop label**—An incoming label at an LSR that is popped and forwarded over a specific traffic-engineering link to a neighbor.
- **Swap label**—An incoming label at an LSR that is swapped to an outgoing label and forwarded over a specific downstream traffic engineering link.
- **Delegation label**—An incoming label at an LSR that is popped. A new set of labels is pushed before the packet is forwarded.
- **Delegation hop**— A transit hop that allocates a delegation label.
- **Application label depth (AppLD)**—Maximum number of application or service labels (for example, VPN, LDP, or IPv6 explicit-null labels) that can be beneath the RSVP transport labels. It is configured on a per-node basis, and is equally applicable for all LSPs, and is neither signaled nor advertised.
- **Outbound label depth (OutLD)**—Maximum number of labels that can be pushed before a packet is forwarded. This is local to the node, and is neither signaled nor advertised.
- **Additional transport label depth (AddTLD)**—Maximum number of other transport labels that can be added (for example, bypass label). This is a per-LSP parameter that is neither signaled or advertised. The value is discerned by checking if the LSP has been signaled with link protection (AddTLD=1) or without link protection (AddTLD=0).
- **Effective transport label depth (ETLD)**— Number of transport labels that the LSP hop can potentially send to its downstream hop. This value is signaled per LSP in the hop attributes subobject. The hop attributes subobject is added to the record route object (RRO) in the path message.

## Pop-and-Forward LSP Tunnel Label and Signaling

Every traffic engineering link is allocated a pop label that is installed in the mpls.0 routing table with a forwarding action to pop the label and forward the packet over the traffic engineering link to the downstream neighbor of the RSVP-TE tunnel.

For pop-and-forward LSP tunnels, the pop label for the traffic engineering link is allocated when the first RESV message for a pop-and-forward transit LSP arrives over that traffic

engineering link. This is done to avoid preallocating pop labels and installing them in networks where pop-and-forward LSPs are not configured.

**NOTE:** For the pop-and-forward LSP tunnels to function effectively, we recommend that you configure the `maximum-labels` statement on all the interfaces in the RSVP-TE network.

Figure 55 on page 623 displays pop labels at all interfaces for neighboring devices.

**Figure 55: Pop-and-Forward LSP Tunnel Labels**

There are two pop-and-forward LSP tunnels—T1 and T2. Tunnel T1 is from Device A to Device E on path A-B-C-D-E. Tunnel T2 is from Device F to Device E on path F-B-C-D-E. Both the tunnels, T1 and T2, share the same traffic engineering links B-C, C-D, and D-E.

As RSVP-TE signals the setup of the pop-and-forward tunnel T1, the LSR D receives the RESV message from the egress E. Device D checks the next-hop traffic engineering link (D-E) and provides the pop label (250) in the RESV message for the tunnel. The label is sent in the label object and is also recorded in the label subobject (with the pop label bit set) carried in the RRO. Similarly, Device C provides the pop label (200) for the next-hop traffic engineering link C-D and Device B provides the pop label (150) for the next-hop traffic engineering link B-C. For the tunnel T2, the transit LSRs provide the same pop labels as described for tunnel T1.

Both the label edge routers (LERs), Device A and Device F, push the same stack of labels [150(top), 200, 250] for tunnels T1 and T2, respectively. The recorded labels in the RRO are used by the ingress LER to construct a stack of labels.

The pop-and-forward LSP tunnel labels are compatible with transit interfaces that use swap labels. Labels can be mixed across transit hops in a single MPLS RSVP-TE LSP, where certain LSRs can use pop labels and others can use swap labels. The ingress device constructs the appropriate label stack based on the label type recorded from every transit LSR.

## Pop-and-Forward LSP Tunnel Label Stacking

### Construction of Label Stack at the Ingress

The ingress LER checks the type of label received from each transit hop as recorded in the RRO in the RESV message and generates the appropriate label stack to use for the pop-and-forward tunnel.

The following logic is used by the ingress LER while constructing the label stack:

- Each RRO label subobject is processed starting with the label subobject from the first downstream hop.
- Any label provided by the first downstream hop is always pushed on the label stack. If the label type is a pop label, then any label from the succeeding downstream hop is also pushed on the constructed label stack.
- If the label type is a swap label, then any label from the succeeding downstream hop is not pushed on the constructed label stack.

### Auto-Delegation of Label Stack

---

The ingress device runs the Constrained Shortest Path First (CSPF) to compute the path, and if the hop length is greater than the OutLD-AppLD-AddTLD, the ingress device cannot impose the entire label stack to reach the egress device.

When requesting RSVP-TE to signal the path, the ingress device always requests autodelegation for the LSP, where one or more transit hops automatically select themselves as delegation hops to push the label stack to reach the next delegation hop. Junos OS uses an algorithm based on the received Effective Transport Label-Stack Depth (ETLD), that each transit executes to decide whether it should autoselect itself as a delegation hop. This algorithm is based on the section on ETLD in the Internet draft draft-ietf-mpls-rsvp-shared-labels-00.txt (expires September 11 2017), *Signaling RSVP-TE Tunnels on a Shared MPLS Forwarding Plane*.

The label stack imposed by the ingress device delivers the packet up to the first delegation hop. Each delegation hop's label stack also includes the delegation label of the next delegation hop at the bottom of the stack.

[Figure 56 on page 625](#) displays labels at every device interface, where Device D and Device I are delegation hops, *[Label] P* is the pop label, and *[Label] D* is the delegation label. The RSVP-TE pop-and-forward LSP tunnel is A-B-C-D-E-F-G-H-I-J-K-L. Delegation label 1250 represents (300, 350, 400, 450, 1500); Delegation label 1500 represents (550, 600).

Figure 56: Pop-and-Forward LSP Tunnel Pop and Delegation Labels

In this approach, for the tunnel, the ingress LER Device A pushes (150, 200, 1250). At LSR Device D, the delegation label 1250 gets popped and labels 300, 350, 400, 450, and 1500 get pushed. At LSR Device I, the delegation label 1500 gets popped and the remaining set of labels (550, 600) get pushed. In Junos OS, the pop and push action occurs as a swap to the bottom label of the outgoing stack and push the remaining labels.

A delegation label and the LSP segment that it covers can be shared by multiple pop-and-forward LSPs. A LSP delegation segment consist of an ordered set of hops (IP addresses and labels) as seen in the RESV RRO. The delegation label (and the segment that it covers) is not owned by a particular LSP, but can be shared. When all LSPs using a delegation label are deleted, the delegation label (and route) is deleted.

## Pop-and-Forward LSP Tunnel Link Protection

To provide link protection at a point of local repair (PLR) with a pop-and-forward data plane, the LSR allocates a separate pop label for the traffic engineering link that is used for the RSVP-TE tunnels that request link protection from the ingress device. No signaling extensions are required to support link protection for the RSVP-TE tunnels over the pop-and-forward data plane.

Figure 57 on page 625 displays pop labels at every device interface; labels marked with P are pop labels that offer link protection for the traffic-engineering link.

Figure 57: Pop-and Forward LSP Tunnel Link Protection

At each LSR, link-protected pop labels can be allocated for each traffic engineering link, and a link-protecting facility bypass LSP (which is not a pop-and-forward LSP, but rather a normal bypass LSP) can be created to protect the traffic engineering link. These labels can be sent in the RESV message by the LSR for LSPs requesting link protection over the specific traffic engineering link. Because the facility bypass terminates at the next hop (merge point), the incoming pop label on the packet at the PLR is what the merge point expects.

For example, LSR Device B can install a facility bypass LSP for the link-protected pop label 151. When the traffic engineering link B-C is up, LSR Device B pops 151 and sends the packet to C. If the traffic engineering link B-C is down, the LSR can pop 151 and send the packet through the facility backup to Device C.

## RSVP-TE Pop-and-Forward LSP Tunnel Supported and Unsupported Features

Junos OS supports the following features with RSVP-TE pop-and-forward LSP tunnels:

- Pop labels per RSVP neighbor for unprotected LSP.
- Pop labels per RSVP neighbor for LSPs requesting link protection using facility bypass
- Autodelegation of LSP segment.
- Mixed label mode, where certain transit LSRs do not support pop-and-forward LSP tunnels
- LSP ping and traceroute
- All existing CSPF constraint.
- Load balancing of traffic between pop-and-forward LSPs and regular point-to-point RSVP-TE LSP.
- Autobandwidth, LDP tunneling, and TE++ container LSP.
- Aggregated Ethernet interface.
- Virtual platforms support, such as Juniper Networks vMX Virtual Router.
- 64-bit support
- Logical systems

Junos OS does not support the following functionality for RSVP-TE pop-and-forward LSP tunnels:

- Node link protection
- Detour protection for MPLS fast reroute
- Point-to-multipoint LSPs.
- Switch-away LSP.
- Generalized MPLS (GMPLS) LSPs (including bidirectional LSPs, associated LSPs, VLAN user-to-network interface [UNI] and so on)
- IP Flow Information Export (protocol) (IPFIX) inline flow sampling for MPLS template

- RFC 3813, *Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)*
- IPv4 Explicit-null (Inserting label 0 at the bottom of the label stack is not supported. If there are service labels beneath the RSVP-TE pop-and-forward label stack, because the penultimate hop for the LSP copies the EXP value to the service label, this can allow continuity of class of service (CoS) across the MPLS forwarding plane).
- Ultimate-hop popping (UHP)
- Graceful Routing Engine switchover (GRES)
- Nonstop active routing (NSR)

## RSVP Overview

The RSVP protocol is used by routers to deliver quality-of-service (QoS) requests to all nodes along data flow path(s) and to establish and maintain state for the requested service. RSVP requests generally result in resource reservations in each node along the data path. RSVP has the following attributes:

- Makes resource reservations for unidirectional data flows.
- Allows the receiver of a data flow to initiate and maintain the resource reservation used for that flow, as shown in [Figure 58 on page 633](#).
- Maintains a soft state in routers and hosts, providing graceful support for dynamic membership changes and automatic adaptation to routing changes.
- Depends upon present and future routing protocols, but is not a routing protocol itself.
- Provides several reservation models or styles to fit a variety of applications.
- Supports both IPv4 and IPv6. Note, you can configure the Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. For more information, see the *MPLS Applications Feature Guide*.

**Figure 58: RSVP Reservation Request and Data Flow**

## RSVP Operation Overview

RSVP creates independent sessions to handle each data flow. A session is identified by a combination of the destination address, an optional destination port, and a protocol. Within a session, there can be one or more senders. Each sender is identified by a combination of its source address and source port. An out-of-band mechanism, such as a session announcement protocol or human communication, is used to communicate the session identifier to all senders and receivers.

A typical RSVP session involves the following sequence of events:

1. A potential sender starts sending RSVP path messages to the session address.
2. A receiver, wanting to join the session, registers itself if necessary. For example, a receiver in a multicast application would register itself with IGMP.
3. The receiver receives the path messages.

4. The receiver sends appropriate Resv messages toward the sender. These messages carry a flow descriptor, which is used by routers along the path to make reservations in their link-layer media.
5. The sender receives the Resv message and then starts sending application data.

This sequence of events is not necessarily strictly synchronized. For example, receivers can register themselves before receiving path messages from the sender, and application data can flow before the sender receives Resv messages. Application data that is delivered before the actual reservation contained in the Resv message typically is treated as best-effort, non-real-time traffic with no CoS guarantee.

---

## Understanding the RSVP Signaling Protocol

RSVP is a signaling protocol that handles bandwidth allocation and true traffic engineering across an MPLS network. Like LDP, RSVP uses discovery messages and advertisements to exchange LSP path information between all hosts. However, RSVP also includes a set of features that control the flow of traffic through an MPLS network. Whereas LDP is restricted to using the configured IGP's shortest path as the transit path through the network, RSVP uses a combination of the Constrained Shortest Path First (CSPF) algorithm and Explicit Route Objects (EROs) to determine how traffic is routed through the network.

Basic RSVP sessions are established in exactly the same way that LDP sessions are established. By configuring both MPLS and RSVP on the appropriate transit interfaces, you enable the exchange of RSVP packets and the establishment of LSPs. However, RSVP also lets you configure link authentication, explicit LSP paths, and link coloring.

This topic contains the following sections:

- [RSVP Fundamentals on page 634](#)
- [Bandwidth Reservation Requirement on page 635](#)
- [Explicit Route Objects on page 635](#)
- [Constrained Shortest Path First on page 636](#)
- [Link Coloring on page 637](#)

### RSVP Fundamentals

RSVP uses unidirectional and simplex flows through the network to perform its function. The inbound router initiates an RSVP path message and sends it downstream to the outbound router. The path message contains information about the resources needed for the connection. Each router along the path begins to maintain information about a reservation.

When the path message reaches the outbound router, resource reservation begins. The outbound router sends a reservation message upstream to the inbound router. Each router along the path receives the reservation message and sends it upstream, following the path of the original path message. When the inbound router receives the reservation message, the unidirectional network path is established.

The established path remains open as long as the RSVP session is active. The session is maintained by the transmission of additional path and reservation messages that report the session state every 30 seconds. If a router does not receive the maintenance messages for 3 minutes, it terminates the RSVP session and reroutes the LSP through another active router.

### Bandwidth Reservation Requirement

When a bandwidth reservation is configured, reservation messages propagate the bandwidth value throughout the LSP. Routers must reserve the bandwidth specified across the link for the particular LSP. If the total bandwidth reservation exceeds the available bandwidth for a particular LSP segment, the LSP is rerouted through another LSR. If no segments can support the bandwidth reservation, LSP setup fails and the RSVP session is not established.

### Explicit Route Objects

Explicit Route Objects (EROs) limit LSP routing to a specified list of LSRs. By default, RSVP messages follow a path that is determined by the network IGP's shortest path. However, in the presence of a configured ERO, the RSVP messages follow the path specified.

EROs consist of two types of instructions: loose hops and strict hops. When a loose hop is configured, it identifies one or more transit LSRs through which the LSP must be routed. The network IGP determines the exact route from the inbound router to the first loose hop, or from one loose hop to the next. The loose hop specifies only that a particular LSR be included in the LSP.

When a strict hop is configured, it identifies an exact path through which the LSP must be routed. Strict-hop EROs specify the exact order of the routers through which the RSVP messages are sent.

You can configure loose-hop and strict-hop EROs simultaneously. In this case, the IGP determines the route between loose hops, and the strict-hop configuration specifies the exact path for particular LSP path segments.

[Figure 59 on page 636](#) shows a typical RSVP-signaled LSP that uses EROs.

Figure 59: Typical RSVP-Signaled LSP with EROs

In the topology shown in [Figure 59 on page 636](#), traffic is routed from Host C1 to Host C2. The LSP can pass through Routers R4 or Router R7. To force the LSP to use R4, you can set up either a loose-hop or strict-hop ERO that specifies R4 as a hop in the LSP. To force a specific path through Router R4, R3, and R6, configure a strict-hop ERO through the three LSRs.

### Constrained Shortest Path First

Whereas IGP uses the Shortest Path First (SPF) algorithm to determine how traffic is routed within a network, RSVP uses the Constrained Shortest Path First (CSPF) algorithm to calculate traffic paths that are subject to the following constraints:

- LSP attributes—Administrative groups such as link coloring, bandwidth requirements, and EROs
- Link attributes—Colors on a particular link and available bandwidth

These constraints are maintained in the traffic engineering database (TED). The database provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors.

In determining which path to select, CSPF follows these rules:

- Computes LSPs one at a time, beginning with the highest priority LSP—the one with the lowest setup priority value. Among LSPs of equal priority, CSPF starts with those that have the highest bandwidth requirement.
- Prunes the traffic engineering database of links that are not full duplex and do not have sufficient reservable bandwidth.
- If the LSP configuration includes the **include** statement, prunes all links that do not share any included colors.

- If the LSP configuration includes the **exclude** statement, prunes all links that contain excluded colors. If a link does not have a color, it is accepted.
- Finds the shortest path toward the LSP's outbound router, taking into account any EROs. For example, if the path must pass through Router A, two separate SPF algorithms are computed: one from the inbound router to Router A and one from Router A to the outbound router.
- If several paths have equal cost, chooses the one with a last-hop address the same as the LSP's destination.
- If several equal-cost paths remain, selects the path with the least number of hops.
- If several equal-cost paths remain, applies CSPF load-balancing rules configured on the LSP.

## Link Coloring

RSVP allows you to configure administrative groups for CSPF path selection. An administrative group is typically named with a color, assigned a numeric value, and applied to the RSVP interface for the appropriate link. Lower numbers indicate higher priority.

After configuring the administrative group, you can either exclude, include, or ignore links of that color in the TED:

- If you exclude a particular color, all segments with an administrative group of that color are excluded from CSPF path selection.
- If you include a particular color, only those segments with the appropriate color are selected.
- If you neither exclude nor include the color, the metrics associated with the administrative groups and applied on the particular segments determine the path cost for that segment.

The LSP with the lowest total path cost is selected into the TED.

## RSVP-TE protocol extensions for FRR

Starting with Junos OS Release 16.1, RSVP Traffic Engineering (TE) protocol extensions to support Refresh-interval Independent RSVP (RI-RSVP) defined RFC 8370 for fast reroute (FRR) facility protection were introduced to allow greater scalability of label-switched paths (LSPs) faster convergence times and decrease RSVP signaling message overhead from periodic refreshes. Junos RSVP-TE runs in enhanced FRR aka RI-RSVP mode by default that includes protocol extensions to support RI-RSVP for FRR facility bypass originally specified in RFC 4090.

The RI-RSVP protocol extensions implemented in Junos are fully backward compatible. In mixed environments, where a subset of LSPs traverse nodes that do not include this feature, Junos RSVP-TE running in enhanced FRR mode will automatically turn off the new protocol extensions in its signaling exchanges with nodes that do not support the new extensions.

As part of enhanced FRR profile, a number of changes were made and new defaults adopted. These are listed here.

- RSVP-TE runs “enhanced” FRR, or RI-RSVP mode, by default, which includes enhancements to facilitate scaled up scenarios. These new protocol extensions can be disabled on a router with the `no-enhanced-frr-bypass` command.
- RSVP refresh reduction extensions defined in RFC 2961 are enabled by default. The user can disable them with the `no-reliable` command (see below).

**NOTE:** Node-id based Hellos are enabled by default as enhanced FRR or RI-RSVP extensions require the exchange of Node-id based Hello messages. Node-id based Hellos can be disabled with `node-hello` command. As refresh-reduction extensions and node-id based Hello messages are essential for enhanced FRR or RI-RSVP extensions, disabling either of them will automatically turn off enhanced FRR extensions on the node.

- The default refresh time for RSVP messages has increased from 30 seconds to 20 minutes.
- The default value for `keep-multiplier`, which is 3, is applied to the new default refresh time.
- Local reversion is disabled by default. The existing CLI configuration for node Hellos, `[edit protocols rsvp node-hello]`, is still available but the action is redundant. If enabled, a message is displayed to indicate that the configuration is not necessary in conjunction with enhanced FRR.
- The existing commands to disable message reliability are now used to disable RSVP refresh reduction. To revert back to the previous default enabling refresh reduction, use the `delete` version of the following commands:
  - Set `no-reliable` on a given interface to disable FRR scalability enhancements automatically for all LSPs traversing the interface. Likewise, to run RSVP-TE without FRR facility protection enhancements, and without refresh-reduction, disable refresh reduction on each interface. Use one of the commands shown here:
    - `[edit protocols rsvp interface name no-reliable]`
    - `[edit logical-systems name protocols rsvp interface name no-reliable]`
- Graceful restart and nonstop active routing (NSR) are not supported while the LSP undergoes local repair or while the LSP is refreshed during backup LSP signaling. This limitation exists already in the implementation because GR or NSR switchover during FRR local-repair makes for multiple failure scenario.

- The following operational commands have been updated to include new information about the new procedures introduced for the RSVP TE protocol extensions for FRR facility protection.
  - **show rsvp version** displays whether enhanced FRR procedures are enabled.
  - **show rsvp neighbor detail** displays whether enhanced FRR procedures are enabled on the neighbor.
  - **show rsvp interface detail** displays conditional PathTear statistics.
  - **show rsvp statistics** displays sent and received statistics for conditional PathTear, along with other statistics.
  - **show rsvp session extensive** displays whether the node is a merge point, and if it is, shows the Point of Local Repair (PLR) address.
- The previous CLI configuration options for enabling or disabling message bundling have been deprecated (the existing configurations are accepted, but a warning is displayed in the show configuration output). These commands are the following:
  - **[edit protocols rsvp interface *name* aggregate]**
  - **[edit logical-systems *name* protocols rsvp interface *name* aggregate]**
  - **[edit protocols rsvp interface *name* no-aggregate]**
  - **[edit logical-systems *name* protocols rsvp interface *name* no-aggregate]**
- The following CLI configuration options have been made redundant by the current changes (the existing configurations are accepted, but a warning is displayed in the show configuration output):
  - **[edit protocols rsvp interface *name* reliable]**
  - **[edit logical-systems *name* protocols rsvp interface *name* reliable]**

Release History Table

Release	Description
16.1	Starting with Junos OS Release 16.1, RSVP Traffic Engineering (TE) protocol extensions to support Refresh-interval Independent RSVP (RI-RSVP) defined RFC 8370 for fast reroute (FRR) facility protection were introduced to allow greater scalability of label-switched paths (LSPs) faster convergence times and decrease RSVP signaling message overhead from periodic refreshes.

## Junos OS RSVP Protocol Implementation

---

The Junos implementation of RSVP supports RSVP version 1. The software includes support for all mandatory objects and RSVP message types, and supports message integrity and node authentications through the Integrity object.

The primary purpose of the Junos RSVP software is to support dynamic signaling within MPLS label-switched paths (LSPs). Supporting resource reservations over the Internet is only a secondary purpose of the Junos OS implementation. Since supporting resource reservations is secondary, the Junos RSVP software does not support the following features:

- IP multicasting sessions.
- Traffic control. The software cannot make resource reservations for real-time video or audio sessions.

With regard to the protocol mechanism, packet processing, and RSVP objects supported, the Junos OS implementation of the software is interoperable with other RSVP implementations.

## RSVP Authentication

---

The Junos OS supports both the RSVP authentication style described in RFC 2747 (allowing for multivendor compatibility) and the RSVP authentication style described in Internet draft draft-ietf-rsvp-md5-03.txt. The Junos OS uses the authentication style described in Internet draft draft-ietf-rsvp-md5-08.txt by default. If the router receives an RFC 2747-style RSVP authentication from a neighbor, it switches to this style of authentication for that neighbor. The RSVP authentication style for each neighboring router is determined separately.

## Supported RSVP Standards

---

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for RSVP.

- RFC 2205, *Resource ReSerVation Protocol (RSVP)—Version 1 Functional Specification*
- RFC 2210, *The Use of RSVP with IETF Integrated Services*
- RFC 2211, *Specification of the Controlled-Load Network Element Service*
- RFC 2212, *Specification of Guaranteed Quality of Service*
- RFC 2215, *General Characterization Parameters for Integrated Service Network Elements*
- RFC 2745, *RSVP Diagnostic Messages*
- RFC 2747, *RSVP Cryptographic Authentication* (updated by RFC 3097)
- RFC 2750, *RSVP Extensions for Policy Control* (RFC is not supported. Fully compliant with devices that support this RFC).
- RFC 2961, *RSVP Refresh Overhead Reduction Extensions*

- RFC 3097, *RSVP Cryptographic Authentication—Updated Message Type Value*
- RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*

The Null Service Object for maximum transmission unit (MTU) signaling in RSVP is not supported.

- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource Reservation Protocol-Traffic Engineering (RSVP-TE) Extensions*

Only Section 9, “Fault Handling,” is supported.

- RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*

- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*

- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*

(OSPF extensions can carry traffic engineering information over unnumbered links.)

- RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*

- RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*

The RRO node ID subobject is for use in inter-AS link and node protection configurations.

- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*

The following RFCs do not define standards, but provide information about RSVP and related technologies. The IETF classifies them variously as “Experimental” or “Informational.”

- RFC 2209, *Resource ReSerVation Protocol (RSVP)—Version 1 Message Processing Rules*
- RFC 2216, *Network Element Service Specification Template*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

## RSVP and IGP Hello Packets and Timers

---

RSVP monitors the status of the interior gateway protocol (IGP) (IS-IS or OSPF) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because hello packets are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

In the Junos OS, RSVP typically relies on IGP hello packet detection to check for node failures. RSVP sessions are kept up even if RSVP hello packets are no longer being received, so long as the router continues to receive IGP hello packets. RSVP sessions are maintained until either the router stops receiving IGP hello packets or the RSVP Path and Resv messages time out. Configuring a short time for the IS-IS or OSPF hello timers allows these protocols to detect node failures quickly.

RSVP hellos can be relied on when the IGP does not recognize a particular neighbor (for example, if IGP is not enabled on the interface) or if the IGP is RIP (not IS-IS or OSPF). Also, the equipment of other vendors might be configured to monitor RSVP sessions based on RSVP hello packets. This equipment might also take an RSVP session down due to a loss of RSVP hello packets.

We do not recommend configuring a short RSVP hello timer. If quick discovery of a failed neighbor is needed, configure short IGP (OSPF or IS-IS) hello timers.

OSPF and IS-IS have infrastructure to manage rapid hello message sending and receiving reliably, even if the routing protocols or some other process are straining the processing capability of the router. Under the same circumstances, RSVP hellos might time out prematurely even though the neighbor is functioning normally.

## RSVP Message Types

---

RSVP uses the following types of messages to establish and remove paths for data flows, establish and remove reservation information, confirm the establishment of reservations, and report errors:

- [Path Messages on page 644](#)
- [Resv Messages on page 644](#)
- [PathTear Messages on page 644](#)
- [ResvTear Messages on page 645](#)
- [PathErr Messages on page 645](#)
- [ResvErr Messages on page 645](#)
- [ResvConfirm Messages on page 645](#)

---

## Understanding RSVP Automatic Mesh

---

When adding sites to BGP and MPLS VPNs that use RSVP signaling, more configuration is needed to add provider edge (PE) routers than is needed to add customer edge (CE) devices. RSVP automatic mesh helps to reduce this configuration burden.

Service providers often use BGP and MPLS VPNs to efficiently scale the network while delivering revenue-generating services. In these environments, BGP is used to distribute the VPN routing information across the service provider's network, while MPLS is used to forward that VPN traffic from one VPN site to another. BGP and MPLS VPNs are based on a peer model. To add a new CE device (site) to an existing VPN, you need to configure the CE router at the new site and the PE router connected to the CE router. You do not have to modify the configuration of all of the other PE routers participating in the VPN. The other PE routers automatically learn about the routes associated with the new site, a process called automatic discovery (AD).

The requirements are a bit different if you need to add a new PE router to the network. A BGP and MPLS VPN requires that the BGP session be fully meshed and that there also be a full mesh of PE router-to-PE router MPLS label-switched paths (LSPs) between all of the PE routers in the network. When you add a new PE router to the network, all of the existing PE routers must be reconfigured to peer with the new PE router. Much of the configuration effort can be reduced if you configure BGP route reflectors (mitigating the full mesh requirement for BGP) and if you configure (LDP) as the signaling protocol for MPLS.

However, if you need to add a new PE router to a network configured with a full mesh of RSVP-signaled LSPs, you must reconfigure each of the PE routers to have a peer relationship with the new PE router. You can configure RSVP automatic mesh to address this particular operational scenario. When you enable RSVP automatic mesh, RSVP LSPs are dynamically created between a new PE router and the existing PE routers, eliminating the need to reconfigure all of the PE routers manually. For dynamic LSP creation to function properly, BGP must be configured to exchange routes between all of the participating PE routers. If two BGP peers do not exchange routes, it is not possible to configure a dynamic LSP between them. The local router's inet.0 routing table must include a labeled route to each potential IBGP next-hop (future potential PE routers or LSP destinations).

RSVP includes numerous capabilities that are not available in LDP, including fast reroute, end-point control, and link management. RSVP automatic mesh helps to reduce the operation and maintenance requirements for RSVP, making it possible to deploy RSVP in larger and more complicated networks.

Every PE router can reach every other PE router in the network because this information is distributed by the IGP. A PE router can set up a point-to-point RSVP LSP to any other PE router in the network as long as it knows that such an LSP is required. To build a full mesh of LSPs between the PE routers requires that each PE router know which of the other PE routers make up the full mesh.

**NOTE:** In Junos OS, RSVP automatic mesh is configured using the `rsvp-te` configuration statement at the `[edit routing-options dynamic-tunnels dynamic-tunnel-name]` hierarchy level. The `rsvp-te` configuration statement is also available for use in routing instances as a provider-tunnel option. When implemented as a provider-tunnel option, `rsvp-te` is used to configure the RSVP point-to-multipoint LSPs for multiprotocol BGP multicast VPNs, not to configure RSVP automatic mesh.

## Path Messages

Each sender host transmits path messages downstream along the routes provided by the unicast and multicast routing protocols. Path messages follow the exact paths of application data, creating path states in the routers along the way, thus enabling routers to learn the previous-hop and next-hop node for the session. Path messages are sent periodically to refresh path states.

The refresh interval is controlled by a variable called the *refresh-time*, which is the periodical refresh timer expressed in seconds. A path state times out if a router does not receive a specified number of consecutive path messages. This number is specified by a variable called *keep-multiplier*. Path states are kept for  $(\textit{keep-multiplier} + 0.5) \times 1.5 \times \textit{refresh-time}$  seconds.

---

## Resv Messages

Each receiver host sends reservation request (Resv) messages upstream toward senders and sender applications. Resv messages must follow exactly the reverse path of path messages. Resv messages create and maintain a reservation state in each router along the way.

Resv messages are sent periodically to refresh reservation states. The refresh interval is controlled by the same refresh time variable, and reservation states are kept for  $(\textit{keep-multiplier} + 0.5) \times 1.5 \times \textit{refresh-time}$  seconds.

---

## PathTear Messages

PathTear messages remove (tear down) path states as well as dependent reservation states in any routers along a path. PathTear messages follow the same path as path messages. A PathTear typically is initiated by a sender application or by a router when its path state times out.

PathTear messages are not required, but they enhance network performance because they release network resources quickly. If PathTear messages are lost or not generated, path states eventually time out when they are not refreshed, and the resources associated with the path are released.

## ResvTear Messages

---

ResvTear messages remove reservation states along a path. These messages travel upstream toward senders of the session. In a sense, ResvTear messages are the reverse of Resv messages. ResvTear messages typically are initiated by a receiver application or by a router when its reservation state times out.

ResvTear messages are not required, but they enhance network performance because they release network resources quickly. If ResvTear messages are lost or not generated, reservation states eventually time out when they are not refreshed, and the resources associated with the reservation are released.

## PathErr Messages

---

When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. PathErr messages are advisory; these messages do not alter any path state along the way.

## ResvErr Messages

---

When a reservation request fails, a ResvErr error message is delivered to all the receivers involved. ResvErr messages are advisory; these messages do not alter any reservation state along the way.

## ResvConfirm Messages

---

Receivers can request confirmation of a reservation request, and this confirmation is sent with a ResvConfirm message. Because of the complex RSVP flow-merging rules, a confirmation message does not necessarily provide end-to-end confirmation of the entire path. Therefore, ResvConfirm messages are an indication, not a guarantee, of potential success.

Juniper Networks routers never request confirmation using the ResvConfirm message; however, a Juniper Networks router can send a ResvConfirm message if it receives a request from another vendor's equipment.

## RSVP Reservation Styles

---

A reservation request includes options for specifying the reservation style. The reservation styles define how reservations for different senders within the same session are treated and how senders are selected.

Two options specify how reservations for different senders within the same session are treated:

- Distinct reservation—Each receiver establishes its own reservation with each upstream sender.
- Shared reservation—All receivers make a single reservation that is shared among many senders.

Two options specify how senders are selected:

- Explicit sender—List all selected senders.
- Wildcard sender—Select all senders, which then participate in the session.

The following reservation styles, formed by a combination of these four options, currently are defined:

- Fixed filter (FF)—This reservation style consists of distinct reservations among explicit senders. Examples of applications that use fixed-filter-style reservations are video applications and unicast applications, which both require flows that have a separate reservation for each sender. The fixed filter reservation style is enabled on RSVP LSPs by default.
- Wildcard filter (WF)—This reservation style consists of shared reservations among wildcard senders. This type of reservation reserves bandwidth for any and all senders, and propagates upstream toward all senders, automatically extending to new senders as they appear. A sample application for wildcard filter reservations is an audio application in which each sender transmits a distinct data stream. Typically, only a few senders are transmitting at any one time. Such a flow does not require a separate reservation for each sender; a single reservation is sufficient.
- Shared explicit (SE)—This reservation style consists of shared reservations among explicit senders. This type of reservation reserves bandwidth for a limited group of senders. A sample application is an audio application similar to that described for wildcard filter reservations.

---

## RSVP Refresh Reduction

RSVP relies on soft-state to maintain the path and reservation states on each router. If the corresponding refresh messages are not sent periodically, the states eventually time out and reservations are deleted. RSVP also sends its control messages as IP datagrams with no reliability guarantee. It relies on periodic refresh messages to handle the occasional loss of Path or Resv messages.

The RSVP refresh reduction extensions, based on RFC 2961, addresses the following problems that result from relying on periodic refresh messages to handle message loss:

- Scalability—The scaling problem arises from the periodic transmission and processing overhead of refresh messages, which increases as the number of RSVP sessions increases.
- Reliability and latency—The reliability and latency problem stems from the loss of nonrefresh RSVP messages or one-time RSVP messages such as PathTear or PathErr. The time to recover from such a loss is usually tied to refresh interval and the keepalive timer.

The RSVP refresh reduction capability is advertised by enabling the refresh reduction (RR) capable bit in the RSVP common header. This bit is only significant between RSVP neighbors.

RSVP refresh reduction includes the following features:

- RSVP message bundling using the bundle message
- RSVP Message ID to reduce message processing overhead
- Reliable delivery of RSVP messages using Message ID, Message Ack, and Message Nack
- Summary refresh to reduce the amount of information transmitted every refresh interval

The RSVP refresh reduction specification (RFC 2961) allows you to enable some or all of the above capabilities on a router. It also describes various procedures that a router can use to detect the refresh reduction capabilities of its neighbor.

The Junos OS supports all of the refresh reduction extensions, some of which can be selectively enabled or disabled. The Junos OS supports Message ID and therefore can perform reliable message delivery only for Path and Resv messages.

For information about how to configure RSVP refresh reduction, see [“Configuring RSVP Refresh Reduction” on page 651](#).

---

## MTU Signaling in RSVP

The maximum transmission unit (MTU) is the largest size packet or frame, in bytes, that can be sent in a network. An MTU that is too large might cause retransmissions. Too small an MTU might cause the router to send and handle relatively more header overhead and acknowledgments. There are default values for MTUs associated with various protocols. You can also explicitly configure an MTU on an interface.

When an LSP is created across a set of links with different MTU sizes, the ingress router does not know what the smallest MTU is on the LSP path. By default, the MTU for an LSP is 1,500 bytes.

If this MTU is larger than the MTU of one of the intermediate links, traffic might be dropped, because MPLS packets cannot be fragmented. Also, the ingress router is not aware of this type of traffic loss, because the control plane for the LSP would still function normally.

To prevent this type of packet loss in MPLS LSPs, you can configure MTU signaling in RSVP. This feature is described in RFC 3209. Juniper Networks supports the Integrated Services object for MTU signaling in RSVP. The Integrated Services object is described in RFCs 2210 and 2215. MTU signaling in RSVP is disabled by default.

To avoid packet loss due to MTU mismatches, the ingress router needs to do the following:

- Signal the MTU on the RSVP LSP—To prevent packet loss from an MTU mismatch, the ingress router needs to know what the smallest MTU value is along the path taken by the LSP. Once this MTU value is obtained, the ingress router can assign it to the LSP.

- Fragment packets—Using the assigned MTU value, packets that exceed the size of the MTU can be fragmented into smaller packets on the ingress router before they are encapsulated in MPLS and sent over the RSVP-signaled LSP.

Once both MTU signaling and packet fragmentation have been enabled on an ingress router, any route resolving to an RSVP LSP on this router uses the signaled MTU value. For information about how to configure this feature, see [“Configuring MTU Signaling in RSVP” on page 671](#).

The following sections describe how MTU signaling in RSVP works:

- [How the Correct MTU Is Signaled in RSVP on page 648](#)
- [Determining an Outgoing MTU Value on page 649](#)
- [MTU Signaling in RSVP Limitations on page 649](#)

---

## How the Correct MTU Is Signaled in RSVP

---

How the correct MTU is signaled in RSVP varies depending on whether the network devices (for example, routers) explicitly support MTU signaling in RSVP or not.

If the network devices support MTU signaling in RSVP, the following occur when you enable MTU signaling:

- The MTU is signaled from the ingress router to the egress router by means of the Adspec object. Before forwarding this object, the ingress router enters the MTU value associated with the interface over which the path message is sent. At each hop in the path, the MTU value in the Adspec object is updated to the minimum of the received value and the value of the outgoing interface.
- The ingress router uses the traffic specification (Tspec) object to specify the parameters for the traffic it is going to send. The MTU value signaled for the Tspec object at the ingress router is the maximum MTU value (9192 bytes for M Series and T Series routers, 9500 bytes for PTX Series Packet Transport Routers). This value does not change en route to the egress router.
- When the Adspec object arrives at the egress router, the MTU value is correct for the path (meaning it is the smallest MTU value discovered). The egress router compares the MTU value in the Adspec object to the MTU value in the Tspec object. It signals the smaller MTU using the Flowspec object in the Resv message.
- When the Resv object arrives at the ingress router, the MTU value in this object is used as the MTU for the next hops that use the LSP.

In a network where there are devices that do not support MTU signaling in RSVP, you might have the following behaviors:

- If the egress router does not support MTU signaling in RSVP, the MTU is set to 1,500 bytes by default.
- A Juniper Networks transit router that does not support MTU signaling in RSVP sets an MTU value of 1,500 bytes in the Adspec object by default.

- Related Documentation**
- *Media MTU Overview*
  - *Configuring the Media MTU*

## Determining an Outgoing MTU Value

The outgoing MTU value is the smaller of the values received in the Adspec object compared to the MTU value of the outgoing interface. The MTU value of the outgoing interface is determined as follows:

- If you configure an MTU value under the **[family mpls]** hierarchy level, this value is signaled.
- If you do not configure an MTU, the **inet** MTU is signaled.

## MTU Signaling in RSVP Limitations

The following are limitations to MTU signaling in RSVP:

- Changes in the MTU value might cause a temporary loss of traffic in the following situations:
  - For link protection and node protection, the MTU of the bypass is only signaled at the time the bypass becomes active. During the time it takes for the new path MTU to be propagated, packet loss might occur because of an MTU mismatch.
  - For fast reroute, the MTU of the path is updated only after the detour becomes active, causing a delay in an update to the MTU at the ingress router. Until the MTU is updated, packet loss might occur if there is an MTU mismatch.

In both cases, only packets that are larger than the detour or bypass MTU are lost.

- When an MTU is updated, it triggers a change in the next hop. Any change in the next hop causes the route statistics to be lost.
- The minimum MTU supported for MTU signaling in RSVP is 1,488 bytes. This value prevents a false or incorrectly configured value from being used.
- For single-hop LSPs, the MTU value displayed by the **show** commands is the RSVP-signaled value. However, this MPLS value is ignored and the correct IP value is used.

## Minimum RSVP Configuration

To enable RSVP on a single interface, include the **rsvp** statement and specify the interface using the **interface** statement. This is the minimum RSVP configuration. All other RSVP configuration statements are optional.

```
rsvp {
  interface interface-name;
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

To enable RSVP on all interfaces, substitute **all** for the *interface-name* variable.

If you have configured interface properties on a group of interfaces and want to disable RSVP on one of the interfaces, include the **disable** statement:

```
interface interface-name {  
  disable;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp interface interface-name ]**
- **[edit logical-systems *logical-system-name* protocols rsvp interface interface-name ]**

---

## Configuring RSVP and MPLS

The primary purpose of the Junos RSVP software is to support dynamic signaling within label-switched paths (LSPs). When you enable both MPLS and RSVP on a router, MPLS becomes a client of RSVP. No additional configuration is required to bind MPLS and RSVP.

You can configure MPLS to set up signaled paths by using the **label-switched-path** statement at the **[edit protocols mpls]** hierarchy level. Each LSP translates into a request for RSVP to initiate an RSVP session. This request is passed through the internal interface between label switching and RSVP. After examining the request information, checking RSVP states, and checking the local routing tables, RSVP initiates one session for each LSP. The session is sourced from the local router and is destined for the target of the LSP.

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, RSVP notifies MPLS of its status. It is up to MPLS to initiate backup paths or continue retrying the initial path.

To pass label-switching signaling information, RSVP supports four additional objects: Label Request object, Label object, Explicit Route object, and Record Route object. For an LSP to be set up successfully, all routers along the path must support MPLS, RSVP, and the four objects. Of the four objects, the Record Route object is not mandatory.

To configure MPLS and make it a client of RSVP, do the following:

- Enable MPLS on all routers that will participate in the label switching (this is, on all routers that might be part of a label-switching path).
- Enable RSVP on all routers and on all router interfaces that form the LSP.
- Configure the routers at the beginning of the LSP.

## Example: Configuring RSVP and MPLS

The following shows a sample configuration for a router at the beginning of an LSP:

```
[edit]
protocols {
  mpls {
    label-switched-path sf-to-london {
      to 192.168.1.4;
    }
  }
  rsvp {
    interface so-0/0/0;
  }
}
```

The following shows a sample configuration for all the other routers that form the LSP:

```
[edit]
protocols {
  mpls {
    interface so-0/0/0;
  }
  rsvp {
    interface so-0/0/0;
  }
}
```

## Configuring RSVP Interfaces

The following sections describe how to configure RSVP interfaces:

- [Configuring RSVP Refresh Reduction on page 651](#)
- [Configuring the RSVP Hello Interval on page 653](#)
- [Configuring RSVP Authentication on page 654](#)
- [Configuring the Bandwidth Subscription for Class Types on page 655](#)
- [Configuring the RSVP Update Threshold on an Interface on page 655](#)
- [Configuring RSVP for Unnumbered Interfaces on page 656](#)

### Configuring RSVP Refresh Reduction

You can configure RSVP refresh reduction on each interface by including the following statements in the interface configuration:

- **aggregate** and **reliable**—Enable all RSVP refresh reduction features: RSVP message bundling, RSVP message ID, reliable message delivery, and summary refresh.

In order to have refresh reduction and reliable delivery, you must include the **aggregate** and **reliable** statements.

- **no-aggregate**—Disable RSVP message bundling and summary refresh.

- **no-reliable**—Disable RSVP message ID, reliable message delivery, and summary refresh.

For more information on RSVP refresh reduction, see [“RSVP Refresh Reduction” on page 646](#).

If the **no-reliable** statement is configured on the router (reliable message delivery is disabled), the router accepts RSVP messages that include the Message ID object but ignores the Message ID object and continues performing standard message processing. No error is generated in this case, and RSVP operates normally.

However, not all combinations between two neighbors with different refresh reduction capabilities function correctly. For example, a router is configured with either the **aggregate** statement and **no-reliable** statement or with the **reliable** and **no-aggregate** statements. If an RSVP neighbor sends a Summary Refresh object to this router, no error is generated, but the Summary Refresh object cannot be processed. Consequently, RSVP states can time out on this router if the neighbor is relying only on Summary Refresh to refresh those RSVP states.

We recommend, unless there are specific requirements, that you configure RSVP refresh reduction in a similar manner on each RSVP neighbor.

To enable all RSVP refresh reduction features on an interface, include the **aggregate** statement:

```
aggregate;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

To disable RSVP message bundling and summary refresh, include the **no-aggregate** statement:

```
no-aggregate;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

To enable RSVP message ID and reliable message delivery on an interface, include the **reliable** statement:

```
reliable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

To disable RSVP message ID, reliable message delivery, and summary refresh, include the **no-reliable** statement:

```
no-reliable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

### Determining the Refresh Reduction Capability of RSVP Neighbors

To determine the RSVP refresh reduction capability of an RSVP neighbor, you need the following information:

- The RR bit advertised by the neighbor
- The local configuration of RSVP refresh reduction
- The actual RSVP messages received from the neighbor

To obtain this information, you can issue a **show rsvp neighbor detail** command. Sample output follows:

```
user@host> show rsvp neighbor detail
```

```
RSVP neighbor: 6 learned
  Address: 192.168.224.178 via: fxp1.0 status: Up
    Last changed time: 10:06, Idle: 5 sec, Up cnt: 1, Down cnt: 0
    Message received: 36
    Hello: sent 69, received: 69, interval: 9 sec
    Remote instance: 0x60b8feba, Local instance: 0x74bc7a8d
    Refresh reduction: not operational

  Address: 192.168.224.186 via: fxp2.0 status: Down
    Last changed time: 10:17, Idle: 40 sec, Up cnt: 0, Down cnt: 0
    Message received: 6
    Hello: sent 20, received: 0, interval: 9 sec
    Remote instance: 0x0, Local instance: 0x2ae1b339
    Refresh reduction: incomplete
    Remote end: disabled, Ack-extension: enabled

  Address: 192.168.224.188 via: fxp2.0 status: Up
    Last changed time: 4:15, Idle: 0 sec, Up cnt: 1, Down cnt: 0
    Message received: 55
    Hello: sent 47, received: 31, interval: 9 sec
    Remote instance: 0x6436a35b, Local instance: 0x663849f0
    Refresh reduction: operational
    Remote end: enabled, Ack-extension: enabled
```

For more information on the **show rsvp neighbor detail** command.

## Configuring the RSVP Hello Interval

RSVP monitors the status of the interior gateway protocol (IGP) (IS-IS or OSPF) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares

a neighbor down (because hello packets are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

For Juniper Networks routers, configuring a shorter or longer RSVP hello interval has no impact on whether or not an RSVP session is brought down. RSVP sessions are kept up even if RSVP hello packets are no longer being received. RSVP sessions are maintained until either the router stops receiving IGP hello packets or the RSVP Path and Resv messages time out. However, starting from Junos OS Release 16.1, when RSVP hello messages time-out, the RSVP sessions are brought down.

The RSVP hello interval might also be impacted when another vendor's equipment brings down an RSVP session. For example, a neighboring non-Juniper Networks router might be configured to monitor RSVP hello packets.

To modify how often RSVP sends hello packets, include the **hello-interval** statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Configuring RSVP Authentication

All RSVP protocol exchanges can be authenticated to guarantee that only trusted neighbors participate in setting up reservations. By default, RSVP authentication is disabled.

RSVP authentication uses a Hashed Message Authentication Code (HMAC)-MD5 message-based digest. This scheme produces a message digest based on a secret authentication key and the message contents. (The message contents also include a sequence number.) The computed digest is transmitted with RSVP messages. Once you have configured authentication, all received and transmitted RSVP messages with all neighbors are authenticated on this interface.

MD5 authentication provides protection against forgery and message modification. It also can prevent replay attacks. However, it does not provide confidentiality, because all messages are sent in clear text.

By default, authentication is disabled. To enable authentication, configure a key on each interface by including the **authentication-key** statement:

```
authentication-key key;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

## Configuring the Bandwidth Subscription for Class Types

By default, RSVP allows 100 percent of the bandwidth for a class type to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

For detailed instructions on how to configure the bandwidth subscription for class types, see [“Configuring the Bandwidth Subscription Percentage for LSPs” on page 974](#).

## Configuring the RSVP Update Threshold on an Interface

The interior gateway protocols (IGPs) maintain the traffic engineering database, but the current available bandwidth on the traffic engineering database links originates from RSVP. When a link's bandwidth changes, RSVP informs the IGPs, which can then update the traffic engineering database and forward the new bandwidth information to all network nodes. The network nodes then know how much bandwidth is available on the traffic engineering database link (local or remote), and CSPF can correctly compute the paths.

However, IGP updates can consume excessive system resources. Depending on the number of nodes in a network, it might not be desirable to perform an IGP update for small changes in bandwidth. By configuring the **update-threshold** statement at the **[edit protocols rsvp]** hierarchy level, you can adjust the threshold at which a change in the reserved bandwidth triggers an IGP update.

You can configure a value of from 1 percent through 20 percent (the default is 10 percent) for when to trigger an IGP update. If the change in the reserved bandwidth is greater than or equal to the configured threshold percentage of the static bandwidth on that interface, then an IGP update occurs. For example, if you have configured the **update-threshold** statement to be 15 percent and the router discovers that the reserved bandwidth on a link has changed by 10 percent of the link bandwidth, RSVP does not trigger an IGP update. However, if the reserved bandwidth on a link changes by 20 percent of the link bandwidth, RSVP triggers an IGP update.

To adjust the threshold at which a change in the reserved bandwidth triggers an IGP update, include the **update-threshold** statement:

```
update-threshold percentage;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp interface interface-name]**
- **[edit logical-systems logical-system-name protocols rsvp interface interface-name]**

Because of the update threshold, it is possible for Constrained Shortest Path First (CSPF) to compute a path using outdated traffic engineering database bandwidth information on a link. If RSVP attempts to establish an LSP over that path, it might find that there is insufficient bandwidth on that link. When this happens, RSVP triggers an IGP traffic engineering database update, flooding the updated bandwidth information on the

network. CSPF can then recompute the path by using the updated bandwidth information, and attempt to find a different path, avoiding the congested link. Note that this functionality is the default and does not need any additional configuration.

You can configure the **rsvp-error-hold-time** statement at the **[edit protocols mpls]** hierarchy level or the **[edit logical-systems logical-system-name protocols mpls]** hierarchy level to improve the accuracy of the traffic engineering database (including the accuracy of bandwidth estimates for LSPs) using information provided by PathErr messages. See [“Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages” on page 955](#).

## Configuring RSVP for Unnumbered Interfaces

The Junos OS supports RSVP traffic engineering over unnumbered interfaces. Traffic engineering information about unnumbered links is carried in the IGP traffic engineering extensions for OSPF and IS-IS as described in RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*, and RFC 4205, *Intermediate System to Intermediate System (IS-IS) Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*. Unnumbered links can also be specified in the MPLS traffic engineering signaling as described in RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*. This feature allows you avoid having to configure IP addresses for each interface participating in the RSVP-signaled network.

To configure RSVP for unnumbered interfaces, you must configure the router with a router ID using the **router-id** statement specified at the **[edit routing-options]** hierarchy level. The router ID must be available for routing (you can typically use the loopback address). The RSVP control messages for the unnumbered links are sent using the router ID address (rather than a randomly selected address).

To configure link protection and fast reroute on a router with unnumbered interfaces enabled, you must configure at least two addresses. We recommend that you configure a secondary interface on the loopback in addition to configuring the router ID.

Release History Table

Release	Description
16.1	However, starting from Junos OS Release 16.1, when RSVP hello messages time-out, the RSVP sessions are brought down.

## Configuring RSVP Node-ID Hellos

You can configure node-ID based RSVP hellos to ensure that Juniper Networks routers can interoperate with the equipment of other vendors. By default, Junos OS uses interface-based RSVP hellos. Node-ID based RSVP hellos are specified in RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*. RSVP node-ID hellos are useful if you have configured BFD to detect problems over RSVP interfaces, allowing you to disable interface hellos for these interfaces. You can also use node-ID hellos for graceful restart procedures.

Node-ID hellos can be enabled globally for all RSVP neighbors. By default, node-ID hello support is disabled. If you have not enabled RSVP node IDs on the router, the Junos OS does not accept any node-ID hello packets.

To enable RSVP node-ID hellos globally on the router, include the [node-hello](#) statement at the following hierarchy levels:

- [\[edit protocols rsvp\]](#)
- [\[edit logical-systems \*logical-systems-name\* protocols rsvp\]](#)

You can also explicitly disable RSVP interface hellos globally. This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the [hello-interval](#) statement. This configuration disables RSVP interface hellos globally, but enables RSVP interface hellos on the specified interface (the RSVP interface you configure the [hello-interval](#) statement on). This configuration might be necessary in a heterogeneous network in which some devices support RSVP node-ID hellos and other devices support RSVP interface hellos.

To disable RSVP interface hellos globally on the router, include the [no-interface-hello](#) statement at the following hierarchy levels:

- [\[edit protocols rsvp\]](#)
- [\[edit logical-systems \*logical-systems-name\* protocols rsvp\]](#)

## Example: Configuring RSVP-Signaled LSPs

This example shows how to create an LSP between routers in an IP network using RSVP as the signaling protocol.

