#### YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

#### END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <https://support.juniper.net/support/eula/>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

# Table of Contents

	About the Documentation . . . . .	xlvi
	Documentation and Release Notes . . . . .	xlvi
	Using the Examples in This Manual . . . . .	xlvi
	Merging a Full Example . . . . .	xlvi

	Self-Help Online Tools and Resources . . . . .	l
	Opening a Case with JTAC . . . . .	l
<b>Part 1</b>	<b>AAA for Subscriber Management</b>	
<b>Chapter 1</b>	<b>AAA for Subscriber Management . . . . .</b>	<b>3</b>
	AAA Service Framework Overview . . . . .	3
<b>Chapter 2</b>	<b>RADIUS for Subscriber Management . . . . .</b>	<b>5</b>
	RADIUS for Subscriber Access Overview . . . . .	5
	RADIUS Server Options for Subscriber Access . . . . .	5
	Global RADIUS Options for Subscriber Access . . . . .	9
	Standard and Vendor-Specific RADIUS Attributes . . . . .	10
	RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework . . . . .	11
	RADIUS IETF Attributes Supported by the AAA Service Framework . . . . .	11
	Juniper Networks VSAs Supported by the AAA Service Framework . . . . .	19
	AAA Access Messages and Supported RADIUS Attributes and Juniper Networks VSAs for Junos OS . . . . .	34
	AAA Accounting Messages and Supported RADIUS Attributes and Juniper Networks VSAs for Junos OS . . . . .	41
	DSL Forum Vendor-Specific Attributes . . . . .	45
	DSL Forum VSAs Support in AAA Access and Accounting Messages for Junos OS . . . . .	47
	RADIUS Support for Microsoft Corporation VSAs for DNS Server Addresses . . . . .	48
	Support for Cisco Systems VSAs . . . . .	49
	Subscriber Management RADIUS Dictionary Files . . . . .	49
	Interface Text Descriptions for Inclusion in RADIUS Attributes . . . . .	50
	RADIUS Servers for Subscriber Access . . . . .	51
	Configuring Router or Switch Interaction with RADIUS Servers . . . . .	51
	Configuring Options that Apply to All RADIUS Servers . . . . .	54

Configuring a Timeout Grace Period to Specify When RADIUS Servers Are Considered Down or Unreachable . . . . .	55
Storage and Reporting of Interface Descriptions to Uniquely Identify Subscribers . . . . .	55
Interface Description Storage and Reporting Overview . . . . .	55
Interface Description Storage and Reporting Configuration . . . . .	59
Access Profiles for Subscriber Access . . . . .	59
Configuring an Access Profile for Subscriber Management . . . . .	60
Configuring RADIUS Server Parameters for Subscriber Access . . . . .	61
Configuring RADIUS Server Options for Subscriber Access . . . . .	61
Filtering RADIUS Attributes and VSAs from RADIUS Messages . . . . .	65
Configuring a Calling-Station-ID with Additional Options . . . . .	68
Session Options for Subscriber Access . . . . .	71
Understanding Session Options for Subscriber Access . . . . .	72
Subscriber Session Timeouts . . . . .	72
Limits on Subscriber Sessions per Username and Access Profile . . . . .	75
Section . . . . .	?
Subscriber Username Modification . . . . .	76
Configuring Subscriber Session Timeout Options . . . . .	77
Limiting the Number of Active Sessions per Username and Access Profile . . . . .	78
Configuring Username Modification for Subscriber Sessions . . . . .	79
Removing Inactive Dynamic Subscriber VLANs . . . . .	82
RADIUS NAS Port Attributes and Options . . . . .	83
Manual Configuration of the NAS-Port-ID RADIUS Attribute . . . . .	83
Configuring a NAS-Port-ID with Additional Options . . . . .	85
Configuring the Order in Which Optional Values Appear in the NAS-Port-ID . . . . .	86
Enabling Unique NAS-Port Attributes (RADIUS Attribute 5) for Subscribers . . . . .	88
RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN Overview . . . . .	89
NAS-Port-Type RADIUS Attribute . . . . .	90
NAS-Port RADIUS Attribute . . . . .	90
NAS-Port Options Configuration and Subscriber Network Access Models . . . . .	90
NAS-Port Options Definition . . . . .	90
Guidelines for Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN . . . . .	91
Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN . . . . .	92
Manual Configuration of the NAS-Port-Type RADIUS Attribute . . . . .	93
Configuring the RADIUS NAS-Port-Type per Physical Interface . . . . .	95
Configuring the RADIUS NAS-Port-Type per VLAN . . . . .	96
Configuring the RADIUS NAS-Port-Type per Stacked VLAN . . . . .	98
Configuring the RADIUS NAS-Port Extended Format per Physical Interface . . . . .	99
Configuring the RADIUS NAS-Port Extended Format per VLAN . . . . .	101
Configuring the RADIUS NAS-Port Extended Format per Stacked VLAN . . . . .	102