- [Requirements on page 657](#)
- [Overview and Topology on page 658](#)
- [Configuration on page 658](#)
- [Verification on page 660](#)

### Requirements

Before you begin, delete security services from the device. See *Example: Deleting Security Services*.

## Overview and Topology

Using RSVP as a signaling protocol, you can create LSPs between routers in an IP network. In this example, you configure a sample network as shown in [Figure 60 on page 658](#).

*Figure 60: Typical RSVP-Signaled LSP*

To establish an LSP between routers, you must individually enable the MPLS family and configure RSVP on each of the transit interfaces in the MPLS network. This example shows how to enable MPLS and configure RSVP on the ge-0/0/0 transit interface. Additionally, you must enable the MPLS process on all of the MPLS interfaces in the network.

This example shows how to define an LSP from R1 to R7 on the ingress router (R1) using R7's loopback address (10.0.9.7). The configuration reserves 10 Mbps of bandwidth. Additionally, the configuration disables the CSPF algorithm, ensuring that Hosts C1 and C2 use the RSVP-signaled LSP that correspond to the network IGP's shortest path.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols rsvp interface ge-0/0/0.0
set protocols mpls label-switched-path r1-r7 to 10.0.9.7
set protocols mpls label-switched-path r1-r7 bandwidth 10m
set protocols mpls interface all
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure RSVP:

1. Enable the MPLS family on all transit interfaces in the MPLS network.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family mpls
```

2. Enable RSVP on each transit interface in the MPLS network.

```
[edit]
user @host# set protocols rsvp interface ge-0/0/0
```

3. Enable the MPLS process on the transit interface in the MPLS network.

```
[edit]
user@host# set protocols mpls interface ge-0/0/0
```

4. Define the LSP on the ingress router.

```
[edit protocols mpls]
user@host# set label-switched-path r1-r7 to 10.0.9.7
```

5. Reserve 10 Mbps of bandwidth on the LSP.

```
[edit protocols mpls]
user @host# set label-switched-path r1-r7 bandwidth 10m
```

**Results** Confirm your configuration by entering the **show** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@host# show
...
interfaces {
  ge-0/0/0 {
    family mpls;
  }
}
```

```

...
protocols {
  rsvp {
    interface ge-0/0/0.0;
  }
  mpls {
    label-switched-path r1-r7 {
      to 10.0.9.7;
      bandwidth 10m;
    }
    interface all;
  }
}
...

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying RSVP Neighbors on page 660](#)
- [Verifying RSVP Sessions on page 660](#)
- [Verifying the Presence of RSVP-Signaled LSPs on page 661](#)

### Verifying RSVP Neighbors

**Purpose** Verify that each device shows the appropriate RSVP neighbors—for example, that Router R1 in [Figure 60 on page 658](#) lists both Router R3 and Router R2 as RSVP neighbors.

**Action** From the CLI, enter the **show rsvp neighbor** command.

```

user@r1> show rsvp neighbor

```

RSVP neighbor: 2 learned						
Address	Idle	Up/Dn	LastChange	HelloInt	HelloTx/Rx	
10.0.6.2	0	3/2	13:01	3	366/349	
10.0.3.3	0	1/0	22:49	3	448/448	

The output shows the IP addresses of the neighboring routers. Verify that each neighboring RSVP router loopback address is listed.

### Verifying RSVP Sessions

**Purpose** Verify that an RSVP session has been established between all RSVP neighbors. Also, verify that the bandwidth reservation value is active.

**Action** From the CLI, enter the **show rsvp session detail** command.

```

user@r1> show rsvp session detail

```

```
Ingress RSVP: 1 sessions
10.0.9.7
  From: 10.0.6.1, LSPstate: Up, ActiveRoute: 0
  LSPname: r1-r7, LSPpath: Primary
  Bidirectional, Upstream label in: -, Upstream label out: -
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent: 100000
  Resv style: 1 FF, Label in: -, Label out: 100000
  Time left: -, Since: Thu Jan 26 17:57:45 2002
  Tspec: rate 10Mbps size 10Mbps peak Infbps m 20 M 1500
  Port number: sender 3 receiver 17 protocol 0
  PATH rcvfrom: localclient
  PATH sentto: 10.0.4.13 (ge-0/0/1.0) 1467 pkts
  RESV rcvfrom: 10.0.4.13 (ge-0/0/1.0) 1467 pkts
  Record route: <self> 10.0.4.13 10.0.2.1 10.0.8.10
```

The output shows the detailed information, including session IDs, bandwidth reservation, and next-hop addresses, for each established RSVP session. Verify the following information:

- Each RSVP neighbor address has an entry for each neighbor, listed by loopback address.
- The state for each LSP session is **Up**.
- For **Tspec**, the appropriate bandwidth value, **10Mbps**, appears.

### Verifying the Presence of RSVP-Signaled LSPs

**Purpose** Verify that the routing table of the entry (ingress) router has a configured LSP to the loopback address of the other router. For example, verify that the **inet.3** routing table of the R1 entry router in [Figure 60 on page 658](#) has a configured LSP to the loopback address of Router R7.

**Action** From the CLI, enter the **show route table inet.3** command.

```
user@r1> show route table inet.3

inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.9.7/32          *[RSVP/7] 00:05:29, metric 10
                    > to 10.0.4.17 via ge-0/0/0.0, label-switched-path r1-r7
```

The output shows the RSVP routes that exist in the **inet.3** routing table. Verify that an RSVP-signaled LSP is associated with the loopback address of the exit (egress) router, R7, in the MPLS network.

## Example: Configuring RSVP Automatic Mesh

---

Service providers often use BGP and MPLS VPNs to efficiently scale the network while delivering revenue-generating services. In these environments, BGP is used to distribute the VPN routing information across the service provider's network, while MPLS is used to forward that VPN traffic from one VPN site to another.

When adding a new PE router that will participate in BGP and MPLS VPNs, all of the previously existing PE routers must be configured to peer with the new PE router for both BGP and MPLS. As each new PE router is added to the service provider's network, the configuration burden soon becomes too much to handle.

The configuration requirements for BGP peering can be reduced with the use of route reflectors. In RSVP signaled MPLS networks, RSVP automatic mesh can minimize the configuration burden for the MPLS portion of the network. Configuring **rsvp-te** on all PE routers allows RSVP to automatically create the needed LSPs when a new PE router is added.

- [Requirements on page 662](#)
- [Overview on page 662](#)
- [Configuration on page 663](#)
- [Verification on page 664](#)

### Requirements

This example uses the following hardware and software components:

- A router running Junos OS Release 10.1 or later.
- A BGP and MPLS VPN using RSVP as the MPLS label-switched path (LSP) signaling protocol.

### Overview

This example shows how to configure RSVP automatic mesh on a PE router using the **rsvp-te** configuration statement. In order for RSVP automatic mesh to function properly, all of the PE routers in the full mesh configuration must have the **rsvp-te** statement configured. This ensures that any new PE routers that are added later will also benefit from the automatic mesh feature, provided that they too are configured with the **rsvp-te** statement.

Given this requirement, this example only shows the configuration on the newly added PE router. It is assumed that RSVP automatic mesh has already been configured on the existing PE routers.

### Topology

---

In [Figure 61 on page 663](#), there are three existing PE routers, PE1, PE2, and PE3, in the topology. PE4 has been added, and RSVP automatic mesh will be configured. The cloud

represents the service provider network, and the network address, 192.0.2.0/24, is shown in the center of the figure.

*Figure 61: Service Provider Network with PE Routers*

## Configuration

Configuring RSVP automatic mesh involves performing these tasks:

- Enabling the **rsvp-te** configuration statement at the **[edit routing-options dynamic-tunnels *dynamic-tunnel-name*]** hierarchy level.
- Configuring the required **destination-networks** element.

This configuration element specifies the IPv4 prefix range for the destination network. Only tunnels within the specified prefix range can be created.

- Configuring the required **label-switched-path-template** element.

This configuration element takes either **default-template** or the name of a preconfigured LSP template as an argument. The **default-template** is a system-defined template that requires no user configuration.

- [Configuring RSVP Automatic Mesh on page 664](#)
- [Results on page 664](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### PE4 Router

```
set routing-options dynamic-tunnels dt-1 rsvp-te rsvp-te-1 label-switched-path-template
  default-template
set routing-options dynamic-tunnels dt-1 rsvp-te rsvp-te-1 destination-networks
  192.0.2.0/24
```

## Configuring RSVP Automatic Mesh

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To enable RSVP automatic mesh:

1. Configure **rsvp-te** at the **[edit routing-options dynamic-tunnels]** hierarchy level.

```
[edit routing-options dynamic-tunnels]
user@PE4# set dt-1 rsvp-te rsvp-te-1 label-switched-path-template
default-template
```

2. Configure **destination-networks** at the **[edit routing-options dynamic-tunnels]** hierarchy level.

```
[edit routing-options dynamic-tunnels]
user@PE4# set dt-1 rsvp-te rsvp-te-1 destination-networks 192.0.2.0/24
```

## Results

Issue the **show** command from the **[edit routing-options dynamic-tunnels]** hierarchy level to see the results of your configuration:

```
[edit routing-options dynamic-tunnels]
user@PE4#show
dt-1 {
  rsvp-te rsvp-te-1 {
    label-switched-path-template {
      default-template;
    }
    destination-networks {
      192.0.2.0/24;
    }
  }
}
```

## Verification

- [Verifying the Existence of RSVP Automatic Mesh Tunnels on Router PE4 on page 664](#)
- [Verifying the Existence of MPLS LSPs on Router PE4 on page 665](#)

## Verifying the Existence of RSVP Automatic Mesh Tunnels on Router PE4

**Purpose** To verify the operation of the newly configured PE4 router, issue the **show dynamic-tunnels database** command from operational mode. This command will show the destination network to which dynamic tunnels can be created.

**Action**      `user@PE4> show dynamic-tunnels database`  
                  Table: inet.3  
                  Destination-network: 192.0.2.0/24

### Verifying the Existence of MPLS LSPs on Router PE4

**Purpose**      To verify the existence of MPLS LSPs on the PE4 router, issue the `show mpls lsp` command from operational mode. This command will show the state of the MPLS LSPs.

**Action**      `user@PE4> show mpls lsp`

```
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
Egress LSP: 3 sessions
To From State Rt Style Labelin Labelout LSPname
192.0.2.104 192.0.2.103 Up 0 1 FF 3 - PE2-PE4
192.0.2.104 192.0.2.102 Up 0 1 FF 3 - PE2-PE4
192.0.2.104 192.0.2.101 Up 0 1 FF 3 - PE1-PE4
Total 3 displayed, Up 3, Down 0
Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Related Documentation**

- [Understanding RSVP Automatic Mesh on page 643](#)
- [rsvp-te on page 2312](#)

## Configuring Hello Acknowledgments for Nonsession RSVP Neighbors

The **hello-acknowledgements** statement controls the hello acknowledgment behavior between RSVP neighbors regardless of whether or not they are in the same session.

Hello messages received from RSVP neighbors that are not part of a common RSVP session are discarded. If you configure the **hello-acknowledgements** statement at the **[edit protocols rsvp]** hierarchy level, hello messages from nonsession neighbors are acknowledged with a hello acknowledgment message. When hellos are received from nonsession neighbors, an RSVP neighbor relationship is created and periodic hello messages can now be received from the nonsession neighbor. The **hello-acknowledgements** statement is disabled by default. Configuring this statement allows RSVP-capable routers to be discovered using hello packets and verifies that the interface is able to receive RSVP packets before sending any MPLS LSP setup messages.

Once you enable hello acknowledgments for nonsession RSVP neighbors, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or you change the configuration. Interface-based neighbors are not automatically aged out.

```
hello-acknowledgements;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

---

## Switching LSPs Away from a Network Node

You can configure the router to switch active LSPs away from a network node using a bypass LSP enabled for an interface. This feature might be used to maintain active networks when a device needs to be replaced without interrupting traffic transiting the network. The LSPs can be either static or dynamic.

1. You first need to configure either link or node protection for the traffic that needs to pass around the network device you intend to disable. To function properly, the bypass LSP must use a different logical interface than the protected LSP.
2. To prepare the router to begin switching traffic away from a network node, configure the **always-mark-connection-protection-tlv** statement:

```
always-mark-connection-protection-tlv;
```

The router then marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality.

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls interface *interface-name*]
  - [edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]
3. You then need to configure the **switch-away-lsps** statement to switch the traffic from the protected LSP to the bypass LSP, effectively bypassing the default downstream network device. The actual link itself is not brought down by this configuration.

To configure the router to switch traffic away from a network node, configure the **switch-away-lsps** statement:

```
switch-away-lsps;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]

Note the following limitations related to switching active LSPs away from a network node:

- The switch-away feature is supported on MX Series routers only.
- The switch-away feature is not supported for switching traffic from primary point-to-multipoint LSPs to bypass point-to-multipoint LSPs. If you configure the

**switch-away-lsps** statement for a point-to-multipoint LSP, traffic is not switched to the bypass point-to-multipoint LSP.

- If you configure the switch-away feature on an interface along the path of a dynamic LSP, new dynamic LSPs cannot be established over that path. The switch-away feature prevents the make-before-break behavior of RSVP-signaled LSPs. The make-before-break behavior normally causes the router to first attempt to re-signal a dynamic LSP before tearing down the original.

**Related Documentation**

- [Configuring Node Protection or Link Protection for LSPs on page 695](#)

## Configuring RSVP Setup Protection

You can configure the facility-backup fast reroute mechanism to provide setup protection for LSPs which are in the process of being signaled. Both point-to-point LSPs and point-to-multipoint LSPs are supported. This feature is applicable in the following scenario:

1. A failed link or node is present on the strict explicit path of an LSP before the LSP is signaled.
2. There is also a bypass LSP protecting the link or node.
3. RSVP signals the LSP through the bypass LSP. The LSP appears as if it was originally set up along its primary path and then failed over to the bypass LSP because of the link or node failure.
4. When the link or node has recovered, the LSP can be automatically reverted to the primary path.

You should configure the **setup-protection** statement at the **[edit protocols rsvp]** on each of the routers along the LSP path on which you want to enable LSP setup protection. You should also configure IGP traffic engineering on all of the routers on the LSP path. You can issue a **show rsvp session** command to determine whether or not the LSP has setup protection enabled on a router acting as a point of local repair (PLR) or a merge point.

To enable RSVP setup protection, include the **setup-protection** statement

```
setup-protection;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

## Configuring Load Balancing Across RSVP LSPs

By default, when you have configured several RSVP LSPs to the same egress router, the LSP with the lowest metric is selected and carries all traffic. If all of the LSPs have the same metric, one of the LSPs is selected at random and all traffic is forwarded over it.

Alternatively, you can load-balance traffic across all of the LSPs by enabling per-packet load balancing.

To enable per-packet load balancing on an ingress LSP, configure the **policy-statement** statement as follows:

```
[edit policy-options]
policy-statement policy-name {
  then {
    load-balance per-packet;
  }
  accept;
}
```

You then need to apply this statement as an export policy to the forwarding table.

Once per-packet load balancing is applied, traffic is distributed equally between the LSPs (by default).

You need to configure per-packet load balancing if you want to enable PFE fast reroute. To enable PFE fast reroute, include the **policy-statement** statement for per-packet load balancing shown in this section in the configuration of each of the routers where a reroute might take place. See also [“Configuring Fast Reroute” on page 381](#).

You can also load-balance the traffic between the LSPs in proportion to the amount of bandwidth configured for each LSP. This capability can better distribute traffic in networks with asymmetric bandwidth capabilities across external links, since the configured bandwidth of an LSP typically reflects the traffic capacity of that LSP.

To configure RSVP LSP load balancing, include the **load-balance** statement with the **bandwidth** option:

```
load-balance {
  bandwidth;
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

Keep the following information in mind when you use the **load-balance** statement:

- If you configure the **load-balance** statement, the behavior of currently running LSPs is not altered. To force currently running LSPs to use the new behavior, you can issue a **clear mpls lsp** command.

- The **load-balance** statement only applies to ingress LSPs that have per-packet load balancing enabled.
- For Differentiated Services–aware traffic engineered LSPs, the bandwidth of an LSP is calculated by summing the bandwidth of all of the class types.

## Configuring RSVP Automatic Mesh

You can configure RSVP to establish point-to-point label-switched paths (LSPs) automatically for any new PE router added to a full mesh of LSPs. To enable this feature, you must configure the **rsvp-te** statement on all of the PE routers in the full mesh.

**NOTE:** You cannot configure RSVP automatic mesh in conjunction with CCC. CCC cannot use the dynamically generated LSPs.

To configure RSVP automatic mesh, include the **rsvp-te** statement:

```
rsvp-te {
  destination-networks network-prefix;
  label-switched-path-template (Multicast) {
    default-template;
    template-name;
  }
}
```

You can configure these statements at the following hierarchy levels:

- [edit routing-options dynamic-tunnels *tunnel-name*]
- [edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*]

You must also configure the following statements to enable RSVP automatic mesh:

- **destination-networks**—Specify the IP version 4 (IPv4) prefix range for the destination network. Dynamic tunnels within the specified IPv4 prefix range can be initiated.
- **label-switched-path-template (Multicast)**—You can configure either the default template explicitly using the **default-template** option, or you can configure an LSP template of your own using the **template-name** option. The LSP template acts as a model configuration for the dynamically generated LSPs.

## Configuring Timers for RSVP Refresh Messages

RSVP uses two related timing parameters:

- **refresh-time**—The refresh time controls the interval between the generation of successive refresh messages. The default value for the refresh time is 45 seconds. This number is derived from the **refresh-time** statement's default value of 30, multiplied by a fixed value of 1.5. This computation differs from RFC 2205, which states that the refresh time should be multiplied by a random value in the range from 0.5 through 1.5.  
  
Refresh messages include path and Resv messages. Refresh messages are sent periodically so that reservation states in neighboring nodes do not time out. Each path and Resv message carries the refresh timer value, and the receiving node extracts this value from the messages.
- **keep-multiplier**—The keep multiplier is a small, locally configured integer from 1 through 255. The default value is 3. It indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

To determine the lifetime of a reservation state, use the following formula:

$$lifetime = (keep-multiplier + 0.5) \times (1.5 \times refresh-time)$$

In the worst case, (**keep-multiplier** – 1) successive refresh messages must be lost before a reservation state is deleted.

We do not recommend configuring a short RSVP hello timer. If quick discovery of a failed neighbor is needed, configure short IGP (OSPF or IS-IS) hello timers.

By default, the refresh timer value is 30 seconds. To modify this value, include the **refresh-time** statement:

```
refresh-time seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

The default value of the keep multiplier is 3. To modify this value, include the **keep-multiplier** statement:

```
keep-multiplier number;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

## Preempting RSVP Sessions

Whenever bandwidth is insufficient to handle all RSVP sessions, you can control the preemption of RSVP sessions. By default, an RSVP session is preempted only by a new higher-priority session.

To always preempt a session when the bandwidth is insufficient, include the **preemption** statement with the **aggressive** option:

```
preemption aggressive;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

To disable RSVP session preemption, include the **preemption** statement with the **disabled** option:

```
preemption disabled;
```

To return to the default (that is, preempt a session only for a new higher-priority session), include the **preemption** statement with the **normal** option:

```
preemption normal;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

## Configuring MTU Signaling in RSVP

To configure maximum transmission unit (MTU) signaling in RSVP, you need to configure MPLS to allow IP packets to be fragmented before they are encapsulated in MPLS. You also need to configure MTU signaling in RSVP. For troubleshooting purposes, you can configure MTU signaling alone without enabling packet fragmentation.

To configure MTU signaling in RSVP, include the **path-mtu** statement:

```
path-mtu {
  allow-fragmentation;
  rsvp {
    mtu-signaling;
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]

- [\[edit logical-systems \*logical-system-name\* protocols mpls\]](#)

The following sections describe how to enable packet fragmentation and MTU signaling in RSVP:

- [Enabling MTU Signaling in RSVP on page 672](#)
- [Enabling Packet Fragmentation on page 672](#)

## Enabling MTU Signaling in RSVP

To enable MTU signaling in RSVP, include the **rsvp mtu-signaling** statement:

```
rsvp mtu-signaling;
```

You can include this statement at the following hierarchy levels:

- [\[edit protocols mpls path-mtu\]](#)
- [\[edit logical-systems \*logical-system-name\* protocols mpls path-mtu\]](#)

Once you have committed the configuration, changes in the MTU signaling behavior for RSVP take effect the next time the path is refreshed.

You can configure the **mtu-signaling** statement by itself at the [\[edit protocols mpls path-mtu rsvp\]](#) hierarchy level. This can be useful for troubleshooting. If you configure just the **mtu-signaling** statement, you can use the **show rsvp session detail** command to determine what the smallest MTU is on an LSP. The **show rsvp session detail** command displays the MTU value received and sent in the Adspec object.

## Enabling Packet Fragmentation

To allow IP packets to be fragmented before they are encapsulated in MPLS, include the **allow-fragmentation** statement:

```
allow-fragmentation;
```

You can include this statement at the following hierarchy levels:

- [\[edit protocols mpls path-mtu\]](#)
- [\[edit logical-systems \*logical-system-name\* protocols mpls path-mtu\]](#)

**NOTE:** Do not configure the **allow-fragmentation** statement alone. Always configure it in conjunction with the **mtu-signaling** statement.

---

## Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (PHP).

[Figure 46 on page 487](#) illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet

to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

Figure 62: Penultimate-Hop Popping for an LSP

You can also configure ultimate-hop popping (UHP) (as shown in [Figure 47 on page 488](#)) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate-hop popping LSP, the penultimate router (Router P2 in [Figure 47 on page 488](#)) performs the standard MPLS label swapping operation (in this example, label 2 for label 3) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

Figure 63: Ultimate-Hop Popping for an LSP

The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band OAM
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs
- Point-to-multipoint LSPs
- CCC
- `traceroute` command

For more information about UHP behavior, see Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a VT interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- Layer 2 VPNs and Layer 2 circuits—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the VC label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- Layer 3 VPN—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward the CE router. However, if you have configured the **vrf-table-label** statement for the Layer 3 VPN routing instance, the inner LSI label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

**NOTE:** UHP for Layer 3 VPNs configured with the **vrf-table-label** statement is supported on MX Series 5G Universal Routing Platforms only.

- VPLS—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

**NOTE:** UHP for VPLS configured with the `no-tunnel-service` statement is supported on MX 3D Series routers only.

- **IPv4 over MPLS**—A packet arrives at the PE router (egress of the UHP LSP) with one label ( $S=1$ ). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route ( $S=1$ ) points to the `inet.0` routing table.
- **IPv6 over MPLS**—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label ( $S=0$ ), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the inner label in the `mpls.0` routing table redirects back to the `mpls.0` routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the `inet6.0` routing table.
- **Enabling both PHP and UHP LSPs**—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the `install-nexthop` statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the `ultimate-hop-popping` statement:

```
ultimate-hop-popping;
```

Include this statement at the `[edit protocols mpls label-switched-path label-switched-path-name]` hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the `[edit protocols mpls]` hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the router. You can also configure the `ultimate-hop-popping` statement under the equivalent `[edit logical-routers]` hierarchy levels.

**NOTE:** When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a PathTear message along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).

If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the **enhanced-ip** option for the **network-services** statement:

```
network-services enhanced-ip;
```

You configure this statement at the **[edit chassis]** hierarchy level. Once you have configured the **network-services** statement, you need to reboot the router to enable UHP behavior.

**Related  
Documentation**

- [MPLS Label Allocation on page 329](#)

---

## Configuring RSVP to Pop the Label on the Ultimate-Hop Router

---

You can control the label value advertised on the egress router of an LSP. The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. When ultimate-hop popping is enabled, label 0 (IP version 4 [IPv4] Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure ultimate-hop popping for RSVP, include the **explicit-null** statement:

```
explicit-null;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

**Related  
Documentation**

- [MPLS Label Overview on page 329](#)
- [MPLS Label Allocation on page 329](#)

## Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs

By default, for both point-to-point and point-to-multipoint LSPs, penultimate-hop popping is used for MPLS traffic. MPLS labels are removed from packets on the router just before the egress router of the LSP. The plain IP packets are then forwarded to the egress router. For ultimate-hop popping, the egress router is responsible for both removing the MPLS label and processing the plain IP packet.

It can be beneficial to enable ultimate-hop popping on point-to-multipoint LSPs, particularly when transit traffic is traversing the same egress device. If you enable ultimate-hop popping, a single copy of traffic can be sent over the incoming link, saving significant bandwidth. By default, ultimate-hop popping is disabled.

You enable ultimate-hop popping for point-to-multipoint LSPs by configuring the **tunnel-services** statement. When you enable ultimate-hop popping, the Junos OS selects one of the available virtual loopback tunnel (VT) interfaces to loop back the packets to the PFE for IP forwarding. By default, the VT interface selection process is performed automatically. Bandwidth admission control is used to limit the number of LSPs that can be used on one VT interface. Once all the bandwidth is consumed on one interface, the Junos OS selects another VT interface with sufficient bandwidth for admission control.

If an LSP requires more bandwidth than is available from any of the VT interfaces, ultimate-hop popping cannot be enabled and penultimate-hop popping is enabled instead.

For ultimate-hop popping on point-to-multipoint LSPs to function properly, the egress router must have a PIC that provides tunnel services, such as the tunnel services PIC or the adaptive services PIC. Tunnel services are needed for popping the final MPLS label and for returning packets for IP address lookups.

You can explicitly configure which VT interfaces handle the RSVP traffic by including the **devices** option for the **tunnel-services** statement. The **devices** option allows you to specify which VT interfaces are to be used by RSVP. If you do not configure this option, all of the VT interfaces available to the router can be used.

To enable ultimate-hop popping for the egress point-to-multipoint LSPs on a router, configure the **tunnel-services** statement:

```
tunnel-services {
  devices device-names;
```

```
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

To enable ultimate-hop popping for egress point-to-multipoint LSPs, you must also configure the **interface** statement with the **all** option:

```
interface all;
```

You must configure this statement at the **[edit protocols rsvp]** hierarchy level.

---

## Tracing RSVP Protocol Traffic

To trace RSVP protocol traffic, include the **traceoptions** statement:

```
traceoptions {  
  file filename <files number> <size size> <world-readable | no-world-readable>;  
  flag flag <flag-modifier> <disable>;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

You can specify the following RSVP-specific flags in the RSVP **traceoptions** statement:

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**.

- **all**—All tracing operations.
- **error**—All detected error conditions
- **event**—RSVP-related events (helps to trace events related to RSVP graceful restart)
- **lmp**—RSVP-Link Management Protocol (LMP) interactions
- **packets**—All RSVP packets
- **path**—All path messages
- **pathtear**—PathTear messages
- **resv**—Resv messages
- **resvtear**—ResvTear messages

- **route**—Routing information
- **state**—Session state transitions, including when RSVP-signaled LSPs come up and go down.

**NOTE:** Use the **all trace** flag and the **detail** flag modifier with caution because these might cause the CPU to become very busy.

To view the log file generated when you enable RSVP traceoptions, issue the **show log file-name** command, where **file-name** is the file you specified using the **traceoptions** statement.

For general information about tracing and global tracing options, see the *Junos OS Routing Protocols Library*.

## Examples: Tracing RSVP Protocol Traffic

Trace RSVP path messages in detail:

```
[edit]
protocols {
  rsvp {
    traceoptions {
      file rsvp size 10m files 5;
      flag path;
    }
  }
}
```

Trace all RSVP messages:

```
[edit]
protocols {
  rsvp {
    traceoptions {
      file rsvp size 10m files 5;
      flag packets;
    }
  }
}
```

Trace all RSVP error conditions:

```
[edit]
protocols {
  rsvp {
    traceoptions {
      file rsvp size 10m files 5;
      flag error;
    }
  }
}
```

Trace RSVP state transitions:

```
[edit]
protocols {
  rsvp {
    traceoptions {
      file rsvp-data;
      flag state;
    }
  }
}
```

### RSVP Log File Output

The following is sample output generated by issuing the **show log file-name** command on a router on which RSVP traceoptions have been enabled with the **state** flag configured. The RSVP-signaled LSP E-D is shown being torn down on Mar 11 14:04:36.707092. On Mar 11 14:05:30.101492, it is shown coming back up.

## Link Protection

Link protection helps to ensure that traffic going over a specific interface to a neighboring router or switch can continue to reach this router (switch) if that interface fails. When link protection is configured for an interface and an LSP that traverses this interface, a bypass LSP is created that will handle this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. The path used can be configured explicitly, or you can rely on CSPF. The RSVP metric for the bypass LSP is set in the range of 20,000 through 29,999 (this value is not user configurable).

If a link-protected interface fails, traffic is quickly switched to the bypass LSP. Note that a bypass LSP cannot share the same egress interface with the LSPs it monitors.

In [Figure 64 on page 681](#), link protection is enabled on Interface B between Router 1 and Router 2. It is also enabled on LSP A, an LSP that traverses the link between Router 1 and Router 2. If the link between Router 1 and Router 2 fails, traffic from LSP A is quickly switched to the bypass LSP generated by link protection.

**Figure 64: Link Protection Creating a Bypass LSP for the Protected Interface**

Although LSPs traversing an interface can be configured to take advantage of link protection, it is important to note that it is specifically the interface that benefits from link protection. If link protection is enabled on an interface but not on a particular LSP traversing that interface, then if the interface fails, that LSP will also fail.

**NOTE:** Link protection does not work on unnumbered interfaces.

To protect traffic over the entire route taken by an LSP, you should configure fast reroute. For more information, see [“Configuring Fast Reroute” on page 381](#).

## Multiple Bypass LSPs for Link Protection

---

By default, link protection relies on a single bypass LSP to provide path protection for an interface. However, you can also specify multiple bypass LSPs to provide link protection for an interface. You can individually configure each of these bypass LSPs or create a single configuration for all of the bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.

The following algorithm describes how and when an additional bypass LSP is activated for an LSP:

1. If any currently active bypass can satisfy the requirements of the LSP (bandwidth, link protection, or node-link protection), the traffic is directed to that bypass.
2. If no active bypass LSP is available, scan through the manual bypass LSPs in first-in, first-out (FIFO) order, skipping those that are already active (each manual bypass can only be activated once). The first inactive manual bypass that can satisfy the requirements is activated and traffic is directed to that bypass.
3. If no manual bypass LSPs are available and if the **max-bypasses** statement activates multiple bypass LSPs for link protection, determine whether an automatically configured bypass LSP can satisfy the requirements. If an automatically configured bypass LSP is available and if the total number of active automatically configured bypass LSPs does not exceed the maximum bypass LSP limit (configured with the **max-bypasses** statement), activate another bypass LSP.

For information about how to configure multiple bypass LSPs for link protection, see [“Configuring Bypass LSPs” on page 689](#).

## Node Protection

---

Node protection extends the capabilities of link protection. Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. Node protection ensures that traffic from an LSP traversing a neighboring router can continue to reach its destination even if the neighboring router fails.

When you enable node protection for an LSP, you must also enable link protection. Once enabled, node protection and link protection establish the following types of bypass LSPs:

- Next-hop bypass LSP—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass LSP is established when you enable either node protection or link protection.
- Next-next-hop bypass LSP—Provides an alternate route for an LSP to get around a neighboring router en route to the destination router. This type of bypass LSP is established exclusively when node protection is configured. If a next-next-hop bypass LSP cannot be created, an attempt is made to signal a next-hop bypass LSP.

In [Figure 65 on page 683](#), node protection is enabled on Interface B on Router 1. Node protection is also enabled on LSP A, an LSP that traverses the link transiting Router 1, Router 2, and Router 3. If Router 2 suffers a hardware or software failure, traffic from LSP A is switched to the next-next-hop bypass LSP generated by node protection.

**Figure 65: Node Protection Creating a Next-Next-Hop Bypass LSP**

The time needed by node protection to switch traffic to a next-next-hop bypass LSP can be significantly longer than the time needed by link protection to switch traffic to a next-hop bypass LSP. Link protection relies on a hardware mechanism to detect a link failure, allowing it to quickly switch traffic to a next-hop bypass LSP.

Node failures are often due to software problems on the node router. Node protection relies on the receipt of hello messages from a neighboring router to determine whether it is still functioning. The time it takes node protection to divert traffic partly depends on how often the node router sends hello messages and how long it takes the node-protected router to react to having not received a hello message. However, once the failure is detected, traffic can be quickly diverted to the next-next-hop bypass LSP.

**NOTE:**

Node protection provides traffic protection in the event of an error or interruption of the physical link between two routers. It does not provide protection in the event of control plane errors. The following provides an example of a control plane error:

- A transit router changes the label of a packet due to a control plane error.
- When the ingress router receives the packet, it considers the label change to be a catastrophic event and deletes both the primary LSP and the associated bypass LSP.

## Fast Reroute, Node Protection, and Link Protection

This document discusses the following sections:

- [LSP Protection Overview on page 684](#)
- [LSP Protection Types Comparison on page 684](#)
- [One-to-One Backup Implementation on page 685](#)
- [Facility Backup Implementation on page 686](#)

### LSP Protection Overview

RSVP-TE extensions establish backup label-switched path (LSP) tunnels for local repair of LSP tunnels. These mechanisms enable immediate re-direction of traffic onto backup LSP tunnels, in the event of a failure.

RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, describes two different types of traffic protection for RSVP-signaled LSPs:

- One-to-one backup—In this method, detour LSPs for each protected LSP is created at each potential point of local repair.
- Facility backup—In this method, a bypass tunnel is created to protect a set of LSPs that have similar backup constraints at a potential failure point, by taking advantage of the MPLS label stacking.

The one-to-one backup and the facility backup methods protect links and nodes during network failure, and can co-exist in a mixed network.

### LSP Protection Types Comparison

In the Junos OS, the one-to-one backup of traffic protection is provided by fast reroute. Each LSP requires a protecting LSP to be signaled at each hop except the egress router. This method of LSP protection cannot be shared.

In the facility backup method, the LSP traffic protection is provided on the node and link. Each LSP requires a protecting LSP to be signaled at each hop except the egress router. Unlike fast reroute, this protecting LSP can be shared by other LSPs.

[Table 24 on page 684](#) summarizes the traffic protection types.

**Table 24: One-to-One Backup Compared with Facility Backup**

Comparison	One-to-One Backup	Facility Backup
Name of the protecting LSP	Detour LSP	Bypass LSP
Sharing of the protecting LSP	Cannot be shared	Can be shared by multiple LSPs
Junos configuration statements	<b>fast-reroute</b>	<b>node-link-protection</b> and <b>link-protection</b>

## One-to-One Backup Implementation

In the one-to-one backup method, the points of local repair maintain separate backup paths for each LSP passing through a facility. The backup path terminates by merging back with the primary path at a node called the merge point. In this approach, the merge point can be any node downstream from the protected facility.

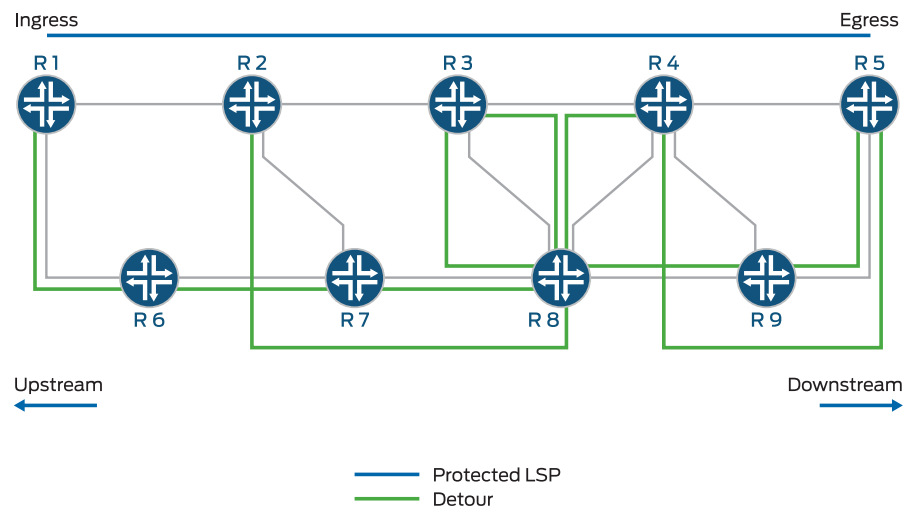

In the one-to-one backup method, an LSP is established that intersects the original LSP downstream of the point of link or node failure. A separate backup LSP is established for each LSP that is backed up.

One-to-one backup is appropriate under the following circumstances:

- Protection of a small number of LSPs relative to the total number of LSPs.
- Path selection criteria, such as bandwidth, priority, and link coloring for detour paths is critical.
- Control of individual LSPs is important.

In [Figure 66 on page 685](#), Routers R1 and R5 are the ingress and egress routers, respectively. A protected LSP is established between the two routers transiting Routers R2, R3, and R4. Router R2 provides user traffic protection by creating a partial backup LSP that merges with the protected LSP at Router R4. This partial one-to-one backup LSP is called a detour. Detours are always calculated to avoid the immediate downstream link and node, providing against both link and node failure.

*Figure 66: One-to-One Backup*

In the example, the protected LSP is R1-R2-R3-R4-R5, and the following detours are established:

- Router R1—R1-R6-R7-R8-R3
- Router R2—R2-R7-R8-R4

- Router R3—**R3-R8-R9-R5**
- Router R4—**R4-R9-R5**

To protect an LSP that traverses **N** nodes fully, there can be as many as **(N - 1)** detours. The point of local repair sends periodic refresh messages to maintain each backup path, as a result maintaining state information for backup paths protecting individual LSPs is a significant resource burden for the point of local repair. To minimize the number of LSPs in the network, it is desirable to merge a detour back to its protected LSP, when feasible. When a detour LSP intersects its protected LSP at an LSR with the same outgoing interface, it is merged.

## Facility Backup Implementation

In the facility backup approach, a point of local repair maintains a single backup path to protect a set of primary LSPs traversing the point of local repair, the facility, and the merge point. The facility backup is based on interface rather than on LSP. While fast reroute protects interfaces or nodes along the entire path of a LSP, the facility backup protection can be applied on interfaces as needed. As a result, fewer states need to be maintained and refreshed which results in a scalable solution. The facility backup method is also called many-to-one backup.

The facility backup method takes advantage of the MPLS label stack. Instead of creating a separate LSP for every backed-up LSP, a single LSP is created that serves to back up a set of LSPs. Such an LSP tunnel is called a bypass tunnel. In this method, a router immediately upstream from a link failure uses an alternate interface to forward traffic to its downstream neighbor, and the merge point should be the node immediately downstream to the facility. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link. A single bypass path can safeguard a set of protected LSPs. When an outage occurs, the router immediately upstream from the link outage switches protected traffic to the bypass link, then signals the link failure to the ingress router.

The bypass tunnel must intersect the path of the original LSP(s) somewhere downstream of the point of local repair. This constrains the set of LSPs being backed up through that bypass tunnel to those that pass through some common downstream nodes. All LSPs that pass through the point of local repair and through this common node, and that do not also use the facilities involved in the bypass tunnel are candidates for this set of LSPs.

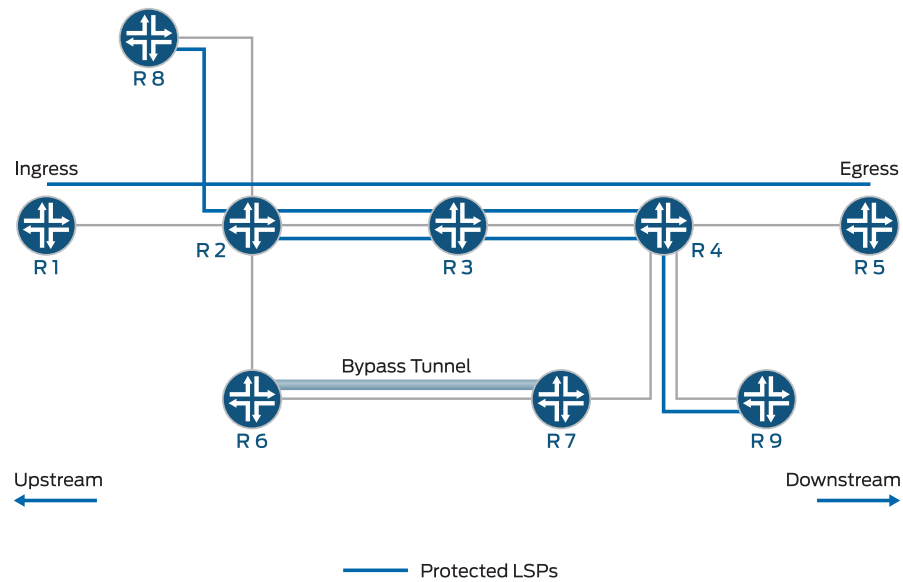

The facility backup method is appropriate in the following situations:

- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

In [Figure 67 on page 687](#), Routers R1 and R5 are the ingress and egress routers, respectively. Router R2 has established a bypass tunnel that protects against the failure of Router R2-R3 link and Router R3 node. A bypass tunnel is established between Routers R6 and R7. There are three different protected LSPs that are using the same bypass tunnel for protection.

Figure 67: Facility Backup

8042700

The facility backup method provides a scalability improvement, wherein the same bypass tunnel is also used to protect LSPs from any of Routers R1, R2, or R8 to any of Routers R4, R5, or R9.

#### Related Documentation

- [Fast Reroute Overview on page 379](#)
- [Configuring Fast Reroute on page 381](#)
- [Node Protection on page 682](#)
- [Configuring Node Protection or Link Protection for LSPs on page 695](#)

## Configuring Link Protection on Interfaces Used by LSPs

When you configure node protection or link protection on a router for LSPs as described in “[Configuring Node Protection or Link Protection for LSPs](#)” on page 695, you also must configure the **link-protection** statement on the RSVP interfaces used by the LSPs.

To configure link protection on the interfaces used by the LSPs, include the **link-protection** statement:

```
link-protection {
  disable;
  admin-group
    exclude group-names;
    include-all group-names;
    include-any group-names;
}
bandwidth bps;
```

```

bypass bypass-name {
  bandwidth bps;
  description text;
  hop-limit number;
  no-cspf;
  path address <strict | loose>;
  priority setup-priority reservation-priority;
  to address;
}
class-of-service cos-value;
hop-limit number;
max-bypasses number;
no-cspf;
no-node-protection;
optimize-timer seconds;
path address <strict | loose>;
priority setup-priority reservation-priority;
subscription percent {
  ct0 percent;
  ct1 percent;
  ct2 percent;
  ct3 percent;
}
}

```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

All the statements under **link-protection** are optional.

The following sections describe how to configure link protection:

- [Configuring Bypass LSPs on page 689](#)
- [Configuring Administrative Groups for Bypass LSPs on page 689](#)
- [Configuring the Bandwidth for Bypass LSPs on page 690](#)
- [Configuring Class of Service for Bypass LSPs on page 691](#)
- [Configuring the Hop Limit for Bypass LSPs on page 691](#)
- [Configuring the Maximum Number of Bypass LSPs on page 691](#)
- [Disabling CSPF for Bypass LSPs on page 692](#)
- [Disabling Node Protection for Bypass LSPs on page 692](#)
- [Configuring the Optimization Interval for Bypass LSPs on page 693](#)
- [Configuring an Explicit Path for Bypass LSPs on page 693](#)
- [Configuring the Amount of Bandwidth Subscribed for Bypass LSPs on page 694](#)
- [Configuring Priority and Preemption for Bypass LSPs on page 694](#)

## Configuring Bypass LSPs

You can configure specific bandwidth and path constraints for a bypass LSP. You can also individually configure each bypass LSP generated when you enable multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints (if any).

If you specify the **bandwidth**, **hop-limit**, and **path** statements for the bypass LSP, these values take precedence over the values configured at the **[edit protocols rsvp interface interface-name link-protection]** hierarchy level. The other attributes (**subscription**, **no-node-protection**, and **optimize-timer**) are inherited from the general constraints.

To configure a bypass LSP, specify a name for the bypass LSP using the **bypass** statement. The name can be up to 64 characters in length.

```
bypass bypass-name {
  bandwidth bps;
  description text;
  class-of-service cos-value;
  hop-limit number;
  no-cspf;
  path address <strict | loose>;
  priority setup-priority reservation-priority;
  to address;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp interface interface-name link-protection]**
- **[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection]**

### Configuring the Next-Hop or Next-Next-Hop Node Address for Bypass LSPs

If you configure a bypass LSP, you must also configure the **to** statement. The **to** statement specifies the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.

## Configuring Administrative Groups for Bypass LSPs

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups. You can configure administrative groups for bypass LSPs. For more information about configuring administrative groups, see [“Configuring Administrative Groups for LSPs” on page 429](#).

To configure administrative groups for bypass LSPs, include the **admin-group** statement:

```
admin-group {  
  exclude group-names;  
  include-all group-names;  
  include-any group-names;  
}
```

To configure an administrative group for all of the bypass LSPs, include the **admin-group** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

To configure an administrative groups for a specific bypass LSP, include the **admin-group** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Bandwidth for Bypass LSPs

You can specify the amount of bandwidth allocated for automatically generated bypass LSPs or you can individually specify the amount of bandwidth allocated for each LSP.

If you have enabled multiple bypass LSPs, this statement is required.

To specify the bandwidth allocation, include the **bandwidth** statement:

```
bandwidth bps;
```

For automatically generated bypass LSPs, include the **bandwidth** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

For individually configured bypass LSPs, include the **bandwidth** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring Class of Service for Bypass LSPs

You can specify the class-of-service value for bypass LSPs by including the **class-of-service** statement:

```
class-of-service cos-value;
```

To apply a class-of-service value to all the automatically generated bypass LSPs, include the **class-of-service** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

To configure a class-of-service value for a specific bypass LSPs, include the **class-of-service** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Hop Limit for Bypass LSPs

You can specify the maximum number of hops a bypass can traverse. By default, each bypass can traverse a maximum of 255 hops (the ingress and egress routers count as one hop each, so the minimum hop limit is two).

To configure the hop limit for bypass LSPs, include the **hop-limit** statement:

```
hop-limit number;
```

For automatically generated bypass LSPs, include the **hop-limit** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

For individually configured bypass LSPs, include the **hop-limit** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Maximum Number of Bypass LSPs

You can specify the maximum number of dynamic bypass LSPs permitted for protecting an interface using the **max-bypasses** statement at the [edit protocols rsvp **interface**

***interface-name link-protection***] hierarchy level. When this statement is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled.

By default, this option is disabled and only one bypass is enabled for each interface. You can configure a value of between 0 through 99 for the **max-bypasses** statement. Configuring a value of 0 prevents the creation of any dynamic bypass LSPs for the interface. If you configure a value of 0 for the **max-bypasses** statement, you need to configure one or more static bypass LSPs to enable link protection on the interface.

If you configure the **max-bypasses** statement, you must also configure the **bandwidth** statement (discussed in [“Configuring the Bandwidth for Bypass LSPs” on page 690](#)).

To configure the maximum number of bypass LSPs for a protected interface, include the **max-bypasses** statement:

```
max-bypasses number;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Disabling CSPF for Bypass LSPs

Under certain circumstances, you might need to disable CSPF computation for bypass LSPs and use the configured Explicit Route Object (ERO) if available. For example, a bypass LSP might need to traverse multiple OSPF areas or IS-IS levels, preventing the CSPF computation from working. To ensure that link and node protection function properly in this case, you have to disable CSPF computation for the bypass LSP.

You can disable CSPF computation for all bypass LSPs or for specific bypass LSPs.

To disable CSPF computation for bypass LSPs, include the **no-cspf** statement:

```
no-cspf;
```

For a list of hierarchy levels where you can include this statement, see the statement summary for this statement.

## Disabling Node Protection for Bypass LSPs

You can disable node protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

To disable node protection for bypass LSPs, include the **no-node-protection** statement:

```
no-node-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Configuring the Optimization Interval for Bypass LSPs

You can configure an optimization interval for bypass LSPs using the **optimize-timer** statement. At the end of this interval, an optimization process is initiated that attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all of the bypasses, or both. You can configure an optimization interval from 1 through 65,535 seconds. A default value of 0 disables bypass LSP optimization.

When you configure the **optimize-timer** statement, bypass LSPs are reoptimized automatically when you configure or change the configuration of any of the following:

- Administrative group for a bypass LSP—The configuration for an administrative group has been changed on a link along the path used by the bypass LSP. Configure an administrative group using the **admin-group** statement at the [edit protocols rsvp **interface** *interface-name* link-protection] hierarchy level.
- Fate sharing group—The configuration for a fate sharing group has been changed. Configure a fate sharing group using the **group** statement at the [edit routing-options **fate-sharing**] hierarchy level.
- IS-IS overload—The configuration for IS-IS overload has been changed on a router along the path used by the bypass LSP. Configure IS-IS overload using the **overload** statement at the [edit protocols isis] hierarchy level.
- IGP metric—The IGP metric has been changed on a link along the path used by the bypass LSP.

To configure the optimization interval for bypass LSPs, include the **optimize-timer** statement:

```
optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Configuring an Explicit Path for Bypass LSPs

By default, when you establish a bypass LSP to an adjacent neighbor, CSPF is used to discover the least-cost path. The **path** statement allows you to configure an explicit path (a sequence of strict or loose routes), giving you control over where and how the bypass LSP is established. To configure an explicit path, include the **path** statement:

```
path address <strict | loose>;
```

For automatically generated bypass LSPs, include the **path** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

For individually configured bypass LSPs, include the **path** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Amount of Bandwidth Subscribed for Bypass LSPs

You can configure the amount of bandwidth subscribed to bypass LSPs. You can configure the bandwidth subscription for the whole bypass LSP or for each class type that might traverse the bypass LSP. You can configure any value between 1 percent and 65,535 percent. By configuring a value less than 100 percent, you are undersubscribing the bypass LSPs. By configuring a value greater than 100 percent, you are oversubscribing the bypass LSPs.

The ability to oversubscribe the bandwidth for the bypass LSPs makes it possible to more efficiently use network resources. You can configure the bandwidth for the bypass LSPs based on the average network load as opposed to the peak load.

To configure the amount of bandwidth subscribed for bypass LSPs, include the **subscription** statement:

```
subscription percentage {
  ct0 percentage;
  ct1 percentage;
  ct2 percentage;
  ct3 percentage;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Configuring Priority and Preemption for Bypass LSPs

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to release the bandwidth. You do this by preempting the existing LSP.

For more detailed information on configuring setup priority and reservation priority for LSPs, see [“Configuring Priority and Preemption for LSPs” on page 428](#).

To configure the bypass LSP’s priority and preemption properties, include the **priority** statement:

```
priority setup-priority reservation-priority;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring Node Protection or Link Protection for LSPs

When you configure node protection or link protection on a router or switch, bypass LSPs are created to the next-hop or next-next-hop routers (switches) for the LSPs traversing the router (switch). You must configure node protection or link protection for each LSP that you want protected. To extend protection along the entire path used by an LSP, you must configure protection on each router that the LSP traverses.

You can configure node protection or link protection for both static and dynamic LSPs.

To configure node protection on a router for a specified LSP, include the **node-link-protection** statement:

```
node-link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]

To configure link protection on a router for a specified LSP, include the [link-protection](#) statement:

```
link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]

**NOTE:** To complete the configuration of node or link protection, you must also configure link protection on all unidirectional RSVP interfaces that the LSPs traverse, as described in [“Configuring Link Protection on Interfaces Used by LSPs” on page 687](#).

## Configuring Inter-AS Node and Link Protection

---

To interoperate with other vendors' equipment, the Junos OS supports the record route object (RRO) node ID subobject for use in inter-AS link and node protection configurations. The RRO node ID subobject is defined in RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*. This functionality is enabled by default in Junos OS Release 9.4 and later.

If you have Juniper Networks routers running Junos OS Release 9.4 and later releases in the same MPLS-TE network as routers running Junos OS Release 8.4 and earlier releases, you might need to disable the RRO node ID subobject by configuring the **no-node-id-subobject** statement:

```
no-node-id-subobject;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

## RSVP Graceful Restart

---

RSVP graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

RSVP graceful restart is described in the following sections:

- [RSVP Graceful Restart Standard on page 697](#)
- [RSVP Graceful Restart Terminology on page 697](#)
- [RSVP Graceful Restart Operation on page 697](#)
- [Processing the Restart Cap Object on page 698](#)

## RSVP Graceful Restart Standard

RSVP graceful restart is described in RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions* (only Section 9, “Fault Handling”).

## RSVP Graceful Restart Terminology

### R

<b>Recovery time (in milliseconds)</b>	<p>Applies only when the control channel is up (the hello exchange is complete) before the restart time. Applies only to nodal faults.</p> <p>When a graceful restart is in progress, the time left to complete a recovery is advertised. At other times, this value is zero. The maximum advertised recovery time is 2 minutes (120,000 milliseconds).</p> <p>During the recovery time, a restarting node attempts to recover its lost states with assistance from its neighbors. The neighbor of the restarting node must send the path messages with the recovery labels to the restarting node within a period of one-half the recovery time. The restarting node considers its graceful restart complete after its advertised recovery time.</p>
<b>Restart time (in milliseconds)</b>	<p>The default value is 60,000 milliseconds (1 minute). The restart time is advertised in the hello message. The time indicates how long a neighbor should wait to receive a hello message from a restarting router before declaring that router dead and purging states.</p> <p>The Junos OS can override a neighbor’s advertised restart time if the time is greater than one-third the local restart time. For example, given the default restart time of 60 seconds, a router would wait 20 seconds or less to receive a hello message from a restarting neighbor. If the restart time is zero, the restarting neighbor can immediately be declared dead.</p>

## RSVP Graceful Restart Operation

For RSVP graceful restart to function, the feature must be enabled on the global routing instance. RSVP graceful restart can be disabled at the protocol level (for RSVP alone) or at the global level for all protocols.

RSVP graceful restart requires the following of a restarting router and the router’s neighbors:

- For the restarting router, RSVP graceful restart attempts to maintain the routes installed by RSVP and the allocated labels, so that traffic continues to be forwarded without disruption. RSVP graceful restart is done quickly enough to reduce or eliminate the impact on neighboring nodes.
- The neighboring routers must have RSVP graceful restart helper mode enabled, thus allowing them to assist a router attempting to restart RSVP.

An object called Restart Cap that is sent in RSVP hello messages advertises a node’s restart capability. The neighboring node sends a Recover Label object to the restarting

node to recover its forwarding state. This object is essentially the old label that the restarting node advertised before the node went down.

The following lists the RSVP graceful restart behaviors, which vary depending on the configuration and on which features are enabled:

- If you disable helper mode, the Junos OS does not attempt to help a neighbor restart RSVP. Any information that arrives with a Restart Cap object from a neighbor is ignored.
- When you enable graceful restart under the routing instance configuration, the router can restart gracefully with the help of its neighbors. RSVP advertises a Restart Cap object (RSVP RESTART) in hello messages in which restart and recovery times are specified (neither value is 0).
- If you explicitly disable RSVP graceful restart under the **[protocols rsvp]** hierarchy level, the Restart Cap object is advertised with restart and recovery times specified as 0. The restart of neighboring routers is supported (unless helper mode is disabled), but the router itself does not preserve the RSVP forwarding state and cannot recover its control state.
- If after a restart RSVP realizes that no forwarding state has been preserved, the Restart Cap object is advertised with restart and recovery times specified as 0.
- If graceful restart and helper mode are disabled, RSVP graceful restart is completely disabled. The router neither recognizes nor advertises the RSVP graceful restart objects.

You cannot explicitly configure values for the restart and recovery times.

Unlike other protocols, there is no way for RSVP to determine that it has completed a restart procedure, other than a fixed timeout. All RSVP graceful restart procedures are timer-based. A **show rsvp version** command might indicate that the restart is still in progress even if all RSVP sessions are back up and the routes are restored.

---

## Processing the Restart Cap Object

The following assumptions are made about a neighbor based on the Restart Cap object (assuming that a control channel failure can be distinguished unambiguously from a node restart):

- A neighbor that does not advertise the Restart Cap object in its hello messages cannot assist a router with state or label recovery, nor can it perform an RSVP graceful restart.
- After a restart, a neighbor advertising a Restart Cap object with a restart time equal to any value and a recovery time equal to 0 has not preserved its forwarding state. When a recovery time equals 0, the neighbor is considered dead and any states related to this neighbor are purged, regardless of the value of the restart time.
- After a restart, a neighbor advertising its recovery time with a value other than 0 can keep or has kept the forwarding state. If the local router is helping its neighbor with restart or recovery procedures, it sends a Recover Label object to this neighbor.

## Configuring RSVP Graceful Restart

The following RSVP graceful restart configurations are possible:

- Graceful restart and helper mode are both enabled (the default).
- Graceful restart is enabled but helper mode is disabled. A router configured in this way can restart gracefully, but cannot help a neighbor with its restart and recovery procedures.
- Graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully, but can help a restarting neighbor.
- Graceful restart and helper mode both are disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). The router behaves like a router that does not support RSVP graceful restart.

**NOTE:** In order to turn on RSVP graceful restart, you must set the global graceful restart timer to at least 180 seconds.

The following sections describe how to configure RSVP graceful restart:

- [Enabling Graceful Restart for All Routing Protocols on page 699](#)
- [Disabling Graceful Restart for RSVP on page 699](#)
- [Disabling RSVP Helper Mode on page 700](#)
- [Configuring the Maximum Helper Recovery Time on page 700](#)
- [Configuring the Maximum Helper Restart Time on page 700](#)

### Enabling Graceful Restart for All Routing Protocols

To enable graceful restart for RSVP, you need to enable graceful restart for all the protocols that support graceful restart on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

To enable graceful restart on the router, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems *logical-system-name* routing-options]**

### Disabling Graceful Restart for RSVP

By default, RSVP graceful restart and RSVP helper mode are enabled when you enable graceful restart. However, you can disable one or both of these capabilities.

To disable RSVP graceful restart and recovery, include the **disable** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level:

```
disable;
```

## Disabling RSVP Helper Mode

To disable RSVP helper mode, include the **helper-disable** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level:

```
helper-disable;
```

## Configuring the Maximum Helper Recovery Time

To configure the amount of time the router retains the state of its RSVP neighbors while they undergo a graceful restart, include the **maximum-helper-recovery-time** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to recover.

```
maximum-helper-recovery-time seconds;
```

## Configuring the Maximum Helper Restart Time

To configure the delay between when the router discovers that a neighboring router has gone down and when it declares the neighbor down, include the **maximum-helper-restart-time** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to restart.

```
maximum-helper-restart-time seconds;
```

---

## RSVP LSP Tunnels Overview

A Resource Reservation Protocol (RSVP) label-switched path (LSP) tunnel enables you to send RSVP LSPs inside other RSVP LSPs. This enables a network administrator to provide traffic engineering from one end of the network to the other. A useful application for this feature is to connect customer edge (CE) routers with provider edge (PE) routers by using an RSVP LSP, and then tunnel this edge LSP inside a second RSVP LSP traveling across the network core.

You should have a general understanding of MPLS and label switching concepts. For more information about MPLS, see the *Junos MPLS Applications Configuration Guide*.

An RSVP LSP tunnel adds the concept of a forwarding adjacency, similar to the one used for generalized Multiprotocol Label Switching (GMPLS). (For more information about GMPLS, see *Junos GMPLS Feature Guide*.)

The forwarding adjacency creates a tunneled path for sending data between peer devices in an RSVP LSP network. Once a forwarding adjacency LSP (FA-LSP) has been established, other LSPs can be sent over the FA-LSP by using Constrained Shortest Path

First (CSPF), Link Management Protocol (LMP), Open Shortest Path First (OSPF), and RSVP.

To enable an RSVP LSP tunnel, the Junos OS uses the following mechanisms:

- LMP—Originally designed for GMPLS, LMP establishes forwarding adjacencies between RSVP LSP tunnel peers, and maintains and allocates resources for traffic engineering links.
- OSPF extensions—OSPF was designed to route packets to physical and logical interfaces related to a Physical Interface Card (PIC). This protocol has been extended to route packets to virtual peer interfaces defined in an LMP configuration.
- RSVP-TE extensions—RSVP-TE was designed to signal the setup of packet LSPs to physical interfaces. The protocol has been extended to request path setup for packet LSPs traveling to virtual peer interfaces defined in an LMP configuration.

**NOTE:** Beginning with Junos OS Release 15.1, multi-instance support is extended to MPLS RSVP-TE. This support is available only for virtual router instance type. A router can create and participate in multiple independent TE topology partitions, which allows each partitioned TE domain to scale independently. Multi-instance RSVP-TE provides the flexibility to hand pick the control-plane entities that need to be instance-aware, for example, a router can participate in multiple TE instances while still running a single BGP instance.

The Junos OS implementation of MPLS RSVP-TE is scaled to enhance the usability, visibility, configuration, and troubleshooting of LSPs in Junos OS Release 16.1.

These enhancements make the RSVP-TE configuration easier at scale by:

- Ensuring the LSP data-plane readiness during LSP resignaling before traffic traverses the LSP with the RSVP-TE LSP self-ping mechanism.

An LSP should not start to carry traffic unless it is known to have been programmed in the data plane. Data exchange in the LSP data plane, such as LSP ping requests, happens at the ingress router before switching traffic to an LSP, or to its MBB instance. In large networks, this traffic can overwhelm an LSP egress router, as the egress LSP needs to respond to the LSP ping requests. The LSP self-ping mechanism enables the ingress LER to create LSP ping response messages and send them over the LSP data plane. On receiving these messages, the egress LER forwards them to the ingress, indicating the liveliness of the LSP data plane. This ensures that the LSP does not start to carry traffic before the data plane has been programmed.

- Removing the current hard limit of 64K LSPs on an ingress router and scaling the total number of LSPs with RSVP-TE signaled LSPs. There can be up to 64K LSPs configured on a per-egress basis. Earlier, this limit was the aggregate number of LSPs that could be configured on the ingress LER.

- Preventing abrupt tearing down of LSPs by the ingress router because of delay in signaling the LSP at the transit routers.
- Enabling a flexible view of LSP data-sets to facilitate LSP characteristic data visualization.

**NOTE:** Starting with Junos OS Release 17.4, a default timer of 1800 seconds for self-ping is introduced.

The following limitations exist for LSP hierarchies:

- Circuit cross-connect (CCC)-based LSPs are not supported.
- Graceful restart is not supported.
- Link protection is not available for FA-LSPs or at the egress point of the forwarding adjacency.
- Point-to-multipoint LSPs are not supported across FA-LSPs.

## Example: RSVP LSP Tunnel Configuration

**Figure 68: RSVP LSP Tunnel Topology Diagram**

Figure 68 on page 702 shows an end-to-end RSVP LSP called **e2e\_lsp\_r0r5** that originates on Router 0 and terminates on Router 5. In transit, this LSP traverses the FA-LSP **fa\_lsp\_r1r4**. The return path is represented by the end-to-end RSVP LSP **e2e\_lsp\_r5r0** that travels over the FA-LSP **fa\_lsp\_r4r1**.

On Router 0, configure the end-to-end RSVP LSP that travels to Router 5. Use a strict path that traverses Router 1 and the LMP traffic engineering link traveling from Router 1 to Router 4.

**Router 0**

```
[edit]
interfaces {
  so-0/0/3 {
    unit 0 {
      family inet {
        address 10.1.2.1/30;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.41.222/32;
      }
      family mpls;
    }
  }
}
routing-options {
  forwarding-table {
    export pplb;
  }
}

    interface all;
    interface fxp0.0 {
      disable;
    }
  }
  mpls {
    admin-groups {
      fa 1;
      backup 2;
      other 3;
    }
    label-switched-path e2e_lsp_r0r5 { # An end-to-end LSP traveling to Router 5.
      to 10.255.41.221;
      bandwidth 30k;
      primary path-fa; # Reference the requested path here.
    }
    path path-fa { # Configure the strict path here.
      10.1.2.2 strict;
      172.16.30.2 strict; # This traverses the TE link heading to Router 4.
    }
    interface all;
    interface fxp0.0 {
      disable;
    }
  }
}
```

```

interface so-3/2/1.0 {
  admin-group other;
}
interface so-0/0/3.0 {
  admin-group other;
}
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface fxp0.0 {
      disable;
    }
    interface all;
  }
}
}
policy-options {
  policy-statement pplb {
    then {
      load-balance per-packet;
    }
  }
}
}

```

On Router 1, configure an FA-LSP to reach Router 4. Establish an LMP traffic engineering link and LMP peer relationship with Router 4. Reference the FA-LSP in the traffic engineering link and add the peer interface into both OSPF and RSVP.

When the return path end-to-end LSP arrives at Router 1, the routing platform performs a routing lookup and can forward traffic to Router 0. Make sure you configure OSPF correctly between Routers 0 and 1.

```

On Router 4, configure a return path FA-LSP to reach Router 1. Establish an LMP traffic engineering link and LMP peer relationship with Router 1. Reference the FA-LSP in the traffic engineering link and add the peer interface into both OSPF and RSVP.

When the initial end-to-end LSP arrives at Router 4, the routing platform performs a routing lookup and can forward traffic to Router 5. Make sure you configure OSPF correctly between Router 4 and Router 5.

Router 4

```

On Router 5, configure the return path end-to-end RSVP LSP that travels to Router 0. Use a strict path that traverses Router 4 and the LMP traffic engineering link traveling from Router 4 to Router 1.

}

```

## Verifying Your Work

To verify that your RSVP LSP tunnel is working correctly, issue the following commands:

- **show ted database (extensive)**
- **show rsvp session name (extensive)**
- **show link-management**
- **show link-management te-link name (detail)**

To see these commands used with the configuration example, see the following sections:

- [Router 0 on page 715](#)
- [Router 1 on page 719](#)

### Router 0

On Router 0, you can verify that the FA-LSPs appear as valid paths in the traffic engineering database. In this case, look for the paths from Router 1 (10.255.41.216) and Router 4 (10.255.41.217) that reference the LMP traffic engineering link addresses of 172.16.30.1 and 172.16.30.2. You can also issue the **show rsvp session extensive** command to look for the path of the end-to-end LSP as it travels to Router 5 over the FA-LSP.

```
user@router0> show ted database
```

```

## Configuring Link Management Protocol Peers

After you set up traffic engineering links, configure LMP network peers with the **peer** *peer-name* statement at the **[edit protocols link-management]** hierarchy level. A peer is the network device with which your routing platform communicates and establishes an FA-LSP. Designate a peer name, configure the peer router ID as the address (often a loopback address), and apply the traffic engineering link to be associated with this peer. Remember to configure both sides of a peering relationship to enable bidirectional communication.

Unlike GMPLS, you must not configure a control channel for a peer. If you include a control channel, the commit operation fails.

```
[edit]
protocols {
  link-management {
    peer peer-name { # Configure the name of your network peer.
      address ip-address; # Include the router ID of the peer.
      te-link te-link-name; # Assign a TE link to this peer.
    }
  }
}
```

**Related Documentation**

- [Example: RSVP LSP Tunnel Configuration on page 702](#)

## Configuring Link Management Protocol Traffic Engineering Links

To begin your RSVP LSP tunnel configuration, configure LMP traffic engineering links on both the ingress and egress routing platforms. Because traffic engineering links define a unidirectional connection between peer devices, you must configure traffic engineering links in both directions between peers to enable the bidirectional transport of packets.

To configure traffic engineering links in LMP, include the **te-link** *te-link-name* statement at the **[edit protocols link-management]** hierarchy level. Define the traffic engineering link options shown below, especially the label-switched path to be used as the FA-LSP to reach the peer. Optionally, you can specify the traffic engineering metric for the traffic engineering link (TE link). By default, the traffic engineering metric is derived from the CSPF computation.

```
[edit]
protocols {
  link-management {
    te-link te-link-name { # Name of the TE link.
      label-switched-path lsp-name; # LSP used for the forwarding adjacency.
      local-address ip-address; # Local IP address associated with the TE link.
      remote-address ip-address; # Remote IP address mapped to the TE link.
      te-metric value; # Traffic engineering metric used for the TE link.
    }
  }
}
```

```
}
```

**Related Documentation** • [Example: RSVP LSP Tunnel Configuration on page 702](#)

## Configuring Peer Interfaces in OSPF and RSVP

After you establish LMP peers, you must add peer interfaces to OSPF and RSVP. A peer interface is a virtual interface used to support the control adjacency between two peers.

The peer interface name must match the **peer *peer-name*** statement configured in LMP at the **[edit protocols link-management]** hierarchy level. Because actual protocol packets are sent and received by peer interfaces, the peer interfaces can be signaled and advertised to peers like any other physical interface configured for OSPF and RSVP. To configure OSPF routing for LMP peers, include the **peer-interface** statement at the **[edit protocols ospf area *area-number*]** hierarchy level. To configure RSVP signaling for LMP peers, include the **peer-interface** statement at the **[edit protocols rsvp]** hierarchy level.

```
[edit]
protocols {
  rsvp {
    peer-interface peer-name { # Configure the name of your LMP peer.
    }
  }
  ospf {
    area area-number {
      peer-interface peer-name { # Configure the name of your LMP peer.
      }
    }
  }
}
```

**Related Documentation** • [Example: RSVP LSP Tunnel Configuration on page 702](#)

## Defining Label-Switched Paths for the FA-LSP

Next, define your FA-LSP by including the **label-switched-path** statement at the **[edit protocols mpls]** hierarchy level. Include the router ID of the peer in the **to** statement at the **[edit protocols mpls label-switched-path]** hierarchy level. Because packet LSPs are unidirectional, you must create one FA-LSP to reach the peer and a second FA-LSP to return from the peer.

```
[edit]
protocols {
  mpls {
    label-switched-path lsp-name {
      from ip-address;
      to ip-address;
    }
  }
}
```

```

    primary path-name;
    secondary path-name;
    no-cspf; # This statement to disable CSPF is optional.
  }
}

```

Related Documentation • [Example: RSVP LSP Tunnel Configuration on page 702](#)

## Establishing FA-LSP Path Information

When you configure explicit LSP paths for an FA-LSP, you must use the traffic engineering link remote address as your next-hop address. When CSPF is supported, you can use any path option you wish. However, when CSPF is disabled with the **no-cspf** statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level, you must use strict paths.

```

[edit]
protocols {
  mpls {
    path path-name {
      next-hop-address (strict | loose);
    }
  }
}

```

**NOTE:** If the end-to-end LSP originates on the same routing platform as the FA-LSP, you must disable CSPF and use strict paths.

Related Documentation • [Example: RSVP LSP Tunnel Configuration on page 702](#)

## Option: Tearing Down RSVP LSPs Gracefully

You can tear down an RSVP LSP in a two-step process that gracefully withdraws the RSVP session used by the LSP. For all neighbors that support graceful teardown, a request for the teardown is sent by the routing platform to the destination endpoint for the LSP and all RSVP neighbors in the path. The request is included within the **ADMIN\_STATUS** field of the RSVP packet. When neighbors receive the request, they prepare for the RSVP session to be withdrawn. A second message is sent by the routing platform to complete the teardown of the RSVP session. If a neighbor does not support graceful teardown, the request is handled as a standard session teardown rather than a graceful one.

To perform a graceful teardown of an RSVP session, issue the **clear rsvp session gracefully** command. Optionally, you can specify the source and destination address of the RSVP session, the LSP identifier of the RSVP sender, and the tunnel identifier of the RSVP

session. To use these qualifiers, include the **connection-source**, **connection-destination**, **lsp-id**, and **tunnel-id** options when you issue the **clear rsvp session gracefully** command.

You can also configure the amount of time that the routing platform waits for neighbors to receive the graceful teardown request before initiating the actual teardown by including the **graceful-deletion-timeout** statement at the **[edit protocols rsvp]** hierarchy level. The default graceful deletion timeout value is 30 seconds, with a minimum value of 1 second and a maximum value of 300 seconds. To view the current value configured for graceful deletion timeout, issue the **show rsvp version** operational mode command.

## LDP Introduction

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to data link layer-switched paths.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding), or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

## Understanding the LDP Signaling Protocol

---

LDP is a signaling protocol that runs on a device configured for MPLS support. The successful configuration of both MPLS and LDP initiates the exchange of TCP packets across the LDP interfaces. The packets establish TCP-based LDP sessions for the exchange of MPLS information within the network. Enabling both MPLS and LDP on the appropriate interfaces is sufficient to establish LSPs.

LDP is a simple, fast-acting signaling protocol that automatically establishes LSP adjacencies within an MPLS network. Routers then share LSP updates such as hello packets and LSP advertisements across the adjacencies. Because LDP runs on top of an IGP such as IS-IS or OSPF, you must configure LDP and the IGP on the same set of interfaces. After both are configured, LDP begins transmitting and receiving LDP messages through all LDP-enabled interfaces. Because of LDP's simplicity, it cannot perform the true traffic engineering which RSVP can perform. LDP does not support bandwidth reservation or traffic constraints.

When you configure LDP on a label-switching router (LSR), the router begins sending LDP discovery messages out all LDP-enabled interfaces. When an adjacent LSR receives LDP discovery messages, it establishes an underlying TCP session. An LDP session is then created on top of the TCP session. The TCP three-way handshake ensures that the LDP session has bidirectional connectivity. After they establish the LDP session, the LDP neighbors maintain, and terminate, the session by exchanging messages. LDP advertisement messages allow LSRs to exchange label information to determine the next hops within a particular LSP. Any topology changes, such as a router failure, generate LDP notifications that can terminate the LDP session or generate additional LDP advertisements to propagate an LSP change.

## Example: Configuring LDP-Signaled LSPs

---

This example shows how to create and configure LDP instances within an MPLS network.

- [Requirements on page 728](#)
- [Overview on page 728](#)
- [Configuration on page 728](#)
- [Verification on page 730](#)

## Requirements

Before you begin:

- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.
- Configure an IGP across your network. (The LDP configuration is added to the existing IGP configuration and included in the MPLS configuration.)
- Configure a network to use LDP for LSP establishment by enabling MPLS on all transit interfaces in the MPLS network.

**NOTE:** Because LDP runs on top of an IGP such as IS-IS or OSPF, you must configure LDP and the IGP on the same set of interfaces.

## Overview

To configure LDP-signaled LSPs, you must enable the MPLS family on all transit interfaces in the MPLS network and include all the transit interfaces under the `[protocols mpls]` and `[protocols ldp]` hierarchy levels.

In this example, you enable the MPLS family and create an LDP instance on all the transit interfaces. Additionally, you enable the MPLS process on all the transit interfaces in the MPLS network. In this example, you configure a sample network as shown in [Figure 69 on page 728](#).

Figure 69: Typical LDP-Signaled LSP

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level and then enter **commit** from configuration mode.

For Router R1, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
```

For Router R2, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
set interfaces ge-0/0/1 unit 0 family mpls
set protocols mpls ge-0/0/1 unit 0
set protocols ldp interface ge-0/0/0.1 unit 0
```

For Router R3, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
```

#### Step-by-Step Procedure

To enable LDP instances within an MPLS network:

1. Enable the MPLS family on the transit interface on Router R1.

```
[edit]
user@R1# set interfaces ge-0/0/0 unit 0 family mpls
```

2. Enable the MPLS process on the transit interface.

```
[edit]
user@R1# set protocols mpls interface ge-0/0/0 unit 0
```

3. Create the LDP instance on the transit interface.

```
[edit]
user@R1# set protocols ldp interface ge-0/0/0 unit 0
```

**Results** Confirm your configuration by entering the **show** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@R1# show
...
interfaces {
  ge-0/0/0 {
    unit 0 {
```

```
        family inet {
            address 10.100.37.20/24;
        }
        family mpls;
    }
}
...
protocols {
    mpls {
        interface all;
    }
    ldp {
        interface ge-0/0/0.0;
    }
}
```

If you are done configuring the device, enter the **commit** command from the configuration mode to activate the configuration.

## Verification

Confirm that the configuration is working properly.

## Supported LDP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for LDP.

- RFC 3212, *Constraint-Based LSP Setup using LDP*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- Internet draft draft-napierala-mpls-targeted-mldp-01.txt, *Using LDP Multipoint Extensions on Targeted LDP Sessions*

The following RFCs do not define standards, but provide information about LDP. The IETF classifies them as “Informational.”

- RFC 3215, *LDP State Machine*
- RFC 5036, *LDP Specification*

For the following features described in the indicated sections of the RFC, Junos OS supports one of the possible modes but not the others:

- Label distribution control (section 2.6.1): Ordered mode is supported, but not Independent mode.
- Label retention (section 2.6.2): Liberal mode is supported, but not Conservative mode.

- Label advertisement (section 2.6.3): Both Downstream Unsolicited mode and Downstream on Demand mode are supported.
  - RFC 5443, *LDP IGP Synchronization*
  - RFC 6826, *Multipoint LDP In-Band Signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*
- Junos OS support limited to point-to-multipoint extensions for LDP.

## Junos OS LDP Protocol Implementation

The Junos OS implementation of LDP supports LDP version 1. The Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. The Junos OS allows an MPLS tunnel next hop to all egress routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge resolves to an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

## LDP Operation

You must configure LDP for each interface on which you want LDP to run. LDP creates LSP trees rooted at each egress router for the router ID address that is the subsequent BGP next hop. The ingress point is at every router running LDP. This process provides an inet.3 route to every egress router. If BGP is running, it will attempt to resolve next hops by using the inet.3 table first, which binds most, if not all, of the BGP routes to MPLS tunnel next hops.

Two adjacent routers running LDP become neighbors. If the two routers are connected by more than one interface, they become neighbors on each interface. When LDP routers become neighbors, they establish an LDP session to exchange label information. If per-router labels are in use on both routers, only one LDP session is established between them, even if they are neighbors on multiple interfaces. For this reason, an LDP session is not related to a particular interface.

LDP operates in conjunction with a unicast routing protocol. LDP installs LSPs only when both LDP and the routing protocol are enabled. For this reason, you must enable both LDP and the routing protocol on the same set of interfaces. If this is not done, LSPs might not be established between each egress router and all ingress routers, which might result in loss of BGP-routed traffic.

You can apply policy filters to labels received from and distributed to other routers through LDP. Policy filters provide you with a mechanism to control the establishment of LSPs.

For LDP to run on an interface, MPLS must be enabled on a logical interface on that interface. For more information, see the *Logical Interfaces*.

## LDP Message Types

LDP uses the message types described in the following sections to establish and remove mappings and to report errors. All LDP messages have a common structure that uses a type, length, and value (TLV) encoding scheme.

- [Discovery Messages on page 732](#)
- [Session Messages on page 732](#)
- [Advertisement Messages on page 733](#)
- [Notification Messages on page 733](#)

### Discovery Messages

Discovery messages announce and maintain the presence of a router in a network. Routers indicate their presence in a network by sending hello messages periodically. Hello messages are transmitted as UDP packets to the LDP port at the group multicast address for all routers on the subnet.

LDP uses the following discovery procedures:

- Basic discovery—A router periodically sends LDP link hello messages through an interface. LDP link hello messages are sent as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Extended discovery—LDP sessions between routers not directly connected are supported by LDP extended discovery. A router periodically sends LDP targeted hello messages to a specific address. Targeted hello messages are sent as UDP packets addressed to the LDP discovery port at the specific address. The targeted router decides whether to respond to or ignore the targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages to the initiating router.

### Session Messages

Session messages establish, maintain, and terminate sessions between LDP peers. When a router establishes a session with another router learned through the hello message, it uses the LDP initialization procedure over TCP transport. When the initialization procedure is completed successfully, the two routers are LDP peers and can exchange advertisement messages.

## Advertisement Messages

Advertisement messages create, change, and delete label mappings for forwarding equivalence classes (FECs). Requesting a label or advertising a label mapping to a peer is a decision made by the local router. In general, the router requests a label mapping from a neighboring router when it needs one and advertises a label mapping to a neighboring router when it wants the neighbor to use a label.

## Notification Messages

Notification messages provide advisory information and signal error information. LDP sends notification messages to report errors and other events of interest. There are two kinds of LDP notification messages:

- Error notifications, which signal fatal errors. If a router receives an error notification from a peer for an LDP session, it terminates the LDP session by closing the TCP transport connection for the session and discarding all label mappings learned through the session.
- Advisory notifications, which pass information to a router about the LDP session or the status of some previous message received from the peer.

## Discovery Messages

---

Discovery messages announce and maintain the presence of a router in a network. Routers indicate their presence in a network by sending hello messages periodically. Hello messages are transmitted as UDP packets to the LDP port at the group multicast address for all routers on the subnet.

LDP uses the following discovery procedures:

- Basic discovery—A router periodically sends LDP link hello messages through an interface. LDP link hello messages are sent as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Extended discovery—LDP sessions between routers not directly connected are supported by LDP extended discovery. A router periodically sends LDP targeted hello messages to a specific address. Targeted hello messages are sent as UDP packets addressed to the LDP discovery port at the specific address. The targeted router decides whether to respond to or ignore the targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages to the initiating router.

## Session Messages

---

Session messages establish, maintain, and terminate sessions between LDP peers. When a router establishes a session with another router learned through the hello message, it uses the LDP initialization procedure over TCP transport. When the initialization procedure

is completed successfully, the two routers are LDP peers and can exchange advertisement messages.

## Advertisement Messages

---

Advertisement messages create, change, and delete label mappings for forwarding equivalence classes (FECs). Requesting a label or advertising a label mapping to a peer is a decision made by the local router. In general, the router requests a label mapping from a neighboring router when it needs one and advertises a label mapping to a neighboring router when it wants the neighbor to use a label.

## Notification Messages

---

Notification messages provide advisory information and signal error information. LDP sends notification messages to report errors and other events of interest. There are two kinds of LDP notification messages:

- Error notifications, which signal fatal errors. If a router receives an error notification from a peer for an LDP session, it terminates the LDP session by closing the TCP transport connection for the session and discarding all label mappings learned through the session.
- Advisory notifications, which pass information to a router about the LDP session or the status of some previous message received from the peer.

## Tunneling LDP LSPs in RSVP LSPs

---

You can tunnel LDP LSPs over RSVP LSPs. The following sections describe how tunneling of LDP LSPs in RSVP LSPs works:

- [Tunneling LDP LSPs in RSVP LSPs Overview on page 734](#)
- [Label Operations on page 736](#)

## Tunneling LDP LSPs in RSVP LSPs Overview

---

If you are using RSVP for traffic engineering, you can run LDP simultaneously to eliminate the distribution of external routes in the core. The LSPs established by LDP are tunneled through the LSPs established by RSVP. LDP effectively treats the traffic-engineered LSPs as single hops.

When you configure the router to run LDP across RSVP-established LSPs, LDP automatically establishes sessions with the router at the other end of the LSP. LDP control packets are routed hop-by-hop, rather than carried through the LSP. This routing allows you to use simplex (one-way) traffic-engineered LSPs. Traffic in the opposite direction flows through LDP-established LSPs that follow unicast routing rather than through traffic-engineered tunnels.

If you configure LDP over RSVP LSPs, you can still configure multiple OSPF areas and IS-IS levels in the traffic engineered core and in the surrounding LDP cloud.

Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance. This allows splitting of a single routing and MPLS domain into multiple domains so that each domain can be scaled independently. BGP labeled unicast can be used to stitch these domains for service forwarding equivalence classes (FECs). Each domain uses intra-domain LDP-over-RSVP LSP for MPLS forwarding.

**NOTE:** With the introduction of the multi-instance support for LDP-over-RSVP LSPs, you cannot enable MPLS on an interface that is already assigned to another routing instance. Adding an interface that is part of another routing instance at the `[edit protocols mpls]` hierarchy level, throws a configuration error at the time of commit.

## Benefits of Tunneling LDP LSPs in RSVP LSPs

Tunneling LDP LSPs in RSVP LSPs provides the following benefits:

- Provides convergence of different traffic types such as IPv4, IPv6, unicast, and multicast across Layer 2 and Layer 3 VPNs.
- Enables flexible access connectivity options that can accommodate multiple topologies, different protocols, and multiple administrative boundaries.
- Enables secure interworking among multiple providers.
- Enables provision of differentiated services on a per customer basis because RSVP-TE supports traffic engineering, bandwidth guarantees, and link and node redundancy capabilities.
- Reduces the number of LSPs required in the core, which reduces the resource requirements of the protocols and routers as well as reducing convergence time.
- Provides cost-efficient rollouts with minimal network disruption because the LSPs are built using point-to-point TE tunnels to directly attached neighbors. These TE tunnels only go to the next hop, not end to end. Then when LDP is run over those tunnels, the sessions are built to the directly connected neighbor. When there is a change in the network, such as adding a new node, the directly connected neighbors of the new node have RSVP and LDP sessions. Thus, the RSVP LSPs are only to the next hop, and LDP takes care of advertising labels for the new addresses.

### Release History Table

Release	Description
15.1	Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance.

### Related Documentation

## Label Operations

Figure 70 on page 736 depicts an LDP LSP being tunneled through an RSVP LSP. (For definitions of label operations, see “MPLS Label Overview” on page 329.) The shaded inner oval represents the RSVP domain, whereas the outer oval depicts the LDP domain. RSVP establishes an LSP through routers B, C, D, and E, with the sequence of labels L3, L4. LDP establishes an LSP through Routers A, B, E, F, and G, with the sequence of labels L1, L2, L5. LDP views the RSVP LSP between Routers B and E as a single hop.

When the packet arrives at Router A, it enters the LSP established by LDP, and a label (L1) is pushed onto the packet. When the packet arrives at Router B, the label (L1) is swapped with another label (L2). Because the packet is entering the traffic-engineered LSP established by RSVP, a second label (L3) is pushed onto the packet.

This outer label (L3) is swapped with a new label (L4) at the intermediate router (C) within the RSVP LSP tunnel, and when the penultimate router (D) is reached, the top label is popped. Router E swaps the label (L2) with a new label (L5), and the penultimate router for the LDP-established LSP (F) pops the last label.

Figure 70: Swap and Push When LDP LSPs Are Tunneled Through RSVP LSPs

Figure 71 on page 737 depicts a double push label operation (L1L2). A double push label operation is used when the ingress router (A) for both the LDP LSP and the RSVP LSP tunneled through it is the same device. Note that Router D is the penultimate hop for the LDP-established LSP, so L2 is popped from the packet by Router D.

Figure 71: Double Push When LDP LSPs Are Tunneled Through RSVP LSPs

## LDP Session Protection

LDP session protection is based on the LDP targeted hello functionality defined in RFC 5036, *LDP Specification*, and is supported by the Junos OS as well as the LDP implementations of most other vendors. It involves sending unicast User Datagram Protocol (UDP) hello packets to a remote neighbor address and receiving similar packets from the neighbor router.

If you configure LDP session protection on a router, the LDP sessions are maintained as follows:

1. An LDP session is established between a router and a remote neighboring router.
2. If all of the direct links between the routers go down, the LDP session remains up so long as there is IP connectivity between the routers based on another connection over the network.
3. When the direct link between the routers is reestablished, the LDP session is not restarted. The routers simply exchange LDP hellos with each other over the direct link. They can then begin forwarding LDP-signaled MPLS packets using the original LDP session.

By default, LDP targeted hellos are set to the remote neighbor so long as the LDP session is up, even if there are no more link neighbors to that router. You can also specify the duration you would like to maintain the remote neighbor connection in the absence of link neighbors. When the last link neighbor for a session goes down, the Junos OS starts an LDP session protection timer. If this timer expires before any of the link neighbors come back up, the remote neighbor connection is taken down and the LDP session is terminated. If you configure a different value for the timer while it is currently running, the Junos OS updates the timer to the specified value without disrupting the current state of the LDP session.

## LDP Native IPv6 Support Overview

---

IPv6 connectivity often relies on tunneling IPv6 over an IPv4 MPLS core with IPv4-signaled MPLS label-switched paths (LSPs). This requires the IPv4-signaled LSPs to be configured statically or established dynamically by IPv6 provider edge routers. Because of the growing demand of IPv6, it has become imperative to deploy an IPv6 MPLS core with an IPv6-signaled LSP to provide IPv6 connectivity. In Junos OS, LDP is supported in an IPv6 network only, and in an IPv6/IPv4 dual-stack network as described in *RFC 7552*. Apart from providing a single session for both IPv4 and IPv6 networks, Junos OS LDP supports separate IPv4 sessions for IPv4 only, and IPv6 sessions for IPv6 only.

You can configure the address family as **inet** for IPv4 or **inet6** for IPv6, or both. If the family address is not configured, then the default address of family inet is enabled. When both IPv4 and IPv6 are configured, you can use the **transport-preference** statement to configure the preferred transport to be either **IPv4** or **IPv6**. Based on the preference, LDP attempts to establish a TCP connection using IPv4 or IPv6. By default, IPv6 is selected. The **dual-transport** statement allows Junos OS LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The **inet-lsr-id** and **inet6-lsr-id** IDs are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

## Longest Match Support for LDP Overview

---

LDP is often used to establish MPLS label-switched paths (LSPs) throughout a complete network domain using an IGP such as OSPF or IS-IS. In such a network, all links in the domain have IGP adjacencies as well as LDP adjacencies. LDP establishes the LSPs on the shortest path to a destination as determined by IGP. In Junos OS, the LDP implementation does an exact match lookup on the IP address of the forwarding equivalence class (FEC) in the routing information base (RIB) or IGP routes for label mapping. This exact mapping requires MPLS end-to-end LDP endpoint IP addresses to be configured in all the label edge routers (LERs). This defeats the purpose of IP hierarchical design or default routing in access devices. Configuring **longest-match** allows LDP to set up LSP based on the routes aggregated or summarized across OSPF areas or IS-IS levels in the inter-domain.

### Related Documentation

- [longest-match on page 2138](#)
- [Example: Configuring Longest Match for LDP on page 744](#)
- [Configuring Longest Match for LDP on page 743](#)

## Minimum LDP Configuration

To enable LDP with minimal configuration:

1. Enable all relevant interfaces under family MPLS. In the case of directed LDP, the loopback interface needs to be enabled with family MPLS.
2. (Optional) Configure the relevant interfaces under the **[edit protocol mpls]** hierarchy level.
3. Enable LDP on a single interface, include the **ldp** statement and specify the interface using the **interface** statement.

This is the minimum LDP configuration. All other LDP configuration statements are optional.

```
ldp {
  interface interface-name;
}
```

To enable LDP on all interfaces, specify **all** for *interface-name*.

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

Related Documentation • [ldp on page 2358](#)

## Enabling and Disabling LDP

LDP is routing-instance-aware. To enable LDP on a specific interface, include the following statements:

```
ldp {
  interface interface-name;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

To enable LDP on all interfaces, specify **all** for *interface-name*.

If you have configured interface properties on a group of interfaces and want to disable LDP on one of the interfaces, include the **interface** statement with the **disable** option:

```
interface interface-name {
  disable;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Configuring the LDP Timer for Hello Messages

---

LDP hello messages enable LDP nodes to discover one another and to detect the failure of a neighbor or the link to the neighbor. Hello messages are sent periodically on all interfaces where LDP is enabled.

There are two types of LDP hello messages:

- Link hello messages—Sent through the LDP interface as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Targeted hello messages—Sent as UDP packets addressed to the LDP discovery port at a specific address. Targeted hello messages are used to support LDP sessions between routers that are not directly connected. A targeted router determines whether to respond or ignore a targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages back to the initiating router.

By default, LDP sends hello messages every 5 seconds for link hello messages and every 15 seconds for targeted hello messages. You can configure the LDP timer to alter how often both types of hello messages are sent. However, you cannot configure a time for the LDP timer that is greater than the LDP hold time. For more information, see [“Configuring the Delay Before LDP Neighbors Are Considered Down” on page 741](#).

## Configuring the LDP Timer for Link Hello Messages

To modify how often LDP sends link hello messages, specify a new link hello message interval for the LDP timer using the **hello-interval** statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the LDP Timer for Targeted Hello Messages

To modify how often LDP sends targeted hello messages, specify a new targeted hello message interval for the LDP timer by configuring the **hello-interval** statement as an option for the **targeted-hello** statement:

```
targeted-hello {  
    hello-interval seconds;  
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

## Configuring the Delay Before LDP Neighbors Are Considered Down

The hold time determines how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. The values sent by each neighbor do not have to match.

The hold time should normally be at least three times the hello interval. The default is 15 seconds for link hello messages and 45 seconds for targeted hello messages. However, it is possible to configure an LDP hold time that is close to the value for the hello interval.

**NOTE:** By configuring an LDP hold time close to the hello interval (less than three times the hello interval), LDP neighbor failures might be detected more quickly. However, this also increases the possibility that the router might declare an LDP neighbor down that is still functioning normally. For more information, see [“Configuring the LDP Timer for Hello Messages” on page 740](#).

The LDP hold time is also negotiated automatically between LDP peers. When two LDP peers advertise different LDP hold times to one another, the smaller value is used. If an LDP peer router advertises a shorter hold time than the value you have configured, the peer router’s advertised hold time is used. This negotiation can affect the LDP keepalive interval as well.

If the local LDP hold time is not shortened during LDP peer negotiation, the user-configured keepalive interval is left unchanged. However, if the local hold time is reduced during peer negotiation, the keepalive interval is recalculated. If the LDP hold time has been reduced during peer negotiation, the keepalive interval is reduced to one-third of the new hold time value. For example, if the new hold-time value is 45 seconds, the keepalive interval is set to 15 seconds.

This automated keepalive interval calculation can cause different keepalive intervals to be configured on each peer router. This enables the routers to be flexible in how often they send keepalive messages, because the LDP peer negotiation ensures they are sent more frequently than the LDP hold time.

When you reconfigure the hold-time interval, changes do not take effect until after the session is reset. The hold time is negotiated when the LDP peering session is initiated and cannot be renegotiated as long as the session is up (required by RFC 5036, *LDP Specification*). To manually force the LDP session to reset, issue the **clear ldp session** command.

## Configuring the LDP Hold Time for Link Hello Messages

To modify how long an LDP node should wait for a link hello message before declaring the neighbor down, specify a new time in seconds using the **hold-time** statement:

```
hold-time seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the LDP Hold Time for Targeted Hello Messages

To modify how long an LDP node should wait for a targeted hello message before declaring the neighbor down, specify a new time in seconds using the **hold-time** statement as an option for the **targeted-hello** statement:

```
targeted-hello {  
  hold-time seconds;  
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

## Enabling Strict Targeted Hello Messages for LDP

---

Use strict targeted hello messages to prevent LDP sessions from being established with remote neighbors that have not been specifically configured. If you configure the **strict-targeted-hellos** statement, an LDP peer does not respond to targeted hello messages coming from a source that is not one of its configured remote neighbors. Configured remote neighbors can include:

- Endpoints of RSVP tunnels for which LDP tunneling is configured
- Layer 2 circuit neighbors

If an unconfigured neighbor sends a hello message, the LDP peer ignores the message and logs an error (with the **error** trace flag) indicating the source. For example, if the LDP peer received a targeted hello from the Internet address 10.0.0.1 and no neighbor with this address is specifically configured, the following message is printed to the LDP log file:

```
LDP: Ignoring targeted hello from 10.0.0.1
```

To enable strict targeted hello messages, include the **strict-targeted-hellos** statement:

```
strict-targeted-hellos;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the Interval for LDP Keepalive Messages

---

The keepalive interval determines how often a message is sent over the session to ensure that the keepalive timeout is not exceeded. If no other LDP traffic is sent over the session in this much time, a keepalive message is sent. The default is 10 seconds. The minimum value is 1 second.

The value configured for the keepalive interval can be altered during LDP session negotiation if the value configured for the LDP hold time on the peer router is lower than

the value configured locally. For more information, see [“Configuring the Delay Before LDP Neighbors Are Considered Down” on page 741](#).

To modify the keepalive interval, include the **keepalive-interval** statement:

```
keepalive-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the LDP Keepalive Timeout

After an LDP session is established, messages must be exchanged periodically to ensure that the session is still working. The keepalive timeout defines the amount of time that the neighbor LDP node waits before deciding that the session has failed. This value is usually set to at least three times the keepalive interval. The default is 30 seconds.

To modify the keepalive interval, include the **keepalive-timeout** statement:

```
keepalive-timeout seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The value configured for the **keepalive-timeout** statement is displayed as the hold time when you issue the **show ldp session detail** command.

## Configuring Longest Match for LDP

In order to allow LDP to learn the routes aggregated or summarized across OSPF areas or ISIS levels in inter-domain, Junos OS allows you to configure longest match for LDP based on *RFC5283*.

Before you configure longest match for LDP, you must do the following:

1. Configure the device interfaces.
2. Configure the MPLS protocol.
3. Configure the OSPF protocol.

To configure longest match for LDP, you must do the following:

1. Configure longest match for the LDP protocol.

```
[edit protocols ldp]
user@host# set longest-match
```

2. Configure the LDP protocol on the interface.

```
[edit protocols ldp]
user@host# set interface interface-name
```

For example, to configure the interfaces:

```
[edit protocols ldp]
user@host# set interface ge-0/0/2.0
user@host# set interface lo0.0
```

---

## Example: Configuring Longest Match for LDP

This example shows how to configure longest match for LDP based on *RFC5283*. This allows LDP to learn the routes aggregated or summarized across OSPF areas or ISIS levels in inter-domain.. The longest match policy provides per prefix granularity.

- [Requirements on page 744](#)
- [Overview on page 744](#)
- [Configuration on page 745](#)
- [Verification on page 750](#)

### Requirements

This example uses the following hardware and software components:

- Six MX Series routers with OSPF protocol, and LDP enabled on the connected interfaces.
- Junos OS Release 16.1 or later running on all devices.

Before you begin:

- Configure the device interfaces.
- Configure OSPF.

### Overview

LDP is often used to establish MPLS label-switched paths (LSPs) throughout a complete network domain using an IGP such as OSPF or IS-IS. In such a network, all links in the domain have IGP adjacencies as well as LDP adjacencies. LDP establishes the LSPs on the shortest path to a destination as determined by IP forwarding. In Junos OS, the LDP implementation does an exact match lookup on the IP address of the FEC in the RIB or IGP routes for label mapping. This exact mapping requires MPLS end-to-end LDP endpoint IP addresses to be configured in all the LERs. This defeats the purpose of IP hierarchical design or default routing in access devices. Configuring **longest-match** helps to overcome

this by suppressing the exact match behaviour and setup LSP based on the longest matching route on per-prefix basis.

### Topology

In the topology, [Figure 72 on page 745](#) shows the longest match for LDP is configured on Device R0 .

*Figure 72: Example Longest Match for LDP*

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
R0
set interfaces ge-0/0/0 unit 0 family inet address 22.22.22.1/24

### Configuring Device R0

---

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R0:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 22.22.22.1/24

set ge-0/0/1 unit 0 family inet address 15.15.15.1/24

set ge-0/0/2 unit 0 family inet address 11.11.11.1/24
set ge-0/0/2 unit 0 family iso
set ge-0/0/2 unit 0 family mpls
```

2. Assign the loopback addresses to the device.

```
[edit interfaces lo0 unit 0 family]
set inet address 10.255.112.1/32 primary
set inet address 10.255.112.1/32 preferred
set iso address 49.0002.0192.0168.0001.00
```

3. Configure the router ID.

```
[edit routing-options]
set router-id 10.255.112.1
```

4. Configure the MPLS protocol on the interface.

```
[edit protocols mpls]
set interface ge-0/0/2.0
```

5. Configure the OSPF protocol on the interface.

```
[edit protocols ospf]
set area 0.0.0.1 interface ge-0/0/2.0
set area 0.0.0.1 interface lo0.0 passive
```

6. Configure longest match for the LDP protocol.

```
[edit protocols ldp]
set longest-match
```

7. Configure the LDP protocol on the interface.

```
[edit protocols ldp]
set interface ge-0/0/2.0
set interface lo0.0
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 22.22.22.1/24;
    }
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 15.15.15.1/24;
    }
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 11.11.11.1/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.112.1/32 {
        primary;
        preferred;
      }
    }
    family iso {
      address 49.0002.0192.0168.0001.00;
    }
  }
}
```

```
}  
}
```

```
user@R0# show protocols  
mpls {  
  interface ge-0/0/2.0;  
}  
ospf {  
  area 0.0.0.1 {  
    interface ge-0/0/2.0;  
    interface lo0.0 {  
      passive;  
    }  
  }  
}  
ldp {  
  longest-match;  
  interface ge-0/0/2.0;  
  interface lo0.0;  
}
```

```
user@R0# show routing-options  
router-id 10.255.112.1;
```

If you are done configuring the device, enter **commit** from the configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Routes on page 750](#)
- [Verifying LDP Overview Information on page 754](#)
- [Verify the LDP Entries in the Internal Topology Table on page 756](#)
- [Verify Only FEC Information of LDP Route on page 758](#)
- [Verify FEC and Shadow Routes of LDP on page 758](#)

---

### Verifying the Routes

**Purpose** Verify that the expected routes are learned.

**Action** On Device R0, from operational mode, run the **show route** command to display the routes in the routing table.

```
user@R0> show route
```

```
inet.0: 62 destinations, 62 routes (62 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.4.0.0/16      *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0

```

**Meaning** The output shows all the routes in the routing table of Device R0.

#### Verifying LDP Overview Information

---

**Purpose** Display LDP overview information.

**Action** On Device R0, from operational mode, run the **show ldp overview** command to display the overview of the LDP.

```
user@R0> show ldp overview
```

```
Instance: master
  Reference count: 2
  Router ID: 10.255.112.1
  Message id: 8

## Configuring LDP Route Preferences

When several protocols calculate routes to the same destination, route preferences are used to select which route is installed in the forwarding table. The route with the lowest preference value is selected. The preference value can be a number in the range 0 through 255. By default, LDP routes have a preference value of 9.

To modify the route preferences, include the **preference** statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## LDP Graceful Restart

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

You can configure LDP graceful restart in both the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and on a specific routing instance. LDP graceful restart is disabled by default, because at the global level, graceful restart is disabled by default. However, helper mode (the ability to assist a neighboring router attempting a graceful restart) is enabled by default.

The following are some of the behaviors associated with LDP graceful restart:

- Outgoing labels are not maintained in restarts. New outgoing labels are allocated.
- When a router is restarting, no label-map messages are sent to neighbors that support graceful restart until the restarting router has stabilized (label-map messages are immediately sent to neighbors that do not support graceful restart). However, all other messages (keepalive, address-message, notification, and release) are sent as usual. Distributing these other messages prevents the router from distributing incomplete information.
- Helper mode and graceful restart are independent. You can disable graceful restart in the configuration, but still allow the router to cooperate with a neighbor attempting to restart gracefully.

## Configuring LDP Graceful Restart

When you alter the graceful restart configuration at either the **[edit routing-options graceful-restart]** or **[edit protocols ldp graceful-restart]** hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

By default, graceful restart helper mode is enabled, but graceful restart is disabled. Thus, the default behavior of a router is to assist neighboring routers attempting a graceful restart, but not to attempt a graceful restart itself.

To configure LDP graceful restart, see the following sections:

- [Enabling Graceful Restart on page 761](#)
- [Disabling LDP Graceful Restart or Helper Mode on page 762](#)
- [Configuring Reconnect Time on page 763](#)
- [Configuring Recovery Time and Maximum Recovery Time on page 763](#)

### Enabling Graceful Restart

To enable LDP graceful restart, you also need to enable graceful restart on the router. To enable graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

**NOTE:** ACX Series routers do not support [edit logical-systems *logical-system-name* routing-options] hierarchy level.

The **graceful-restart** statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

By default, LDP graceful restart is enabled when you enable graceful restart at both the LDP protocol level and on all the routing instances. However, you can disable both LDP graceful restart and LDP graceful restart helper mode.

## Disabling LDP Graceful Restart or Helper Mode

To disable LDP graceful restart and recovery, include the **disable** statement:

```
ldp {
  graceful-restart {
    disable;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can disable helper mode at the LDP protocols level only. You cannot disable helper mode for a specific routing instance. To disable LDP helper mode, include the **helper-disable** statement:

```
ldp {
  graceful-restart {
    helper-disable;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The following LDP graceful restart configurations are possible:

- LDP graceful restart and helper mode are both enabled.
- LDP graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully but can help a restarting neighbor.

- LDP graceful restart and helper mode are both disabled. The router does not use LDP graceful restart or the graceful restart type, length, and value (TLV) sent in the initialization message. The router behaves as a router that cannot support LDP graceful restart.

A configuration error is issued if you attempt to enable graceful restart and disable helper mode.

## Configuring Reconnect Time

After the LDP connection between neighbors fails, neighbors wait a certain amount of time for the gracefully restarting router to resume sending LDP messages. After the wait period, the LDP session can be reestablished. You can configure the wait period in seconds. This value is included in the fault tolerant session TLV sent in LDP initialization messages when LDP graceful restart is enabled.

Suppose that Router A and Router B are LDP neighbors. Router A is the restarting Router. The reconnect time is the time that Router A tells Router B to wait after Router B detects that Router A restarted.

To configure the reconnect time, include the **reconnect-time** statement:

```
graceful-restart {
  reconnect-time seconds;
}
```

You can set the reconnect time to a value in the range from 30 through 300 seconds. By default, it is 60 seconds.

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

## Configuring Recovery Time and Maximum Recovery Time

The recovery time is the amount of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This period is also typically the amount of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

To prevent a neighboring router from being adversely affected if it receives a false value for the recovery time from the restarting router, you can configure the maximum recovery time on the neighboring router. A neighboring router maintains its state for the shorter of the two times. For example, Router A is performing an LDP graceful restart. It has sent a recovery time of 900 seconds to neighboring Router B. However, Router B has its maximum recovery time configured at 400 seconds. Router B will only wait for 400 seconds before it purges its LDP information from Router A.

To configure recovery time, include the **recovery-time** statement and the **maximum-neighbor-recovery-time** statement:

```
graceful-restart {
  maximum-neighbor-recovery-time seconds;
```

```
recovery-time seconds;
}
```

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

## Filtering Inbound LDP Label Bindings

You can filter received LDP label bindings, applying policies to accept or deny bindings advertised by neighboring routers. To configure received-label filtering, include the **import** statement:

```
import [ policy-names ];
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named policy (configured at the **[edit policy-options]** hierarchy level) is applied to all label bindings received from all LDP neighbors. All filtering is done with **from** statements. [Table 25 on page 764](#) lists the only **from** operators that apply to LDP received-label filtering.

*Table 25: from Operators That Apply to LDP Received-Label Filtering*

from Operator	Description
<b>interface</b>	Matches on bindings received from a neighbor that is adjacent over the specified interface
<b>neighbor</b>	Matches on bindings received from the specified LDP router ID
<b>next-hop</b>	Matches on bindings received from a neighbor advertising the specified interface address
<b>route-filter</b>	Matches on bindings with the specified prefix

If a binding is filtered, it still appears in the LDP database, but is not considered for installation as part of a label-switched path (LSP).

Generally, applying policies in LDP can be used only to block the establishment of LSPs, not to control their routing. This is because the path that an LSP follows is determined by unicast routing, and not by LDP. However, when there are multiple equal-cost paths to the destination through different neighbors, you can use LDP filtering to exclude some of the possible next hops from consideration. (Otherwise, LDP chooses one of the possible next hops at random.)

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels; so if multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface. When a router has multiple adjacencies to the same neighbor, take care to ensure that the filter

does what is expected. (Generally, using **next-hop** and **interface** is not appropriate in this case.)

If a label has been filtered (meaning that it has been rejected by the policy and is not used to construct an LSP), it is marked as filtered in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.6/32 (Filtered)
Output label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.1/32 (Filtered)
```

For more information about how to configure policies for LDP, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

## Examples: Filtering Inbound LDP Label Bindings

Accept only /32 prefixes from all neighbors:

```
[edit]
protocols {
  ldp {
    import only-32;
    ...
  }
}
policy-options {
  policy-statement only-32 {
    term first {
      from {
        route-filter 0.0.0.0/0 upto /31;
      }
      then reject;
    }
    then accept;
  }
}
```

Accept 131.108/16 or longer from router ID 10.10.255.2 and accept all prefixes from all other neighbors:

```
[edit]
protocols {
  ldp {
    import nosy-neighbor;
    ...
  }
}
policy-options {
  policy-statement nosy-neighbor {
    term first {
```

```

    from {
      neighbor 10.10.255.2;
      route-filter 131.108.0.0/16 orlonger accept;
      route-filter 0.0.0.0/0 orlonger reject;
    }
  }
  then accept;
}

```

## Filtering Outbound LDP Label Bindings

You can configure export policies to filter LDP outbound labels. You can filter outbound label bindings by applying routing policies to block bindings from being advertised to neighboring routers. To configure outbound label filtering, include the **export** statement:

```
export [policy-name];
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named export policy (configured at the **[edit policy-options]** hierarchy level) is applied to all label bindings transmitted to all LDP neighbors. The only **from** operator that applies to LDP outbound label filtering is **route-filter**, which matches bindings with the specified prefix. The only **to** operators that apply to outbound label filtering are the operators in [Table 26 on page 766](#).

*Table 26: to Operators for LDP Outbound-Label Filtering*

to Operator	Description
<b>interface</b>	Matches on bindings sent to a neighbor that is adjacent over the specified interface
<b>neighbor</b>	Matches on bindings sent to the specified LDP router ID
<b>next-hop</b>	Matches on bindings sent to a neighbor advertising the specified interface address

If a binding is filtered, the binding is not advertised to the neighboring router, but it can be installed as part of an LSP on the local router. You can apply policies in LDP to block the establishment of LSPs, but not to control their routing. The path an LSP follows is determined by unicast routing, not by LDP.

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels. If multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface.

Do not use the **next-hop** and **interface** operators when a router has multiple adjacencies to the same neighbor.

Filtered labels are marked in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
100007 10.10.255.2/32
3 10.10.255.3/32
Output label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
3 10.10.255.1/32
100001 10.10.255.6/32 (Filtered)
```

For more information about how to configure policies for LDP, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

### Examples: Filtering Outbound LDP Label Bindings

Block transmission of the route for **10.10.255.6/32** to any neighbors:

```
[edit protocols]
ldp {
  export block-one;
}
policy-options {
  policy-statement block-one {
    term first {
      from {
        route-filter 10.10.255.6/32 exact;
      }
      then reject;
    }
    then accept;
  }
}
```

Send only **131.108/16** or longer to router ID **10.10.255.2**, and send all prefixes to all other routers:

```
[edit protocols]
ldp {
  export limit-lsps;
}
policy-options {
  policy-statement limit-lsps {
    term allow-one {
      from {
        route-filter 131.108.0.0/16 orlonger;
      }
      to {
        neighbor 10.10.255.2;
      }
      then accept;
    }
  }
}
```

```
term block-the-rest {  
  to {  
    neighbor 10.10.255.2;  
  }  
  then reject;  
}  
then accept;  
}
```

---

## Specifying the Transport Address Used by LDP

Routers must first establish a TCP session between each other before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

To configure the LDP transport address, include the `transport-address` statement:

```
transport-address (router-id | interface);
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you specify the **router-id** option, the address of the router identifier is used as the transport address (unless otherwise configured, the router identifier is typically the same as the loopback address). If you specify the **interface** option, the interface address is used as the transport address for any LDP sessions to neighbors that can be reached over that interface. Note that the router identifier is used as the transport address by default.

You cannot specify the **interface** option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the **router-id** option.

**Related Documentation**

- [transport-address on page 2400](#)

---

## Configuring the Prefixes Advertised into LDP from the Routing Table

You can control the set of prefixes that are advertised into LDP and cause the router to be the egress router for those prefixes. By default, only the loopback address is advertised into LDP. To configure the set of prefixes from the routing table to be advertised into LDP, include the **egress-policy** statement:

```
egress-policy policy-name;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** If you configure an egress policy for LDP that does not include the loopback address, it is no longer advertised in LDP. To continue to advertise the loopback address, you need to explicitly configure it as a part of the LDP egress policy.

**NOTE:** Support for `inet.0` and `inet.3` labeled unicast BGP route for protocol LDP (MX Series)—In Junos OS Release 16.1R6-S3, 16.1R7, 18.1R2, LDP egress policy is supported on both `inet.0` and `inet.3` routing Information bases (RIBs) also known as routing table for labeled unicast BGP routes. If a routing policy is configured with a specific (`inet.0` and `inet.3`) RIB, the egress policy is applied on the specified RIB. If no RIB is specified and a prefix is present on both `inet.0` and `inet.3` RIBs for labeled unicast BGP routes, then `inet.3` RIB is preferred. However, prior to Junos OS Release 12.3R1 and starting with Junos OS Release 16.1R1, LDP egress policy is always preferred on `inet.0` RIB and support for `inet.3` RIB egress policy for labeled unicast BGP routes was disabled. In Junos OS Release 12.3R1 and later releases up to Junos OS Release 16.1R1, LDP egress policy was supported in `inet.3` RIBs, in addition to `inet.0` RIBs, for labeled-unicast BGP routes.

The named policy (configured at the `[edit policy-options]` or `[edit logical-systems logical-system-name policy-options]` hierarchy level) is applied to all routes in the routing table. Those routes that match the policy are advertised into LDP. You can control the set of neighbors to which those prefixes are advertised by using the `export` statement. Only `from` operators are considered; you can use any valid `from` operator. For more information, see the *Junos OS Routing Protocols Library*.

**NOTE:** ACX Series routers do not support `[edit logical-systems]` hierarchy level.

### Example: Configuring the Prefixes Advertised into LDP

Advertise all connected routes into LDP:

```
[edit protocols]
ldp {
  egress-policy connected-only;
}
[edit policy-options]
policy-statement connected-only {
  from {
    protocol direct;
  }
}
```

```

    then accept;
  }
}

```

Release History Table

Release	Description
16.1R6-S3;16.1R7;18.1R2	<b>Support for inet.0 and inet.3 labeled unicast BGP route for protocol LDP (MX Series)</b> —In Junos OS Release 16.1R6-S3, 16.1R7, 18.1R2, LDP egress policy is supported on both inet.0 and inet.3 routing Information bases (RIBs) also known as routing table for labeled unicast BGP routes. If a routing policy is configured with a specific (inet.0 and inet.3) RIB, the egress policy is applied on the specified RIB. If no RIB is specified and a prefix is present on both inet.0 and inet.3 RIBs for labeled unicast BGP routes, then inet.3 RIB is preferred. However, prior to Junos OS Release 12.3R1 and starting with Junos OS Release 16.1R1, LDP egress policy is always preferred on inet.0 RIB and support for inet.3 RIB egress policy for labeled unicast BGP routes was disabled. In Junos OS Release 12.3R1 and later releases up to Junos OS Release 16.1R1, LDP egress policy was supported in inet.3 RIBs, in addition to inet.0 RIBs, for labeled-unicast BGP routes.

## Configuring FEC Deaggregation

When an LDP egress router advertises multiple prefixes, the prefixes are bound to a single label and aggregated into a single forwarding equivalence class (FEC). By default, LDP maintains this aggregation as the advertisement traverses the network.

Normally, because an LSP is not split across multiple next hops and the prefixes are bound into a single LSP, load-balancing across equal-cost paths does not occur. You can, however, load-balance across equal-cost paths if you configure a load-balancing policy and deaggregate the FECs.

Deaggregating the FECs causes each prefix to be bound to a separate label and become a separate LSP.

To configure deaggregated FECs, include the **deaggregate** statement:

```
deaggregate;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For all LDP sessions, you can configure deaggregated FECs only globally.

Deaggregating a FEC allows the resulting multiple LSPs to be distributed across multiple equal-cost paths and distributes LSPs across the multiple next hops on the egress segments but installs only one next hop per LSP.

To aggregate FECs, include the **no-deaggregate** statement:

```
no-deaggregate;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For all LDP sessions, you can configure aggregated FECs only globally.

**Related Documentation**

- [Configuring VPLS Load Balancing](#)
- [Example: Load Balancing BGP Traffic](#)

## Configuring Policers for LDP FECs

You can configure the Junos OS to track and police traffic for LDP FECs. LDP FEC policers can be used to do any of the following:

- Track or police the ingress traffic for an LDP FEC.
- Track or police the transit traffic for an LDP FEC.
- Track or police LDP FEC traffic originating from a specific forwarding class.
- Track or police LDP FEC traffic originating from a specific virtual routing and forwarding (VRF) site.
- Discard false traffic bound for a specific LDP FEC.

**NOTE: Support for inet.0 and inet.3 labeled unicast BGP route for protocol LDP (MX Series)**—In Junos OS Release 16.1R6-S3, 16.1R7, 18.1R2, LDP egress policy is supported on both inet.0 and inet.3 routing Information bases (RIBs) also known as routing table for labeled unicast BGP routes. If a routing policy is configured with a specific (inet.0 and inet.3) RIB, the egress policy is applied on the specified RIB. If no RIB is specified and a prefix is present on both inet.0 and inet.3 RIBs for labeled unicast BGP routes, then inet.3 RIB is preferred. However, prior to Junos OS Release 12.3R1 and starting with Junos OS Release 16.1R1, LDP egress policy is always preferred on inet.0 RIB and support for inet.3 RIB egress policy for labeled unicast BGP routes was disabled. In Junos OS Release 12.3R1 and later releases up to Junos OS Release 16.1R1, LDP egress policy was supported in inet.3 RIBs, in addition to inet.0 RIBs, for labeled-unicast BGP routes.

To police traffic for an LDP FEC, you must first configure a filter. Specifically, you need to configure either the **interface** statement or the **interface-set** statement at the **[edit firewall family protocol-family filter filter-name term term-name from]** hierarchy level. The **interface** statement allows you to match the filter to a single interface. The **interface-set** statement allows you to match the filter to multiple interfaces.

For more information on how to configure the **interface** statement, the **interface-set** statement, and policers for LDP FECs, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

Once you have configured the filters, you need to include them in the **policing** statement configuration for LDP. To configure policers for LDP FECs, include the **policing** statement:

```
policing {
  fec fec-address {
    ingress-traffic filter-name;
    transit-traffic filter-name;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The **policing** statement includes the following options:

- **fec**—Specify the FEC address for the LDP FEC you want to police.
- **ingress-filter**—Specify the name of the ingress traffic filter.
- **transit-traffic**—Specify the name of the transit traffic filter.

Release History Table

Release	Description
16.1R6-S3;16.1R7;18.1R2	<b>Support for inet.0 and inet.3 labeled unicast BGP route for protocol LDP (MX Series)</b> —In Junos OS Release 16.1R6-S3, 16.1R7, 18.1R2, LDP egress policy is supported on both inet.0 and inet.3 routing Information bases (RIBs) also known as routing table for labeled unicast BGP routes. If a routing policy is configured with a specific (inet.0 and inet.3) RIB, the egress policy is applied on the specified RIB. If no RIB is specified and a prefix is present on both inet.0 and inet.3 RIBs for labeled unicast BGP routes, then inet.3 RIB is preferred. However, prior to Junos OS Release 12.3R1 and starting with Junos OS Release 16.1R1, LDP egress policy is always preferred on inet.0 RIB and support for inet.3 RIB egress policy for labeled unicast BGP routes was disabled. In Junos OS Release 12.3R1 and later releases up to Junos OS Release 16.1R1, LDP egress policy was supported in inet.3 RIBs, in addition to inet.0 RIBs, for labeled-unicast BGP routes.

## Configuring LDP IPv4 FEC Filtering

By default, when a targeted LDP session is established, the Junos OS always exchanges both the IPv4 forwarding equivalence classes (FECs) and the Layer 2 circuit FECs over the targeted LDP session. For an LDP session to an indirectly connected neighbor, you might only want to export Layer 2 circuit FECs to the neighbor if the session was specifically configured to support Layer 2 circuits or VPLS.

In a mixed vendor network where all non-BGP prefixes are advertised into LDP, the LDP database can become large. For this type of environment, it can be useful to prevent the advertisement of IPv4 FECs over LDP sessions formed because of Layer 2 circuit or LDP

VPLS configuration. Similarly, it can be useful to filter any IPv4 FECs received in this sort of environment.

If all the LDP neighbors associated with an LDP session are Layer 2 only, you can configure the Junos OS to advertise only Layer 2 circuit FECs by configuring the **l2-smart-policy** statement. This feature also automatically filters out the IPv4 FECs received on this session. Configuring an explicit export or import policy that is activated for **l2-smart-policy** disables this feature in the corresponding direction.

If one of the LDP session's neighbors is formed because of a discovered adjacency or if the adjacency is formed because of an LDP tunneling configuration on one or more RSVP LSPs, the IPv4 FECs are advertised and received using the default behavior.

To prevent LDP from exporting IPv4 FECs over LDP sessions with Layer 2 neighbors only and to filter out IPv4 FECs received over such sessions, include the **l2-smart-policy** statement:

```
l2-smart-policy;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary for this statement.

## Configuring BFD for LDP LSPs

You can configure Bidirectional Forwarding Detection (BFD) for LDP LSPs. The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the router stops receiving a reply after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than the failure detection mechanisms of static routes, providing faster detection.

An error is logged whenever a BFD session for a path fails. The following shows how BFD for LDP LSP log messages might appear:

```
RPD_LDP_BFD_UP: LDP BFD session for FEC 10.255.16.14/32 is up
RPD_LDP_BFD_DOWN: LDP BFD session for FEC 10.255.16.14/32 is down
```

You can also configure BFD for RSVP LSPs, as described in [“Configuring BFD for RSVP-Signaled LSPs” on page 90](#).

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

To enable BFD for LDP LSPs, include the **oam** and **bfd-liveness-detection** statements:

```
oam {
  bfd-liveness-detection {
    detection-time threshold milliseconds;
    ecmp;
    failure-action {
      remove-nexthop;
      remove-route;
    }
    holddown-interval seconds;
    ingress-policy ingress-policy-name;
    minimum-interval milliseconds;
    minimum-receive-interval milliseconds;
    minimum-transmit-interval milliseconds;
    multiplier detection-time-multiplier;
    no-adaptation;
    transmit-interval {
      minimum-interval milliseconds;
      threshold milliseconds;
    }
    version (0 | 1 | automatic);
  }
  fec fec-address {
    bfd-liveness-detection {
      detection-time threshold milliseconds;
      ecmp;
      failure-action {
        remove-nexthop;
        remove-route;
      }
      holddown-interval milliseconds;
      ingress-policy ingress-policy-name;
      minimum-interval milliseconds;
      minimum-receive-interval milliseconds;
      minimum-transmit-interval milliseconds;
      multiplier detection-time-multiplier;
      no-adaptation;
      transmit-interval {
        minimum-interval milliseconds;
        threshold milliseconds;
      }
      version (0 | 1 | automatic);
    }
    no-bfd-liveness-detection;
    periodic-traceroute {
      disable;
      exp exp-value;
      fanout fanout-value;
      frequency minutes;
      paths number-of-paths;
      retries retry-attempts;
      source address;
      ttl ttl-value;
      wait seconds;
    }
  }
}
```

```

    }
  }
  lsp-ping-interval seconds;
  periodic-traceroute {
    disable;
    exp exp-value;
    fanout fanout-value;
    frequency minutes;
    paths number-of-paths;
    retries retry-attempts;
    source address;
    ttl ttl-value;
    wait seconds;
  }
}

```

You can enable BFD for the LDP LSPs associated with a specific forwarding equivalence class (FEC) by configuring the FEC address using the **fec** option at the **[edit protocols ldp]** hierarchy level. Alternatively, you can configure an Operation Administration and Management (OAM) ingress policy to enable BFD on a range of FEC addresses. For more information, see “[Configuring OAM Ingress Policies for LDP](#)” on page 999.

You cannot enable BFD LDP LSPs unless their equivalent FEC addresses are explicitly configured or OAM is enabled on the FECs using an OAM ingress policy. If BFD is not enabled for any FEC addresses, the BFD session will not come up.

You can configure the **oam** statement at the following hierarchy levels:

- **[edit protocols ldp]**
- **[edit logical-systems *logical-system-name* protocols ldp]**

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

The **oam** statement includes the following options:

- **fec**—Specify the FEC address. You must either specify a FEC address or configure an OAM ingress policy to ensure that the BFD session comes up.
- **lsp-ping-interval**—Specify the duration of the LSP ping interval in seconds. To issue a ping on an LDP-signaled LSP, use the **ping mpls ldp** command. For more information, see the [CLI Explorer](#).

The **bfd-liveness-detection** statement includes the following options:

- **ecmp**—Cause LDP to establish BFD sessions for all ECMP paths configured for the specified FEC. If you configure the **ecmp** option, you must also configure the **periodic-traceroute** statement for the specified FEC. If you do not do so, the commit operation fails. You can configure the **periodic-traceroute** statement at the global hierarchy level (**[edit protocols ldp oam]**) while only configuring the **ecmp** option for a specific FEC (**[edit protocols ldp oam fec address bfd-liveness-detection]**).
- **holddown-interval**—Specify the duration the BFD session should remain up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.
- **minimum-interval**—Specify the minimum transmit and receive interval. If you configure the **minimum-interval** option, you do not need to configure the **minimum-receive-interval** option or the **minimum-transmit-interval** option.
- **minimum-receive-interval**—Specify the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- **minimum-transmit-interval**—Specify the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- **multiplier**—Specify the detection time multiplier. The range is from 1 through 255.
- **version**—Specify the BFD version. The options are BFD version 0 or BFD version 1. By default, the Junos OS software attempts to automatically determine the BFD version.

---

## Configuring ECMP-Aware BFD for LDP LSPs

When you configure BFD for a FEC, a BFD session is established for only one active local next-hop for the router. However, you can configure multiple BFD sessions, one for each FEC associated with a specific equal-cost multipath (ECMP) path. For this to function properly, you also need to configure LDP LSP periodic traceroute. (See [“Configuring LDP LSP Traceroute” on page 899](#).) LDP LSP traceroute is used to discover ECMP paths. A BFD session is initiated for each ECMP path discovered. Whenever a BFD session for one of the ECMP paths fails, an error is logged.

LDP LSP traceroute is run periodically to check the integrity of the ECMP paths. The following might occur when a problem is discovered:

- If the latest LDP LSP traceroute for a FEC differs from the previous traceroute, the BFD sessions associated with that FEC (the BFD sessions for address ranges that have changed from previous run) are brought down and new BFD sessions are initiated for the destination addresses in the altered ranges.
- If the LDP LSP traceroute returns an error (for example, a timeout), all the BFD sessions associated with that FEC are torn down.

To configure LDP to establish BFD sessions for all ECMP paths configured for the specified FEC, include the **ecmp** statement.

```
ecmp;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Along with the **ecmp** statement, you must also include the **periodic-traceroute** statement, either in the global LDP OAM configuration (at the **[edit protocols ldp oam]** or **[edit logical-systems logical-system-name protocols ldp oam]** hierarchy level) or in the configuration for the specified FEC (at the **[edit protocols ldp oam fec address]** or **[edit logical-systems logical-system-name protocols ldp oam fec address]** hierarchy level). Otherwise, the commit operation fails.

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

## Configuring a Failure Action for the BFD Session on an LDP LSP

You can configure route and next-hop properties in the event of a BFD session failure event on an LDP LSP. The failure event could be an existing BFD session that has gone down or could be a BFD session that never came up. LDP adds back the route or next hop when the relevant BFD session comes back up.

You can configure one of the following failure action options for the **failure-action** statement in the event of a BFD session failure on the LDP LSP:

- **remove-nexthop**—Removes the route corresponding to the next hop of the LSP's route at the ingress node when a BFD session failure event is detected.
- **remove-route**—Removes the route corresponding to the LSP from the appropriate routing tables when a BFD session failure event is detected. If the LSP is configured with ECMP and a BFD session corresponding to any path goes down, the route is removed.

To configure a failure action in the event of a BFD session failure on an LDP LSP, include either the **remove-nexthop** option or the **remove-route** option for the **failure-action** statement:

```
failure-action {
  remove-nexthop;
  remove-route;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the Holddown Interval for the BFD Session

You can specify the duration the BFD session should be up before adding a route or next hop by configuring the **holddown-interval** statement at either the **[edit protocols ldp oam bfd-liveness-detection]** hierarchy level or at the **[edit protocols ldp oam fec address bfd-liveness-detection]** hierarchy level. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

```
holddown-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring LDP Link Protection

You can configure Label Distribution Protocol (LDP) link protection for both unicast and multicast LDP label-switched paths (LSPs) to provide resiliency during link or node failure.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
  - a. RSVP
  - b. MPLS with traffic engineering capability.
  - c. OSPF with traffic engineering capability.

**NOTE:** For multicast LDP link protection with loop-free alternative (LFA), enable link protection.

```
[edit protocols]
user@R0# set ospf area 0 interface all link-protection
```

To configure LDP link protection:

1. Enable point-to-multipoint LDP LSPs.

```
[edit protocols]
user@R0# set ldp p2mp
```

2. Enable LDP on all the interfaces of Router R0 (excluding the management interface) and configure link protection with dynamic RSVP bypass LSP.

```
[edit protocols]
user@R0# set ldp interface all link-protection dynamic-rsvp-lsp
```

```
user@R0# set ldp interface fxp0.0 disable
```

3. Verify and commit the configuration.

For example:

```
[edit protocols]
user@R0# show protocols
rsvp {
  interface all;
  interface fxp0.0 {
    disable;
  }
}
mpls {
  traffic-engineering;
  interface all;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface all {
      metric 1;
    }
    interface fxp0.0 {
      disable;
    }
  }
}
ldp {
  interface all {
    link-protection {
      dynamic-rsvp-lsp;
    }
  }
  interface fxp0.0 {
    disable;
  }
  p2mp;
}
```

```
[edit]
user@R0# commit
commit complete
```

### Introduction to LDP

---

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to the data link LSPs.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding) or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

### Junos OS LDP Protocol Implementation

---

The Junos OS implementation of LDP supports LDP version 1. Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. Junos OS allows an MPLS tunnel next hop to all egress routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge resolves to

an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

### Understanding Multipoint Extensions to LDP

An LDP defines mechanisms for setting up point-to-point, multipoint-to-point, point-to-multipoint, and multipoint-to-multipoint LSPs in the network. The point-to-multipoint and multipoint-to-multipoint LSPs are collectively referred to as multipoint LSPs, where traffic flows from a single source to multiple destinations, and from multiple sources to multiple destinations, respectively. The destination or egress routers are called leaf nodes, and traffic from the source traverses one or more transit nodes before reaching the leaf nodes.

**NOTE:** Junos OS does not provide support for multipoint-to-multipoint LSPs.

By taking advantage of the MPLS packet replication capability of the network, multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

### Using Multipoint Extensions to LDP on Targeted LDP Sessions

The specification for the multipoint extensions to LDP requires that the two endpoints of an LDP session are directly connected by a Layer 2 medium, or are considered to be neighbors by the network's IGP. This is referred to as an LDP link session. When the two endpoints of an LDP session are not directly connected, the session is referred to as a targeted LDP session.

Past Junos OS implementations support multicast LDP for link sessions only. With the introduction of the LDP link protection feature, the multicast LDP capabilities are extended to targeted LDP sessions. [Figure 73 on page 781](#) shows a sample topology.

*Figure 73: Multicast LDP Support for Targeted LDP Session*

Routers R7 and R8 are the upstream (LSR-U) and downstream (LSR-D) label-switched routers (LSRs), respectively, and deploy multicast LDP. The core router, Router R5, has RSVP-TE enabled.

When LSR-D is setting up the point-to-multipoint LSP with root and LSP ID attributes, it determines the upstream LSR-U as a next-hop on the best path to the root (currently, this next-hop is assumed to be an IGP next hop).

With the multicast LDP support on targeted LDP sessions, you can determine if there is an LSP next hop to LSR-U which is on LSR-D's path to root, where LSR-D and LSR-U are not directly connected neighbors, but targeted LDP peers. The point-to-multipoint label advertised on the targeted LDP session between LSR-D and LSR-U is not used unless there is an LSP between LSR-D and LSR-U. Therefore, a corresponding LSP in the reverse direction from LSR-U to LSR-D is required.

Data is transmitted on the point-to-multipoint LSP using unicast replication of packets, where LSR-U sends one copy to each downstream LSR of the point-to-multipoint LSP.

The data transmission is implemented in the following ways:

1. The point-to-multipoint capabilities on the targeted LDP session are negotiated.
2. The algorithm to select the upstream LSR is changed, where if IGP next hops are unavailable, or in other words, there is no LDP link session between LSR-D and LSR-U, an RSVP LSP is used as the next hop to reach LSR-U.
3. The incoming labels received over the targeted LDP sessions are installed as a branch next hop for this point-to-multipoint FEC route with the LDP label as the inner label and the RSVP label as the outer label.

---

### Current Limitations of LDP Link Protection

When there is a link or node failure in an LDP network deployment, fast traffic recovery should be provided to recover impacted traffic flows for mission-critical services. In the case of multipoint LSPs, when one of the links of the point-to-multipoint tree fails, the subtrees might get detached until the IGP reconverges and the multipoint LSP is established using the best path from the downstream router to the new upstream router.

In fast reroute using local repair for LDP traffic, a backup path (repair path) is pre-installed in the Packet Forwarding Engine. When the primary path fails, traffic is rapidly moved to the backup path without having to wait for the routing protocols to converge. Loop-free alternate (LFA) is one of the methods used to provide IP fast reroute capability in the core and service provider networks.

Without LFA, when a link or a router fails or is returned to service, the distributed routing algorithms compute the new routes based on the changes in the network. The time during which the new routes are computed is referred to as routing transition. Until the routing transition is completed, the network connectivity is interrupted because the routers adjacent to a failure continue to forward the data packets through the failed component until an alternative path is identified.

However, LFA does not provide full coverage in all network deployments because of the IGP metrics. As a result, this is a limitation to the current LDP link protection schemes.

Figure 74 on page 783 illustrates a sample network with incomplete LFA coverage, where traffic flows from the source router (S) to the destination router (D) through Router R1. Assuming that each link in the network has the same metric, if the link between the Router S and Router R1 fails, Router R4 is not an LFA that protects the S-R1 link, so traffic resiliency is lost. Thus, full coverage is not achieved by using plain LFA. In typical networks, there is always some percentage of LFA coverage gap with plain LFA.

Figure 74: Incomplete Coverage Problem with LFA

### Using RSVP LSP as a Solution

The key to protect the traffic flowing through LDP LSPs is to have an explicit tunnel to re-route the traffic in the event of a link or node failure. The explicit path has to terminate on the next downstream router, and the traffic needs to be accepted on the explicit path, where the RPF check should pass.

RSVP LSPs help overcome the current limitations of loop-free alternate (LFA) for both point-to-point and point-to-multipoint LDP LSPs by extending the LFA coverage in the following methods:

- [Manually Configured RSVP LSPs on page 783](#)
- [Dynamically Configured RSVP LSPs on page 784](#)

#### Manually Configured RSVP LSPs

Considering the example used in Figure 74 on page 783, when the S-R1 link fails, and Router R4 is not an LFA for that particular link, a manually created RSVP LSP is used as a patch to provide complete LFA coverage. The RSVP LSP is pre-signaled and pre-installed in the Packet Forwarding Engine of Router S, so that it can be used as soon as Router S detects that the link has failed.

Figure 75: Manually Configured RSVP LSP Coverage

In this case, an RSVP LSP is created between Routers S, R4, and R3 as illustrated in [Figure 75 on page 784](#). A targeted LDP session is created between Router S and Router R3, as a result of which, when the S-R1 link fails, traffic reaches Router R3. Router R3 forwards the traffic to Router R2, as it is the shortest path to reach the destination, Router D.

#### ***Dynamically Configured RSVP LSPs***

In this method, the RSVP LSPs are created automatically and pre-installed in the system so that they can be used immediately when there is a link failure. Here, the egress is the node on the other side of the link being protected, thereby improving the LFA coverage.

Considering the example used in [Figure 74 on page 783](#), in order to protect traffic against the potential failure of the S-R1 link, because Router R4 is not an LFA for that particular link, an RSVP bypass LSP is automatically created to Router R1, which is the node on the far side of the protected link as illustrated in [Figure 76 on page 785](#). From Router R1, traffic is forwarded to its original destination, Router D.

The RSVP LSP is pre-signaled and pre-installed in the Packet Forwarding Engine of Router S so that it can be used as soon as Router S detects that the link has failed.

Figure 76: Dynamically Configured RSVP LSP Coverage

An alternative mode of operation is not to use LFA at all, and to always have the RSVP LSP created to cover all link failures.

To enable dynamic RSVP LSPs, include the **dynamic-rsvp-lsp** statement at the **[edit protocols ldp interface *interface-name* link-protection]** hierarchy level, in addition to enabling the RSVP protocol on the appropriate interfaces.

Some of the benefits of enabling dynamic RSVP LSPs include:

- Ease of configuration.
- 100 percent coverage against link failure as long as there is an alternate path to the far end of the link being protected.
- Setting up and tearing down of the RSVP bypass LSP is automatic.
- RSVP LSP only used for link protection and not for forwarding traffic while the link being protected is up.
- Reduces the total number of RSVP LSPs required on the system.

### Understanding Multicast LDP Link Protection

A point-to-multipoint LDP label-switched path (LSP) is an LDP-signaled LSP that is point-to-multipoint, and is referred to as multicast LDP.

A multicast LDP LSP can be used to send traffic from a single root or ingress node to a number of leaf or egress nodes traversing one or more transit nodes. Multicast LDP link protection enables fast reroute of traffic carried over point-to-multipoint LDP LSPs in case of a link failure. When one of the links of the point-to-multipoint tree fails, the subtrees might get detached until the IGP reconverges and the multipoint LSP is established using the best path from the downstream router to the new upstream router.

To protect the traffic flowing through the multicast LDP LSP, you can configure an explicit tunnel to re-route the traffic in the event of link failure. The explicit path has to terminate on the next downstream router. The reverse path forwarding for the traffic should be successful.

Multicast LDP link protection introduces the following features and functionality:

- Use of dynamic RSVP LSP as bypass tunnels

The RSVP LSP's Explicit Route Object (ERO) is calculated using Constrained Shortest Path First (CSPF) with the constraint as the link to avoid. The LSP is signaled and torn down dynamically whenever link protection is necessary.

- Make-before-break

The make-before-break feature ensures that there is minimum packet loss when attempting to signal a new LSP path before tearing down the old LSP path for the multicast LDP LSP.

- Targeted LDP session

A targeted adjacency to the downstream label-switching router (LSR) is created for two reasons:

- To keep the session up after link failure.
- To use the point-to-multipoint label received from the session to send traffic to the downstream LSR on the RSVP LSP bypass tunnel.

When the downstream LSR sets up the multicast LDP LSP with the root node and LSP ID, it uses that upstream LSR, which is on the best path toward the root.

**NOTE:** Multicast LDP link protection is not required when there are multiple link adjacencies (parallel links) to the downstream LSR.

---

### Different Modes for Providing LDP Link Protection

---

Following are three different modes of operation available for unicast and multicast LDP link protection:

- **Case A: LFA only**

Under this mode of operation, multicast LDP link protection is provided using an existing viable loop-free alternate (LFA). In the absence of a viable LFA, link protection is not provided for the multicast LDP LSP.

- **Case B: LFA and Dynamic RSVP LSP**

Under this mode of operation, multicast LDP link protection is provided using an existing viable LFA. In the absence of a viable LFA, an RSVP bypass LSP is created automatically to provide link protection for the multicast LDP LSP.

- **Case C: Dynamic RSVP LSP only**

Under this mode of operation, LFA is not used for link protection. Multicast LDP link protection is provided by using automatically created RSVP bypass LSP.

Figure 77 on page 787 is a sample topology illustrating the different modes of operation for multicast LDP link protection. Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 and Router R1 are the upstream and downstream label-switched routers (LSRs), respectively. A multicast LDP LSP runs among the root and leaf nodes.

Figure 77: Multicast LDP Link Protection Sample Topology

Considering that Router R0 needs to protect the multicast LDP LSP in the case that the R0-R1 link fails, the different modes of link protection operate in the following manner:

- **Case A: LFA only**

Router R0 checks if a viable LFA path exists that can avoid the R0-R1 link to reach Router R1. Based on the metrics, Router R2 is a valid LFA path for the R0-R1 link and is used to forward unicast LDP traffic. If multiple multicast LDP LSPs use the R0-R1 link, the same LFA (Router R2) is used for multicast LDP link protection.

When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the LFA path by Router R0, and the unicast LDP label to reach Router R1 (L100) is pushed on top of the multicast LDP label (L21).

- **Case B: LFA and Dynamic RSVP LSP**

Router R0 checks if a viable LFA path exists that can avoid the R0-R1 link to reach Router R1. Based on the metrics, Router R2 is a valid LFA path for the R0-R1 link and is used to forward unicast LDP traffic. If multiple multicast LDP LSPs use the R0-R1 link, the same LFA (Router R2) is used for multicast LDP link protection. When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the LFA path by Router R0.

However, if the metric on the R2-R1 link was 50 instead of 10, Router 2 is a not a valid LFA for the R0-R1 link. In this case, an RSVP LSP is automatically created to protect the multicast LDP traffic traveling between Routers R0 and R1.

- **Case C: Dynamic RSVP LSP only**

An RSVP LSP is signaled automatically from Router R0 to Router R1 through Router R2, avoiding interface ge-1/1/0. If multiple multicast LDP LSPs use the R0-R1 link, the same RSVP LSP is used for multicast LDP link protection.

When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the RSVP LSP by Router R0, and the RSVP label to reach Router R1 (L100) is pushed on top of the multicast LDP label (L21).

### Label Operation for LDP Link Protection

Using the same network topology as in Figure 5, [Figure 78 on page 788](#) illustrates the label operation for unicast and multicast LDP link protection.

*Figure 78: LDP Label Operation Sample Topology*

Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 and Router R1 are the upstream and downstream label-switched routers (LSRs), respectively. A multicast LDP LSP runs among the root and leaf nodes. An unicast LDP path connects Router R1 to Router R5.

The label operation is performed differently under the following modes of LDP link protection:

- [Case A: LFA Only on page 788](#)
- [Case B: LFA and Dynamic RSVP LSP on page 792](#)
- [Case C: Dynamic RSVP LSP Only on page 794](#)

#### Case A: LFA Only

Using the **show route detail** command output on Router R0, the unicast LDP traffic and multicast LDP traffic can be derived.

```

Label 299840 is traffic arriving at Router R0 that corresponds to unicast LDP traffic to Router R1. Label 299856 is traffic arriving at Router 0 that corresponds to multicast LDP traffic from the root node R5 to the leaf egress nodes, R3 and R4.

The main path for both unicast and multicast LDP LSPs is through interface ge-0/0/1 (the link to Router R1), and the LFA path is through interface ge-0/0/2 (the link to Router R2). The LFA path is not used unless the ge-0/0/1 interface goes down.

In the label operation for Case A, the LFA-only mode of operation is different for unicast and multicast LDP traffic:

- Unicast label operation

For unicast LDP traffic, the FECs and associated labels are advertised on all the links in the network on which LDP is enabled. This means that in order to provide LFA action for the unicast LDP traffic to Router R4, instead of swapping the incoming label for label 299824 advertised by Router R1 for FEC R4, Router R0 simply swaps the incoming

label for label 299808 advertised by Router R2 for FEC R4. This is the standard Junos OS LFA operation for unicast LDP traffic.

Figure 79 on page 790 illustrates the label operation for unicast traffic when the R0-R1 link fails. The grey boxes show the label operation for unicast LDP traffic under normal condition, and the dotted boxes show the label operation for unicast LDP traffic when the R0-R1 link fails.

Figure 79: Unicast LDP Label Operation

- Multicast label operation

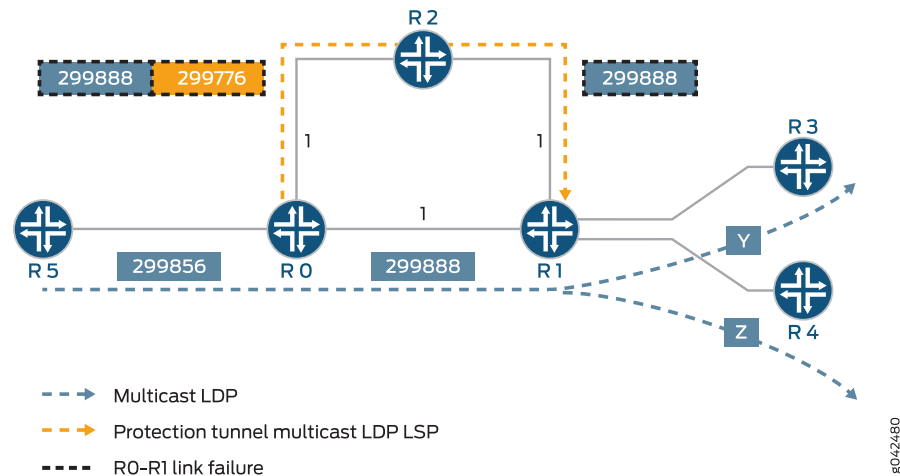

The label operation for multicast LDP traffic differs from the unicast LDP label operation, because multipoint LSP labels are only advertised along the best path from the leaf node to the ingress node. As a result, Router R2 has no knowledge of the multicast LDP. To overcome this, the multicast LDP LSP traffic is simply tunneled inside the unicast LDP LSP path through Router R2 that terminates at Router R1.

In order to achieve this, Router R0 first swaps the incoming multicast LDP LSP label 299856 to label 299888 advertised by Router R1. Label 299776 is then pushed on top, which is the LDP label advertised by Router R2 for FEC R1. When the packet arrives at Router R2, the top label is popped out due to penultimate hop-popping. This means that the packet arrives at Router R1 with the multicast LDP label 299888 that Router R1 had originally advertised to Router R0.

Figure 80 on page 791 illustrates the label operation for multicast LDP traffic when the R0-R1 link fails. The blue boxes show the label operation for multicast LDP traffic under normal condition, and the dotted boxes show the label operation for multicast LDP traffic when the R0-R1 link fails.

Figure 80: Multicast LDP Label Operation

When the metric on the R2-R1 link is set to 1000 instead of 1, Router R2 is not a valid LFA for Router R0. In this case, if Router R2 receives a packet destined for Router R1, R3, or R4 before its IGP has converged, the packet is sent back to Router R0, resulting in looping packets.

Because Router R0 has no viable LFA, no backup paths are installed in the Packet Forwarding Engine. If the R0-R1 link fails, traffic flow is interrupted until the IGP and LDP converge and new entries are installed on the affected routers.

The **show route detail** command displays the state when no LFA is available for link protection.

```

### Case B: LFA and Dynamic RSVP LSP

In this mode of operation, if there is a viable LFA neighbor, the label operation behavior is similar to that of Case A, LFA only mode. However, if there is no viable LFA neighbor, an RSVP bypass tunnel is automatically created.

If the metric on the link R2-R1 is set to 1000 instead of 1, Router R2 is not an LFA for Router R0. On learning that there are no LFA paths to protect the R0-R1 link failure, an RSVP bypass tunnel is automatically created with Router R1 as the egress node and follows a path that avoids the R0-R1 link (for instance, R0-R2-R1).

If the R0-R1 link fails, the unicast LDP and multicast LDP traffic is tunneled through the RSVP bypass tunnel. The RSVP bypass tunnel is not used for normal forwarding and is used only to provide link protection to LDP traffic in the case of R0-R1 link failure.

Using the **show route detail** command, the unicast and multicast LDP traffic can be derived.

```

user@host> show route detail

```

The main path for both unicast and multicast LDP LSP is through interface ge-0/0/1 (the link to Router R1), and the LFA path is through interface ge-0/0/2 (the link to Router R2). The LFA path is not used unless the ge-0/0/1 interface goes down.

Label 299840 is traffic arriving at Router R0 that corresponds to unicast LDP traffic to Router R4. Label 299856 is traffic arriving at Router R0 that corresponds to multicast LDP traffic from the root node R5 to the leaf egress nodes, R3 and R4.

As seen in the **show route detail** command output, the label operations for the protection path are the same for unicast LDP and multicast LDP traffic. The incoming LDP label at Router R0 is swapped to the LDP label advertised by Router R1 to Router R0. The RSVP label 299872 for the bypass tunnel is then pushed onto the packet. Penultimate hop-popping is used on the bypass tunnel, causing Router R2 to pop that label. Thus the packet arrives at Router R1 with the LDP label that it had originally advertised to Router R0.

[Figure 81 on page 794](#) illustrates the label operation for unicast LDP and multicast LDP traffic protected by the RSVP bypass tunnel. The grey and blue boxes represent label values used under normal conditions for unicast and multicast LDP traffic, respectively. The dotted boxes represent label values used when the R0-R1 link fails.

Figure 81: LDP Link Protection Label Operation

**Case C: Dynamic RSVP LSP Only**

In this mode of operation, LFA is not used at all. A dynamic RSVP bypass LSP is automatically created in order to provide link protection. The output from the **show route detail** command and the label operations are similar to Case B, LFA and dynamic RSVP LSP mode.

**Sample Multicast LDP Link Protection Configuration**

To enable multicast LDP link protection, the following configuration is required on Router R0:

**NOTE:** In this sample, multicast LDP link protection is enabled on the ge-1/0/0 interface of Router R0 that connects to Router R1, although typically all the interfaces need to be configured for link protection.

Router R0

```
protocols {
  rsvp {
    interface all;
    interface ge-0/0/0.0 {
      disable;
    }
  }
  mpls {
    interface all;
    interface ge-0/0/0.0 {
      disable;
    }
  }
  ospf {
```

```

traffic-engineering;
area 0.0.0.0 {
  interface lo0.0;
  interface ge-0/0/1.0 {
    link-protection;
  }
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
}
}
ldp {
  make-before-break {
    timeout seconds;
    switchover-delay seconds;
  }
  interface ge-1/1/0.0 {
    link-protection {
      disable;
      dynamic-rsvp-lsp;
    }
  }
}
}

```

The following configuration statements apply to the different modes of multicast LDP protection as follows:

- **link-protection** statement at **[edit protocols ospf interface ge-0/0/1.0]**

This configuration is applied only for Case A (LFA only) and Case B (LFA and dynamic RSVP LSP) modes of multicast LDP link protection. Configuring link protection under an IGP is not required for Case C (dynamic RSVP LSP only).

- **link-protection** statement at **[edit protocols ldp interface ge-0/0/1.0]**

This configuration is required for all modes of multicast LDP protection. However, if the only LDP traffic present is unicast, and dynamic RSVP bypasses are not required, then this configuration is not required, as the **link-protection** statement at the **[edit protocols ospf interface ge-0/0/1.0]** hierarchy level results in LFA action for the LDP unicast traffic.

- **dynamic-rsvp-lsp** statement at **[edit protocols ldp interface ge-0/0/1.0 link-protection]**

This configuration is applied only for Case B (LFA and dynamic RSVP LSP) and Case C (dynamic RSVP LSP only) modes of LDP link protection. Dynamic RSVP LSP configuration does not apply to Case A (LFA only).

### Make-Before-Break

The make-before-break feature is enabled by default on Junos OS and provides some benefits for point-to-multipoint LSPs.

For a point-to-multipoint LSP, a label-switched router (LSR) selects the LSR that is its next hop to the root of the LSP as its upstream LSR. When the best path to reach the root changes, the LSR chooses a new upstream LSR. During this period, the LSP might

be temporarily broken, resulting in packet loss until the LSP reconverges to a new upstream LSR. The goal of make-before-break in this case is to minimize the packet loss. In cases where the best path from the LSR to the root changes but the LSP continues to forward traffic to the previous next hop to the root, a new LSP should be established before the old LSP is withdrawn to minimize the duration of packet loss.

Taking for example, after a link failure, a downstream LSR (for instance, LSR-D) still receives and/or forwards packets to the other downstream LSRs, as it continues to receive packets from the one hop RSVP LSP. Once routing converges, LSR-D selects a new upstream LSR (LSR-U) for this point-to-multipoint LSP's FEC (FEC-A). The new LSR might already be forwarding packets for FEC-A to the downstream LSRs other than LSR-D. After LSR-U receives a label for FEC-A from LSR-D, it notifies LSR-D when it has learnt that LSP for FEC-A has been established from the root to itself. When LSR-D receives such a notification, it changes its next hop for the LSP root to LSR-U. This is a route delete and add operation on LSR-D. At this point, LSR-D does an LSP switchover, and traffic tunneled through RSVP LSP or LFA is dropped, and traffic from LSR-U is accepted. The new transit route for LSR-U is added. The RPF check is changed to accept traffic from LSR-U and to drop traffic from the old upstream LSR, or the old route is deleted and the new route is added.

The assumption is that LSR-U has received a make-before-break notification from its upstream router for the FEC-A point-to-multipoint LSP and has installed a forwarding state for the LSP. At that point it should signal LSR-D by means of make-before-break notification that it has become part of the tree identified by FEC-A and that LSR-D should initiate its switchover to the LSP. Otherwise, LSR-U should remember that it needs to send notification to LSR-D when it receives a make-before-break notification from the upstream LSR for FEC-A and installs a forwarding state for this LSP. LSR-D continues to receive traffic from the old next hop to the root node using one hop RSVP LSP or LFA path until it switches over to the new point-to-multipoint LSP to LSR-U.

The make-before-break functionality with multicast LDP link protection includes the following features:

- Make-before-break capability

An LSR advertises that it is capable of handling make-before-break LSPs using the capability advertisement. If the peer is not make-before-break capable, the make-before-break parameters are not sent to this peer. If an LSR receives a make-before-break parameter from a downstream LSR (LSR-D) but the upstream LSR (LSR-U) is not make-before-break capable, the LSR immediately sends a make-before-break notification to LSR-D, and the make-before-break capable LSP is not established. Instead, the normal LSP is established.

- Make-before-break status code

The make-before-break status code includes:

- 1—make-before-break request
- 2—make-before-break acknowledgment

When a downstream LSR sends a label-mapping message for point-to-multipoint LSP, it includes the make-before-break status code as 1 (request). When the upstream

LSR updates the forwarding state for the point-to-multipoint LSP, it informs the downstream LSR with a notification message containing the make-before-break status code as 2 (acknowledgment). At that point, the downstream LSR does an LSP switchover.

### Caveats and Limitations

---

The Junos OS implementation of the LDP link protection feature has the following caveats and limitations:

- Make-before-break is not supported for the following point-to-multipoint LSPs on an egress LSR:
  - Next-generation multicast virtual private network (MVPN) with virtual routing and forwarding (VRF) label
  - Static LSP
- The following features are not supported:
  - Nonstop active routing for point-to-multipoint LSP in Junos OS Releases 12.3, 13.1 and 13.2
  - Graceful restart switchover point-to-multipoint LSP
  - Link protection for routing instance

**See Also**   • [Example: Configuring LDP Link Protection on page 797](#)

## Example: Configuring LDP Link Protection

This example shows how to configure Label Distribution Protocol (LDP) link protection for both unicast and multicast LDP label-switched paths (LSPs).

- [Requirements on page 797](#)
- [Overview on page 798](#)
- [Configuration on page 799](#)
- [Verification on page 804](#)

### Requirements

---

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series, MX Series, or T Series routers with one root node and two leaf nodes running a point-to-multipoint LDP LSP.
- Junos OS Release 12.3 or later running on all the routers.

Before you begin:

1. Configure the device interfaces.
2. Configure the following protocols:

- a. RSVP
- b. MPLS
- c. OSPF or any other IGP
- d. LDP

---

## Overview

LDP link protection enables fast reroute of traffic carried over LDP LSPs in case of a link failure. LDP point-to-multipoint LSPs can be used to send traffic from a single root or ingress node to a number of leaf nodes or egress nodes traversing one or more transit nodes. When one of the links of the point-to-multipoint tree fails, the subtrees can get detached until the IGP reconverges and multicast LDP initiates label mapping using the best path from the downstream router to the new upstream router. To protect the traffic in the event of a link failure, you can configure an explicit tunnel so that traffic can be rerouted using the tunnel. Junos OS supports make-before-break capabilities to ensure minimum packet loss when attempting to signal a new LSP path before tearing down the old LSP path. This feature also adds targeted LDP support for multicast LDP link protection.

When configuring LDP link protection, be aware of the following considerations:

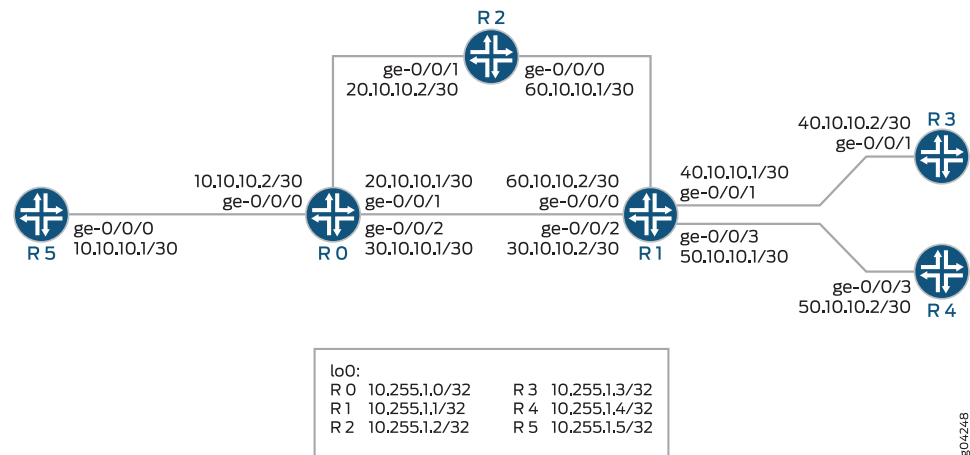

- Configure traffic engineering under IGP (if it is not supported by default), and include the interfaces configured for MPLS and RSVP so that constrained-based link protected dynamic RSVP LSP is signaled by RSVP using Constrained Shortest Path First (CSPF). When this condition is not satisfied, RSVP LSP might not come up and LDP cannot use it as a protected next hop.
- Configure a path between two label-switched routers (LSRs) to provide IP connectivity between the routers when there is a link failure. This enables CSPF to calculate an alternate path for link protection. When the connectivity between the routers is lost, the LDP targeted adjacency does not come up and dynamic RSVP LSP cannot be signaled, resulting in no protection for the LDP forwarding equivalence class (FEC) for which the peer is the downstream LSR.
- If link protection is active only on one LSR, then the other LSR should not be configured with the **strict-targeted-hellos** statement. This enables the LSR without link protection to allow asymmetric remote neighbor discovery and send periodic targeted hellos to the LSR that initiated the remote neighbor. When this condition is not satisfied, LDP targeted adjacency is not formed.
- LDP must be enabled on the loopback interface of the LSR to create remote neighbors based on LDP tunneling, LDP-based virtual private LAN service (VPLS), Layer 2 circuits, or LDP session protection. When this condition is not satisfied, LDP targeted adjacency is not formed.
- For unicast LDP LSP, loop-free alternate (LFA) should be configured in IGP.

- The ingress route to merge point should have at least one next hop avoiding the primary link between the merge point and the point of local repair for unicast LDP LSP.
- Point of local repair should have a unicast LDP label for the backup next hop to reach the merge point.

### Topology

Figure 82: LDP Link Protection

In this example, Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 is the point of local repair.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
R5

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R0:

1. Configure the Router R0 interfaces.

**[edit interfaces]**

```

user@R0# set ge-0/0/0 unit 0 family inet address 10.10.10.2/30
user@R0# set ge-0/0/0 unit 0 family mpls
user@R0# set ge-0/0/1 unit 0 family inet address 20.10.10.1/30
user@R0# set ge-0/0/1 unit 0 family mpls
user@R0# set ge-0/0/2 unit 0 family inet address 30.10.10.1/30
user@R0# set ge-0/0/2 unit 0 family mpls
user@R0# set lo0 unit 0 family inet address 10.255.1.0/32

```

2. Configure the router ID and autonomous system of Router R0.

**[edit routing-options]**

```

user@R0# set router-id 10.255.1.0
user@R0# set autonomous-system 100

```

3. Enable RSVP on all the interfaces of Router R0 (excluding the management interface).

**[edit protocols]**

```

user@R0# set rsvp interface all
user@R0# set rsvp interface fxp0.0 disable

```

4. Enable MPLS on all the interfaces of Router R0 (excluding the management interface) along with traffic engineering capabilities.

**[edit protocols]**

```

user@R0# set mpls traffic-engineering
user@R0# set mpls interface all
user@R0# set mpls interface fxp0.0 disable

```

5. Enable OSPF on all the interfaces of Router R0 (excluding the management interface), assign equal cost metric for the links, and enable traffic engineering capabilities.

**[edit protocols]**

```

user@R0# set ospf traffic-engineering
user@R0# set ospf area 0.0.0.0 interface all metric 1
user@R0# set ospf area 0.0.0.0 interface fxp0.0 disable

```

**NOTE:** For multicast LDP link protection with loop-free alternative (LFA), enable the following configuration under the [edit protocols] hierarchy level:

```

set ospf area 0 interface all link-protection

```

6. Enable LDP on all the interfaces of Router R0 (excluding the management interface) and configure link protection with dynamic RSVP bypass LSP.

```
[edit protocols]
user@R0# set ldp interface all link-protection dynamic-rsvp-lsp
user@R0# set ldp interface fxp0.0 disable
user@R0# set ldp p2mp
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 10.10.10.2/30;
    }
    family mpls;
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 20.10.10.1/30;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 30.10.10.1/30;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.1.0/32;
    }
  }
}
```

```
user@R0# show routing-options
router-id 10.255.1.0;
autonomous-system 100;
```

```
user@R0# show protocols
rsvp {
```

```
interface all;
interface fxp0.0 {
  disable;
}
}
mpls {
  traffic-engineering;
  interface all;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface all {
      metric 1;
    }
    interface fxp0.0 {
      disable;
    }
  }
}
ldp {
  interface all {
    link-protection {
      dynamic-rsvp-lsp;
    }
  }
  interface fxp0.0 {
    disable;
  }
  p2mp;
}
```

---

## Verification

Verify that the configuration is working properly.

- [Verifying the Bypass RSVP LSP Path on page 804](#)
- [Verifying Label Operation on page 805](#)

### *Verifying the Bypass RSVP LSP Path*

**Purpose** Verify that the bypass RSVP LSP path has been created on the point of local repair (PLR).

**Action** From operational mode, run the **show route table mpls.0** command.

```
user@R0> show route table mpls.0

## Understanding Multicast-Only Fast Reroute

---

Starting in Junos OS Release 14.1, Multicast-only fast reroute (MoFRR) functionality is available, in which packet loss is minimized in PIM and multipoint LDP domains. MoFRR minimizes packet loss in a network when there is a link failure. It works by enhancing multicast routing protocols like Protocol Independent Multicast (PIM) and multipoint Label Distribution Protocol (multipoint LDP). MoFRR is supported on MX Series routers with MPC line cards. As a prerequisite, the router must be set to **network-services enhanced-ip** mode, and all the line-cards in the router must be MPCs.

With MoFRR enabled, join messages are sent on primary and backup upstream paths. Data packets are received from both the primary path and the backup paths. The redundant packets are discarded based on priority (weights that are assigned to the primary and backup paths). When a failure is detected on the primary path, the repair is made by changing the interface on which packets are accepted to the secondary interface. Because the repair is local, it is fast—greatly improving convergence times in the event of a link failure on the primary path.

Currently, the most likely real-world application for MoFRR is streaming IPTV. IPTV streams are multicast as UDP streams. Therefore, any lost packets are not retransmitted, and this can result in a less-than-satisfactory user experience. MoFRR can be used to improve this situation.

When fast reroute is applied to unicast streams, an upstream router preestablishes MPLS label-switched paths (LSPs) or precomputes an IP loop-free alternate (LFA) fast reroute backup path to handle failure of a segment in the downstream path.

In multicast routing, the traffic distribution graphs are usually originated by the receiver. This is unlike unicast routing, which usually establishes the path from the source to the receiver. Protocols that are capable of establishing multicast distribution graphs are PIM (for IP), multipoint LDP (for MPLS), and RSVP-TE (for MPLS). Of these, PIM and multipoint LDP receivers initiate the distribution graph setup, and therefore these are the two multicast protocols for which MoFRR is supported.

In a multicast tree, performing a reactive repair upon detection of a network-component failure can lead to significant traffic loss due to delay in setting up the alternative path. MoFRR reduces traffic loss in a multicast distribution tree when a network component fails. With MoFRR, one of the downstream routers that supports this feature sets up an alternative path toward the source to receive a backup live stream of the same multicast traffic. When a failure is detected on the primary stream, the MoFRR router switches to the backup stream.

With MoFRR enabled, for each (S,G) entry, two of the available upstream interfaces are used to send a join message and to receive multicast traffic. The protocol attempts to select two disjoint paths if two such paths are available. If disjoint paths are not available, the protocol selects two non-disjoint paths. If two non-disjoint paths are not available, only a primary path is selected with no backup. MoFRR is supported for both IPv4 and IPv6 protocol families.

In the context of load balancing, MoFRR prioritizes the disjoint backup in favor of load balancing the available paths.

Figure 83 on page 808 shows two paths from the egress provider edge (PE) router to the ingress PE router.

Figure 83: MoFRR Sample Topology

8041674

When enabled with MoFRR functionality, the egress router sets up two multicast trees, a primary path and a backup path, toward the multicast source for each (S,G). In other words, the egress router propagates the same (S,G) join messages toward two different upstream neighbors, thus creating two multicast trees.

One of the multicast trees goes through plane 1 and the other through plane 2, as shown in Figure 83 on page 808. For each (S,G), the egress PE router forwards traffic received on the primary path and drops traffic received on the backup path.

MoFRR is supported on both equal-cost multipath (ECMP) paths and non-ECMP paths. Unicast loop-free alternate (LFA) routes need to be enabled to support MoFRR on non-ECMP paths. LFA routes are enabled with the **link-protection** statement in the interior gateway protocol (IGP) configuration. When you enable link protection on an OSPF or IS-IS interface, Junos OS creates a backup LFA path to the primary next hop for all destination routes that traverse the protected interface.

Junos OS implements MoFRR in the IP network for IP MoFRR and at the MPLS label-edge router (LER) for multipoint LDP MoFRR.

Multipoint LDP MoFRR is used at the egress node of an MPLS network, where the packets are forwarded to an IP network. In the case of multipoint LDP MoFRR, the two paths toward the upstream PE router are established for receiving two streams of MPLS packets at the LER. One of the streams (the primary) is accepted, and the other one (the backup) is dropped at the LER. The backup stream is accepted if the primary path fails. A prerequisite for this feature is inband signaling support, as described in [“Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs” on page 856](#).

## PIM Functionality

Junos OS supports MoFRR for shortest-path tree (SPT) joins in PIM source-specific multicast (SSM) and any-source multicast (ASM). MoFRR is supported for both SSM and ASM ranges. To enable MoFRR for (\*G) joins, the `mofrr-asm-starg` configuration statement needs to be included. For each group G, either (S,G) or (\*G) (not both) will undergo MoFRR. (S,G) always takes precedence over (\*G).

With MoFRR enabled, a PIM router propagates join messages on two upstream RPF interfaces to receive multicast traffic on both links for the same join request. Preference is given to two paths that do not converge to the same immediate upstream router. PIM installs appropriate multicast routes with upstream RPF next hops with two (primary and backup) interfaces.

When the primary path fails, the backup path is upgraded to primary, and traffic is forwarded accordingly. If there are alternate paths available, a new backup path is calculated and the appropriate multicast route is updated or installed.

MoFRR can be enabled along with PIM join load balancing (with the `join-load-balance automatic` statement). However, in such cases the distribution of join messages among the links might not be even. When a new ECMP link is added, join messages on the primary path are redistributed and load-balanced. The join messages on the backup path might still follow the same path and might not be evenly redistributed.

MoFRR is enabled with a `[edit routing-options multicast stream-protection]` configuration and is managed by a set of filter policies. When an egress PIM router receives a join message or an IGMP report, the router checks for the MoFRR configuration.

If the MoFRR configuration is not present, PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 83 on page 808](#)).

If the MoFRR configuration is present, Junos OS checks for a policy configuration.

If a policy is not present, Junos OS checks for primary and backup paths (upstream interfaces), and takes the following actions:

- If primary and backup paths are not available—PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 83 on page 808](#)).
- If primary and backup paths are available—PIM sends the join message upstream toward two of the available upstream neighbors. Junos OS sets up primary and

secondary multicast paths to receive multicast traffic (for example, plane 1 in [Figure 83 on page 808](#)).

If a policy is present, Junos OS checks whether the policy allows MoFRR for this (S,G), and takes the following actions:

- If the policy check fails—PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 83 on page 808](#)).
- If the policy check passes—Junos OS checks for primary and backup paths (upstream interfaces).
  - If the primary and backup paths are not available, PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 83 on page 808](#)).
  - If the primary and backup paths are available, PIM sends the join message upstream toward two of the available upstream neighbors. Junos OS sets up primary and secondary multicast paths to receive multicast traffic (for example, plane 1 in [Figure 83 on page 808](#)).

## Multipoint LDP Functionality

To avoid MPLS traffic duplication, the usual implementation of multipoint LDP selects only one upstream path. (See section 2.4.1.1. Determining One's 'upstream LSR' in RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*.)

For multipoint LDP MoFRR, the multipoint LDP node selects two separate upstream peers and sends two separate labels, one to each upstream peer. The same algorithm described in RFC 6388 is used to select the primary upstream path. The backup upstream path selection again uses the same algorithm but excludes the primary upstream LSR as a candidate. Two streams of MPLS traffic are sent to the egress node from the two different upstream peers. The MPLS traffic from only one of the upstream neighbors is selected as the primary path to accept the traffic, and the other path becomes the backup path. The traffic on the backup path is dropped. When the primary upstream path fails, the traffic from the backup path is then accepted. The multipoint LDP node selects the two upstream paths based on the interior gateway protocol (IGP) root node next hop.

A forwarding equivalency class (FEC) is a group of IP packets that are forwarded in the same manner, over the same path, and with the same forwarding treatment. Normally, the label that is put on a particular packet represents the FEC to which that packet is assigned. In MoFRR, two routes are placed into the mpls.0 table for each FEC—one route for the primary label and the other route for the backup label.

If there are parallel links toward the same immediate upstream node, both parallel links are considered to be the primary. At any point in time, the upstream node sends traffic on only one of the multiple parallel links.

A bud node is an LSR that is an egress LSR, but also has one or more directly connected downstream LSRs. In the case of a bud node, the traffic from the primary upstream path is forwarded to a downstream LSR. If the primary upstream path fails, the MPLS traffic from the backup upstream path is forwarded to the downstream LSR. This means that

the downstream LSR next hop is added to both MPLS routes along with the egress next hop.

MoFRR for multipoint LDP is enabled with a **[edit routing-options multicast stream-protection]** configuration and is managed by a set of filter policies.

If the multipoint LDP point-to-multipoint FEC is enabled for MoFRR, the following additional considerations are factored into upstream path selection:

- The targeted LDP sessions are skipped if there is a nontargeted LDP session. If there is a single targeted LDP session, the targeted LDP session is selected, but the corresponding point-to-multipoint FEC loses the MoFRR capability because there is no interface associated with the targeted LDP session.
- All interfaces that belong to the same upstream LSR are considered to be the primary path.
- For any root-node route updates, the upstream path is changed based on the latest next hops from the IGP. If a better path is available, multipoint LDP attempts to switch to the better path.

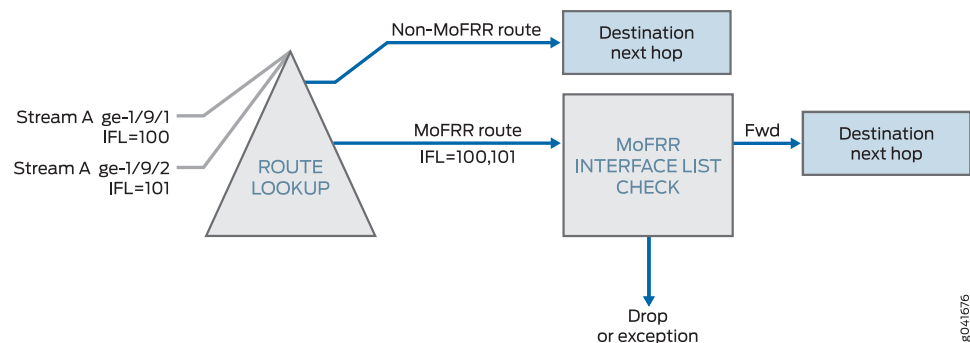

## Packet Forwarding

For both PIM and multipoint LDP, multicast source stream selection is performed at the incoming interface. This prevents duplicate streams from being sent across the fabric and prevents multiple route lookups that result in drops, thus preserving fabric bandwidth and maximizing forwarding performance.

For PIM, each IP multicast stream contains the same destination address. Regardless of the interface on which the packets arrive, the packets have the same route. An interface list is attached to the route. Junos OS checks the interface upon which each packet arrives and forwards only those that are from the primary interface. If the interface matches a secondary interface, the packets are dropped. If no match is found, the packets are handled as exceptions in the control plane.

This process is shown in [Figure 84 on page 811](#).

**Figure 84: MoFRR IP Route Lookup in the Packet Forwarding Engine**

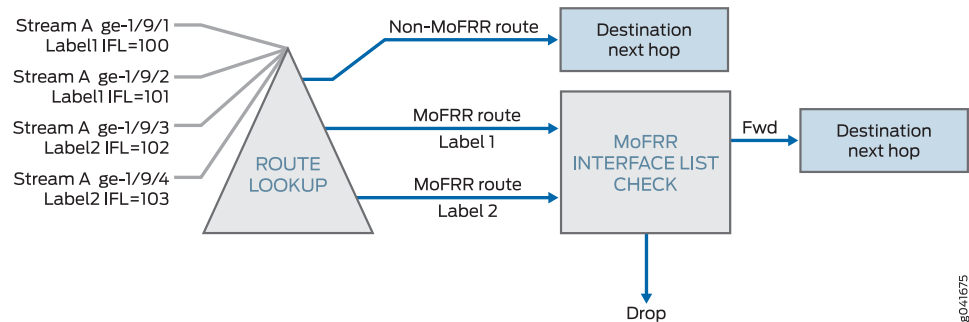

For multipoint LDP, multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check.

Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.

This process is shown in Figure 85 on page 812.

**Figure 85: MoFRR MPLS Route Lookup in the Packet Forwarding Engine**

## Limitations and Caveats

MoFRR has the following limitations and caveats:

- MoFRR failure detection is supported for immediate link protection of the router on which MoFRR is enabled and not on all the links (end-to-end) in the multicast traffic path.
- MoFRR supports FRR on two selected disjoint paths toward the source. Two of the selected upstream neighbors cannot be on the same interface—in other words, two upstream neighbors on a LAN segment. The same is true if the upstream interface happens to be a multicast tunnel interface.
- Detection of the maximum end-to-end disjoint upstream paths is not supported. The egress router only makes sure that there is a disjoint upstream node (the immediate previous hop). PIM and multipoint LDP do not support the equivalent of explicit route objects (EROs). Hence, disjoint upstream path detection is limited to control over the immediately previous hop node. Because of this limitation, the path to the upstream node of the previous hop selected as primary and backup might be shared.
- MoFRR does not apply to multipoint LDP traffic received on an RSVP tunnel because the RSVP tunnel is not associated with any interface.
- Some traffic loss is seen in the following scenarios:
  - A better upstream path becomes available on an egress node.
  - MoFRR is enabled or disabled on the egress node while there is an active traffic stream flowing.
- PIM join load balancing for join messages for backup paths are not supported.
- For a multicast group G, MoFRR is not allowed for both (S,G) and (\*,G) join messages. (S,G) join messages have precedence over (\*,G).
- MoFRR is not supported for multicast traffic streams that use two different multicast groups. Each (S,G) combination is treated as a unique multicast traffic stream.

- The bidirectional PIM range is not supported for MoFRR.
- PIM dense-mode is not supported for MoFRR
- Mixed upstream MoFRR is not supported. This refers to PIM multipoint LDP in-band signaling, wherein one upstream path is through multipoint LDP and the second upstream path is through PIM.
- Multicast statistics for the backup traffic stream are not maintained by PIM and therefore are not available in the operational output of **show** commands.
- Multipoint LDP labels as inner labels are not supported.
- If the source is reachable through multiple ingress provider edge (PE) routers, multipoint LDP MoFRR is not supported.
- Targeted upstream sessions are not selected as the upstream node for MoFRR.
- Rate monitoring is not supported.
- Multipoint LDP link protection on the backup path is not supported because there is no support for MoFRR inner labels.

**Release History Table**

Release	Description
14.1	Starting in Junos OS Release 14.1, Multicast-only fast reroute (MoFRR) functionality is available, in which packet loss is minimized in PIM and multipoint LDP domains.

## Configuring Multicast-Only Fast Reroute

---

You can configure multicast-only fast reroute (MoFRR) to minimize packet loss in a network when there is a link failure.

When fast reroute is applied to unicast streams, an upstream router preestablishes MPLS label-switched paths (LSPs) or precomputes an IP loop-free alternate (LFA) fast reroute backup path to handle failure of a segment in the downstream path.

In multicast routing, the traffic distribution graphs are usually originated by the receiver. This is unlike unicast routing, which usually establishes the path from the source to the receiver. Protocols that are capable of establishing multicast distribution graphs are PIM (for IP), multipoint LDP (for MPLS) and RSVP-TE (for MPLS). Of these, PIM and multipoint LDP receivers initiate the distribution graph setup, and therefore:

- On the QFX series, MoFRR is supported in PIM domains.
- On the MX Series and SRX Series, MoFRR is supported in PIM and multipoint LDP domains.

The configuration steps are the same for enabling MoFRR for PIM on all devices that support this feature, unless otherwise indicated. Configuration steps that are not applicable to multipoint LDP MoFRR are also indicated.

(For MX Series routers only) MoFRR is supported on MX Series routers with MPC line cards. As a prerequisite, all the line cards in the router must be MPCs.

To configure MoFRR on routers or switches:

1. (For MX Series and SRX Series routers only) Set the router to enhanced IP mode.

```
[edit chassis]
user@host# set network-services enhanced-ip
```

2. Enable MoFRR.

```
[edit routing-options multicast]
user@host# set stream-protection
```

3. (Optional) Configure a routing policy that filters for a restricted set of multicast streams to be affected by your MoFRR configuration.

You can apply filters that are based on source or group addresses.

For example:

```
[edit policy-options]
policy-statement mofrr-select {
  term A {
    from {
      source-address-filter 225.1.1.1/32 exact;
```

```

    }
    then {
        accept;
    }
}
term B {
    from {
        source-address-filter 226.0.0.0/8 orlonger;
    }
    then {
        accept;
    }
}
term C {
    from {
        source-address-filter 227.1.1.0/24 orlonger;
        source-address-filter 227.4.1.0/24 orlonger;
        source-address-filter 227.16.1.0/24 orlonger;
    }
    then {
        accept;
    }
}
term D {
    from {
        source-address-filter 227.1.1.1/32 exact
    }
    then {
        reject; #MoFRR disabled
    }
}
...
}

```

4. (Optional) If you configured a routing policy to filter the set of multicast groups to be affected by your MoFRR configuration, apply the policy for MoFRR stream protection.

```

[edit routing-options multicast stream-protection]
user@host# set policy policy-name

```

For example:

```

routing-options {
    multicast {
        stream-protection {
            policy mofrr-select
        }
    }
}

```

5. (Optional) In a PIM domain with MoFRR, allow MoFRR to be applied to any-source multicast (ASM) (\*G) joins.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-asm-starg
```

6. (Optional) In a PIM domain with MoFRR, allow only a disjoint RPF (an RPF on a separate plane) to be selected as the backup RPF path.

This is not supported for multipoint LDP MoFRR. In a multipoint LDP MoFRR domain, the same label is shared between parallel links to the same upstream neighbor. This is not the case in a PIM domain, where each link forms a neighbor. The **mofrr-disjoint-upstream-only** statement does not allow a backup RPF path to be selected if the path goes to the same upstream neighbor as that of the primary RPF path. This ensures that MoFRR is triggered only on a topology that has multiple RPF upstream neighbors.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-disjoint-upstream-only
```

7. (Optional) In a PIM domain with MoFRR, prevent sending join messages on the backup path, but retain all other MoFRR functionality.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-no-backup-join
```

8. (Optional) In a PIM domain with MoFRR, allow new primary path selection to be based on the unicast gateway selection for the unicast route to the source and to change when there is a change in the unicast selection, rather than having the backup path be promoted as primary. This ensures that the primary RPF hop is always on the best path.

When you include the **mofrr-primary-selection-by-routing** statement, the backup path is not guaranteed to get promoted to be the new primary path when the primary path goes down.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-primary-path-selection-by-routing
```

## Example: Configuring Multicast-Only Fast Reroute in a Multipoint LDP Domain

This example shows how to configure multicast-only fast reroute (MoFRR) to minimize packet loss in a network when there is a link failure.

Multipoint LDP MoFRR is used at the egress node of an MPLS network, where the packets are forwarded to an IP network. In the case of multipoint LDP MoFRR, the two paths toward the upstream provider edge (PE) router are established for receiving two streams of MPLS packets at the label-edge router (LER). One of the streams (the primary) is accepted, and the other one (the backup) is dropped at the LER. The backup stream is accepted if the primary path fails.

- [Overview on page 817](#)
- [CLI Quick Configuration on page 818](#)
- [Configuration on page 824](#)
- [Verification on page 829](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

In a multipoint LDP domain, for MoFRR to work, only the egress PE router needs to have MoFRR enabled. The other routers do not need to support MoFRR.

MoFRR is supported on MX Series platforms with MPC line cards. As a prerequisite, the router must be set to **network-services enhanced-ip** mode, and all the line-cards in the platform must be MPCs.

This example requires Junos OS Release 14.1 or later on the egress PE router.

### Overview

In this example, Device R3 is the egress edge router. MoFRR is enabled on this device only.

OSPF is used for connectivity, though any interior gateway protocol (IGP) or static routes can be used.

For testing purposes, routers are used to simulate the source and the receiver. Device R4 and Device R8 are configured to statically join the desired group by using the **set protocols igmp interface interface-name static group group** command. In the case when a real multicast receiver host is not available, as in this example, this static IGMP configuration is useful. On the receivers, to make them listen to the multicast group address, this example uses **set protocols sap listen group**.

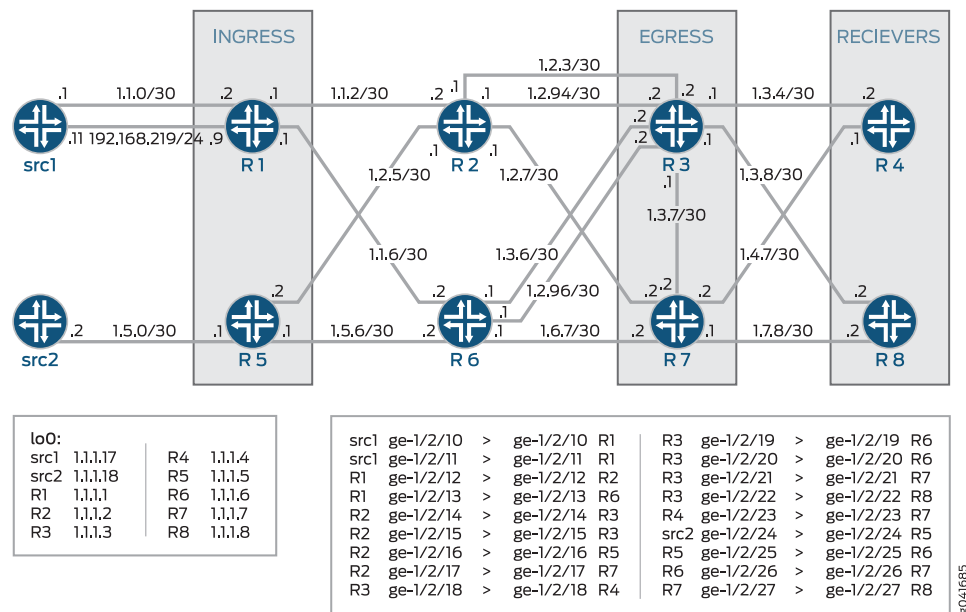

MoFRR configuration includes a policy option that is not shown in this example, but is explained separately. The option is configured as follows:

```
stream-protection {
  policy policy-name;
}
```

## Topology

Figure 86 on page 818 shows the sample network.

Figure 86: MoFRR in a Multipoint LDP Domain

“CLI Quick Configuration” on page 818 shows the configuration for all of the devices in Figure 86 on page 818.

The section “Configuration” on page 824 describes the steps on Device R3.

## CLI Quick Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device src1**

```
set interfaces ge-1/2/10 unit 0 description src1-to-R1
set interfaces ge-1/2/10 unit 0 family inet address 1.1.0.1/30
set interfaces ge-1/2/11 unit 0 description src1-to-R1
set interfaces ge-1/2/11 unit 0 family inet address 192.168.219.11/24
set interfaces lo0 unit 0 family inet address 1.1.1.17/32
set protocols ospf area 0.0.0.0 interface all
set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

Device src2	<pre> set interfaces ge-1/2/24 unit 0 description src2-to-R5 set interfaces ge-1/2/24 unit 0 family inet address 1.5.0.2/30 set interfaces lo0 unit 0 family inet address 1.1.1.18/32 set protocols rsvp interface all set protocols ospf area 0.0.0.0 interface all set protocols ospf area 0.0.0.0 interface lo0.0 passive </pre>

## Configuration

**Step-by-Step  
Procedure**

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R3:

1. Enable enhanced IP mode.

```
[edit chassis]
user@R3# set network-services enhanced-ip
```

2. Configure the device interfaces.

```
[edit interfaces]
user@R3# set ge-1/2/14 unit 0 description R3-to-R2
user@R3# set ge-1/2/14 unit 0 family inet address 1.2.3.2/30
user@R3# set ge-1/2/14 unit 0 family mpls
user@R3# set ge-1/2/18 unit 0 description R3-to-R4
user@R3# set ge-1/2/18 unit 0 family inet address 1.3.4.1/30
user@R3# set ge-1/2/18 unit 0 family mpls
user@R3# set ge-1/2/19 unit 0 description R3-to-R6
user@R3# set ge-1/2/19 unit 0 family inet address 1.3.6.2/30
user@R3# set ge-1/2/19 unit 0 family mpls
user@R3# set ge-1/2/21 unit 0 description R3-to-R7
user@R3# set ge-1/2/21 unit 0 family inet address 1.3.7.1/30
user@R3# set ge-1/2/21 unit 0 family mpls
user@R3# set ge-1/2/22 unit 0 description R3-to-R8
user@R3# set ge-1/2/22 unit 0 family inet address 1.3.8.1/30
user@R3# set ge-1/2/22 unit 0 family mpls
user@R3# set ge-1/2/15 unit 0 description R3-to-R2
user@R3# set ge-1/2/15 unit 0 family inet address 1.2.94.2/30
user@R3# set ge-1/2/15 unit 0 family mpls
user@R3# set ge-1/2/20 unit 0 description R3-to-R6
user@R3# set ge-1/2/20 unit 0 family inet address 1.2.96.2/30
user@R3# set ge-1/2/20 unit 0 family mpls
user@R3# set lo0 unit 0 family inet address 1.1.1.3/32 primary
```

3. Configure the autonomous system (AS) number.

```
user@R3# set routing-options autonomous-system 10
```

4. Configure the routing policies.

```
[edit policy-options policy-statement mldppim-ex]
user@R3# set term B from source-address-filter 192.168.0.0/24 orlonger
user@R3# set term B from source-address-filter 192.168.219.11/32 orlonger
user@R3# set term B then accept
user@R3# set term A from source-address-filter 1.1.0.1/30 orlonger
user@R3# set term A then accept
[edit policy-options policy-statement static-route-tobgp]
user@R3# set term static from protocol static
user@R3# set term static from protocol direct
user@R3# set term static then accept
```

5. Configure PIM.

```
[edit protocols pim]
user@R3# set mldp-inband-signalling policy mldppim-ex
```

```
user@R3# set interface lo0.0
user@R3# set interface ge-1/2/18.0
user@R3# set interface ge-1/2/22.0
```

6. Configure LDP.

```
[edit protocols ldp]
user@R3# set interface all
user@R3# set p2mp
```

7. Configure an IGP or static routes.

```
[edit protocols ospf]
user@R3# set traffic-engineering
user@R3# set area 0.0.0.0 interface all
user@R3# set area 0.0.0.0 interface fxp0.0 disable
user@R3# set area 0.0.0.0 interface lo0.0 passive
```

8. Configure internal BGP.

```
[edit protocols bgp group ibgp]
user@R3# set local-address 1.1.1.3
user@R3# set peer-as 10
user@R3# set neighbor 1.1.1.1
user@R3# set neighbor 1.1.1.5
```

9. Configure MPLS and, optionally, RSVP.

```
[edit protocols mpls]
user@R3# set interface all
[edit protocols rsvp]
user@R3# set interface all
```

10. Enable MoFRR.

```
[edit routing-options multicast]
user@R3# set stream-protection
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R3# show chassis
network-services enhanced-ip;
```

```
user@R3# show interfaces

## Verification

Confirm that the configuration is working properly.

- [Checking the LDP Point-to-Multipoint Forwarding Equivalency Classes on page 829](#)
- [Examining the Label Information on page 830](#)
- [Checking the Multicast Routes on page 832](#)
- [Checking the LDP Point-to-Multipoint Traffic Statistics on page 833](#)

### Checking the LDP Point-to-Multipoint Forwarding Equivalency Classes

**Purpose** Make sure the MoFRR is enabled, and determine what labels are being used.

**Action** user@R3> show ldp p2mp fec

```
LDP P2MP FECs:
P2MP root-addr 1.1.1.1, grp: 232.1.1.1, src: 192.168.219.11
MoFRR enabled
Fec type: Egress (Active)
Label: 301568
P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11
MoFRR enabled
Fec type: Egress (Active)
Label: 301600
```

**Meaning** The output shows that MoFRR is enabled, and it shows that the labels 301568 and 301600 are being used for the two multipoint LDP point-to-multipoint LSPs.

---

### Examining the Label Information

---

**Purpose** Make sure that the egress device has two upstream interfaces for the multicast group join.

**Action** user@R3> show route label 301568 detail

```

(Active)
P2MP path type: Transit/Egress
  Output Session (label): 1.1.1.6:0 (301584) (Backup)
  Egress Nexthops: Interface ge-1/2/18.0
                  Interface ge-1/2/22.0
  RPF Nexthops:   Interface ge-1/2/15.0, 1.2.94.1, 301568, 1
                  Interface ge-1/2/20.0, 1.2.96.1, 301584, 65534
                  Interface ge-1/2/14.0, 1.2.3.1, 301568, 1
                  Interface ge-1/2/19.0, 1.3.6.1, 301584, 65534
  Attached FECs:  P2MP root-addr 1.1.1.1, grp: 232.1.1.1, src: 192.168.219.11
(Active)
P2MP path type: Transit/Egress
  Output Session (label): 1.1.1.6:0 (301600) (Primary)
  Egress Nexthops: Interface ge-1/2/18.0
                  Interface ge-1/2/22.0
  RPF Nexthops:   Interface ge-1/2/15.0, 1.2.94.1, 301616, 65534
                  Interface ge-1/2/20.0, 1.2.96.1, 301600, 1
                  Interface ge-1/2/14.0, 1.2.3.1, 301616, 65534
                  Interface ge-1/2/19.0, 1.3.6.1, 301600, 1
  Attached FECs:  P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11
(Active)
P2MP path type: Transit/Egress
  Output Session (label): 1.1.1.2:0 (301616) (Backup)
  Egress Nexthops: Interface ge-1/2/18.0
                  Interface ge-1/2/22.0
  RPF Nexthops:   Interface ge-1/2/15.0, 1.2.94.1, 301616, 65534
                  Interface ge-1/2/20.0, 1.2.96.1, 301600, 1
                  Interface ge-1/2/14.0, 1.2.3.1, 301616, 65534
                  Interface ge-1/2/19.0, 1.3.6.1, 301600, 1
  Attached FECs:  P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11
(Active)
```

**Meaning** The output shows primary and backup sessions, and RPF next hops.

### Checking the LDP Point-to-Multipoint Traffic Statistics

**Purpose** Make sure that both primary and backup statistics are listed.

**Action** user@R3> `show ldp traffic-statistics p2mp`

P2MP FEC Statistics:

FEC(root_addr:lsp_id/grp,src)	Nexthop	Packets	Bytes
Shared			
1.1.1.1:232.1.1.1,192.168.219.11, Label: 301568	1.3.8.2	0	0
No	1.3.4.2	0	0
1.1.1.1:232.1.1.1,192.168.219.11, Label: 301584, Backup route	1.3.4.2	0	0
No	1.3.8.2	0	0
1.1.1.1:232.1.1.2,192.168.219.11, Label: 301600	1.3.8.2	0	0
No	1.3.4.2	0	0
1.1.1.1:232.1.1.2,192.168.219.11, Label: 301616, Backup route	1.3.4.2	0	0
No	1.3.8.2	0	0
No			

**Meaning** The output shows both primary and backup routes with the labels.

## Example: Configuring LDP Downstream on Demand

This example shows how to configure LDP downstream on demand. LDP is commonly configured using downstream unsolicited advertisement mode, meaning label advertisements for all routes are received from all LDP peers. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between the access and aggregation networks and to reduce the processing requirements for the control plane.

Downstream nodes could potentially receive tens of thousands of label bindings from upstream aggregation nodes. Instead of learning and storing all label bindings for all possible loopback addresses within the entire MPLS network, the downstream aggregation node can be configured using LDP downstream on demand to only request the label

bindings for the FECs corresponding to the loopback addresses of those egress nodes on which it has services configured.

- [Requirements on page 835](#)
- [Overview on page 835](#)
- [Configuration on page 835](#)
- [Verification on page 839](#)

## Requirements

This example uses the following hardware and software components:

- M Series router
- Junos OS 12.2

## Overview

You can enable LDP downstream on demand label advertisement for an LDP session by including the [downstream-on-demand](#) statement at the `[edit protocols ldp session]` hierarchy level. If you have configured downstream on demand, the Juniper Networks router advertises the downstream on demand request to its peer routers. For a downstream on demand session to be established between two routers, both have to advertise downstream on demand mode during LDP session establishment. If one router advertises downstream unsolicited mode and the other advertises downstream on demand, downstream unsolicited mode is used.

## Configuration

### Configuring LDP Downstream on Demand

**Step-by-Step Procedure** To configure a LDP downstream on demand policy and then configure that policy and enable LDP downstream on demand on the LDP session:

1. Configure the downstream on demand policy (DOD-Request-Loopbacks in this example).

This policy causes the router to forward label request messages only to the FECs that are matched by the DOD-Request-Loopbacks policy.

```
[edit policy-options]
user@host# set prefix-list Request-Loopbacks 10.1.1.1/32
user@host# set prefix-list Request-Loopbacks 10.1.1.2/32
user@host# set prefix-list Request-Loopbacks 10.1.1.3/32
user@host# set prefix-list Request-Loopbacks 10.1.1.4/32
user@host# set policy-statement DOD-Request-Loopbacks term 1 from prefix-list
Request-Loopbacks
user@host# set policy-statement DOD-Request-Loopbacks term 1 then accept
```

2. Specify the DOD-Request-Loopbacks policy using the `dod-request-policy` statement at the `[edit protocols ldp]` hierarchy level.

The policy specified with the **dod-request-policy** statement is used to identify the prefixes to send label request messages. This policy is similar to an egress policy or an import policy. When processing routes from the inet.0 routing table, the Junos OS software checks for routes matching the **DOD-Request-Loopbacks** policy (in this example). If the route matches the policy and the LDP session is negotiated with DOD advertisement mode, label request messages are sent to the corresponding downstream LDP session.

```
[edit protocols ldp]
user@host# set dod-request-policy DOD-Request-Loopbacks
```

3. Include the **downstream-on-demand** statement in the configuration for the LDP session to enable downstream on demand distribution mode.

```
[edit protocols ldp]
user@host# set session 1.1.1.1 downstream-on-demand
```

### Distributing LDP Downstream on Demand Routes into Labeled BGP

#### Step-by-Step Procedure

To distribute LDP downstream on demand routes into labeled BGP, use a BGP export policy.

1. Configure the LDP route policy (**redistribute\_ldp** in this example).

```
[edit policy-options]
user@host# set policy-statement redistribute_ldp term 1 from protocol ldp
user@host# set policy-statement redistribute_ldp term 1 from tag 1000
user@host# set policy-statement redistribute_ldp term 1 then accept
```

2. Include the LDP route policy, **redistribute\_ldp** in the BGP configuration (as a part of the BGP group configuration **ebgp-to-abr** in this example).

BGP forwards the LDP routes based on the **redistribute\_ldp** policy to the remote PE router

```
[edit protocols bgp]
user@host# set group ebgp-to-abr type external
user@host# set group ebgp-to-abr local-address 192.168.0.1
user@host# set group ebgp-to-abr peer-as 65319
user@host# set group ebgp-to-abr local-as 65320
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet unicast
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet labeled-unicast
    rib inet.3
user@host# set group ebgp-to-abr neighbor 192.168.6.1 export redistribute_ldp
```

**Step-by-Step Procedure** To restrict label propagation to other routers configured in downstream unsolicited mode (instead of downstream on demand), configure the following policies:

1. Configure the **dod-routes** policy to accept routes from LDP.

```
user@host# set policy-options policy-statement dod-routes term 1 from protocol
ldp
user@host# set policy-options policy-statement dod-routes term 1 from tag
1145307136
user@host# set policy-options policy-statement dod-routes term 1 then accept
```

2. Configure the **do-not-propagate-du-sessions** policy to not forward routes to neighbors 1.1.1.1, 2.2.2.2, and 3.3.3.3.

```
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 to neighbor 1.1.1.1
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 to neighbor 2.2.2.2
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 to neighbor 3.3.3.3
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 then reject
```

3. Configure the **filter-dod-on-du-sessions** policy to prevent the routes examined by the **dod-routes** policy from being forwarded to the neighboring routers defined in the **do-not-propagate-du-sessions** policy.

```
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions
term 1 from policy dod-routes
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions
term 1 to policy do-not-propagate-du-sessions
```

4. Specify the **filter-dod-routes-on-du-session** policy as the export policy for BGP group **ebgp-to-abr**.

```
[edit protocols bgp]
user@host# set group ebgp-to-abr neighbor 192.168.6.2 export
filter-dod-routes-on-du-sessions
```

**Results** From configuration mode, confirm your configuration by entering the **show policy-options** and **show protocols ldp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host#
show policy-options
prefix-list Request-Loopbacks {
  10.1.1.1/32;
```

```
    10.1.1.2/32;
    10.1.1.3/32;
    10.1.1.4/32;
}
policy-statement DOD-Request-Loopbacks {
    term 1 {
        from {
            prefix-list Request-Loopbacks;
        }
        then accept;
    }
}
policy-statement redistribute_ldp {
    term 1 {
        from {
            protocol ldp;
            tag 1000;
        }
        then accept;
    }
}
```

```
user@host#
```

```
show protocols ldp
```

```
dod-request-policy DOD-Request-Loopbacks;
session 1.1.1.1 {
    downstream-on-demand;
}
```

```
user@host#
```

```
show protocols bgp
```

```
group ebgp-to-abr {
    type external;
    local-address 192.168.0.1;
    peer-as 65319;
    local-as 65320;
    neighbor 192.168.6.1 {
        family inet {
            unicast;
            labeled-unicast {
                rib {
                    inet.3;
                }
            }
        }
        export redistribute_ldp;
    }
}
```

## Verification

### Verifying Label Advertisement Mode

**Purpose** Confirm that the configuration is working properly.

Use the **show ldp session** command to verify the status of the label advertisement mode for the LDP session.

**Action** Issue the **show ldp session** and **show ldp session detail** commands:

- The following command output for the **show ldp session** command indicates that the **Adv. Mode** (label advertisement mode) is **DOD** (meaning the LDP downstream on demand session is operational):

```
user@host> show ldp session
```

Address	State	Connection	Hold time	Adv. Mode
1.1.1.2	Operational	Open	22	DOD

- The following command output for the **show ldp session detail** command indicates that the **Local Label Advertisement mode** is **Downstream unsolicited**, the default value (meaning downstream on demand is not configured on the local session). Conversely, the **Remote Label Advertisement mode** and the **Negotiated Label Advertisement mode** both indicate that **Downstream on demand** is configured on the remote session

```
user@host> show ldp session detail
```

```
Address: 1.1.1.2, State: Operational, Connection: Open, Hold time: 24
Session ID: 1.1.1.1:0--1.1.1.2:0
Next keepalive in 4 seconds
Passive, Maximum PDU: 4096, Hold time: 30, Neighbor count: 1
Neighbor types: configured-tunneled
Keepalive interval: 10, Connect retry interval: 1
Local address: 1.1.1.1, Remote address: 1.1.1.2
Up for 17:54:52
Capabilities advertised: none
Capabilities received: none
Protection: disabled
Local - Restart: disabled, Helper mode: enabled,
Remote - Restart: disabled, Helper mode: enabled
Local maximum neighbor reconnect time: 120000 msec
Local maximum neighbor recovery time: 240000 msec
Local Label Advertisement mode: Downstream unsolicited
Remote Label Advertisement mode: Downstream on demand
Negotiated Label Advertisement mode: Downstream on demand
Nonstop routing state: Not in sync
Next-hop addresses received:
  1.1.1.2
```

## Configuring LDP Native IPv6 Support

LDP is supported in an IPv6-only network, and in an IPv6 or IPv4 dual-stack network as described in *RFC 7552*. Configure the address family as **inet** for IPv4 or **inet6** for IPv6 or both, and the transport preference to be either **IPv4** or **IPv6**. The **dual-transport** statement allows Junos OS LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The **inet-lsr-id** and **inet6-lsr-id** IDs are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Before you configure IPv6 as dual-stack, be sure you configure the routing and signaling protocols.

To configure LDP native IPv6 support, you must do the following:

1. Enable forwarding equivalence class (FEC) deaggregation in order to use different labels for different address families.

```
[edit protocols ldp]  
set deaggregate
```

2. Configure LDP address families.

```
[edit protocols ldp]  
set family inet6  
set family inet
```

3. Configure the **transport-preference** statement to select the preferred transport for the TCP connection when both IPv4 and IPv6 are enabled. By default, IPv6 is used as the TCP transport for establishing an LDP connection.

```
[edit protocols ldp]  
set transport-preference ipv4
```

4. (Optional) Configure dual-transport to allow LDP to establish a separate IPv4 session with an IPv4 neighbor, and an IPv6 session with an IPv6 neighbor. Configure **inet-lsr-id** as the LSR ID for IPv4, and **inet6-lsr-id** as the LSR ID for IPv6.

```
[edit protocols ldp dual-transport]  
set inet-lsr-id inet-lsr-id  
set inet6-lsr-id inet6-lsr-id
```

For example, configure **inet-lsr-id** as 10.255.0.1, and **inet6-lsr-id** as 1.1.1.1.

```
[edit protocols ldp dual-transport]  
set inet-lsr-id 10.255.0.1
```

```
set inet6-lsr-id 1.1.1.1
```

## Example: Configuring LDP Native IPv6 Support

This example shows how to allow the Junos OS Label Distribution Protocol (LDP) to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. This helps avoid tunneling of IPv6 over IPv4 MPLS core with IPv4-signaled MPLS label-switched paths (LSPs).

- [Requirements on page 841](#)
- [Overview on page 841](#)
- [Configuration on page 842](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series routers
- Junos OS Release 16.1 or later running on all devices

Before you configure IPv6 as dual-stack, be sure you configure the routing and signaling protocols.

### Overview

LDP is supported in an IPv6 only network, and in an IPv6 or IPv4 dual-stack network as described in *RFC 7552*. Configure the address family as **inet** for IPv4 or **inet6** for IPv6. By default, IPv6 is used as the TCP transport for the LDP session with its peers when both IPv4 and IPv6 are enabled. The dual-transport statement allows Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The **inet-lsr-id** and **inet6-lsr-id** are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

### Topology

[Figure 87 on page 841](#) shows the LDP IPv6 configured as dual-stack on Device R1 and Device R2.

*Figure 87: Example LDP Native IPv6 Support*

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
R1
set interfaces ge-1/0/0 unit 0 family inet address 192.168.12.1/24
set interfaces ge-1/0/0 unit 0 family iso
set interfaces ge-1/0/0 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set interfaces ge-1/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.1/32
set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1010.00
set interfaces lo0 unit 0 family inet6 address 2001:db8::1/128
set protocols isis interface ge-1/0/0.0
set protocols isis interface lo0.0
set protocols mpls interface ge-1/0/0.0
set protocols ldp deaggregate
set protocols ldp interface ge-1/0/0.0
set protocols ldp interface lo0.0
set protocols ldp family inet6
set protocols ldp family inet
```

```
R2
set interfaces ge-1/0/1 unit 0 family inet address 192.168.12.2/24
set interfaces ge-1/0/1 unit 0 family iso
set interfaces ge-1/0/1 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set interfaces ge-1/0/1 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.2/32
set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.2020.00
set interfaces lo0 unit 0 family inet6 address 2001:db8::2/128
set protocols isis interface ge-1/0/1.0
set protocols isis interface lo0.0
set protocols mpls interface ge-1/0/1.0
set protocols ldp deaggregate
set protocols ldp interface ge-1/0/1.0
set protocols ldp interface lo0.0
set protocols ldp family inet6
set protocols ldp family inet
```

### Configuring R1

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see “Using the CLI Editor in Configuration Mode” in the *CLI User Guide*.

To configure Device R1:

1. Configure the interfaces.

```
[edit interfaces]
```

```
set ge-1/0/0 unit 0 family inet address 192.168.12.1/24
set ge-1/0/0 unit 0 family iso
set ge-1/0/0 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set ge-1/0/0 unit 0 family mpls
```

2. Assign a loopback address to the device.

```
[edit interfaces lo0 unit 0]
set family inet address 10.255.0.1/32
set family iso address 49.0001.1720.1600.1010.00
set family inet6 address 2001:db8::1/128
```

3. Configure the IS-IS interfaces.

```
[edit protocols isis]
set interface ge-1/0/0.0
set interface lo0.0
```

4. Configure MPLS to use LDP interfaces on the device.

```
[edit protocols mpls]
set protocols mpls interface ge-1/0/0.0
set interface ge-1/0/0.0
set interface lo0.0
```

5. Enable forwarding equivalence class (FEC) deaggregation in order to use different labels for different address families.

```
[edit protocols ldp]
set deaggregate
```

6. Configure LDP address families.

```
[edit protocols ldp]
set family inet6
set family inet
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
ge-1/0/0 {
  unit 0 {
```

```
family inet {
    address 192.168.12.1/24;
}
family iso;
family inet6 {
    address 2001:db8:0:12::/64 {
        eui-64;
    }
}
family mpls;
}
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.1/32;
        }
        family iso {
            address 49.0001.1720.1600.1010.00
        }
        family inet6 {
            address 2001:db8::1/128;
        }
    }
}
```

```
user@R1# show protocols
mpls {
    interface ge-1/0/0.0;
}
isis {
    interface ge-1/0/0.0;
    interface lo0.0;
}
ldp {
    deaggregate;
    interface ge-1/0/0.0;
    interface lo0.0;
    family {
        inet6;
        inet;
    }
}
```

---

## Verification

Confirm that the configuration is working properly.

- [Verifying the Route Entries in the mpls.0 Table on page 845](#)
- [Verifying the Route Entries in the inet.3 Table on page 845](#)
- [Verifying the Route Entries in the inet6.3 Table on page 846](#)
- [Verifying the LDP Database on page 846](#)

- [Verifying the LDP Neighbor Information on page 846](#)
- [Verifying the LDP Session Information on page 847](#)

### *Verifying the Route Entries in the mpls.0 Table*

**Purpose** Display mpls.0 route table information.

**Action** On Device R1, from operational mode, run the **show route table mpls.0** command to display mpls.0 route table information.

```
user@R1> show route table mpls.0
```

```
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                *[MPLS/0] 05:19:58, metric 1
                  Receive
1                *[MPLS/0] 05:19:58, metric 1
                  Receive
2                *[MPLS/0] 05:19:58, metric 1
                  Receive
13               *[MPLS/0] 05:19:58, metric 1
                  Receive
299824           *[LDP/9] 04:28:45, metric 1
                  > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0, Pop
299824(S=0)      *[LDP/9] 04:28:45, metric 1
                  > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0, Pop
299888           *[LDP/9] 00:56:12, metric 1
                  > to 192.168.12.2 via ge-1/0/0.0, Pop
299888(S=0)      *[LDP/9] 00:56:12, metric 1
                  > to 192.168.12.2 via ge-1/0/0.0, Pop
```

**Meaning** The output shows the mpls.0 route table information.

### *Verifying the Route Entries in the inet.3 Table*

**Purpose** Display inet.3 route table information.

**Action** On Device R1, from operational mode, run the **show route table inet.3** command to display inet.3 route table information.

```
user@R1> show route table inet.3
```

```
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.0.2/32    *[LDP/9] 00:58:38, metric 1
                  > to 192.168.12.2 via ge-1/0/0.0
```

**Meaning** The output shows the inet.3 route table information.

**Verifying the Route Entries in the inet6.3 Table**

**Purpose** Display inet6.3 route table information.

**Action** On Device R1, from operational mode, run the **show route table inet6.3** command to display inet6.3 route table information.

```
user@R1> show route table inet6.3
```

```
inet6.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2001:db8::2/128    *[LDP/9] 04:31:17, metric 1
                  > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0
```

**Meaning** The output shows the inet6.3 route table information.

**Verifying the LDP Database**

**Purpose** Display the LDP database information.

**Action** On Device R1, from operational mode, run the **show ldp database** command to display LDP database information.

```
user@R1> show ldp database
```

```
Input label database, 10.255.0.1:0--10.255.0.2:0
Labels received: 3
  Label    Prefix
  299840   10.255.0.1/32
    3      10.255.0.2/32
  299808   2001:db8::1/128
    3      2001:db8::2/128

Output label database, 10.255.0.1:0--10.255.0.2:0
Labels advertised: 3
  Label    Prefix
    3      10.255.0.1/32
  299888   10.255.0.2/32
    3      2001:db8::1/128
  299824   2001:db8::2/128
```

**Meaning** The output shows the entries in the LDP database.

**Verifying the LDP Neighbor Information**

**Purpose** Display the LDP neighbor information.

**Action** On Device R1, from operational mode, run the **show ldp neighbor** and **show ldp neighbor extensive** commands to display LDP neighbor information.

```
user@R1> show ldp neighbor
```

Address	Interface	Label space ID	Hold time
fe80::21f:1200:cb6:4c8d	ge-1/0/0.0	10.255.0.2:0	12
192.168.12.2	ge-1/0/0.0	10.255.0.2:0	11

```
user@R1> show ldp neighbor extensive
```

Address	Interface	Label space ID	Hold time
192.168.12.2	ge-1/0/0.0	10.255.0.2:0	11
Transport address: 10.255.0.2, Transport preference: IPv6, Configuration sequence: 10

Reference count: 1			
Hold time: 15, Proposed local/peer: 15/15			
Hello flags: none			
Neighbor types: discovered			
Address	Interface	Label space ID	Hold time
fe80::21f:1200:cb6:4c8d	ge-1/0/0.0	10.255.0.2:0	14
Transport address: 2001:db8::2, Transport preference: IPv6, Configuration sequence: 10			
Up for 00:04:35			
Reference count: 1			
Hold time: 15, Proposed local/peer: 15/15			
Hello flags: none			
Neighbor types: discovered			

**Meaning** The output shows LDP neighbor information of both IPv4 and IPv6 addresses.

### *Verifying the LDP Session Information*

**Purpose** Display the LDP session information.

**Action** On Device R1, from operational mode, run the **show ldp session** and **show ldp session extensive** commands to display LDP session information.

```
user@R1> show ldp session
```

```
session
  Address                State      Connection Hold time  Adv. Mode

Label mapping      3          3           0          0
Label request      0          0           0          0
Label withdraw     0          0           0          0
Label release      0          0           0          0
Label abort        0          0           0          0
```

**Meaning** The output displays information for the LDP session using IPv6 as the TCP transport.

### Configure transport-preference to Select the Preferred Transport

**CLI Quick Configuration** You can configure the **transport-preference** statement to select the preferred transport for a TCP connection when both IPv4 and IPv6 are enabled. By default, IPv6 is used as TCP transport for establishing an LDP connection.

- (Optional) Configure the transport preference for an LDP connection.

```
[edit protocols ldp]
set transport-preference ipv4
```

**Results** From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show protocols
  mpls {
    interface ge-1/0/0.0;
  }
  isis {
    interface ge-1/0/0.0;
    interface lo0.0;
  }
  ldp {
    deaggregate;
    interface ge-1/0/0.0;
    interface lo0.0;
    family {
      inet6;
      inet;
    }
    transport-preference ipv4;
  }
```

### Verification

Confirm that the configuration is working properly.

Label abort	0	0	0	0

**Meaning** The output displays information for the LDP session using IPv6 as the TCP transport.

### Configure dual-transport to Establish Separate Sessions for IPv4 with an IPv4 Neighbor and IPv6 with an IPv6 Neighbor

**Step-by-Step Procedure** You can configure the **dual-transport** statement to allow LDP to establish a separate IPv4 session with an IPv4 neighbor, and an IPv6 session with an IPv6 neighbor. This requires the configuration of **inet-lsr-id** as the LSR ID for IPv4, and **inet6-lsr-id** as the LSR ID for IPv6.

- (Optional) Configure dual-transport to allow LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR.

```
[edit protocols ldp dual-transport]
set inet-lsr-id 10.255.0.1
set inet6-lsr-id 1.1.1.1
```

**Results** From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show protocols
mpls {
  interface ge-1/0/0.0;
}
isis {
  interface ge-1/0/0.0;
  interface lo0.0;
}
ldp {
  deaggregate;
  interface ge-1/0/0.0;
  interface lo0.0;
  family {
    inet6;
    inet;
  }
  dual-transport {
    inet-lsr-id 10.255.0.1;
    inet6-lsr-id 1.1.1.1;
  }
}
```

### Verification

Confirm that the configuration is working properly.

- [Verifying the LDP Neighbor Information on page 853](#)
- [Verifying the LDP Session Information on page 853](#)

*Verifying the LDP Neighbor Information*

**Purpose** Display the LDP neighbor information.

**Action** On Device R1, from operational mode, run the **show ldp neighbor extensive** command to display LDP neighbor information.

user@R1> show ldp neighbor extensive

Address	Interface	Label space ID	Hold time
192.168.12.2	ge-1/0/0.0	10.255.0.2:0	11
Transport address: 10.255.0.2, Configuration sequence: 10			
Up for 00:04:35			
Reference count: 1			
Hold time: 15, Proposed local/peer: 15/15			
Hello flags: none			
Neighbor types: discovered			
Address	Interface	Label space ID	Hold time
fe80::21f:1200:cb6:4c8d	ge-1/0/0.0	10.255.0.2:0	14
Transport address: 2001:db8::2, Configuration sequence: 10			
Up for 00:04:35			
Reference count: 1			
Hold time: 15, Proposed local/peer: 15/15			
Hello flags: none			
Neighbor types: discovered			

**Meaning** The output shows LDP neighbor information for both the IPv4 and IPv6 addresses.

*Verifying the LDP Session Information*

**Purpose** Display the LDP session information.

**Action** On Device R1, from operational mode, run the **show ldp session extensive** command to display LDP neighbor information.

```
user@R1> show ldp session extensive
```

## Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs

The Multipoint Label Distribution Protocol (M-LDP) for point-to-multipoint label-switched paths (LSPs) with in-band signaling is useful in a deployment with an existing IP/MPLS backbone, in which you need to carry multicast traffic, for IPTV for example.

For years, the most widely used solution for transporting multicast traffic has been to use native IP multicast in the service provider core with multipoint IP tunneling to isolate customer traffic. A multicast routing protocol, usually Protocol Independent Multicast (PIM), is deployed to set up the forwarding paths. IP multicast routing is used for forwarding, using PIM signaling in the core. For this model to work, the core network has to be multicast enabled. This allows for effective and stable deployments even in inter-autonomous system (AS) scenarios.

However, in an existing IP/MPLS network, deploying PIM might not be the first choice. Some service providers are interested in replacing IP tunneling with MPLS label encapsulation. The motivations for moving to MPLS label switching is to leverage MPLS traffic engineering and protection features and to reduce the amount of control traffic overhead in the provider core.

To do this, service providers are interested in leveraging the extension of the existing deployments to allow multicast traffic to pass through. The existing multicast extensions for IP/MPLS are point-to-multipoint extensions for RSVP-TE and point-to-multipoint and multipoint-to-multipoint extensions for LDP. These deployment scenarios are discussed in RFC 6826, *Multipoint LDP In-Band Signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*. This feature overview is limited to point-to-multipoint extensions for LDP.

### How M-LDP Works

- [Label Bindings in M-LDP Signaling on page 857](#)
- [M-LDP in PIM-Free MPLS Core on page 857](#)
- [M-LDP in PIM-Enabled MPLS Core on page 859](#)

#### Label Bindings in M-LDP Signaling

The multipoint extension to LDP uses point-to-multipoint and multipoint-to-multipoint forwarding equivalence class (FEC) elements (defined in RFC 5036, *LDP Specification*) along with capability advertisements, label mapping, and signaling procedures. The FEC elements include the idea of the LSP root, which is an IP address, and an “opaque” value, which is a selector that groups together the leaf nodes sharing the same opaque value. The opaque value is transparent to the intermediate nodes, but has meaning for the LSP root. Every LDP node advertises its local incoming label binding to the upstream LDP node on the shortest path to the root IP address found in the FEC. The upstream node receiving the label bindings creates its own local label and outgoing interfaces. This label allocation process might result in packet replication, if there are multiple outgoing branches. As shown in [Figure 88 on page 857](#), an LDP node merges the label bindings for the same opaque value if it finds downstream nodes sharing the same upstream node. This allows for effective building of point-to-multipoint LSPs and label conservation.

Figure 88: Label Bindings in M-LDP Signaling

#### M-LDP in PIM-Free MPLS Core

[Figure 89 on page 858](#) shows a scaled-down deployment scenario. Two separate PIM domains are interconnected by a PIM-free core site. The border routers in this core site support PIM on the border interfaces. Further, these border routers collect and distribute the routing information from the adjacent sites to the core network. The edge routers in Site C run BGP for root-node discovery. Interior gateway protocol (IGP) routes cannot be used for ingress discovery because in most cases the forwarding next hop provided by the IGP would not provide information about the ingress device toward the source. M-LDP inband signaling has a one-to-one mapping between the point-to-multipoint LSP and the (S,G) flow. With in-band signaling, PIM messages are directly translated into M-LDP FEC bindings. In contrast, out-of-band signaling is based on manual

configuration. One application for M-LDP inband signaling is to carry IPTV multicast traffic in an MPLS backbone.

*Figure 89: Sample M-LDP Topology in PIM-Free MPLS Core*

### Configuration

The configuration statement **mldp-inband-signalling** on the label-edge router (LER) enables PIM to use M-LDP in-band signaling for the upstream neighbors when the LER does not detect a PIM upstream neighbor. Static configuration of the MPLS LSP root is included in the PIM configuration, using policy. This is needed when IBGP is not available in the core site or to override IBGP-based LSP root detection.

For example:

```
protocols {
  pim {
    mldp-inband-signalling {
      policy lsp-mapping-policy-example;
    }
  }
}
```

```
policy-options {
  policy-statement lsp-mapping-policy-example {
    term channel1 {
      from {
        source-address-filter ip-prefix</prefix-length>; #policy filter for channel1
      }
      then {
        p2mp-lsp-root {
```

```

        # Statically configured ingress address of edge
        # used by channel1
        address ip-address;
    }
    accept;
}
}
}
}

```

### M-LDP in PIM-Enabled MPLS Core

Starting in Junos OS Release 14.1, in order to migrate existing IPTV services from native IP multicast to MPLS multicast, you need to smoothly transition from PIM to M-LDP point-to-multipoint LSPs with minimal outage. [Figure 90 on page 859](#) shows a similar M-LDP topology as [Figure 89 on page 858](#), but with a different scenario. The core is enabled with PIM, with one source streaming all the IPTV channels. The TV channels are sent as ASM streams with each channel identified by its group address. Previously, these channels were streamed on the core as IP streams and signaled using PIM.

*Figure 90: Sample M-LDP Topology in PIM-Enabled MPLS Core*

By configuring the **mldp-inband-signaling** in this scenario, M-LDP signaling is initiated only when there is no PIM neighbor towards the source. However, because there is always a PIM neighbor towards the source unless PIM is deactivated on the upstream interfaces of the egress PE, PIM takes precedence over M-LDP and M-LDP does not take effect.

### Configuration

To progressively migrate channel by channel to M-LDP MPLS core with few streams using M-LDP upstream and other streams using existing PIM upstream, include the

**selected-mldp-egress** configuration statement along with group based filters in the policy filter for M-LDP inband signaling.

**NOTE:** The M-LDP inband signaling policy filter can include either the **source-address-filter** statement or the **route-filter** statement, or a combination of both.

For example:

```
protocols {
  pim {
    mldp-inband-signalling {
      policy lsp-mapping-policy-example;
    }
  }
}

policy-options {
  policy-statement lsp-mapping-policy-example {
    term channel1 {
      from {
        source-address-filter ip-prefix</prefix-length>; #policy filter for channel1
      }
      then {
        selected-mldp-egress;
        accept;
      }
    }
    term channel2 {
      from {
        source-address-filter ip-prefix</prefix-length>; #policy filter for channel2
        route-filter ip-prefix</prefix-length>; #policy filter on multicast group address
      }
      then {
        selected-mldp-egress;
        p2mp-lsp-root {
          # Statically configured ingress address of edge
          # used by channel2
          address ip-address;
        }
        accept;
      }
    }
    term channel3 {
      from {
        route-filter ip-prefix</prefix-length>; #policy filter on multicast group address
      }
      then {
        selected-mldp-egress;
        accept;
      }
    }
  }
}
```

```
}
}
```

**NOTE:**

Some of the limitations of the above configuration are as follows:

- The `selected-mldp-egress` statement should be configured only on the LER. Configuring the `selected-mldp-egress` statement on non-egress PIM routers can cause path setup failures.
- When policy changes are made to switch traffic from PIM upstream to M-LDP upstream and vice-versa, packet loss can be expected as break-and-make mechanism is performed at the control plane.

### Terminology

The following terms are important for an understanding of M-LDP in-band signaling for multicast traffic.

**Point-to-point LSP**—An LSP that has one ingress label-switched router (LSR) and one egress LSR.

**Multipoint LSP**—Either a point-to-multipoint or a multipoint-to-multipoint LSP.

**Point-to-multipoint LSP**—An LSP that has one ingress LSR and one or more egress LSRs.

**Multipoint-to-point LSP**—An LSP that has one or more ingress LSRs and one unique egress LSR.

**Multipoint-to-multipoint LSP**—An LSP that connects a set of nodes, such that traffic sent by any node in the LSP is delivered to all others.

**Ingress LSR**—An ingress LSR for a particular LSP is an LSR that can send a data packet along the LSP. Multipoint-to-multipoint LSPs can have multiple ingress LSRs. Point-to-multipoint LSPs have only one, and that node is often referred to as the root node.

**Egress LSR**—An egress LSR for a particular LSP is an LSR that can remove a data packet from that LSP for further processing. Point-to-point and multipoint-to-point LSPs have only a single egress node. Point-to-multipoint and multipoint-to-multipoint LSPs can have multiple egress nodes.

**Transit LSR**—An LSR that has reachability to the root of the multipoint LSP through a directly connected upstream LSR and one or more directly connected downstream LSRs.

**Bud LSR**—An LSR that is an egress but also has one or more directly connected downstream LSRs.

**Leaf node**—Either an egress or bud LSR in the context of a point-to-multipoint LSP. In the context of a multipoint-to-multipoint LSP, an LSR is both ingress and egress for the same multipoint-to-multipoint LSP and can also be a bud LSR.

---

### Ingress Join Translation and Pseudo Interface Handling

At the ingress LER, LDP notifies PIM about the (S,G) messages that are received over the in-band signaling. PIM associates each (S,G) message with a pseudo interface. Subsequently, a shortest-path-tree (SPT) join message is initiated toward the source. PIM treats this as a new type of local receiver. When the LSP is torn down, PIM removes this local receiver based on notification from LDP.

---

### Ingress Splicing

LDP provides PIM with a next hop to be associated with each (S,G) entry. PIM installs a PIM (S,G) multicast route with the LDP next hop and other PIM receivers. The next hop is a composite next hop of local receivers + the list of PIM downstream neighbors + a sub-level next hop for the LDP tunnel.

---

### Reverse Path Forwarding

PIM's reverse-path-forwarding (RPF) calculation is performed at the egress node.

PIM performs M-LDP in-band signaling when all of the following conditions are true:

- There are no PIM neighbors toward the source.
- The M-LDP in-band signaling statement is configured.
- The next hop is learned through BGP, or is present in the static mapping (specified in an M-LDP in-band signaling policy).

Otherwise, if LSP root detection fails, PIM retains the (S,G) entry with an RPF state of unresolved.

PIM RPF registers this source address each time unicast routing information changes. Therefore, if the route toward the source changes, the RPF recalculation recurs. BGP protocol next hops toward the source too are monitored for changes in the LSP root. Such changes might cause traffic disruption for short durations.

---

### LSP Root Detection

If the RPF operation detects the need for M-LDP in-band signaling upstream, the LSP root (ingress) is detected. This root is a parameter for LDP LSP signaling.

The root node is detected as follows:

1. If the existing static configuration specifies the source address, the root is taken as given in configuration.
2. A lookup is performed in the unicast routing table. If the source address is found, the protocol next hop toward the source is used as the LSP root.

Prior to Junos OS Release 16.1, M-LDP point-to-multipoint LSP is signaled from an egress to ingress using the root address of the ingress LSR. This root address is

reachable through IGP only, thereby confining the M-LDP point-to-multipoint LSP to a single autonomous system. If the root address is not reachable through an IGP, but reachable through BGP, and if that BGP route is recursively resolved over an MPLS LSP, then the point-to-multipoint LSP is not signaled further from that point towards the ingress LSR root address.

There is a need for these non-segmented point-to-multipoint LSPs to be signaled across multiple autonomous systems, which can be used for the following applications:

- Inter-AS MVPN with non-segmented point-to-multipoint LSPs.
- Inter-AS M-LDP inband signaling between client networks connected by an MPLS core network.
- Inter-area MVPN or M-LDP inband signaling with non-segmented point-to-multipoint LSPs (seamless MPLS multicast).

Starting from Junos OS Release 16.1, M-LDP can signal point-to-multipoint LSPs at ASBR or transit or egress when root address is a BGP route which is further recursively resolved over an MPLS LSP.

---

### Egress Join Translation and Pseudo Interface Handling

At the egress LER, PIM notifies LDP of the (S,G) message to be signaled along with the LSP root. PIM creates a pseudo interface as the upstream interface for this (S,G) message. When an (S,G) prune message is received, this association is removed.

---

### Egress Splicing

At the egress node of the core network, where the (S,G) join message from the downstream site is received, this join message is translated to M-LDP in-band signaling parameters and LDP is notified. Further, LSP teardown occurs when the (S,G) entry is lost, when the LSP root changes, or when the (S,G) entry is reachable over a PIM neighbor.

---

### Supported Functionality

For M-LDP in-band signaling, Junos OS supports the following functionality:

- Egress splicing of the PIM next hop with the LDP route
- Ingress splicing of the PIM route with the LDP next hop
- Translation of PIM join messages to LDP point-to-multipoint LSP setup parameters
- Translation of M-LDP in-band LSP parameters to set up PIM join messages
- Statically configured and BGP protocol next hop-based LSP root detection
- PIM (S,G) states in the PIM source-specific multicast (SSM) and anysource multicasts (ASM) ranges
- Configuration statements on ingress and egress LERs to enable them to act as edge routers
- IGMP join messages on LERs

- Carrying IPv6 source and group address as opaque information toward an IPv4 root node
- Static configuration to map an IPv6 (S,G) to an IPv4 root address

---

### Unsupported Functionality

For M-LDP in-band signaling, Junos OS does *not* support the following functionality:

- Full support for PIM ASM
- The **mpls lsp point-to-multipoint ping** command with an (S,G) option
- Nonstop active routing (NSR)
- Make-before-break (MBB) for PIM
- IPv6 LSP root addresses (LDP does not support IPv6 LSPs.)
- Neighbor relationship between PIM speakers that are not directly connected
- Graceful restart
- PIM dense mode
- PIM bidirectional mode

---

### LDP Functionality

The PIM (S,G) information is carried as M-LDP opaque type-length-value (TLV) encodings. The point-to-multipoint FEC element consists of the root-node address. In the case of next-generation multicast VPNs (NGEN MVPNs), the point-to-multipoint LSP is identified by the root node address and the LSP ID.

---

### Egress LER Functionality

On the egress LER, PIM triggers LDP with the following information to create a point-to-multipoint LSP:

- Root node
- (S,G)
- Next hop

PIM finds the root node based on the source of the multicast tree. If the root address is configured for this (S,G) entry, the configured address is used as the point-to-multipoint LSP root. Otherwise, the routing table is used to look up the route to the source. If the route to the source of the multicast tree is a BGP-learned route, PIM retrieves the BGP next hop address and uses it as the root node for the point-to-multipoint LSP.

LDP finds the upstream node based on the root node, allocates a label, and sends the label mapping to the upstream node. LDP does not use penultimate hop popping (PHP) for in-band M-LDP signaling.

If the root addresses for the source of the multicast tree changes, PIM deletes the point-to-multipoint LSP and triggers LDP to create a new point-to-multipoint LSP. When

this happens, the outgoing interface list becomes NULL, PIM triggers LDP to delete the point-to-multipoint LSP, and LDP sends a label withdraw message to the upstream node.

### Transit LSR Functionality

---

The transit LSR advertises a label to the upstream LSR toward the source of the point-to-multipoint FEC and installs the necessary forwarding state to forward the packets. The transit LSR can be any M-LDP capable router.

### Ingress LER Functionality

---

On the ingress LER, LDP provides the following information to PIM upon receiving the label mapping:

- (S,G)
- Flood next hop

Then PIM installs the forwarding state. If the new branches are added or deleted, the flood next hop is updated accordingly. If all branches are deleted due to a label being withdrawn, LDP sends updated information to PIM. If there are multiple links between the upstream and downstream neighbors, the point-to-multipoint LSP is not load balanced.

**See Also** • [Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs on page 865](#)

## Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs

This example shows how to configure multipoint LDP (M-LDP) in-band signaling for multicast traffic, as an extension to the Protocol Independent Multicast (PIM) protocol or as a substitute for PIM.

- [Requirements on page 865](#)
- [Overview on page 866](#)
- [Configuration on page 866](#)
- [Verification on page 876](#)

### Requirements

---

This example can be configured using the following hardware and software components:

- Junos OS Release 13.2 or later
- MX Series 5G Universal Routing Platforms or M Series Multiservice Edge Routers for the Provider Edge (PE) Routers
- PTX Series Packet Transport Routers acting as transit label-switched routers
- T Series Core Routers for the Core Routers

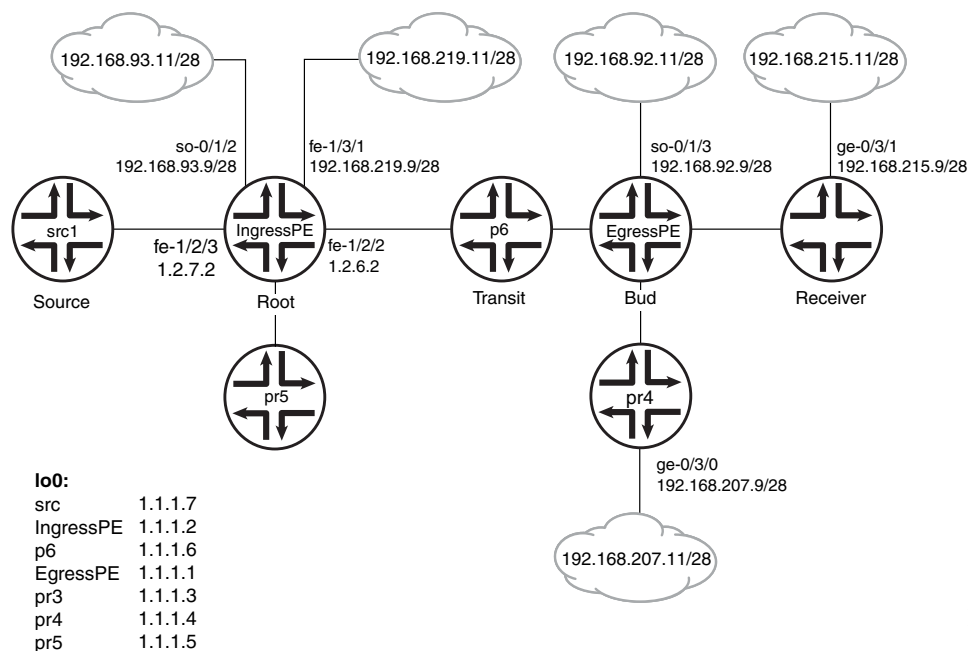

**NOTE:** The PE routers could also be T Series Core Routers but that is not typical. Depending on your scaling requirements, the core routers could also be MX Series 5G Universal Routing Platforms or M Series Multiservice Edge Routers. The Customer Edge (CE) devices could be other routers or switches from Juniper Networks or another vendor.

No special configuration beyond device initialization is required before configuring this example.

### Overview

“CLI Quick Configuration” on page 866 shows the configuration for all of the devices in Figure 91 on page 866. The section “Step-by-Step Procedure” on page 870 describes the steps on Device EgressPE.

Figure 91: M-LDP In-Band Signaling for Point-to-Multipoint LSPs Example Topology

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device src1**

```
set logical-systems src1 interfaces fe-1/2/0 unit 0 family inet address 1.2.7/24

```

**Step-by-Step Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device EgressPE:

1. Configure the interfaces.

Enable MPLS on the core-facing interfaces. On the egress next hops, you do not need to enable MPLS.

```

[edit interfaces]
user@EgressPE# set fe-1/2/0 unit 0 family inet address 1.1.3.1/24
user@EgressPE# set fe-1/2/0 unit 0 family mpls
user@EgressPE# set fe-1/2/2 unit 0 family inet address 1.1.6.1/24
user@EgressPE# set fe-1/2/2 unit 0 family mpls
user@EgressPE# set so-0/1/3 unit 0 point-to-point
user@EgressPE# set so-0/1/3 unit 0 family inet address 192.168.92.9/28
user@EgressPE# set fe-1/2/1 unit 0 family inet address 1.1.4.1/24
user@EgressPE# set fe-1/3/0 unit 0 family inet address 192.168.209.9/28
user@EgressPE# set lo0 unit 0 family inet address 1.1.1.1/32

```

2. Configure IGMP on the egress interfaces.

For testing purposes, this example includes static group and source addresses.

```

[edit protocols igmp]
user@EgressPE# set interface fe-1/3/0.0 version 3
user@EgressPE# set interface fe-1/3/0.0 static group 232.1.1.1 group-count 3

```

```

user@EgressPE# set interface fe-1/3/0.0 static group 232.1.1.1 source 192.168.219.11
user@EgressPE# set interface fe-1/3/0.0 static group 227.1.1.1
user@EgressPE# set interface so-0/1/3.0 version 3
user@EgressPE# set interface so-0/1/3.0 static group 232.1.1.1 group-count 2
user@EgressPE# set interface so-0/1/3.0 static group 232.1.1.1 source 192.168.219.11
user@EgressPE# set interface so-0/1/3.0 static group 232.2.2.2 source 1.2.7.7

```

3. Configure MPLS on the core-facing interfaces.

```

[edit protocols mpls]
user@EgressPE# set interface fe-1/2/0.0
user@EgressPE# set interface fe-1/2/2.0

```

4. Configure BGP.

BGP is a policy-driven protocol, so also configure and apply any needed routing policies.

For example, you might want to export static routes into BGP.

```

[edit protocols bgp group ibgp]
user@EgressPE# set type internal
user@EgressPE# set local-address 1.1.1.1
user@EgressPE# set family inet any
user@EgressPE# set neighbor 1.1.1.2

```

5. (Optional) Configure an MSDP peer connection with Device pr5 in order to interconnect the disparate PIM domains, thus enabling redundant RPs.

```

[edit protocols msdp]
user@EgressPE# set local-address 1.1.1.1
user@EgressPE# set peer 1.1.1.5

```

6. Configure OSPF.

```

[edit protocols ospf area 0.0.0.0]
user@EgressPE# set interface all
user@EgressPE# set interface fxp0.0 disable

```

7. Configure LDP on the core-facing interfaces and on the loopback interface.

```

[edit protocols ldp]
user@EgressPE# set interface fe-1/2/0.0
user@EgressPE# set interface fe-1/2/2.0
user@EgressPE# set interface lo0.0

```

8. Enable point-to-multipoint MPLS LSPs.

```
[edit protocols ldp]
user@EgressPE# set p2mp
```

9. Configure PIM on the downstream interfaces.

```
[edit protocols pim]
user@EgressPE# set interface lo0.0
user@EgressPE# set interface fe-1/3/0.0
user@EgressPE# set interface fe-1/2/1.0
user@EgressPE# set interface so-0/1/3.0
```

10. Configure the RP settings because this device serves as the PIM rendezvous point (RP).

```
[edit protocols pim]
user@EgressPE# set rp local address 1.1.1.1
user@EgressPE# set rp local group-ranges 227.0.0.0/8
user@EgressPE# set rp static address 1.1.1.4
user@EgressPE# set rp static address 1.2.7.7 group-ranges 226.0.0.0/8
```

11. Enable M-LDP in-band signaling and set the associated policy.

```
[edit protocols pim]
user@EgressPE# set mldp-inband-signalling policy mldppim-ex
```

12. Configure the routing policy that specifies the root address for the point-to-multipoint LSP and the associated source addresses.

```
[edit policy-options policy-statement mldppim-ex]
user@EgressPE# set term B from source-address-filter 192.168.0.0/24 orlonger
user@EgressPE# set term B from source-address-filter 192.168.219.11/32 orlonger
user@EgressPE# set term B then p2mp-lsp-root address 1.1.1.2
user@EgressPE# set term B then accept
user@EgressPE# set term A from source-address-filter 1.2.7.0/24 orlonger
user@EgressPE# set term A then accept
```

13. Configure the autonomous system (AS) ID.

```
[edit routing-options]
user@EgressPE# set autonomous-system 64510
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Device EgressPE

user@EgressPE# show interfaces

```

```

user@EgressPE# show routing-options
autonomous-system 64510;

```

Similarly, configure the other egress devices.

If you are done configuring the devices, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Checking the PIM Join States on page 876](#)
- [Checking the PIM Sources on page 880](#)
- [Checking the LDP Database on page 882](#)
- [Looking Up the Route Information for the MPLS Label on page 885](#)
- [Checking the LDP Traffic Statistics on page 886](#)

### Checking the PIM Join States

**Purpose** Display information about PIM join states to verify the M-LDP in-band upstream and downstream details. On the ingress device, the **show pim join extensive** command displays **Pseudo-MLDP** for the downstream interface. On the egress, the **show pim join extensive** command displays **Pseudo-MLDP** for the upstream interface.

**Action** From operational mode, enter the **show pim join extensive** command.

```
user@IngressPE> show pim join extensive
```

**See Also** • [Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs on page 856](#)

**Release History Table**

Release	Description
16.1	Starting from Junos OS Release 16.1, M-LDP can signal point-to-multipoint LSPs at ASBR or transit or egress when root address is a BGP route which is further recursively resolved over an MPLS LSP.
14.1	Starting in Junos OS Release 14.1, in order to migrate existing IPTV services from native IP multicast to MPLS multicast, you need to smoothly transition from PIM to M-LDP point-to-multipoint LSPs with minimal outage.

## LDP Mapping Server for Interoperability of Segment Routing with LDP Overview

In an LDP network with gradual deployment of segment routing, there can be islands of devices that support either only LDP, or only segment routing. For the devices to interwork, the LDP mapping server feature is required to be configured on any device in the segment routing network.

The LDP mapping server feature is implemented using either OSPF or ISIS.

- [Interoperability of Segment Routing with LDP Using OSPF on page 888](#)
- [Interoperability of Segment Routing with LDP Using ISIS on page 889](#)

### Interoperability of Segment Routing with LDP Using OSPF

To implement interoperability of segment routing with LDP using OSPF, an extended prefix link-state advertisement (LSA) with Range type, length, and value (TLV) for all the LDP prefixes is generated, and mapping routes corresponding to the prefix is installed in the inet.3 and mpls.0 routing tables.

[Figure 92 on page 888](#) is a simple LDP network topology used to illustrate the interoperability of segment routing devices with LDP devices using OSPF. The topology has six devices (Devices R1, R2, R3, R4, R5, and R6) with LDP-to-segment routing migration.

*Figure 92: Sample LDP Topology with Interoperability of Segment Routing with LDP Using OSPF*

In the above topology, Devices R1, R2, and R3 are capable of only segment routing, Devices R5 and R6 are capable of only LDP, and Device R4 supports both LDP and segment routing. Here, Device R1 cannot interwork with Device R6 because of interoperability issues.

To enable interoperability between the LDP-capable devices and segment routing devices, any one interface of the device in the segment routing network segment is configured as the LDP mapping server. Currently, the mapping server configures prefixes under the **[edit routing-options source-packet-routing]** hierarchy level. With this feature, the LDP mapping server configuration is applied under the **[edit protocols ospf]** hierarchy level, where a new extended prefix LSA with range TLV for all LDP prefixes is advertised by OSPF. The device capable of segment routing analyzes the extended prefix range TLV and mapping routes corresponding to the prefix are installed in the inet.3 and mpls.0 routing tables.

For example, in [Figure 92 on page 888](#), if Device R2 (in the segment routing network) is the LDP mapping server, the following configuration is included:

```
[edit routing-options]
```

```

user@R2# set source-packet-routing mapping-server-entry
      mapping-server-name prefix-segment-range prefix-range start-prefix loopback-address
user@R2# set source-packet-routing mapping-server-entry mp1 prefix-segment-range
      rg1 start-index 5
user@R2# set source-packet-routing mapping-server-entry mp1 prefix-segment-range
      rg1 size 1

```

**NOTE:** The IP address used as the *start-prefix* is the loopback address of the device in the LDP network (Device R5, in this example).

```

[edit protocols]
user@R2# set ospf source-packet-routing mapping-server mapping-server-name

```

When the LDP mapping server configuration is committed on Device R2, the extended prefix range TLV is flooded across the OSPF area. The devices capable of segment routing (Devices R1, R2, and R3) install OSPF segment routing routes for the specified loopback address with a segment ID (SID) index. The SID index is also updated in the mpls.0 routing table by the segment routing devices.

#### Unsupported Features and Functionality for Interoperability of Segment Routing with LDP using OSPF

- Stitching of segment routing traffic to LDP next hop is not supported.
- Prefix conflict is only detected at the source configuration. When there is a prefix range conflict, the prefix SID from the lower router ID prevails. In such cases, a system log error message—**RPD\_OSPF\_PFX\_SID\_RANGE\_CONFLICT**—is generated.
- IPv6 prefixes are not supported.
- Flooding of the OSPF Extended Prefix Opaque LSA generated by the segment routing mapping server for autonomous systems (ASs) is not supported.
- Inter-area LDP mapping server functionality is not supported.
- ABR functionality of Extended Prefix Opaque LSA is not supported.
- ASBR functionality of Extended Prefix Opaque LSA is not supported.
- Segment routing mapping server Preference TLV is not supported.

### Interoperability of Segment Routing with LDP Using ISIS

To implement interoperability of segment routing with LDP using ISIS, a server-client configuration is required under protocols ISIS and LDP, respectively, and routes from the inet.3 or inet.0 routing tables are used for stitching of segment routing LSP with an LDP LSP and vice-versa.

[Figure 93 on page 890](#) is a simple LDP network topology used to illustrate the interoperability of segment routing devices with LDP devices using an LDP mapping server-client feature. The topology has four provider edge (PE) devices (Devices PE1, PE2, PE3, and PE4) and four provider (P) devices (Devices P5, P6, P7, and P8).

**Figure 93: Sample LDP Topology with Interoperability of Segment Routing with LDP Using ISIS**

Devices PE3, PE4, P6, P7 and P8 are the LDP capable devices. Devices PE1, PE2, P5 and P6 are capable of segment routing with segment routing global block (SRGB) value of 100 and 200, and node segment IDs (SIDs) value of 101, 102, 105 and 106, respectively.

For a service flow to be tunneled to-and-from Device PE3 and Device PE1 using a continuous MPLS tunnel, the islands of devices supporting segment routing and LDP must interoperate.

#### **LDP Mapping Client Functionality (LDP to Segment Routing)**

The LDP client functionality is the LDP-to-segment routing mapping, that is the right-to-left traffic flow in [Figure 93 on page 890](#). On Device P6, an LDP egress policy is configured to advertise all node SIDs and prefix SIDs from the segment routing network on the left. As a result, on Device P6, LDP advertises Devices PE1, PE2 and P5 as the egress FEC label bindings to Device P7.

Device PE3 has learned a service route with Device PE1 as the protocol next hop. Device PE3 has an LDP label binding from the P8 next hop for the PE1 FEC. As a result, Device PE3 sends its service packet to Device P8 as per classic LDP behavior. Device P8 has an LDP label binding from its P7 next hop for the PE1 FEC, therefore Device P8 forwards to Device P7 as per classic LDP behavior.

Device P7 has an LDP label binding from its P6 next hop the PE1 FEC, as a result, Device P7 forwards to Device P6 as per classic LDP behavior.

Device P6 that is acting as an LDP egress for the PE1 FEC, stitches and swaps the incoming egress LDP label for the PE1 FEC with an equivalent segment routing node SID (101 in this example) to forward the traffic to Device P5.

Device P5 pops 101 SID assuming that Device PE1 advertised its node segment 101 with the penultimate-pop flag set, and then forwards traffic to Device PE1. Device PE1 receives the tunneled packet and processes the service label.

As a result, the end-to-end MPLS tunnel is built from an LDP LSP from Device PE3 to Device P6, and the related node segment from Device P6 to Device PE1.

#### **LDP Mapping Server Functionality (Segment Routing to LDP)**

The LDP server functionality is the mapping of segment routing to LDP, that is the left-to-right traffic flow in [Figure 93 on page 890](#). On Device P6 the mapping server prefixes

configuration is included under the **[edit routing-options source-packet-routing]** hierarchy level. When the configuration is applied under the specific IGP, the label binding type, length, and value (TLV) for all the LDP FEC-label bindings from the LDP network are advertised as inet.3 LDP routes.

Here, Device P6 acts as a Segment Routing Mapping Server (SRMS) and advertises the following mappings – (P7,107), (P8,108), (PE3,103), (PE4,104), and (P7,107). If segment routing was supported on Device PE3, the node SID 103 would have been configured on Device PE3. Because Device PE3 does not support segment routing, the policy is configured at the SRMS on Device P6, and Device P6 is responsible for advertising the mappings.

These mapping server advertisements are only understood by the segment routing devices. The segment routing devices install the related node SIDs in the MPLS data plane exactly how the node segments had been advertised by the nodes themselves. For instance, Device PE1 installs the node SID 103 with P5 next hop exactly as if Device PE3 had advertised SID 103.

Device PE1 has a service route with PE3 as its protocol next hop. Device PE1 has a node segment for that IGP route – 103 with P5 next hop. As a result, Device PE1 sends its service packet to Device P5 with two labels – the bottom label, which is the service label, and the top label, which is SID 103. Device P5 swaps 103 for 103 and forwards to Device P6. The next-hop for Device P6 is the IGP route PE3, which is not capable of segment routing. (Device P7 does not advertise the segment routing capability). However, Device P6 has an LDP label binding from that next hop for the same FEC (for example, LDP label 1037). As a result, on Device P6, the IGP swaps 103 for 1037 and forwards to Device P7.

Device P7 swaps this label with the LDP-label received from Device P8, and then forwards it to Device P8. The LDP label is popped by Device P8 and forwarded to Device PE3.

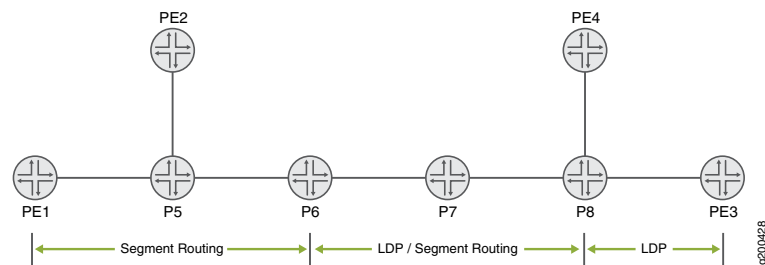

Device PE3 receives the tunneled packet and processes the service label. The end-to-end MPLS tunnel is built from a segment routing node from Devices PE1 to P6, and an LDP LSP from Devices P6 to PE3.

### Segment Routing to LDP Stitching

When the IGP segment routing LSP's IP next hop does not support segment routing, the IGP looks at the inet.3 routing table to see if there is an LDP LSP to the same prefix. If the LDP LSP is present, the IGP stitches the segment routing LSP to the LDP LSP by programming a MPLS transit route that swaps the segment routing label with the LDP label to switch traffic from segment routing domain to the LDP domain.

[Figure 94 on page 892](#) illustrates the stitching of segment routing and LDP LSPs for enabling interoperability.

Figure 94: Stitching Segment Routing and LDP LSPs

In the topology, Device PE3 is LDP-capable and does not support segment routing. The mapping server in the segment routing domain can advertise label binding TLV for devices P7, P8 and PE4. In such a scenario, Device PE1 can have both prefix SID and remote label binding TLV and SID to reach Device PE4. However, Device PE1 prefers prefix SID over remote label binding TLV while programming its ingress segment routing route for Device PE4. As a result, Device PE1 uses the segment routing LSP end-to-end to send traffic to Device PE4, and uses the segment routing-to-LDP stitching while sending traffic to Device PE3.

#### Unsupported Features and Functionality for Interoperability of Segment Routing with LDP using ISIS

- Penultimate-hop popping behaviour for label binding TLV is not supported.
- Advertising of range of prefixes in label binding TLV is not supported.
- Segment Routing Conflict Resolution is not supported.
- LDP traffic statistics does not work.
- Nonstop active routing (NSR) and graceful Routing Engine switchover (GRES) is not supported.
- ISIS inter-level is not supported.
- RFC 7794, *IS-IS Prefix Attributes for Extended IPv4* is not supported.
- Redistributing LDP route as a prefix-sid at the stitching node is not supported.

## Configuring Miscellaneous LDP Properties

The following sections describe how to configure a number of miscellaneous LDP properties:

- [Configuring LDP to Use the IGP Route Metric on page 893](#)
- [Preventing Addition of Ingress Routes to the inet.0 Routing Table on page 893](#)
- [Multiple-Instance LDP and Carrier-of-Carriers VPNs on page 893](#)

- [Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router on page 894](#)
- [Enabling LDP over RSVP-Established LSPs on page 894](#)
- [Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks on page 895](#)
- [Configuring the TCP MD5 Signature for LDP Sessions on page 895](#)
- [Configuring LDP Session Protection on page 897](#)
- [Disabling SNMP Traps for LDP on page 897](#)
- [Configuring LDP Synchronization with the IGP on LDP Links on page 897](#)
- [Configuring LDP Synchronization with the IGP on the Router on page 898](#)
- [Configuring the Label Withdrawal Timer on page 898](#)
- [Ignoring the LDP Subnet Check on page 899](#)

## Configuring LDP to Use the IGP Route Metric

Use the **track-igp-metric** statement if you want the interior gateway protocol (IGP) route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1).

To use the IGP route metric, include the **track-igp-metric** statement:

```
track-igp-metric;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Preventing Addition of Ingress Routes to the inet.0 Routing Table

By configuring the **no-forwarding** statement, you can prevent ingress routes from being added to the inet.0 routing table instead of the inet.3 routing table even if you enabled the **traffic-engineering bgp-igp** statement at the **[edit protocols mpls]** or the **[edit logical-systems logical-system-name protocols mpls]** hierarchy level. By default, the **no-forwarding** statement is disabled.

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

To omit ingress routes from the inet.0 routing table, include the **no-forwarding** statement:

```
no-forwarding;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Multiple-Instance LDP and Carrier-of-Carriers VPNs

By configuring multiple LDP routing instances, you can use LDP to advertise labels in a carrier-of-carriers VPN from a service provider provider edge (PE) router to a customer carrier customer edge (CE) router. This is especially useful when the carrier customer is

a basic Internet service provider (ISP) and wants to restrict full Internet routes to its PE routers. By using LDP instead of BGP, the carrier customer shields its other internal routers from the Internet. Multiple-instance LDP is also useful when a carrier customer wants to provide Layer 2 or Layer 3 VPN services to its customers.

For an example of how to configure multiple LDP routing instances for carrier-of-carriers VPNs, see the *Multiple Instances for Label Distribution Protocol Feature Guide*.

## Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router

The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

To configure ultimate-hop popping, include the **explicit-null** statement:

```
explicit-null;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

For more information about labels, see “MPLS Label Overview” on page 329 and “MPLS Label Allocation” on page 329.

## Enabling LDP over RSVP-Established LSPs

You can run LDP over LSPs established by RSVP, effectively tunneling the LDP-established LSP through the one established by RSVP. To do so, enable LDP on the lo0.0 interface (see “Enabling and Disabling LDP” on page 739). You must also configure the LSPs over which you want LDP to operate by including the **ldp-tunneling** statement at the [edit protocols mpls label-switched-path *lsp-name*] hierarchy level:

```
[edit]
protocols {
  mpls {
    label-switched-path lsp-name {
      from source;
      to destination;
      ldp-tunneling;
    }
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

- Related Documentation**
- [Tunneling LDP LSPs in RSVP LSPs Overview on page 734](#)

## Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This might require that you manually configure the RSVP metric when deploying LDP tunneling over RSVP LSPs in heterogeneous networks.

When a Juniper Networks router is linked to another vendor's router through an RSVP tunnel, and LDP tunneling is also enabled, by default the Juniper Networks router might not use the RSVP tunnel to route traffic to the LDP destinations downstream of the other vendor's egress router if the RSVP path has a metric of 1 larger than the physical OSPF path.

To ensure that LDP tunneling functions properly in heterogeneous networks, you can configure OSPF to ignore the RSVP LSP metric by including the **ignore-lsp-metrics** statement:

```
ignore-lsp-metrics;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ospf traffic-engineering shortcuts]**
- **[edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts]**

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

To enable LDP over RSVP LSPs, you also still need to complete the procedure in Section [“Enabling LDP over RSVP-Established LSPs” on page 894](#).

## Configuring the TCP MD5 Signature for LDP Sessions

You can configure an MD5 signature for an LDP TCP connection to protect against the introduction of spoofed TCP segments into LDP session connection streams.

A router using the MD5 signature option is configured with a password for each peer for which authentication is required. The password is stored encrypted.

LDP hello adjacencies can still be created even when peering interfaces are configured with different security signatures. However, the TCP session cannot be authenticated and is never established.

Starting in Junos OS Release 16.1R1, support for Hashed Message Authentication Code (HMAC) and MD5 authentication for LDP sessions is extended from a per-session configuration to a subnet-match (that is, longest-prefix-match) configuration.

The support for subnet-match authentication provides flexibility in configuring authentication for automatically targeted LDP (TLDP) sessions, making the deployment of remote loop-free alternate (LFA) and FEC 129 pseudowires easy.

To configure an MD5 signature for an LDP TCP connection, include the **session-group** and **authentication-key** statement:

```
session-group prefix-length {
  authentication-key authentication-key;
}
```

Use the **session-group** statement to configure the address for the remote end of the LDP session.

The **md5-authentication-key** (password) can be up to 69 characters long. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks.

You can also configure an authentication key update mechanism for the LDP routing protocol. This mechanism allows you to update authentication keys without interrupting associated routing and signaling protocols such as Open Shortest Path First (OSPF) and Resource Reservation Setup Protocol (RSVP).

To configure the authentication key update mechanism, include the **key-chain** statement at the **[edit security authentication-key-chains]** hierarchy level, and specify the **key** option to create a keychain consisting of several authentication keys.

```
[edit security authentication-key-chains]
key-chain key-chain-name {
  key key {
    secret secret-data;
    start-time yyyy-mm-dd.hh:mm:ss;
  }
}
```

To configure the authentication key update mechanism for the LDP routing protocol, include the **authentication-key-chain** statement at the **[edit protocols ldp]** hierarchy level to associate the protocol with the **[edit security authentication-key-chains]** authentication keys. You must also configure the authentication algorithm by including the **authentication-algorithm algorithm** statement the **[edit protocols ldp]** hierarchy level.

```
[edit protocols ldp]
group group-name {
  neighbor address {
    authentication-algorithm algorithm;
    authentication-key-chain key-chain-name;
  }
}
```

For more information about the authentication key update feature, see *Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols*.

## Configuring LDP Session Protection

An LDP session is normally created between a pair of routers that are connected by one or more links. The routers form one hello adjacency for every link that connects them and associate all the adjacencies with the corresponding LDP session. When the last hello adjacency for an LDP session goes away, the LDP session is terminated. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished.

You can configure the Junos OS to leave the LDP session between two routers up even if there are no hello adjacencies on the links connecting the two routers by configuring the **session-protection** statement. You can optionally specify a time in seconds using the **timeout** option. The session remains up for the duration specified as long as the routers maintain IP network connectivity.

```
session-protection {
  timeout seconds;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Disabling SNMP Traps for LDP

Whenever an LDP LSP makes a transition from up to down, or down to up, the router sends an SNMP trap. However, it is possible to disable the LDP SNMP traps on a router, logical system, or routing instance.

For information about the LDP SNMP traps and the proprietary LDP MIB, see the [SNMP MIB Explorer](#)..

To disable SNMP traps for LDP, specify the **trap disable** option for the **log-updown** statement:

```
log-updown {
  trap disable;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring LDP Synchronization with the IGP on LDP Links

LDP is a protocol for distributing labels in non-traffic-engineered applications. Labels are distributed along the best path determined by the IGP. If synchronization between LDP and the IGP is not maintained, the LSP goes down. When LDP is not fully operational on a given link (a session is not established and labels are not exchanged), the IGP advertises the link with the maximum cost metric. The link is not preferred but remains in the network topology.

LDP synchronization is supported only on active point-to-point interfaces and LAN interfaces configured as point-to-point under the IGP. LDP synchronization is not supported during graceful restart.

To advertise the maximum cost metric until LDP is operational for synchronization, include the **ldp-synchronization** statement:

```
ldp-synchronization {  
  disable;  
  hold-time seconds;  
}
```

To disable synchronization, include the **disable** statement. To configure the time period to advertise the maximum cost metric for a link that is not fully operational, include the **hold-time** statement.

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Configuring LDP Synchronization with the IGP on the Router

You can configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

To configure the time the LDP waits before informing the IGP that the LDP neighbor and session are operational, include the **igp-synchronization** statement and specify a time in seconds for the **holddown-interval** option:

```
igp-synchronization holddown-interval seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Configuring the Label Withdrawal Timer

The label withdrawal timer delays sending a label withdrawal message for a FEC to a neighbor. When an IGP link to a neighbor fails, the label associated with the FEC has to be withdrawn from all the upstream routers if the neighbor is the next hop for the FEC. After the IGP converges and a label is received from a new next hop, the label is readvertised to all the upstream routers. This is the typical network behavior. By delaying label withdrawal by a small amount of time (for example, until the IGP converges and the router receives a new label for the FEC from the downstream next hop), the label withdrawal and sending a label mapping soon could be avoided. The **label-withdrawal-delay** statement allows you to configure this delay time. By default, the delay is 60 seconds.

If the router receives the new label before the timer runs out, the label withdrawal timer is canceled. However, if the timer runs out, the label for the FEC is withdrawn from all of the upstream routers.

By default, LDP waits for 60 seconds before withdrawing labels to avoid resignaling LSPs multiple times while the IGP is reconverging. To configure the label withdrawal delay time in seconds, include the **label-withdrawal-delay** statement:

```
label-withdrawal-delay seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

Ignoring the LDP Subnet Check

In Junos OS Release 8.4 and later releases, an LDP source address subnet check is performed during the neighbor establishment procedure. The source address in the LDP link hello packet is matched against the interface address. This causes an interoperability issue with some other vendors' equipment.

To disable the subnet check, include the **allow-subnet-mismatch** statement:

```
allow-subnet-mismatch;
```

This statement can be included at the following hierarchy levels:

- [edit protocols ldp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols ldp **interface** *interface-name*]

**NOTE:** ACX Series routers do not support [edit logical-systems] hierarchy level.

Release History Table

Release	Description
16.1R1	Starting in Junos OS Release 16.1R1, support for Hashed Message Authentication Code (HMAC) and MD5 authentication for LDP sessions is extended from a per-session configuration to a subnet-match (that is, longest-prefix-match) configuration.

Configuring LDP LSP Traceroute

You can trace the route followed by an LDP-signaled LSP. LDP LSP traceroute is based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*. This feature allows you to periodically trace all paths in a FEC. The FEC topology information is stored in a database accessible from the CLI.

A topology change does not automatically trigger a trace of an LDP LSP. However, you can manually initiate a traceroute. If the traceroute request is for an FEC that is currently in the database, the contents of the database are updated with the results.

The periodic traceroute feature applies to all FECs specified by the **oam** statement configured at the **[edit protocols ldp]** hierarchy level. To configure periodic LDP LSP traceroute, include the **periodic-traceroute** statement:

```
periodic-traceroute {  
  disable;  
  exp exp-value;  
  fanout fanout-value;  
  frequency minutes;  
  paths number-of-paths;  
  retries retry-attempts;  
  source address;  
  ttl ttl-value;  
  wait seconds;  
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ldp oam]**
- **[edit protocols ldp oam fec address]**

You can configure the **periodic-traceroute** statement by itself or with any of the following options:

- **exp**—Specify the class of service to use when sending probes.
- **fanout**—Specify the maximum number of next hops to search per node.
- **frequency**—Specify the interval between traceroute attempts.
- **paths**—Specify the maximum number of paths to search.
- **retries**—Specify the number of attempts to send a probe to a specific node before giving up.
- **source**—Specify the IPv4 source address to use when sending probes.
- **ttl**—Specify the maximum time-to-live value. Nodes that are beyond this value are not traced.
- **wait**—Specify the wait interval before resending a probe packet.

---

## Collecting LDP Statistics

LDP traffic statistics show the volume of traffic that has passed through a particular FEC on a router.

When you configure the **traffic-statistics** statement at the **[edit protocols ldp]** hierarchy level, the LDP traffic statistics are gathered periodically and written to a file. You can configure how often statistics are collected (in seconds) by using the **interval** option. The default collection interval is 5 minutes. You must configure an LDP statistics file; otherwise, LDP traffic statistics are not gathered. If the LSP goes down, the LDP statistics are reset.

To collect LDP traffic statistics, include the **traffic-statistics** statement:

```

traffic-statistics {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval interval;
  no-penultimate-hop;
}

```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

This section includes the following topics:

- [LDP Statistics Output on page 901](#)
- [Disabling LDP Statistics on the Penultimate-Hop Router on page 902](#)
- [LDP Statistics Limitations on page 902](#)

## LDP Statistics Output

The following sample output is from an LDP statistics file:

FEC	Type	Packets	Bytes	Shared
10.255.350.448/32	Transit	0	0	No
	Ingress	0	0	No
10.255.350.450/32	Transit	0	0	Yes
	Ingress	0	0	No
10.255.350.451/32	Transit	0	0	No
	Ingress	0	0	No
220.220.220.1/32	Transit	0	0	Yes
	Ingress	0	0	No
220.220.220.2/32	Transit	0	0	Yes
	Ingress	0	0	No
220.220.220.3/32	Transit	0	0	Yes
	Ingress	0	0	No

May 28 15:02:05, read 12 statistics in 00:00:00 seconds

The LDP statistics file includes the following columns of data:

- **FEC**—FEC for which LDP traffic statistics are collected.
- **Type**—Type of traffic originating from a router, either **Ingress** (originating from this router) or **Transit** (forwarded through this router).
- **Packets**—Number of packets passed by the FEC since its LSP came up.
- **Bytes**—Number of bytes of data passed by the FEC since its LSP came up.
- **Shared**—A **Yes** value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
- **read**—This number (which appears next to the date and time) might differ from the actual number of the statistics displayed. Some of the statistics are summarized before being displayed.

## Disabling LDP Statistics on the Penultimate-Hop Router

Gathering LDP traffic statistics at the penultimate-hop router can consume excessive system resources, on next-hop routes in particular. This problem is exacerbated if you have configured the **deaggregate** statement in addition to the **traffic-statistics** statement. For routers reaching their limit of next-hop route usage, we recommend configuring the **no-penultimate-hop** option for the **traffic-statistics** statement:

```
traffic-statistics {
  no-penultimate-hop;
}
```

For a list of hierarchy levels at which you can configure the **traffic-statistics** statement, see the statement summary section for this statement.

**NOTE:** When you configure the **no-penultimate-hop** option, no statistics are available for the FECs that are the penultimate hop for this router.

Whenever you include or remove this option from the configuration, the LDP sessions are taken down and then restarted.

The following sample output is from an LDP statistics file showing routers on which the **no-penultimate-hop** option is configured:

FEC	Type	Packets	Bytes	Shared
10.255.245.218/32	Transit	0	0	No
	Ingress	4	246	No
10.255.245.221/32	Transit	statistics disabled		
	Ingress	statistics disabled		
13.1.1.0/24	Transit	statistics disabled		
	Ingress	statistics disabled		
13.1.3.0/24	Transit	statistics disabled		
	Ingress	statistics disabled		

## LDP Statistics Limitations

The following are issues related to collecting LDP statistics by configuring the **traffic-statistics** statement:

- You cannot clear the LDP statistics.
- If you shorten the specified interval, a new LDP statistics request is issued only if the statistics timer expires later than the new interval.
- A new LDP statistics collection operation cannot start until the previous one has finished. If the interval is short or if the number of LDP statistics is large, the time gap between the two statistics collections might be longer than the interval.

When an LSP goes down, the LDP statistics are reset.

## Tracing LDP Protocol Traffic

The following sections describe how to configure the trace options to examine LDP protocol traffic:

- [Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels on page 903](#)
- [Tracing LDP Protocol Traffic Within FECs on page 904](#)
- [Examples: Tracing LDP Protocol Traffic on page 904](#)

### Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels

To trace LDP protocol traffic, you can specify options in the global **traceoptions** statement at the **[edit routing-options]** hierarchy level, and you can specify LDP-specific options by including the **traceoptions** statement:

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`. We recommend that you place LDP-tracing output in the file **ldp-log**.

The following trace flags display the operations associated with the sending and receiving of various LDP messages. Each can carry one or more of the following modifiers:

- **address**—Trace the operation of address and address withdrawal messages.
- **binding**—Trace label-binding operations.
- **error**—Trace error conditions.
- **event**—Trace protocol events.
- **initialization**—Trace the operation of initialization messages.
- **label**—Trace the operation of label request, label map, label withdrawal, and label release messages.
- **notification**—Trace the operation of notification messages.
- **packets**—Trace the operation of address, address withdrawal, initialization, label request, label map, label withdrawal, label release, notification, and periodic messages. This modifier is equivalent to setting the **address**, **initialization**, **label**, **notification**, and **periodic** modifiers.

You can also configure the **filter** flag modifier with the **match-on address** sub-option for the **packets** flag. This allows you to trace based on the source and destination addresses of the packets.

- **path**—Trace label-switched path operations.
- **path**—Trace label-switched path operations.
- **periodic**—Trace the operation of hello and keepalive messages.
- **route**—Trace the operation of route messages.
- **state**—Trace protocol state transitions.

## Tracing LDP Protocol Traffic Within FECs

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers.

You can trace LDP protocol traffic within a specific FEC and filter LDP trace statements based on an FEC. This is useful when you want to trace or troubleshoot LDP protocol traffic associated with an FEC. The following trace flags are available for this purpose: **route**, **path**, and **binding**.

The following example illustrates how you might configure the LDP **traceoptions** statement to filter LDP trace statements based on an FEC:

```
[edit protocols ldp traceoptions]
set flag route filter match-on fec policy "filter-policy-for-ldp-fec";
```

This feature has the following limitations:

- The filtering capability is only available for FECs composed of IP version 4 (IPv4) prefixes.
- Layer 2 circuit FECs cannot be filtered.
- When you configure both route tracing and filtering, MPLS routes are not displayed (they are blocked by the filter).
- Filtering is determined by the policy and the configured value for the **match-on** option. When configuring the policy, be sure that the default behavior is always **reject**.
- The only **match-on** option is **fec**. Consequently, the only type of policy you should include is a route-filter policy.

## Examples: Tracing LDP Protocol Traffic

Trace LDP path messages in detail:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5;
      flag path;
    }
  }
}
```

```
}
}
```

Trace all LDP outgoing messages:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5;
      flag packets;
    }
  }
}
```

Trace all LDP error conditions:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5;
      flag error;
    }
  }
}
```

Trace all LDP incoming messages and all label-binding operations:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5 world-readable;
      flag packets receive;
      flag binding;
    }
    interface all {
    }
  }
}
```

Trace LDP protocol traffic for an FEC associated with the LSP:

```
[edit]
protocols {
  ldp {
    traceoptions {

## MPLS and Traffic Engineering

---

Traffic engineering allows you to control the path that data packets follow, bypassing the standard routing model, which uses routing tables. Traffic engineering moves flows from congested links to alternate links that would not be selected by the automatically computed destination-based shortest path. With traffic engineering, you can:

- Make more efficient use of expensive long-haul fibers.
- Control how traffic is rerouted in the face of single or multiple failures.

- Classify critical and regular traffic on a per-path basis.

The core of the traffic engineering design is based on building label-switched paths (LSPs) among routers. An LSP is connection-oriented, like a virtual circuit in Frame Relay or ATM. LSPs are not reliable: Packets entering an LSP do not have delivery guarantees, although preferential treatment is possible. LSPs also are similar to unidirectional tunnels in that packets entering a path are encapsulated in an envelope and switched across the entire path without being touched by intermediate nodes. LSPs provide fine-grained control over how packets are forwarded in a network. To provide reliability, an LSP can use a set of primary and secondary paths.

LSPs can be configured for BGP traffic only (traffic whose destination is outside of an autonomous system [AS]). In this case, traffic within the AS is not affected by the presence of LSPs. LSPs can also be configured for both BGP and interior gateway protocol (IGP) traffic; therefore, both intra-AS and inter-AS traffic is affected by the LSPs.

This section discusses the following topics:

## MPLS Traffic Engineering and Signaling Protocols Overview

Traffic engineering facilitates efficient and reliable network operations while simultaneously optimizing network resources and traffic performance. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) to a potentially less congested physical path across a network. To support traffic engineering, besides source routing, the network must do the following:

- Compute a path at the source by taking into account all the constraints, such as bandwidth and administrative requirements.
- Distribute the information about network topology and link attributes throughout the network once the path is computed.
- Reserve network resources and modify link attributes.

When transit traffic is routed through an IP network, MPLS is often used to engineer its passage. Although the exact path through the transit network is of little importance to either the sender or the receiver of the traffic, network administrators often want to route traffic more efficiently between certain source and destination address pairs. By adding a short label with specific routing instructions to each packet, MPLS switches packets from router to router through the network rather than forwarding packets based on next-hop lookups. The resulting routes are called *label-switched paths (LSPs)*. LSPs control the passage of traffic through the network and speed traffic forwarding.

You can create LSPs manually, or through the use of signaling protocols. Signaling protocols are used within an MPLS environment to establish LSPs for traffic across a transit network. Junos OS supports two signaling protocols—LDP and the Resource Reservation Protocol (RSVP).

MPLS traffic engineering uses the following components:

- MPLS LSPs for packet forwarding
- IGP extensions for distributing information about the network topology and link attributes
- Constrained Shortest Path First (CSPF) for path computation and path selection
- RSVP extensions to establish the forwarding state along the path and to reserve resources along the path

Junos OS also supports traffic engineering across different OSPF regions.

## Traffic Engineering Capabilities

The task of mapping traffic flows onto an existing physical topology is called *traffic engineering*. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide more efficient use of available aggregate bandwidth and long-haul fiber by ensuring that subsets of the network do not become overutilized while other subsets of the network along potential alternate paths are underutilized.

- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservices Internet.

## Components of Traffic Engineering

---

In the Junos<sup>®</sup> operating system (OS), traffic engineering is implemented with MPLS and RSVP. Traffic engineering is composed of four functional components:

- [Packet Forwarding Component on page 918](#)
- [Information Distribution Component on page 919](#)
- [Path Selection Component on page 920](#)
- [Signaling Component on page 921](#)

## Configuring Traffic Engineering for LSPs

---

When you configure an LSP, a host route (a 32-bit mask) is installed in the ingress router toward the egress router; the address of the host route is the destination address of the LSP. The **bgp** option for the **traffic engineering** statement at the **[edit protocols mpls]** hierarchy level is enabled by default (you can also explicitly configure the **bgp** option), allowing only BGP to use LSPs in its route calculations. The other **traffic-engineering** statement options allow you to alter this behavior in the master routing instance. This functionality is not available for specific routing instances. Also, you can enable only one of the **traffic-engineering** statement options (**bgp**, **bgp-igp**, **bgp-igp-both-ribs**, or **mpls-forwarding**) at a time.

.....

**NOTE:** Enabling or disabling any of the **traffic-engineering** statement options causes all the MPLS routes to be removed and then reinserted into the routing tables.

.....

You can configure OSPF and traffic engineering to advertise the LSP metric in summary link-state advertisements (LSAs) as described in the section [“Advertising the LSP Metric in Summary LSAs” on page 914](#).

The following sections describe how to configure traffic engineering for LSPs:

- [Using LSPs for Both BGP and IGP Traffic Forwarding on page 913](#)
- [Using LSPs for Forwarding in Virtual Private Networks on page 913](#)
- [Using RSVP and LDP Routes for Forwarding but Not Route Selection on page 913](#)
- [Advertising the LSP Metric in Summary LSAs on page 914](#)

## Using LSPs for Both BGP and IGP Traffic Forwarding

You can configure BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers by including the **bgp-igp** option for the **traffic-engineering** statement. The **bgp-igp** option causes all inet.3 routes to be moved to the inet.0 routing table.

On the ingress router, include **bgp-igp** option for the **traffic-engineering** statement:

```
traffic-engineering bgp-igp;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

**NOTE:** The **bgp-igp** option for the **traffic-engineering** statement cannot be configured for VPN). VPNs require that routes be in the inet.3 routing table.

## Using LSPs for Forwarding in Virtual Private Networks

VPNs require that routes remain in the inet.3 routing table to function properly. For VPNs, configure the **bgp-igp-both-ribs** option of the **traffic-engineering** statement to cause BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers. The **bgp-igp-both-ribs** option installs the ingress routes in both the inet.0 routing table (for IPv4 unicast routes) and the inet.3 routing table (for MPLS path information).

On the ingress router, include the **traffic-engineering bgp-igp-both-ribs** statement:

```
traffic-engineering bgp-igp-both-ribs;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

When you use the **bgp-igp-both-ribs** statement, the routes from the inet.3 table get copied into the inet.0 table. The copied routes are LDP-signaled or RSVP-signaled, and are likely to have a lower preference than other routes in inet.0. Routes with a lower preference are more likely to be chosen as the active routes. This can be a problem because routing policies only act upon active routes. To prevent this problem, use the **mpls-forwarding** option instead.

## Using RSVP and LDP Routes for Forwarding but Not Route Selection

If you configure the **bgp-igp** or **bgp-igp-both-ribs** options for the **traffic-engineering** statement, high-priority LSPs can supersede IGP routes in the inet.0 routing table. IGP routes might no longer be redistributed since they are no longer the active routes.

If you configure the **mpls-forwarding** option for the **traffic-engineering** statement, LSPs are used for forwarding but are excluded from route selection. These routes are added to both the inet.0 and inet.3 routing tables. LSPs in the inet.0 routing table are given a low preference when the active route is selected. However, LSPs in the inet.3 routing table are given a normal preference and are therefore used for selecting forwarding next hops.

When you activate the **mpls-forwarding** option, routes whose state is **ForwardingOnly** are preferred for forwarding even if their preference is lower than that of the currently active route. To examine the state of a route, execute a **show route detail** command.

To use LSPs for forwarding but exclude them from route selection, include the **mpls-forwarding** option for the **traffic-engineering** statement:

```
traffic-engineering mpls-forwarding;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

When you configure the **mpls-forwarding** option, IGP shortcut routes are copied to the inet.0 routing table only.

Unlike the **bgp-igp-both-ribs** option, the **mpls-forwarding** option allows you to use the LDP-sigaled and RSVP-sigaled routes for forwarding, and keep the BGP and IGP routes active for routing purposes so that routing policies can act upon them.

For example, suppose a router is running BGP and it has a BGP route of 10.10.10.1/32 that it needs to send to another BGP speaker. If you use the **bgp-igp-both-ribs** option, and your router also has a label-switched-path (LSP) to 10.10.10.1, the MPLS route for 10.10.10.1 becomes active in the inet.0 routing table. This prevents your router from advertising the 10.10.10.1 route to the other BGP router. On the other hand, if you use the **mpls-forwarding** option instead of the **bgp-igp-both-ribs** option, the 10.10.10.1/32 BGP route is advertised to the other BGP speaker, and the LSP is still used to forward traffic to the 10.10.10.1 destination.

## Advertising the LSP Metric in Summary LSAs

You can configure MPLS and OSPF to treat an LSP as a link. This configuration allows other routers in the network to use this LSP. To accomplish this goal, you need to configure MPLS and OSPF traffic engineering to advertise the LSP metric in summary LSAs.

For MPLS, include the **traffic-engineering bgp-igp** and **label-switched-path** statements:

```
traffic-engineering bgp-igp;
label-switched-path lsp-name {
  to address;
}
```

You can include these statements at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

For OSPF, include the `lsp-metric-into-summary` statement:

```
lsp-metric-into-summary;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols ospf traffic-engineering shortcuts]`
- `[edit logical-systems logical-system-name protocols ospf traffic-engineering shortcuts]`

For more information about OSPF traffic engineering, see the *Junos OS Routing Protocols Library*.

## Enabling Interarea Traffic Engineering

The Junos OS can signal a contiguous traffic-engineered LSP across multiple OSPF areas. The LSP signaling must be done using either nesting or contiguous signaling, as described in RFC 4206, *Label-Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*. However, contiguous signaling support is limited to just basic signaling. Reoptimization is not supported with contiguous signaling.

The following describes some of the interarea traffic engineering features:

- Interarea traffic engineering can be enabled when the loose-hop area border routers (ABRs) are configured on the ingress router using CSPF for the Explicit Route Object (ERO) calculation within an OSPF area. ERO expansion is completed on the ABRs.
- Interarea traffic engineering can be enabled when CSPF is enabled, but without ABRs specified in the LSP configuration on the ingress router (ABRs can be automatically designated).
- Differentiated Services (DiffServ) traffic engineering is supported as long as the class type mappings are uniform across multiple areas.

To enable interarea traffic engineering, include the `expand-loose-hop` statement in the configuration for each LSP transit router:

```
expand-loose-hop;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls]`
- `[edit logical-systems logical-system-name protocols mpls]`

## Enabling Inter-AS Traffic Engineering for LSPs

Generally, traffic engineering is possible for LSPs that meet the following conditions:

- Both ends of the LSP are in the same OSPF area or at the same IS-IS level.
- The two ends of the LSP are in different OSPF areas within the same autonomous system (AS). LSPs that end in different IS-IS levels are not supported.
- The two ends of an explicit-path LSP are in different OSPF ASs and the autonomous system border routers (ASBRs) are configured statically as the loose hops supported on the explicit-path LSP. For more information, see [“Configuring Explicit-Path LSPs” on page 522](#).

Without statically defined ASBRs on LSPs, traffic engineering is not possible between one routing domain, or AS, and another. However, when the ASs are under the control of single service provider, it is possible in some cases to have traffic engineered LSPs span the ASs and dynamically discover the OSPF ASBRs linking them (IS-IS is not supported with this feature).

Inter-AS traffic engineered LSPs are possible as long as certain network requirements are met, none of the limiting conditions apply, and OSPF passive mode is configured with EBGP. Details are provided in the following sections:

- [Inter-AS Traffic Engineering Requirements on page 916](#)
- [Inter-AS Traffic Engineering Limitations on page 917](#)
- [Configuring OSPF Passive TE Mode on page 917](#)

## Inter-AS Traffic Engineering Requirements

The proper establishment and functioning of inter-AS traffic engineered LSPs depend on the following network requirements, all of which must be met:

- All ASs are under control of a single service provider.
- OSPF is used as the routing protocol within each AS, and EBGP is used as the routing protocol between the ASs.
- ASBR information is available inside each AS.
- EBGP routing information is distributed by OSPF, and an IBGP full mesh is in place within each AS.
- Transit LSPs are *not* configured on the inter-AS links, but *are* configured between entry and exit point ASBRs on each AS.
- The EBGP link between ASBRs in different ASs is a direct link and must be configured as a passive traffic engineering link under OSPF. The remote link address itself, not the loopback or any other link address, is used as the remote node identifier for this passive link. For more information about OSPF passive traffic engineering mode configuration, see [“Configuring OSPF Passive TE Mode” on page 917](#).

In addition, the address used for the remote node of the OSPF passive traffic engineering link must be the same as the address used for the EBGP link. For more information about OSPF and BGP in general, see the *Junos OS Routing Protocols Library*.

## Inter-AS Traffic Engineering Limitations

Only LSP hierarchical, or nested, signaling is supported for inter-AS traffic engineered LSPs. Only point-to-point LSPs are supported (there is no point-to-multipoint support).

In addition, the following limitations apply. Any one of these conditions is sufficient to render inter-AS traffic engineered LSPs impossible, even if the above requirements are met.

- The use of multihop BGP is not supported.
- The use of policers or topologies that prevent BGP routes from being known inside the AS is not supported.
- Multiple ASBRs on a LAN between EBGPeers are not supported. Only one ASBR on a LAN between EBGPeers is supported (others ASBRs can exist on the LAN, but cannot be advertised).
- Route reflectors or policies that hide ASBR information or prevent ASBR information from being distributed inside the ASs are not supported.
- Bidirectional LSPs are not supported (LSPs are unidirectional from the traffic engineering perspective).
- Topologies with both inter-AS and intra-AS paths to the same destination are not supported.

In addition, several features that are routine with all LSPs are not supported with inter-AS traffic engineering:

- Admin group link colors are not supported.
- Secondary standby is not supported.
- Reoptimization is not supported.
- Crankback on transit routers is not supported.
- Diverse path calculation is not supported.
- Graceful restart is not supported.

These lists of limitations or unsupported features with inter-AS traffic engineered LSPs are not exhaustive.

## Configuring OSPF Passive TE Mode

Ordinarily, interior routing protocols such as OSPF are not run on links between ASs. However, for inter-AS traffic engineering to function properly, information about the inter-AS link, in particular, the address on the remote interface, must be made available inside the AS. This information is not normally included either in EBGPeer reachability messages or in OSPF routing advertisements.

To flood this link address information within the AS and make it available for traffic engineering calculations, you must configure OSPF passive mode for traffic engineering

on each inter-AS interface. You must also supply the remote address for OSPF to distribute and include in the traffic engineering database.

To configure OSPF passive mode for traffic engineering on an inter-AS interface, include the **passive** statement for the link at the **[edit protocols ospf area *area-id* interface *interface-name*]** hierarchy level:

```
passive {
  traffic-engineering {
    remote-node-id ip-address; /* IP address at far end of inter-AS link */
  }
}
```

OSPF must be properly configured on the router. The following example configures the inter-AS link **so-1/1/0** to distribute traffic engineering information with OSPF within the AS. The remote IP address is **192.168.207.2**.

```
[edit protocols ospf area 0.0.0.0]
interface so-1/1/0 {
  unit 0 {
    passive {
      traffic-engineering {
        remote-node-id 192.168.207.2;
      }
    }
  }
}
```

---

## Packet Forwarding Component

The packet forwarding component of the Junos traffic engineering architecture is MPLS, which is responsible for directing a flow of IP packets along a predetermined path across a network. This path is called a *label-switched path (LSP)*. LSPs are simplex; that is, the traffic flows in one direction from the head-end (ingress) router to a tail-end (egress) router. Duplex traffic requires two LSPs: one LSP to carry traffic in each direction. An LSP is created by the concatenation of one or more label-switched hops, allowing a packet to be forwarded from one router to another across the MPLS domain.

When an ingress router receives an IP packet, it adds an MPLS header to the packet and forwards it to the next router in the LSP. The labeled packet is forwarded along the LSP by each router until it reaches the tail end of the LSP, the egress router. At this point the MPLS header is removed, and the packet is forwarded based on Layer 3 information such as the IP destination address. The value of this scheme is that the physical path of the LSP is not limited to what the IGP would choose as the shortest path to reach the destination IP address.

This section discusses the following topics:

- [Packet Forwarding Based on Label Swapping on page 919](#)
- [How a Packet Traverses an MPLS Backbone on page 919](#)

**Related Documentation** • [Components of Traffic Engineering on page 912](#)

---

## Packet Forwarding Based on Label Swapping

---

The packet forwarding process at each router is based on the concept of label swapping. This concept is similar to what occurs at each Asynchronous Transfer Mode (ATM) switch in a permanent virtual circuit (PVC). Each MPLS packet carries a 4-byte encapsulation header that contains a 20-bit, fixed-length label field. When a packet containing a label arrives at a router, the router examines the label and copies it as an index to its MPLS forwarding table. Each entry in the forwarding table contains an interface-inbound label pair mapped to a set of forwarding information that is applied to all packets arriving on the specific interface with the same inbound label.

---

## How a Packet Traverses an MPLS Backbone

---

This section describes how an IP packet is processed as it traverses an MPLS backbone network.

At the entry edge of the MPLS backbone, the IP header is examined by the ingress router. Based on this analysis, the packet is classified, assigned a label, encapsulated in an MPLS header, and forwarded toward the next hop in the LSP. MPLS provides a high degree of flexibility in the way that an IP packet can be assigned to an LSP. For example, in the Junos traffic engineering implementation, all packets arriving at the ingress router that are destined to exit the MPLS domain at the same egress router are forwarded along the same LSP.

Once the packet begins to traverse the LSP, each router uses the label to make the forwarding decision. The MPLS forwarding decision is made independently of the original IP header: the incoming interface and label are used as lookup keys into the MPLS forwarding table. The old label is replaced with a new label, and the packet is forwarded to the next hop along the LSP. This process is repeated at each router in the LSP until the packet reaches the egress router.

When the packet arrives at the egress router, the label is removed and the packet exits the MPLS domain. The packet is then forwarded based on the destination IP address contained in the packet's original IP header according to the traditional shortest path calculated by the IP routing protocol.

---

## Information Distribution Component

---

Traffic engineering requires detailed knowledge about the network topology as well as dynamic information about network loading. To implement the information distribution component, simple extensions to the IGPs are defined. Link attributes are included as part of each router's link-state advertisement. IS-IS extensions include the definition of new type length values (TLVs), whereas OSPF extensions are implemented with opaque link-state advertisements (LSAs). The standard flooding algorithm used by the link-state IGPs ensures that link attributes are distributed to all routers in the routing domain. Some of the traffic engineering extensions to be added to the IGP link-state advertisement

include maximum link bandwidth, maximum reserved link bandwidth, current bandwidth reservation, and link coloring.

Each router maintains network link attributes and topology information in a specialized traffic engineering database. The traffic engineering database is used exclusively for calculating explicit paths for the placement of LSPs across the physical topology. A separate database is maintained so that the subsequent traffic engineering computation is independent of the IGP and the IGP's link-state database. Meanwhile, the IGP continues its operation without modification, performing the traditional shortest-path calculation based on information contained in the router's link-state database.

**Related Documentation** • [Components of Traffic Engineering on page 912](#)

---

## Path Selection Component

---

After network link attributes and topology information are flooded by the IGP and placed in the traffic engineering database, each ingress router uses the traffic engineering database to calculate the paths for its own set of LSPs across the routing domain. The path for each LSP can be represented by either a strict or loose explicit route. An explicit route is a preconfigured sequence of routers that should be part of the physical path of the LSP. If the ingress router specifies all the routers in the LSP, the LSP is said to be identified by a strict explicit route. If the ingress router specifies only some of the routers in the LSP, the LSP is described as a loose explicit route. Support for strict and loose explicit routes allows the path selection process to be given broad latitude whenever possible, but to be constrained when necessary.

The ingress router determines the physical path for each LSP by applying a Constrained Shortest Path First (CSPF) algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. Input into the CSPF algorithm includes:

- Topology link-state information learned from the IGP and maintained in the traffic engineering database
- Attributes associated with the state of network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color) that are carried by IGP extensions and stored in the traffic engineering database
- Administrative attributes required to support traffic traversing the proposed LSP (such as bandwidth requirements, maximum hop count, and administrative policy requirements) that are obtained from user configuration

As CSPF considers each candidate node and link for a new LSP, it either accepts or rejects a specific path component based on resource availability or whether selecting the component violates user policy constraints. The output of the CSPF calculation is an explicit route consisting of a sequence of router addresses that provides the shortest path through the network that meets the constraints. This explicit route is then passed to the signaling component, which establishes the forwarding state in the routers along the LSP.

**Related Documentation** • [Components of Traffic Engineering on page 912](#)

---

## Offline Path Planning and Analysis

Despite the reduced management effort resulting from online path calculation, an offline planning and analysis tool is still required to optimize traffic engineering globally. Online calculation takes resource constraints into account and calculates one LSP at a time. The challenge with this approach is that it is not deterministic. The order in which LSPs are calculated plays a critical role in determining each LSP's physical path across the network. LSPs that are calculated early in the process have more resources available to them than LSPs calculated later in the process because previously calculated LSPs consume network resources. If the order in which the LSPs are calculated is changed, the resulting set of physical paths for the LSPs also can change.

An offline planning and analysis tool simultaneously examines each link's resource constraints and the requirements of each LSP. Although the offline approach can take several hours to complete, it performs global calculations, compares the results of each calculation, and then selects the best solution for the network as a whole. The output of the offline calculation is a set of LSPs that optimizes utilization of network resources. After the offline calculation is completed, the LSPs can be established in any order because each is installed according to the rules for the globally optimized solution.

---

## Signaling Component

An LSP is not known to be workable until it is actually established by the signaling component. The signaling component, which is responsible for establishing LSP state and distributing labels, relies on a number of extensions to RSVP:

- The Explicit Route object allows an RSVP path message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The explicit route can be either strict or loose.
- The Label Request object permits the RSVP path message to request that intermediate routers provide a label binding for the LSP that it is establishing.
- The Label object allows RSVP to support the distribution of labels without changing its existing mechanisms. Because the RSVP Resv message follows the reverse path of the RSVP path message, the Label object supports the distribution of labels from downstream nodes to upstream nodes.

---

## Flexible LSP Calculation and Configuration

Traffic engineering involves mapping traffic flow onto a physical topology. You can determine the paths online using constraint-based routing. Regardless of how the physical path is calculated, the forwarding state is installed across the network through RSVP.

The Junos OS supports the following ways to route and configure an LSP:

- You can calculate the full path for the LSP offline and individually configure each router in the LSP with the necessary static forwarding state. This is analogous to the way some Internet service providers (ISPs) configure their IP-over-ATM cores.
- You can calculate the full path for the LSP offline and statically configure the ingress router with the full path. The ingress router then uses RSVP as a dynamic signaling protocol to install a forwarding state in each router along the LSP.
- You can rely on constraint-based routing to perform dynamic online LSP calculation. You configure the constraints for each LSP; then the network itself determines the path that best meets those constraints. Specifically, the ingress router calculates the entire LSP based on the constraints and then initiates signaling across the network.
- You can calculate a partial path for an LSP offline and statically configure the ingress router with a subset of the routers in the path; then you can permit online calculation to determine the complete path.

For example, consider a topology that includes two east-west paths across the United States: one in the north through Chicago and one in the south through Dallas. If you want to establish an LSP between a router in New York and one in San Francisco, you can configure the partial path for the LSP to include a single loose-routed hop of a router in Dallas. The result is an LSP routed along the southern path. The ingress router uses CSPF to compute the complete path and RSVP to install the forwarding state along the LSP.

- You can configure the ingress router with no constraints whatsoever. In this case, normal IGP shortest-path routing is used to determine the path of the LSP. This configuration does not provide any value in terms of traffic engineering. However, it is easy and might be useful in situations when services such as virtual private networks (VPNs) are needed.

In all these cases, you can specify any number of LSPs as backups for the primary LSP, thus allowing you to combine more than one configuration approach. For example, you might explicitly compute the primary path offline, set the secondary path to be constraint-based, and have the tertiary path be unconstrained. If a circuit on which the primary LSP is routed fails, the ingress router notices the outage from error notifications received from a downstream router or by the expiration of RSVP soft-state information. Then the router dynamically forwards traffic to a hot-standby LSP or calls on RSVP to create a forwarding state for a new backup LSP.

- [Need for Spanning Link-State Distribution on page 924](#)
- [Using BGP as a Solution on page 924](#)

- [Supported and Unsupported Features on page 930](#)
- [BGP Link-State Extensions for Source Packet Routing in Networking \(SPRING\) on page 930](#)

## Role of an Interior Gateway Protocol

An interior gateway protocol (IGP) is a type of protocol used for exchanging routing information between devices within an autonomous system (AS). Based on the method of computing the best path to a destination, the IGPs are divided into two categories:

- Link-state protocols—Advertise information about the network topology (directly connected links and the state of those links) to all routers using multicast addresses and triggered routing updates until all the routers running the link-state protocol have identical information about the internetwork. The best path to a destination is calculated based on constraints such as maximum delay, minimum available bandwidth, and resource class affinity.

OSPF and IS-IS are examples of link-state protocols.

- Distance vector protocols—Advertise complete routing table information to directly connected neighbors using a broadcast address. The best path is calculated based on the number of hops to the destination network.

RIP is an example of a distance vector protocol.

As the name implies, the role of an IGP is to provide routing connectivity within or internal to a given routing domain. A routing domain is a set of routers under common administrative control that share a common routing protocol. An AS can consist of multiple routing domains, where IGP functions to advertise and learn network prefixes (routes) from neighboring routers to build a route table that ultimately contains entries for all sources advertising reachability for a given prefix. IGP executes a route selection algorithm to select the best path between the local router and each destination, and provides full connectivity among the routers making up a routing domain.

In addition to advertising internal network reachability, IGPs are often used to advertise routing information that is external to that IGP's routing domain through a process known as route redistribution. Route redistribution is the process of exchanging routing information among distinct routing protocols to tie multiple routing domains together when intra-AS connectivity is desired.

## Limitations of an Interior Gateway Protocol

While each individual IGP has its own advantages and limitations, the biggest limitations of IGP in general are performance and scalability.

IGPs are designed to handle the task of acquiring and distributing network topology information for traffic engineering purposes. While this model has served well, IGPs have inherent scaling limitations when it comes to distributing large databases. IGPs can autodetect neighbors, with which they acquire intra-area network topology information. However, the link-state database or a traffic engineering database has the scope of a single area or AS, thereby limiting applications, such as end-to-end traffic engineering, the benefit of having external visibility to make better decisions.

For label-switched networks, such as MPLS and Generalized MPLS (GMPLS), most existing traffic engineering solutions work in a single routing domain. These solutions do not work when a route from the ingress node to the egress node leaves the routing area or AS of the ingress node. In such cases, the path computation problem becomes complicated because of the unavailability of the complete routing information throughout the network. This is because service providers usually choose not to leak routing information beyond the routing area or AS for scalability constraints and confidentiality concerns.

## Need for Spanning Link-State Distribution

One of the limitations of IGP is its inability to span link-state distribution outside a single area or AS. However, spanning link-state information acquired by an IGP across multiple areas or ASs has the following needs:

- LSP path computation—This information is used to compute the path for MPLS LSPs across multiple routing domains, for example an inter-area TE LSP.
- External path computing entities—External path computing entities, such as Application Layer Traffic Optimization (ALTO) and Path Computation Elements (PCE), perform path computations based on the network topology and current state of connections within the network, including traffic engineering information. This information is typically distributed by IGPs within the network.

However, because the external path computing entities cannot extract this information from the IGPs, they perform network monitoring to optimize network services.

## Using BGP as a Solution

- [Overview on page 924](#)
- [Implementation on page 925](#)

---

### Overview

To meet the needs for spanning link-state distribution across multiple domains, an exterior gateway protocol (EGP) is required to collect link-state and traffic engineering information from an IGP area, share it with external component, and use it for computing paths for interdomain MPLS LSPs.

BGP is a standardized EGP designed to exchange routing and reachability information between autonomous systems (ASs). BGP is a proven protocol that has better scaling properties because it can distribute millions of entries (for example, VPN prefixes) in a scalable fashion. BGP is the only routing protocol in use today that is suited to carry all of the routes in the Internet. This is largely because BGP runs on top of TCP and can make use of TCP flow control. In contrast, the internal gateway protocols (IGPs) do not have flow control. When IGPs have too much route information, they begin to churn. When BGP has a neighboring speaker that is sending information too quickly, BGP can throttle down the neighbor by delaying TCP acknowledgments.

Another benefit of BGP is that it uses type, length, value (TLV) tuples and network layer reachability information (NLRI) that provide seemingly endless extensibility without the need for the underlying protocol to be altered.

The distribution of link-state information across domains is regulated using policies to protect the interests of the service provider. This requires a control over the topology distribution using policies. BGP with its implemented policy framework serves well in the interdomain route distribution. In Junos OS, BGP is completely policy driven. The operator must explicitly configure neighbors to peer with and explicitly accept routes into BGP. Furthermore, routing policy is used to filter and modify routing information. Thus, routing policies provide complete administrative control over the routing tables.

Although, within an AS, both IGP-TE and BGP-TE provide the same set of information, BGP-TE has better scaling characteristics that are inherited from the standard BGP protocol. This makes BGP-TE a more scalable choice for acquiring multi-area/multi-AS topology information.

By using BGP as a solution, the IGP-acquired information is used for distribution into BGP. The ISPs can selectively expose this information with other ISPs, service providers, and content distribution networks (CDNs) through normal BGP peering. This allows for aggregation of the IGP-acquired information across multiple areas and ASs, such that an external path computing entity can access the information by passively listening to a route reflector.

### Implementation

---

In Junos OS, the IGP installs topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. To install IGP topology information into the traffic engineering database, use the **set igp-topology** configuration statement at the **[edit protocols isis traffic-engineering]** and **[edit protocols ospf traffic-engineering]** hierarchy levels. The mechanism to distribute link-state information using BGP includes the process of advertising the traffic engineering database into BGP-TE (import), and installing entries from BGP-TE into the traffic engineering database (export).

*Figure 95: Junos OS Implementation of BGP Link-State Distribution*

- [Traffic Engineering Database Import on page 926](#)
- [Traffic Engineering Database Export on page 927](#)
- [Assigning Credibility Values on page 927](#)
- [Cross-Credibility Path Computation on page 928](#)
- [BGP-TE NLRIs and TLVs on page 928](#)

### **Traffic Engineering Database Import**

To advertise the traffic engineering database into BGP-TE, the link and node entries in the traffic engineering database are converted in the form of routes. These converted routes are then installed by the traffic engineering database on behalf of the corresponding IGP, into a user-visible routing table called **Lsdist.0**, on conditions subject to route policies. The procedure of leaking entries from the traffic engineering database into **Lsdist.0** is called traffic engineering database import as illustrated in [Figure 95 on page 926](#).

There are policies to govern the traffic engineering database import process. By default, no entries are leaked from the traffic engineering database into the **Lsdist.0** table.

Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the **Lsdist.0** routing table as illustrated in [Figure 95 on page 926](#). Prior to Junos OS Release 17.4R1, the traffic engineering database only exported RSVP-TE topology information. Now you can monitor both IGP and traffic engineering topology information. The BGP-LS reads IGP entries from **Lsdist.0** and advertises these entries to the BGP peers. To import IGP topology information into BGP-LS from **Lsdist.0**, use the **set bgp-ls** configuration

statement at the `[edit protocols mpls traffic-engineering database import igp-topology]` hierarchy level.

### *Traffic Engineering Database Export*

BGP can be configured to export or advertise routes from the **lsdist.0** table, subject to policy. This is common for any kind of route origination in BGP. In order to advertise BGP-TE into the traffic engineering database, BGP needs to be configured with the BGP-TE address family, and an export policy that selects routes for redistribution into BGP.

BGP then propagates these routes like any other NLRI. BGP peers that have the BGP-TE family configured and negotiated receive BGP-TE NLRIs. BGP stores the received BGP-TE NLRIs in the form of routes in the **lsdist.0** table, which is the same table that stores locally originated BGP-TE routes. The BGP-installed routes in **lsdist.0** are then distributed to other peers like any other route. Thus, the standard route selection procedure applies to BGP-TE NLRIs received from multiple speakers.

To achieve interdomain TE, the routes in **lsdist.0** are leaked into the traffic engineering database through a policy. This process is called traffic engineering database export as illustrated in [Figure 95 on page 926](#).

There are policies to govern the traffic engineering database export process. By default, no entries are leaked from the **lsdist.0** table into the traffic engineering database.

**NOTE:** For SDN applications, such as PCE and ALTO, the BGP-TE advertised information cannot leak into the traffic engineering database of a router. In such cases, an external server that peers with the routers using BGP-TE is used to move topology information up into the sky/orchestration system that spans the network. These external servers can be deemed as BGP-TE consumers, where they receive BGP-TE routes, but do not advertise them.

### *Assigning Credibility Values*

Once the entries are installed in the traffic engineering database, the BGP-TE learned information is made available for CSPF path computation. The traffic engineering database uses a protocol preference scheme that is based on credibility values. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value. BGP-TE has the capability to advertise information learned from multiple protocols at the same time, and so in addition to the IGP-installed entries in the traffic engineering database, there can be BGP-TE installed entries that correspond to more than one protocol. The traffic engineering database export component creates a traffic engineering database protocol and credibility level for each protocol that BGP-TE supports. These credibility values are configurable in the CLI.

The credibility order for the BGP-TE protocols is as follows:

- Unknown—80
- OSPF—81

- ISIS Level 1—82
- ISIS Level 2—83
- Static—84
- Direct—85

### ***Cross-Credibility Path Computation***

After you assign credibility values, each credibility level is treated as an individual plane. The Constrained Shorted Path First algorithm starts with the highest assigned credibility to the lowest, finding a path within that credibility level.

With BGP-TE, it is essential to compute paths across credibility levels to compute inter-AS paths. For example, different credibility settings are seen on a device from area 0 that computes the path through area 1, because area 0 entries are installed by OSPF, and area 1 entries are installed by BGP-TE.

To enable path computation across credibility levels, include the **cross-credibility-cspf** statement at the **edit protocols mpls**, **[edit protocols mpls label-switched-path lsp-name]**, and **[edit protocols rsvp]** hierarchy levels. At the **[edit protocols rsvp]** hierarchy level, enabling **cross-credibility-cspf** impacts bypass LSPs and loose hop expansion in transit.

Configuring **cross-credibility-cspf** enables path computation across credibility levels using the Constrained Shortest Path First algorithm, wherein the constraint is not performed on a credibility-by-credibility basis, but as a single constraint ignoring the assigned credibility values.

### ***BGP-TE NLRIs and TLVs***

Like other BGP routes, BGP-TE NLRIs can also be distributed through a route reflector that speaks BGP-TE NLRI. Junos OS implements the route reflection support for the BGP-TE family.

The following is a list of supported NLRIs:

- Link NLRI
- Node NLRI
- IPv4 Prefix NLRI (receive and propagate)
- IPv6 Prefix NLRI (receive and propagate)

**NOTE:** Junos OS does not provide support for the route-distinguisher form of the above NLRIs.

---

The following is a list of supported fields in link and node NLRIs:

- Protocol-ID—NLRI originates with the following protocol values:
  - ISIS-L1
  - ISIS-L2

- OSPF
- Identifier—This value is configurable. By default, the identifier value is set to 0.
- Local/Remote node descriptor—These include:
  - Autonomous system
  - BGP-LS Identifier—This value is configurable. By default, the BGP-LS identifier value is set to 0
  - Area-ID
  - IGP router-ID
- Link descriptors (Only for link NLRI)—This includes:
  - Link Local/Remote Identifiers
  - IPv4 interface address
  - IPv4 neighbor address
  - IPv6 neighbor/interface address—The IPv6 neighbor and interface addresses are not originated, but only stored and propagated when received.
  - Multi-topology ID—This value is not originated, but stored and propagated when received.

The following is a list of supported LINK\_STATE attribute TLVs:

- Link attributes:
  - Administrative group
  - Max link bandwidth
  - Max reservable bandwidth
  - Unreserved bandwidth
  - TE default metric
  - SRLG
  - The following TLVs, which are not originated, but only stored and propagated when received:
    - Opaque link attributes
    - MPLS protocol mask
    - Metric
    - Link protection type
    - Link name attribute
- Node attributes:

- IPv4 Router-ID
- Node flag bits—Only the overload bit is set.
- The following TLVs, which are not originated, but only stored and propagated when received:
  - Multi-topology
  - OSPF-specific node properties
  - Opaque node properties
  - Node name
  - IS-IS area identifier
  - IPv6 Router-ID
- Prefix attributes—These TLVs are stored and propagated like any other unknown TLVs.

## Supported and Unsupported Features

Junos OS supports the following features with link-state distribution using BGP:

- Advertisement of multiprotocol assured forwarding capability
- Transmission and reception of node and link-state BGP and BGP-TE NLRIs
- Nonstop active routing for BGP-TE NLRIs
- Policies

Junos OS does **not** support the following functionality for link-state distribution using BGP:

- Aggregated topologies, links, or nodes
- Route distinguisher support for BGP-TE NLRIs
- Multi-topology identifiers
- Multi-instance identifiers (excluding the default instance ID 0)
- Advertisement of the link and node area TLV
- Advertisement of MPLS signaling protocols
- Importing node and link information with overlapping address

## BGP Link-State Extensions for Source Packet Routing in Networking (SPRING)

- [Source Packet Routing in Networking \(SPRING\) on page 931](#)
- [Flow of BGP Link-State SPRING Data on page 931](#)
- [Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING on page 933](#)

Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers. BGP typically learns the link-state information from IGP and distributes it to BGP peers. Besides BGP, the SDN controller can get link-state information directly from IGP if the controller is a part of an IGP domain. However, BGP link-state distribution provides a scalable mechanism to export the topology information. BGP link-state extensions for SPRING is supported on interdomain networks.

### **Source Packet Routing in Networking (SPRING)**

---

SPRING is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to decide the actual path it must take. SPRING engages IGPs, such as IS-IS and OSPF, for advertising network segments. Network segments can represent any instruction, topological or service-based. Within IGP topologies, IGP segments are advertised by the link-state routing protocols. There are two types of IGP segments:

**Adjacency segment**—A one-hop path over a specific adjacency between two nodes in the IGP

**Prefix segment**—A multi-hop, equal-cost, multipath-aware shortest-path to a prefix, as per the state of the IGP topology

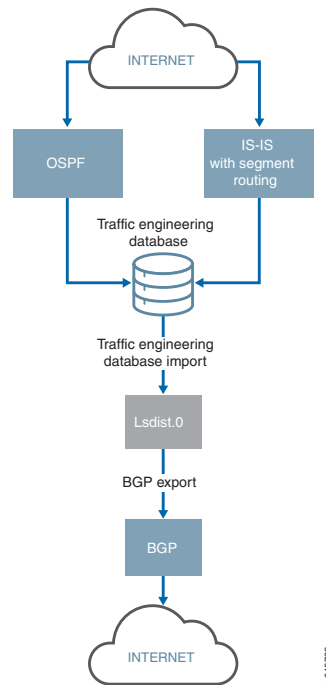

When SPRING is enabled in a BGP network, BGP link-state address family learns the SPRING information from the IGP link-state routing protocols and advertises segments in the form of segment identifiers (SIDs). BGP link-state address family has been extended to carry SIDs and other SPRING-related information to BGP peers. The route reflector can steer a packet through a desired set of nodes and links by prepending the packet with an appropriate combination of tunnels. This feature allows BGP link-state address family to also advertise the SPRING information to BGP peers.

### **Flow of BGP Link-State SPRING Data**

---

[Figure 96 on page 932](#) depicts the data flow of BGP link-state SPRING data that IS-IS pushes to the traffic engineering database.

Figure 96: BGP Link-State Source Packet Routing in Networking (SPRING)

- IGP pushes the SPRING attributes to the traffic engineering database.
- SPRING capabilities and algorithm information are carried forward as node attributes into the traffic engineering database.
- Adjacent SID and LAN adjacent SID information are carried as link attributes.
- Prefix SID or node-SID information is carried as prefix attributes.
- A new set or a change to existing attributes triggers IGP updates to the traffic engineering database with new data.
- RSVP is a prerequisite for link attributes.

**CAUTION:** If traffic engineering is disabled at the IGP level, none of the attributes are pushed to the traffic engineering database.

- All parameters in the BGP traffic engineering NLRI, including the link, node, and prefix descriptors are derived from entries in the traffic engineering database.
- The traffic engineering database imports route entries into the **lsdist.0** routing table from IGP subject to policy.
- The default policy of BGP is to export routes, which are known to BGP only. You configure an export policy for non-BGP routes in the **lsdis.0** routing table. This policy advertises an entry learned from the traffic engineering database.

**NOTE:** Currently, OSPF does not push SPRING information to the BGP link-state address family. IS-IS is the only IGP that pushes SPRING information to the BGP link-state address family.

### Supported BGP Link-State Attributes and TLVs, and Unsupported Features for BGP Link-State with SPRING

BGP link-state with SPRING supports the following attributes and type, length, and values (TLVs) that are originated, received, and propagated in the network:

#### Node attributes

- Segment routing Capabilities
- Segment routing Algorithm

#### Link attributes

- Adjacent-SID
- LAN Adjacent-SID

#### Prefix descriptors

- IP reachability information

#### Prefix attributes

- Prefix SID

The following list supports TLVs that are not originated, but only received and propagated in the network:

#### Prefix descriptors

- Multitopology ID
- OSPF route type

#### Prefix attributes

- Range
- Binding SID

Junos OS does not support the following features with BGP link-state with SPRING extensions:

- IPv6 prefix origination
- Multitopology identifiers
- Traffic engineering database export for SPRING parameters

- New TLVs with tcpdump (existing TLVs are also not supported).
- SPRING over IPv6

**Release History Table**

Release	Description
17.4R1	Starting in Junos OS Release 17.4R1, the traffic engineering database installs interior gateway protocol (IGP) topology information in addition to RSVP-TE topology information in the lsdist.0 routing table
17.2R1	Starting in Junos OS Release 17.2R1, the BGP link-state address family is extended to distribute the source packet routing in networking (SPRING) topology information to software-defined networking (SDN) controllers.

## Example: Configuring Link State Distribution Using BGP

This example shows how to configure BGP to carry link-state information across multiple domains, which is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

- [Requirements on page 934](#)
- [Overview on page 935](#)
- [Configuration on page 935](#)
- [Verification on page 946](#)

### Requirements

This example uses the following hardware and software components:

- Four routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - BGP

- IS-IS
- OSPF

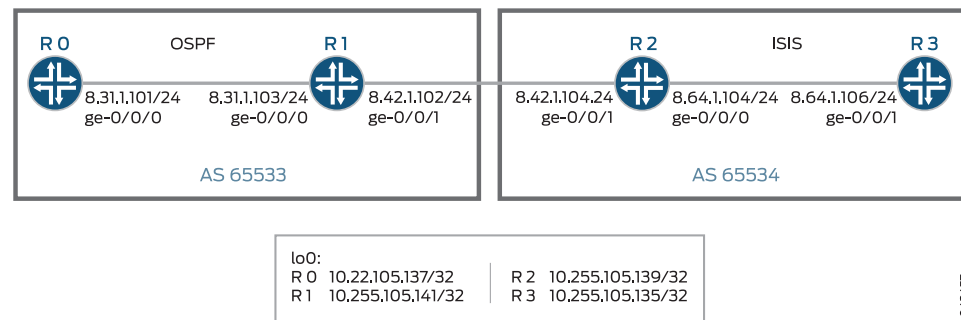

## Overview

Starting with Junos OS Release 14.2, a new mechanism to distribute topology information across multiple areas and autonomous systems (ASs) is introduced by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS label-switched paths (LSPs) spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Starting with Junos OS Release 17.1R1, link state distribution using BGP is supported on QFX10000 switches.

## Topology

Figure 97: Link-State Distribution Using BGP

In Figure 97 on page 935, Routers R0 and R1 and Routers R2 and R3 belong to different autonomous systems. Routers R0 and R1 run OSPF, and Routers R2 and R3 run IS-IS.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
R0
set interfaces ge-0/0/0 unit 0 family inet address 8.31.1.101/24

set protocols isis interface ge-0/0/0.0 level 1 disable
set protocols isis interface lo0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set policy-options policy-statement accept-all from family traffic-engineering
set policy-options policy-statement accept-all then accept

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R1:

1. Configure the Router R1 interfaces.

```

[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 8.31.1.103/24
user@R1# set ge-0/0/0 unit 0 family iso
user@R1# set ge-0/0/0 unit 0 family mpls
user@R1# set ge-0/0/1 unit 0 family inet address 8.42.1.102/24
user@R1# set ge-0/0/1 unit 0 family iso
user@R1# set ge-0/0/1 unit 0 family mpls
user@R1# set lo0 unit 0 family inet address 10.255.105.141/32

```

2. Configure the router ID and autonomous system of Router R1.

```

[edit routing-options]
user@R1# set router-id 10.255.105.141
user@R1# set autonomous-system 65533

```

3. Enable RSVP on all the interfaces of Router R1 (excluding the management interface).

```

[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable

```

4. Enable MPLS on all the interfaces of Router R1 (excluding the management interface).

```

[edit protocols]
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable

```

5. Configure the BGP group for Router R1 to peer with Router R0, and assign the local address and neighbor address.

```
[edit protocols]
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp neighbor 10.255.105.137
```

6. Include the BGP-TE signaling network layer reachability information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@R1# set bgp group ibgp family traffic-engineering unicast
```

7. Enable export of policy nlri2bgp on Router R1.

```
[edit protocols]
user@R1# set bgp group ibgp export nlri2bgp
```

8. Configure the BGP group for Router R1 to peer with Router R2, and assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
```

9. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp family traffic-engineering unicast
```

10. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
```

11. Enable OSPF on the interface connecting Router R1 to Router R0 and on the loopback interface of Router R1, and enable traffic engineering capabilities.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
```

12. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering  
remote-node-id 8.42.1.104
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering  
remote-node-router-id 10.255.105.139
```

13. Configure policies to accept traffic from BGP-TE NLRI.

```
[edit policy-options]
```

```
user@R1# set policy-statement accept-all from family traffic-engineering
```

```
user@R1# set policy-statement accept-all then accept
```

```
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
```

```
user@R1# set policy-statement nlri2bgp term 1 then accept
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces  
ge-0/0/0 {  
  unit 0 {  
    family inet {  
      address 8.31.1.103/24;

    }
  }
}
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R2:

1. Configure the Router R2 interfaces.

```
[edit interfaces]
user@R2# set ge-0/0/0 unit 0 family inet address 8.64.1.104/24
user@R2# set ge-0/0/0 unit 0 family iso
user@R2# set ge-0/0/0 unit 0 family mpls
user@R2# set ge-0/0/1 unit 0 family inet address 8.42.1.104/24
user@R2# set ge-0/0/1 unit 0 family iso
user@R2# set ge-0/0/1 unit 0 family mpls
user@R2# set lo0 unit 0 family inet address 10.255.105.139/32
user@R2# set lo0 unit 0 family iso
```

2. Configure the router ID and autonomous system of Router R2.

```
[edit routing-options]
user@R2# set router-id 10.255.105.139
user@R2# set autonomous-system 65534
```

3. Enable RSVP on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set rsvp interface all
user@R2# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R2 (excluding the management interface).

```
[edit routing-options]
user@R2# set mpls interface all
user@R2# set mpls interface fxp0.0 disable
```

5. Enable import of traffic engineering database parameters using the ted2nlri policy.

```
[edit protocols]
user@R2# set mpls traffic-engineering database import policy ted2nlri
```

6. Configure the BGP group for Router R2 to peer with Router R1.

```
[edit protocols]
user@R2# set bgp group ebgp type external
```

7. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp family traffic-engineering unicast
```

8. Assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R2# set bgp group ebgp peer-as 65533
user@R2# set bgp group ebgp neighbor 8.42.1.102
```

9. Enable export of policy nlri2bgp on Router R2.

```
[edit protocols]
user@R2# set bgp group ebgp export nlri2bgp
```

10. Enable IS-IS on the interface connecting Router R2 with Router R3 and the loopback interface of Router R2.

```
[edit protocols]
user@R2# set isis level 1 disable
user@R2# set isis interface ge-0/0/0.0
user@R2# set isis interface lo0.0
```

11. Enable only IS-IS advertising on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5501.8181
user@R2# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.102
```

12. Configure traffic engineering capability on Router R2.

```
[edit protocols]
user@R2# set ospf traffic-engineering
```

13. Enable only OSPF advertisements on the interface connecting Router R2 with Router R1.

```
[edit protocols]
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-id 8.42.1.102
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-router-id 10.255.105.141
```

14. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces

## Verification

Verify that the configuration is working properly.

- [Verifying the BGP Summary Status on page 946](#)
- [Verifying the MPLS LSP Status on page 947](#)
- [Verifying the Lsdist.0 Routing Table Entries on page 948](#)
- [Verifying the Traffic Engineering Database Entries on page 951](#)

---

### Verifying the BGP Summary Status

**Purpose** Verify that BGP is up and running on Routers R0 and R1.

**Action** From operational mode, run the **show bgp summary** command.

```
user@R0> show bgp summary
```

```
Groups: 1 Peers: 1 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
lsdist.0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
10.255.105.141 65533 20 14 0 79 5:18
Establ
lsdist.0: 10/10/10/0
```

From operational mode, run the **show bgp summary** command.

```
user@R1> show bgp summary
```

```
Groups: 2 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
lsdist.0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
8.42.1.104 65534 24 17 0 70 6:43
Establ
lsdist.0: 10/10/10/0
10.255.105.137 65533 15 23 0 79 6:19
Establ
lsdist.0: 0/0/0/0
```

**Meaning** Router R0 is peered with Router R1.

### Verifying the MPLS LSP Status

**Purpose** Verify the status of the MPLS LSP on Router R0.

**Action** From operational mode, run the **show mpls lsp** command.

```
user@R0> show mpls lsp

Ingress LSP: 1 sessions
To          From          State Rt P    ActivePath    LSPname
10.255.105.135 10.255.105.137 Up    0 *          to-R3-inter-as
Total 1 displayed, Up 1, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** The MPLS LSP from Router R0 to Router R3 is established.

---

### Verifying the lsdist.0 Routing Table Entries

**Purpose** Verify the lsdist.0 routing table entries on Routers R0, R1, and R2.

**Action** From operational mode, run the **show route table lsdist.0** command.

```

user@R0> show route table lsdist.0

lsdist.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

## Configuring Link State Distribution Using BGP

You can enable distribution of topology information across multiple areas and autonomous systems (ASs) by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - IS-IS
  - OSPF

To enable link-state distribution using BGP:

1. Configure an internal BGP group, and assign the local address and neighbor address for the group.

```
[edit protocols]
user@R1# set bgp group internal-group-name type internal
user@R1# set bgp group internal-group-name local-address ip-address
user@R1# set bgp group internal-group-name neighbor ip-address
```

2. Include the BGP-TE signaling network layer reachability information (NLRI) to the internal BGP group.

```
[edit protocols]
user@R1# set bgp group internal-group-name family traffic-engineering unicast
```

3. Enable export of policy on the device.

```
[edit protocols]
user@R1# set bgp group internal-group-name export second-policy-name
```

4. Configure an external BGP group, and assign the local address and neighbor autonomous system to the group.

[edit protocols]

```
user@R1# set bgp group external-group-name type external
user@R1# set bgp group external-group-name neighbor ip-address local-address
ip-address
user@R1# set bgp group external-group-name neighbor ip-address peer-as as-number
```

5. Include the BGP-TE signaling NLRI to the external BGP group.

[edit protocols]

```
user@R1# set bgp group external-group-name family traffic-engineering unicast
```

6. In configuration mode, go to the following hierarchy level:

[edit]

```
user@R1# edit policy-options
```

7. Configure policies to accept traffic from the BGP-TE NLRI.

[edit policy-options]

```
user@R1# set policy-statement policy-name from family traffic-engineering
user@R1# set policy-statement policy-name then accept
user@R1# set policy-statement bgp-import-policy term 1 from family traffic-engineering
user@R1# set policy-statement bgp-import-policy term 1 then next-hop self
user@R1# set policy-statement bgp-import-policy term 1 then accept
```

8. On the remote connecting device, configure policy to accept the OSPF and IS-IS traffic.

[edit policy-options]

```
user@R2# set policy-statement bgp-export-policy term 1 from protocol isis
user@R2# set policy-statement bgp-export-policy term 1 from protocol ospf
user@R2# set policy-statement bgp-export-policy term 1 then accept
user@R2# set policy-statement bgp-export-policy term 2 then reject
```

9. Verify and commit the configuration.

For example:

[edit protocols]

```
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp family traffic-engineering unicast
user@R1# set bgp group ibgp export nlri2bgp
user@R1# set bgp group ibgp neighbor 10.255.105.137
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp family traffic-engineering unicast
```

```

user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-id 8.42.1.104
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-router-id 10.255.105.139

```

[edit policy-options]

```

user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then next-hop self
user@R1# set policy-statement nlri2bgp term 1 then accept

```

[edit]

```

user@R1# commit
commit complete

```

[edit policy-options]

```

user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then next-hop self
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject

```

[edit]

```

user@R2# commit
commit complete

```

## Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages

An essential element of RSVP-based traffic engineering is the traffic engineering database. The traffic engineering database contains a complete list of all network nodes and links participating in traffic engineering, and a set of attributes each of those links can hold. (For more information about the traffic engineering database, see “[Constrained-Path LSP Computation](#)” on page 386.) One of the most important link attributes is bandwidth.

Bandwidth availability on links changes quickly as RSVP LSPs are established and terminated. It is likely that the traffic engineering database will develop inconsistencies relative to the real network. These inconsistencies cannot be fixed by increasing the rate of IGP updates.

Link availability can share the same inconsistency problem. A link that becomes unavailable can break all existing RSVP LSPs. However, its unavailability might not readily be known by the network.

When you configure the **rsvp-error-hold-time** statement, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

You can control the frequency of IGP updates by using the **update-threshold** statement. See [“Configuring the RSVP Update Threshold on an Interface” on page 655](#).

This section discusses the following topics:

- [PathErr Messages on page 956](#)
- [Identifying the Problem Link on page 957](#)
- [Configuring the Router to Improve Traffic Engineering Database Accuracy on page 957](#)

## PathErr Messages

PathErr messages report a wide variety of problems by means of different code and subcode numbers. You can find a complete list of these PathErr messages in RFC 2205, *Resource Reservation Protocol (RSVP), Version 1, Functional Specification* and RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*.

When you configure the **rsvp-error-hold-time** statement, two categories of PathErr messages, which specifically represent link failures, are examined:

- Link bandwidth is low for this LSP: Requested bandwidth unavailable—code 1, subcode 2

This type of PathErr message represents a global problem that affects all LSPs transiting the link. They indicate that the actual link bandwidth is lower than that required by the LSP, and that it is likely that the bandwidth information in the traffic engineering database is an overestimate.

When this type of error is received, the available link bandwidth is reduced in the local traffic engineering database, affecting all future LSP computations.

- Link unavailable for this LSP:
  - Admission Control failure—code 1, any subcode except 2
  - Policy Control failures—code 2

- Service Preempted—code 12
- Routing problem—no route available toward destination—code 24, subcode 5

These types of PathErr messages are generally pertinent to the specified LSP. The failure of this LSP does not necessarily imply that other LSPs could also fail. These errors can indicate maximum transfer unit (MTU) problems, service preemption (either manually initiated by the operator or by another LSP with a higher priority), that a next-hop link is down, that a next-hop neighbor is down, or service rejection because of policy considerations. It is best to route this particular LSP away from the link.

## Identifying the Problem Link

Each PathErr message includes the sender's IP address. This information is propagated unchanged toward the ingress router. A lookup in the traffic engineering database can identify the node that originated the PathErr message.

Each PathErr message carries enough information to identify the RSVP session that triggered the message. If this is a transit router, it simply forwards the message. If this router is the ingress router (for this RSVP session), it has the complete list of all nodes and links the session should traverse. Coupled with the originating node information, the link can be uniquely identified.

## Configuring the Router to Improve Traffic Engineering Database Accuracy

To improve the accuracy of the traffic engineering database, configure the **rsvp-error-hold-time** statement. When this statement is configured, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages also are used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

To configure how long MPLS should remember RSVP PathErr messages and consider them in CSPF computation, include the **rsvp-error-hold-time** statement:

```
rsvp-error-hold-time seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

The time can be a value from 1 to 240 seconds. The default is 25 seconds. Configuring a value of 0 disables the monitoring of PathErr messages.

## DiffServ-Aware Traffic Engineering Introduction

---

Differentiated Services (DiffServ)-aware traffic engineering provides a way to guarantee a specified level of service over an MPLS network. The routers providing DiffServ-aware traffic engineering are part of a differentiated services network domain. All routers participating in a differentiated services domain must have DiffServ-aware traffic engineering enabled.

To help ensure that the specified service level is provided, it is necessary to ensure that no more than the amount of traffic specified is sent over the differentiated services domain. You can accomplish this goal by configuring a policer to police or rate-limit the volume of traffic transiting the differentiated service domain. For more information about how to configure policers for label-switched paths (LSPs), see “[Configuring Policers for LSPs](#)” on page 98.

This feature can help to improve the quality of Internet services such as voice over IP (VoIP). It also makes it possible to better emulate an Asynchronous Transfer Mode (ATM) circuit over an MPLS network.

## DiffServ-Aware Traffic Engineering Standards

---

The following RFCs provide information on DiffServ-aware traffic engineering and multiclass LSPs:

- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diff-Serv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diff-Serv-aware MPLS*

These RFCs are available on the IETF website at <http://www.ietf.org/>.

## DiffServ-Aware Traffic Engineering Terminology

---

### B

**Bandwidth model** The bandwidth model determines the values of the available bandwidth advertised by the interior gateway protocols (IGPs).

### C

**CAC** Call admission control (CAC) checks to ensure there is adequate bandwidth on the path before the LSP is established. If the bandwidth is insufficient, the LSP is not established and an error is reported.

<b>Class type</b>	A collection of traffic flows that is treated equivalently in a differentiated services domain. A class type maps to a queue and is much like a class-of-service (CoS) forwarding class in concept. It is also known as a traffic class.
<b>D</b>	
<b>Differentiated Services</b>	Differentiated Services make it possible to give different treatment to traffic based on the EXP bits in the MPLS header. Traffic must be marked appropriately and CoS must be configured.
<b>Differentiated Services domain</b>	The routers in a network that have Differentiated Services enabled.
<b>DiffServ-aware traffic engineering</b>	A type of constraint-based routing. It can enforce different bandwidth constraints for different classes of traffic. It can also do CAC on each traffic engineering class when an LSP is established.
<b>M</b>	
<b>MAM</b>	The maximum allocation bandwidth constraint model divides the available bandwidth between the different classes. Sharing of bandwidth between the class types is not allowed.
<b>Multiclass LSP</b>	A multiclass LSP functions like a standard LSP, but it also allows you to reserve bandwidth from multiple class types. The EXP bits of the MPLS header are used to distinguish between class types.
<b>R</b>	
<b>RDM</b>	The Russian dolls bandwidth constraint model makes efficient use of bandwidth by allowing the class types to share bandwidth.
<b>T</b>	
<b>Traffic engineering class</b>	A paired class type and priority.
<b>Traffic engineering class map</b>	A map between the class types, priorities, and traffic engineering classes. The traffic engineering class mapping must be consistent across the Differentiated Services domain.

---

## DiffServ-Aware Traffic Engineering Features

DiffServ-aware traffic engineering provides the following features:

- Traffic engineering at a per-class level rather than at an aggregate level
- Different bandwidth constraints for different class types (traffic classes)
- Different queuing behaviors per class, allowing the router to forward traffic based on the class type

In comparison, standard traffic engineering does not consider CoS, and it completes its work on an aggregate basis across all Differentiated Service classes.

DiffServ-aware traffic engineering provides the following advantages:

- Traffic engineering can be performed on a specific class type instead of at the aggregate level.
- Bandwidth constraints can be enforced on each specific class type.
- It forwards traffic based on the EXP bits.

This makes it possible to guarantee service and bandwidth across an MPLS network. With DiffServ-aware traffic engineering, among other services, you can provide ATM circuit emulation, VoIP, and a guaranteed bandwidth service.

The following describes how the IGP, Constrained Shortest Path First (CSPF), and RSVP participate in DiffServ-aware traffic engineering:

- The IGP can advertise the unreserved bandwidth for each traffic engineering class to the other members of the differentiated services domain. The traffic engineering database stores this information.
- A CSPF calculation is performed considering the bandwidth constraints for each class type. If all the constraints are met, the CSPF calculation is considered successful.
- When RSVP signals an LSP, it requests bandwidth for specified class types.

---

## DiffServ-Aware Traffic Engineered LSPs

A DiffServ-aware traffic engineered LSP is an LSP configured to reserve bandwidth for one of the supported class types and to carry traffic for that class type. The following sections discuss this type of LSPs:

- [DiffServ-Aware Traffic Engineered LSPs Overview on page 962](#)
- [DiffServ-Aware Traffic Engineered LSPs Operation on page 963](#)

---

## DiffServ-Aware Traffic Engineered LSPs Overview

A DiffServ-aware traffic engineered LSP is an LSP configured with a bandwidth reservation for a specific class type. This LSP can carry traffic for a single class type. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

The class type must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

For more information about topics related to LSPs and DiffServ-aware traffic engineering, see the following:

- For forwarding classes and class of service, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.
- For EXP bits, see [“MPLS Label Allocation” on page 329](#).
- For differentiated services, see RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*.
- For information about how the IGPs and RSVP have been modified to support Differentiated Services-aware MPLS traffic engineering, see RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*.

---

## DiffServ-Aware Traffic Engineered LSPs Operation

---

When configuring a DiffServ-aware traffic engineered LSP, you specify the class type and the bandwidth associated with it. The following occurs when an LSP is established with bandwidth reservation from a specific class type:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for an LSP, CSPF is used to ensure that the bandwidth constraints are met for the class type carried by the LSP at the specified priority level.  
  
CSPF also checks to ensure that the bandwidth model is configured consistently on each router participating in the LSP. If the bandwidth model is inconsistent, CSPF does not compute the path (except for LSPs from class type ct0).
3. Once a path is found, RSVP signals the LSP using the Classtype object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up.

An LSP that requires bandwidth from a particular class (except class type ct0) cannot be established through routers that do not understand the Classtype object. Preventing the use of routers that do not understand the Classtype object helps to ensure consistency throughout the Differentiated Services domain by preventing the LSP from using a router that cannot support Differentiated Services.

By default, LSPs are signaled with setup priority 7 and holding priority 0. An LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both LSPs configured for DiffServ-aware traffic engineering and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings (either by remarking the EXP settings or by assuming that the traffic arrived with the correct EXP settings from the upstream router).

---

## Multiclass LSP Overview

---

A multiclass LSP is an LSP that can carry several class types. One multiclass LSP can be used to support up to four class types. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB)

associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

Once a multiclass LSP is configured, traffic from all of the class types can:

- Follow the same path
- Be rerouted along the same path
- Be taken down at the same time

Class types must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network.

You can unambiguously map a class type to a queue. On each node router, the CoS queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

The combination of a class type and a priority level forms a traffic engineering class. The IGP can advertise up to eight traffic engineering classes for each link.

For more information about the EXP bits, see [“MPLS Label Allocation” on page 329](#).

For more information about forwarding classes, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

---

## Multiclass LSPs

Multiclass LSPs function like standard LSPs, but they also allow you to configure multiple class types with guaranteed bandwidth. The EXP bits of the MPLS header are used to distinguish between class types. Multiclass LSPs can be configured for a variety of purposes. For example, you can configure a multiclass LSP to emulate the behavior of an ATM circuit. An ATM circuit can provide service-level guarantees to a class type. A multiclass LSP can provide a similar guaranteed level of service.

The following sections discuss multiclass LSPs:

- [Multiclass LSP Overview on page 963](#)
- [Establishing a Multiclass LSP on the Differentiated Services Domain on page 964](#)

---

## Establishing a Multiclass LSP on the Differentiated Services Domain

The following occurs when a multiclass LSP is established on the differentiated services domain:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for a multiclass LSP, CSPF is used to ensure that the constraints are met for all the class types carried by the multiclass LSP (a set of constraints instead of a single constraint).

3. Once a path is found, RSVP signals the LSP using an RSVP object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up. The RSVP object is a hop-by-hop object. Multiclass LSPs cannot be established through routers that do not understand this object. Preventing routers that do not understand the RSVP object from carrying traffic helps to ensure consistency throughout the differentiated services domain by preventing the multiclass LSP from using a router that is incapable of supporting differentiated services.

By default, multiclass LSPs are signaled with setup priority 7 and holding priority 0. A multiclass LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both multiclass LSPs and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings.

## Configuring Routers for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, include the **diffserv-te** statement:

```
diffserv-te {
  bandwidth-model {
    extended-mam;
    mam;
    rdm;
  }
  te-class-matrix {
    traffic-class {
      tnumber {
        priority priority;
        traffic-class cnumber priority priority;
      }
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You must include the **diffserv-te** statement in the configuration on all routers participating in the Differentiated Services domain. However, you are not required to configure the traffic engineering class matrix (by including the **te-class-matrix** statement at the **[edit protocols mpls diffserv-te]** or **[edit logical-systems *logical-system-name* protocols mpls diffserv-te]** hierarchy level).

**NOTE:** To prevent the possibility of an incorrect configuration when migrating to Diffserv-aware traffic engineering, a policy control failure error might be triggered if there is conflict between the old LSPs and the newly configured TE-class matrix.

An old node might request an LSP with setup and hold priorities in such a way that the combination of the ct0 class and the priority does not match with the configured TE-class matrix. All LSPs on the router that are configured prior to configuring diffserv-aware traffic engineering are designated as being from class ct0.

The error appears in the RSVP tracing logs as a Session preempted error. For the router where the error originates, the error could appear as follows:

```
Jun 17 16:35:59 RSVP error for session 10.255.245.6(port/tunnel ID 31133)
  Proto 0: (class ct0, priority 2) is not a valid TE-class Jun 17
16:35:59 RSVP originate PathErr 192.168.37.22->192.168.37.23 Session
preempted
```

For the router receiving the error, the error can appear as follows:

```
Jun 17 16:37:51 RSVP recv PathErr 192.168.37.22->192.168.37.23 Session
preempted LSP to-f(2/31133)
```

To configure DiffServ-aware traffic engineering, complete the procedures in the following sections:

- [Configuring the Bandwidth Model on page 966](#)
- [Configuring Traffic Engineering Classes on page 967](#)
- [Configuring Class of Service for DiffServ-Aware Traffic Engineering on page 969](#)

## Configuring the Bandwidth Model

You must configure a bandwidth model on all routers participating in the Differentiated Services domain. The bandwidth models available are MAM, extended MAM, and RDM:

- Maximum allocation bandwidth constraints model (MAM)—Defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.
- Extended MAM—A proprietary bandwidth model that behaves much like standard MAM. If you configure multiclass LSPs, you must configure the extended MAM bandwidth model.
- Russian-dolls bandwidth allocation model (RDM)—Makes efficient use of bandwidth by allowing the class types to share bandwidth. RDM is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

To configure a bandwidth model, include the **bandwidth-model** statement and specify one of the bandwidth model options:

```
bandwidth-model {
  extended-mam;
  mam;
  rdm;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **diffserv-te**]
- [edit logical-systems *logical-system-name* protocols mpls **diffserv-te**]

**NOTE:** If you change the bandwidth model on an ingress router, all the LSPs enabled on the router are taken down and resigaled.

## Configuring Traffic Engineering Classes

Configuring traffic engineering classes is optional. [Table 27 on page 967](#) shows the default values for everything in the traffic engineering class matrix. The default mapping is expressed in terms of the default forwarding classes defined in the CoS configuration.

*Table 27: Default Values for the Traffic Engineering Class Matrix*

Traffic Engineering Class	Class Type	Queue	Priority
te0	ct0	0	7
te1	ct1	1	7
te2	ct2	2	7
te3	ct3	3	7
te4	ct0	0	0
te5	ct1	1	0
te6	ct2	2	0
te7	ct3	3	0

If you want to override the default mappings, you can configure traffic engineering classes 0 through 7. For each traffic engineering class, you configure a class type (or queue) from 0 through 3. For each class type, you configure a priority from 0 through 7.

To configure traffic engineering classes explicitly, include the **te-class-matrix** statement:

```
te-class-matrix {
  tnumber {
    priority priority;
    traffic-class {
      ctnumber priority priority;
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [diffserv-te](#)]
- [edit logical-systems *logical-system-name* protocols mpls [diffserv-te](#)]

The following example shows how to configure traffic engineering class **te0** with class type **ct1** and a priority of 4:

```
[edit protocols mpls diffserv-te]
te-class-matrix {
  te0 traffic-class ct1 priority 4;
}
```

**NOTE:** If you explicitly configure a value for one of the traffic engineering classes, all the default values in the traffic engineering class matrix are dropped.

When you explicitly configure traffic engineering classes, you must also configure a bandwidth model; otherwise, the configuration commit operation fails.

### Requirements and Limitations for the Traffic Engineering Class Matrix

When you configure a traffic engineering class matrix, be aware of the following requirements and limitations:

- A mapping configuration is local and affects only the router on which it is configured. It does not affect other systems participating in the differentiated services domain. However, for a Differentiated Services domain to function properly, you need to configure the same traffic engineering class matrix on all the routers participating in the same domain.
- When explicitly configuring traffic engineering classes, you must configure the classes in sequence (**te0**, **te1**, **te2**, **te3**, and so on); otherwise, the configuration commit operation fails.

The first traffic engineering class you configure must be **te0**; otherwise, the configuration commit operation fails.

## Configuring Class of Service for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, you must also configure class of service. The following example illustrates a class-of-service configuration that would allocate 25 percent of the link bandwidth to each class:

```
class-of-service {
  interfaces {
    all {
      scheduler-map simple-map;
    }
  }
  scheduler-maps {
    simple-map {
      forwarding-class assured-forwarding scheduler simple_sched;
      forwarding-class best-effort scheduler simple_sched;
      forwarding-class network-control scheduler simple_sched;
      forwarding-class expedited-forwarding scheduler simple_sched;
    }
  }
  schedulers {
    simple_sched {
      transmit-rate percent 25;
      buffer-size percent 25;
    }
  }
}
```

For more information on how to configure class of service, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

## LSP Bandwidth Oversubscription Overview

LSPs are established with bandwidth reservations configured for the maximum amount of traffic you expect to traverse the LSP. Not all LSPs carry the maximum amount of traffic over their links at all times. For example, even if the bandwidth for link A has been completely reserved, actual bandwidth might still be available but not currently in use. This excess bandwidth can be used by allowing other LSPs to also use link A, oversubscribing the link. You can oversubscribe the bandwidth configured for individual class types or specify a single value for all of the class types using an interface.

You can use oversubscription to take advantage of the statistical nature of traffic patterns and to permit higher utilization of links.

The following examples describe how you might use bandwidth oversubscription and undersubscription:

- Use oversubscription on class types where peak periods of traffic do not coincide in time.

- Use oversubscription of class types carrying best-effort traffic. You take the risk of temporarily delaying or dropping traffic in exchange for making better utilization of network resources.
- Give different degrees of oversubscription or undersubscription of traffic for the different class types. For instance, you configure the subscription for classes of traffic as follows:
  - Best effort—**ct0 1000**
  - Voice—**ct3 1**

When you undersubscribe a class type for a multiclass LSP, the total demand of all RSVP sessions is always less than the actual capacity of the class type. You can use undersubscription to limit the utilization of a class type.

The bandwidth oversubscription calculation occurs on the local router only. Because no signaling or other interaction is required from other routers in the network, the feature can be enabled on individual routers without being enabled or available on other routers which might not support this feature. Neighboring routers do not need to know about the oversubscription calculation, they rely on the IGP.

The following sections describe the types of bandwidth oversubscription available in the Junos OS:

- [LSP Size Oversubscription on page 970](#)
- [LSP Link Size Oversubscription on page 970](#)
- [Class Type Oversubscription and Local Oversubscription Multipliers on page 971](#)

---

## LSP Size Oversubscription

For LSP size oversubscription, you simply configure less bandwidth than the peak rate expected for the LSP. You also might need to adjust the configuration for automatic policers. Automatic policers manage the traffic assigned to an LSP, ensuring that it does not exceed the configured bandwidth values. LSP size oversubscription requires that the LSP can exceed its configured bandwidth allocation.

Policing is still possible. However, the policer must be manually configured to account for the maximum bandwidth planned for the LSP, rather than for the configured value.

---

## LSP Link Size Oversubscription

You can increase the maximum reservable bandwidth on the link and use the inflated values for bandwidth accounting. Use the **subscription** statement to oversubscribe the link. The configured value is applied to all class type bandwidth allocations on the link. For more information about link size oversubscription, see [“Configuring the Bandwidth Subscription Percentage for LSPs” on page 974](#).

## Class Type Oversubscription and Local Oversubscription Multipliers

Local oversubscription multipliers (LOMs) allow different oversubscription values for different class types. LOMs are useful for networks where the oversubscription ratio needs to be configured differently on different links and where oversubscription values are required for different classes. You might use this feature to oversubscribe class types handling best-effort traffic, but use no oversubscription for class types handling voice traffic. An LOM is calculated locally on the router. No information related to an LOM is signaled to other routers in the network.

An LOM is configurable on each link and for each class type. The per-class type LOM allows you to increase or decrease the oversubscription ratio. The per-class-type LOM is factored into all local bandwidth accounting for admission control and IGP advertisement of unreserved bandwidths.

The LOM calculation is tied to the bandwidth model (MAM, extended MAM, and Russian dolls) used, because the effect of oversubscription across class types must be accounted for accurately.

**NOTE:** All LOM calculations are performed by the Junos OS and require no user intervention.

The formulas related to the oversubscription of class types are described in the following sections:

- [Class Type Bandwidth and the LOM on page 971](#)
- [LOM Calculation for the MAM and Extended MAM Bandwidth Models on page 972](#)
- [LOM Calculation for the Russian Dolls Bandwidth Model on page 972](#)
- [Example: LOM Calculation on page 973](#)

## Class Type Bandwidth and the LOM

The following formula expresses the relationship between the bandwidth of the class type and the LOM. The normalized bandwidth of the class type ( $N_B$ ) is equal to the reserved bandwidth of the class type ( $R_B$ ) divided by the LOM of the class type ( $L_C$ ):

$$N_B = R_B / L_C$$

When calculating available bandwidth, you need to subtract the normalized bandwidth from the relevant bandwidth constraint.

**NOTE:** When using an LOM, values advertised for the available bandwidth might be larger than the bandwidth constraint values. However, the values advertised in the maximum link bandwidth advertisement are not affected by local oversubscription.

## LOM Calculation for the MAM and Extended MAM Bandwidth Models

The following formulas show how the LOM is calculated for the MAM and extended MAM bandwidth models.

$$\text{Unreserved TE-Class}(i) = \text{LOM}_c \times [ \text{BC}_c - \text{SUM} ( \text{Normalized} ( \text{CT}_c, q ) ) ] \text{ for } q \leq p$$

Or

$$\text{Unreserved TE-Class}(i) = ( \text{LOM}_c \times \text{BC}_c ) - \text{SUM} ( \text{Reserved} ( \text{CT}_c, q ) ) \text{ for } q \leq p$$

where:

- $\text{LOM}_c$ —LOM for class type  $c$ .
- $\text{BC}_c$ —Bandwidth constraint for class type  $c$ .
- $\text{CT}_c$ —Class type  $c$ .
- $\text{TE-Class}(i) \leftrightarrow ( \text{CT}_c, \text{preemption } p )$  in the configured TE-Class mapping.

## LOM Calculation for the Russian Dolls Bandwidth Model

The following formulas show how the LOM is calculated for the Russian dolls bandwidth model:

$$\begin{aligned} \text{Unreserved TE-Class} (i) = & \text{LOM}_c \times \text{MIN} [ \\ & [ \text{BC}_c - \text{SUM} ( \text{Normalized} ( \text{CT}_b, q ) ) ] \text{ for } q \leq p \text{ and } c \leq b \leq 7, \\ & \vdots \\ & [ \text{BC}_0 - \text{SUM} ( \text{Normalized} ( \text{CT}_b, q ) ) ] \text{ for } q \leq p \text{ and } 0 \leq b \leq 7, \\ & ] \end{aligned}$$

where:

- $\text{LOM}_c$ —LOM for class type  $c$ .
- $\text{BC}_c$ —Bandwidth constraint for class type  $c$ .
- $\text{TE-Class}(i) \leftrightarrow ( \text{CT}_c, \text{preemption } p )$  in the configured TE-Class mapping.

Note that the impact of an LSP on the unreserved bandwidth of a class type does not depend only on the LOM for that class type—it also depends on the LOM for the class type of the LSP.

## Example: LOM Calculation

The following example illustrates how an LOM calculation is made for four classes of traffic: **ct0**, **ct1**, **ct2**, and **ct3**.

The class types have been assigned the following values:

```
ct0 = 40
ct1 = 30
ct2 = 20
ct3 = 10
```

These class type values yield the following bandwidth constraints:

```
BC0 = (ct3 + ct2 + ct1 + ct0) = 100
BC1 = (ct3 + ct2 + ct1) = 60
BC2 = (ct3 + ct2) = 30
BC3 = (ct3) = 10
```

LSPs from class type **ct0** can take up to 100 percent of bandwidth on the link. LSPs from class type **ct1** can take up to 60 percent of the bandwidth on the link, and so on.

If you assume for this example that the class types have the following LOM values:

```
LOM(ct0) = 8
LOM(ct1) = 4
LOM(ct2) = 2
LOM(ct3) = 1
```

In the absence of any other reservation, LSPs from class type **ct0** can take up to 800 percent of the available bandwidth ( $8 \times 100 = 800$ ). In the absence of any other reservation, LSPs from class type **ct1** can take up to 240 percent of the available bandwidth ( $4 \times 60 = 240$ ), and so on.

The maximum amount of bandwidth that can be reserved is:

```
ct0 = LOM(ct0) x BC0 = 800
ct1 = LOM(ct1) x BC1 = 240
ct2 = LOM(ct2) x BC2 = 60
ct3 = LOM(ct3) x BC3 = 10
```

For the undersubscribed class type **ct3**, the maximum reservable bandwidth is the same as the bandwidth constraint. For the overbooked class types, these values are not the values of the bandwidth constraint-taking into account the oversubscription for each class type separately. The oversubscription per class type in the sum is not taken into account because ultimately the entire bandwidth constraint can be filled with the bandwidth reservation of just one class type, so you have to account for that class type's bandwidth oversubscription only.

When calculating the available bandwidth for **CTc**, you need to express reservations from other classes as if they were from **CTc**. The reservation from class **ctx** is normalized with the LOM of **ctx**, but it is then multiplied by the LOM of **CTc**.

For the previous example, assume that **LSP1** has class type **ct3** configured with bandwidth of **10** and a priority of **0**.

The values for the reservable bandwidth will be:

```
ct0 = 8 x (100 - 10) = 720
ct1 = 4 x min((100-10), (60-10)) = 200
ct2 = 2 x min((100-10), (60-10), (30-10)) = 40
ct3 = 1 x min((100-10), (60-10), (30-10), (10-10)) = 0
```

These numbers can be rationalized as follows: the normalized reservation is 10 percent. If this bandwidth came from class type **ct0**, it would be equivalent to an overbooked reservation of 80 percent. You can see that 720 percent ( $800 - 80 = 720$ ) of the bandwidth remains available for other LSPs.

## Configuring the Bandwidth Subscription Percentage for LSPs

By default, RSVP allows all of a class type's bandwidth (100 percent) to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

If you want to oversubscribe or undersubscribe all of the class types on an interface using the same percentage bandwidth, configure the percentage using the **subscription** statement:

```
subscription percentage;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

To undersubscribe or oversubscribe the bandwidth for each class type, configure a percentage for each class type (**ct0**, **ct1**, **ct2**, and **ct3**) option for the **subscription** statement. When you oversubscribe a class type, an LOM is applied to calculate the actual bandwidth reserved. See [“Class Type Oversubscription and Local Oversubscription Multipliers” on page 971](#) for more information.

```
subscription {
  ct0 percentage;
  ct1 percentage;
  ct2 percentage;
  ct3 percentage;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

**percentage** is the percentage of class type bandwidth that RSVP allows to be used for reservations. It can be a value from 0 through 65,000 percent. If you specify a value greater than 100, you are oversubscribing the interface or class type.

The value you configure when you oversubscribe a class type is a percentage of the class type bandwidth that can actually be used. The default subscription value is 100 percent.

You can use the **subscription** statement to disable new RSVP sessions for one or more class types. If you configure a percentage of 0, no new sessions (including those with zero bandwidth requirements) are permitted for the class type.

Existing RSVP sessions are not affected by changing the subscription factor. To clear an existing session, issue the **clear rsvp session** command. For more information on the **clear rsvp session** command, see the [CLI Explorer](#).

## Constraints on Configuring Bandwidth Subscription

Be aware of the following issues when configuring bandwidth subscription:

- If you configure bandwidth constraints at the **[edit class-of-service interface interface-name]** hierarchy level, they override any bandwidth configuration you specify at the **[edit protocols rsvp interface interface-name bandwidth]** hierarchy level for Diffserv-TE. Also note that either of the CoS or RSVP bandwidth constraints can override the interface hardware bandwidth constraints.
- If you configure a bandwidth subscription value for a specific interface that differs from the value configured for all interfaces (by including different values for the **subscription** statement at the **[edit protocols rsvp interface interface-name]** and **[edit protocols rsvp interface all]** hierarchy levels), the interface-specific value is used for that interface.
- You can configure subscription for each class type only if you also configure a bandwidth model. If no bandwidth model is configured, the commit operation fails with the following error message:

```
user@host# commit check
[edit protocols rsvp interface all]
'subscription'
RSVP: Must have a diffserv-te bandwidth model configured when configuring
subscription per traffic class.
error: configuration check-out failed
```

- You cannot include the **subscription** statement both in the configuration for a specific class type and the configuration for the entire interface. The commit operation fails with the following error message:

```
user@host# commit check
[edit protocols rsvp interface all]
'subscription'
RSVP: Cannot configure both link subscription and per traffic class
subscription.
error: configuration check-out failed
```

## Configuring LSPs for DiffServ-Aware Traffic Engineering

---

You must configure the Differentiated Services domain (see [“Configuring Routers for DiffServ-Aware Traffic Engineering” on page 965](#)) before you can enable DiffServ-aware traffic engineering for LSPs. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in the LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the LSP to function properly.

**NOTE:** You must configure either MAM or RDM as the bandwidth model when you configure DiffServ-aware traffic engineering for LSPs. See [“Configuring the Bandwidth Model” on page 966](#).

The actual data transmitted over this Differentiated Services domain is carried by an LSP. Each LSP relies on the EXP bits of the MPLS packets to enable DiffServ-aware traffic engineering. Each LSP can carry traffic for a single class type.

All the routers participating in the LSP must be Juniper Networks routers running Junos OS Release 6.3 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the DiffServ-aware traffic engineering LSP cannot traverse these routers.

**NOTE:** You cannot simultaneously configure multiclass LSPs and DiffServ-aware traffic engineering LSPs on the same router.

To enable DiffServ-aware traffic engineering for LSPs, you need to configure the following:

- [Configuring Class of Service for the Interfaces on page 976](#)
- [Configuring IGP on page 977](#)
- [Configuring Traffic-Engineered LSPs on page 977](#)
- [Configuring Policing for LSPs on page 978](#)
- [Configuring Fast Reroute for Traffic-Engineered LSPs on page 978](#)

## Configuring Class of Service for the Interfaces

The existing class-of-service (CoS) infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to accomplish this are configured using the existing Junos OS CoS features.

**NOTE:** The Junos OS does not support CoS on ATM interfaces.

For information about how to configure CoS, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

## Configuring IGP

You can configure either IS-IS or OSPF as the IGP. The IS-IS and OSPF configurations for routers supporting LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

## Configuring Traffic-Engineered LSPs

You configure an LSP by using the standard LSP configuration statements and procedures. To configure DiffServ-aware traffic engineering for the LSP, specify a class type bandwidth constraint by including the **bandwidth** statement:

```
label-switched-path lsp-name {
  bandwidth {
    ctnumber bps;
  }
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for this statement.

If you do not specify a bandwidth for a class type, **ct0** is automatically specified as the queue for the LSP. You can configure only one class type for each LSP, unlike multiclass LSPs.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

You can configure setup and holding priorities for an LSP, but the following restrictions apply:

- The combination of class and priority must be one of the configured traffic engineering classes. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.
- For migration issues, see Internet draft draft-ietf-tewg-diff-te-proto-07.txt.

## Configuring Policing for LSPs

Policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each LSP.

For information about how to configure a policer for an LSP, see [“Configuring Policers for LSPs” on page 98](#).

## Configuring Fast Reroute for Traffic-Engineered LSPs

You can configure fast reroute for traffic engineered LSPs (LSPs carrying a single class of traffic). It is also possible to reserve bandwidth on the detour path for the class of traffic when fast reroute is enabled. The same class type number is used for both the traffic engineered LSP and its detour.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

You can configure the amount of bandwidth to reserve for detours using either the **bandwidth** statement or the **bandwidth-percent** statement. You can only configure one of these statements at a time. If you do not configure either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path (the bandwidth guarantee will be lost if traffic is switched to the detour).

When you configure the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. For information, see [“Configuring Fast Reroute” on page 381](#).

The **bandwidth-percent** statement allows you to specify the bandwidth of the detour path as a percentage of the bandwidth configured for the protected path. For example, if you configure 100 millions bps of bandwidth for the protected path and configure 20 for the **bandwidth-percent** statement, the detour path will have 20 million bps of bandwidth reserved for its use.

To configure the percent of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name* fast-reroute]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* fast-reroute]**

## Configuring Multiclass LSPs

A multiclass LSP is an LSP configured to reserve bandwidth for multiple class types and also carries the traffic for these class types. The differentiated service behavior is determined by the EXP bits.

You must configure the Differentiated Services domain (see [“Configuring Routers for DiffServ-Aware Traffic Engineering” on page 965](#)) before you can enable a multiclass LSP. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in a multiclass LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the multiclass LSP to function properly.

**NOTE:** You must configure extended MAM as the bandwidth model when you configure multiclass LSPs. See [“Configuring the Bandwidth Model” on page 966](#).

All the routers participating in a multiclass LSP must be Juniper Networks routers running Junos OS Release 6.2 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the multiclass LSP cannot traverse these routers.

To enable multiclass LSPs, you need to configure the following:

- [Configuring Class of Service for the Interfaces on page 979](#)
- [Configuring the IGP on page 980](#)
- [Configuring Class-Type Bandwidth Constraints for Multiclass LSPs on page 980](#)
- [Configuring Policing for Multiclass LSPs on page 981](#)
- [Configuring Fast Reroute for Multiclass LSPs on page 981](#)

## Configuring Class of Service for the Interfaces

The existing class-of-service infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to consistently mark traffic are configured with the existing Junos OS CoS features.

**NOTE:** The Junos OS does not support ATM interfaces.

For information about how to configure CoS, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

## Configuring the IGP

You can configure either IS-IS or OSPF. The IS-IS and OSPF configurations for routers supporting multiclass LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

## Configuring Class-Type Bandwidth Constraints for Multiclass LSPs

You configure a multiclass LSP by using the standard LSP configuration statements and procedures. To configure an LSP as a multiclass LSP, specify the class type bandwidth constraints by including the **bandwidth** statement:

```
bandwidth {  
  ct0 bps;  
  ct1 bps;  
  ct2 bps;  
  ct3 bps;  
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for these statements.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

For example, to configure 50 megabytes of bandwidth for class type 1 and 30 megabytes of bandwidth for class type 2, include the **bandwidth** statement as follows:

```
[edit protocols mpls]  
label-switched-path traffic-class {  
  bandwidth {  
    ct1 50M;  
    ct2 30M;  
  }  
}
```

You cannot configure a bandwidth for a class type and also configure a bandwidth at the **[edit protocols mpls label-switched-path *lsp-name* bandwidth]** hierarchy level. For example, the following configuration cannot be committed:

```
[edit protocols mpls]  
label-switched-path traffic-class {  
  bandwidth {  
    20M;  
    ct1 10M;  
  }  
}
```

```
}
```

You can configure setup and holding priorities for a multiclass LSP, but the following restrictions apply:

- The setup and holding priorities apply to all classes for which bandwidth is requested.
- The combination of class and priority must be one of the configured traffic engineering classes. The default traffic engineering class configuration results in multiclass LSPs that cannot preempt and cannot be preempted. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported for multiclass LSPs. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.

## Configuring Policing for Multiclass LSPs

Policing allows you to control the amount of traffic forwarded through a particular multiclass LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each multiclass LSP. You can also enable automatic policing for multiclass LSPs.

For information about how to configure a policer for a multiclass LSP, see [“Configuring Policers for LSPs” on page 98](#) and [“Configuring Automatic Policers” on page 100](#).

## Configuring Fast Reroute for Multiclass LSPs

You can enable fast reroute for multiclass LSPs. The bandwidth guarantees for the class types can be carried over to the detour path in case the primary path of the multiclass LSP fails. The same traffic class types configured for the primary multiclass LSP are also signaled for the detour LSP.

The bandwidth guarantee for the detour path is a percentage of the bandwidth configured for the class types of the primary path. For example, you configure a value of 50 percent for the detour path and the protected LSP carries traffic for class types CT0 through CT3. The detour path is signaled with the same class types (CT0 through CT3) but with 50 percent of the bandwidth configured for the protected LSP.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering, that all of the traffic class types needed are available, and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

The bandwidth percentage for fast reroute is signaled from the ingress router to the egress router. All of the intermediate devices must complete their own CSPF computations and signaling.

When you configure the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying by the bandwidth configured for the primary multiclass LSP. For information about how to configure the bandwidth for the multiclass LSP, see [“Configuring Traffic-Engineered LSPs” on page 977](#).

To configure the percentage of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]

## Configuring the MPLS Transport Profile for OAM

---

- [MPLS Transport Profile Overview on page 985](#)
- [Example: Configuring the MPLS Transport Profile for OAM on page 986](#)

### MPLS Transport Profile Overview

RFC 5654, *Requirements of an MPLS Transport Profile*, describes the requirements for the MPLS Transport Profile (MPLS-TP) that extends capabilities for Operation, Administration, and Maintenance (OAM) when MPLS is used for transport services and transport network operations. These capabilities help in troubleshooting and maintenance of a pseudowire or label-switched path (LSP).

MPLS-TP mechanisms for OAM contain two main components:

- Generic Associated Channel Label (GAL)—A special label that enables an exception mechanism that informs the egress label-switching router (LSR) that a packet it receives on an LSP belongs to an associated control channel or the control plane.
- Generic Associated Channel Header (G-Ach)—A special header field that identifies the type of payload contained in the MPLS label-switched paths (LSPs). G-Ach has the same format as a pseudowire associated control channel header.

For more information about MPLS-TP, see RFC 5654, *Requirements of an MPLS Transport Profile*. For specific information about GAL and G-Ach, see RFC 5586, *MPLS Generic Associated Channel*.

The following capabilities are supported in the Junos OS implementation of MPLS-TP:

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.

- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.

## Example: Configuring the MPLS Transport Profile for OAM

This example shows how to configure the MPLS Transport Profile (MPLS-TP) for sending and receiving of OAM GAL and G-Ach messages across a label-switched path (LSP).

- [Requirements on page 986](#)
- [Overview on page 986](#)
- [Configuration on page 989](#)
- [Verification on page 997](#)

---

### Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series, MX Series, and T Series routers
- Junos OS Release 12.1 or later running on the devices

---

### Overview

Junos OS Release 12.1 and later support MPLS Transport Profile (MPLS-TP) Operation, Administration, and Maintenance (OAM) capabilities. MPLS-TP introduces new capabilities for OAM when MPLS is used for transport services and transport network operations. This includes configuring Generic Associated Channel Label (GAL) and Generic Associated Channel Header (G-Ach) for OAM messages.

This example shows how to configure MPLS-TP OAM capability to send and receive GAL and G-Ach OAM messages without IP encapsulation. In addition, it also shows how to associate two unidirectional RSVP label-switched paths (LSPs) between a pair of routers to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages.

Junos OS Release 12.1 and later support the following MPLS-TP capabilities:

- MPLS-TP OAM capability and the infrastructure required for MPLS applications to send and receive packets with GAL and G-Ach, without IP encapsulation.
- LSP-ping and Bidirectional Forwarding Detection (BFD) applications to send and receive packets using GAL and G-Ach, without IP encapsulation on transport LSPs.
- The association of two unidirectional RSVP LSPs, between a pair of routers, with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. The associated bidirectional LSP model is supported only for associating the primary paths. A single BFD session is established for the associated bidirectional LSP.

Junos OS Release 12.1 and later does not support the following MPLS-TP capabilities:

- Point-to-multipoint RSVP LSPs and BGP LSPs
- Loss Measurement and Delay Measurement

You can enable GAL and G-Ach OAM operation using the following configuration statements:

- **mpls-tp-mode**—Include this statement at the **[edit protocols mpls oam]** hierarchy level to enable GAL and G-Ach OAM operation, without IP encapsulation, on all LSPs in the MPLS network.

```
[edit protocols mpls oam]
mpls-tp-mode;
```

Include this statement at the **[edit protocols mpls label-switched-path *lsp-name* oam]** hierarchy level to enable GAL and G-Ach OAM operation without IP encapsulation on a specific LSP in the network.

```
[edit protocols mpls label-switched-path lsp-name oam]
mpls-tp-mode;
```

**NOTE:** Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the **mpls-tp-mode** statement. These additional channel types provide on-demand connectivity verification (CV) with and without IP/UDP encapsulation.

- On-demand CV (0x0025)—This channel type is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.
- IPv4 (0x0021)—This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

The GACH-TLV is used along with the default LSPING channel type. As per RFC 7026, GACH-TLV is deprecated for 0x0021 and 0x0025 channel types.

To configure a channel type for MPLS-TP, include the **lsping-channel-type *channel-type*** statement at the **[edit protocols mpls label-switched-path *lsp-name* oam mpls-tp-mode]** and **[edit protocols mpls oam mpls-tp-mode]** hierarchy levels.

- **associate-lsp *lsp-name* from *from-ip-address***—Include this statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level to configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls label-switched-path lsp-name ]
associate-lsp lsp-name {
  from from-ip-address;
```

```
}
```

The **from** *from-ip-address* configuration for the LSP is optional. If omitted, it is derived from the **to** address of the ingress LSP configuration.

- **transit-lsp-association**—Include this statement at the **[edit protocols mpls]** hierarchy level to associate two LSPs at a transit router.

```
[edit protocols mpls]
transit-lsp-association transit-association-lsp-group-name {
  lsp-name-1 name-of-associated-lsp-1;
  from-1 address-of-associated-lsp-1;
  lsp-name-2 name-of-associated-lsp-2;
  from-2 address-of-associated-lsp-2;
}
```

The association of the LSPs in the transit nodes is useful for the return LSP path for TTL-expired LSP ping packets or traceroute.

In this example, R0 is the ingress router and R4 is the egress router. R1, R2, R3, and R5 are transit routers. The associated bidirectional LSP is established between the transit routers for sending and receiving the GAL and G-Ach OAM messages.

Figure 98 on page 988 shows the topology used in this example.

**Figure 98: MPLS-TP OAM Associated Bidirectional LSPs**

## Configuration

### CLI Quick Configuration

**NOTE:** This example shows the configuration on all devices and shows step-by-step procedures for configuring the ingress router, R0, and transit router R1. Repeat the step-by-step procedure described for the ingress router, R0, on the egress router, R4. Repeat the step-by-step procedure for the transit router, R1, on the other transit routers, R2, R3, and R5. Be sure to modify the appropriate interface names, addresses, and other parameters appropriately.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### Router R0

```