Configuring the RADIUS NAS-Port Extended Format for ATM Interfaces . . .	105
RADIUS Logical Line Identification . . . . .	106
RADIUS Logical Line Identifier (LLID) Overview . . . . .	107
RADIUS Attributes for LLID Preauthentication Requests . . . . .	108
Configuring Logical Line Identification (LLID) Preauthentication . . . . .	109
Configuring a Port and Password for LLID Preauthentication Requests . . . .	110
Verifying and Managing LLID Preauthentication Configuration . . . . .	111
RADIUS Authentication and Accounting Basic Configuration . . . . .	112
Configuring Authentication and Accounting Parameters for Subscriber Access . . . . .	112
Specifying the Authentication and Accounting Methods for Subscriber Access . . . . .	112
Specifying RADIUS Authentication and Accounting Servers for Subscriber Access . . . . .	113
Example: Configuring RADIUS-Based Subscriber Authentication and Accounting . . . . .	114
Configuring Local Authentication and Authorization for Subscribers . . . . .	117
RADIUS Reauthentication As an Alternative to RADIUS CoA for DHCP Subscribers . . . . .	120
Benefits of Reauthentication . . . . .	120
Functionality . . . . .	121
Dual-Stack Subscribers . . . . .	123
Packet Flow . . . . .	125
Initial Negotiation . . . . .	125
Service Plan Change . . . . .	126
RADIUS Attributes Supported for Reauthentication . . . . .	127
Configuring RADIUS Reauthentication for DHCP Subscribers . . . . .	129
RADIUS Accounting for Subscriber Access . . . . .	131
RADIUS Accounting Statistics for Subscriber Access Overview . . . . .	132
RADIUS Acct-On and Acct-Off Messages . . . . .	133
Configuring Per-Subscriber Session Accounting . . . . .	134
Enabling the Reporting of Accurate Subscriber Accounting Statistics to the CLI . . . . .	137
Understanding RADIUS Accounting Duplicate Reporting . . . . .	138
Layer 3 Wholesale Scenarios . . . . .	138
Other Scenarios . . . . .	139
Filters for Duplicate Accounting Reports . . . . .	139
Configuring Duplication Filters for RADIUS Accounting Duplicate Reporting . . . . .	140
Configuring Per-Service Session Accounting . . . . .	141
Processing Cisco VSAs in RADIUS Messages for Service Provisioning . . . . .	142
Configuring Service Packet Counting for Volume Statistics . . . . .	144
Configuring Service Accounting . . . . .	145
Preservation of RADIUS Accounting Information During an Accounting Server Outage . . . . .	147
Configuring Back-up Options for RADIUS Accounting . . . . .	150
Forcing the Router to Contact the Accounting Server Immediately . . . . .	151
Monitoring Pending RADIUS Accounting Stop Messages . . . . .	151

	Suspending RADIUS Accounting and Baseline Accounting Statistics	
	Overview	153
	Sequence of Events During the Suspension, Baseline, and Resumption of Accounting	154
	Guidelines for Accounting Suspension and Baseline of Statistics	155
	Sample Scenarios of Subscriber Accounting Suspension and Baseline	156
	Configuring RADIUS Accounting Suspension and Baseline Accounting Statistics	157
	Verifying and Managing Subscriber AAA Information	158
	Session Termination Causes and RADIUS Termination Cause Codes	159
	Understanding Session Termination Causes and RADIUS Termination Cause Codes	160
	Mapping Session Termination Causes to Custom Termination Cause Codes	161
	AAA Termination Causes and Code Values	163
	DHCP Termination Causes and Code Values	164
	L2TP Termination Causes and Code Values	165
	PPP Termination Causes and Code Values	185
	VLAN Termination Causes and Code Values	193
<b>Chapter 3</b>	<b>Domain Maps for Subscriber Management</b>	<b>197</b>
	Mapping Subscriber Domains to Access and Session Options	197
	Domain Mapping Overview	198
	Types of Domain Maps and Their Order of Precedence	199
	Wildcard Domain Map	200
	Default Domain Map	200
	Domain Map for Subscriber Usernames With No Domain or Realm Name	200
	Understanding Domain Maps and Logical System/Routing Instance Contexts	200
	Benefits of Using Domain Maps	201
	Configuring a Domain Map	201
	Configuring a Wildcard Domain Map	203
	Specifying an Access Profile in a Domain Map	204
	Specifying an Address Pool in a Domain Map	205
	Specifying a Dynamic Profile in a Domain Map	206
	Specifying an AAA Logical System/Routing Instance in a Domain Map	206
	Specifying a Target Logical System/Routing Instance in a Domain Map	207
	Specifying a Tunnel Profile in a Domain Map	208
	Specifying a Tunnel Switch Profile in a Domain Map	208
	Configuring PADN Parameters for a Domain Map	209
	Configuring Domain and Realm Name Usage for Domain Maps	210
	Specifying Domain and Realm Name Delimiters	210
	Specifying the Parsing Order for Domain and Realm Names	211
	Specifying the Parsing Direction for Domain and Realm Names	212
	Enabling Domain Name Stripping	213
	Verifying Domain Maps	213

<b>Chapter 4</b>	<b>Testing and Troubleshooting AAA</b>	<b>215</b>
	AAA Testing and Troubleshooting	215
	AAA Configuration Testing and Troubleshooting	215
	Testing a Subscriber AAA Configuration	216
	Tracing General Authentication Service (authd) Events for Troubleshooting	220
	Configuring the General Authentication Service Trace Log Filename	221
	Configuring the Number and Size of General Authentication Service Log Files	221
	Configuring Access to the General Authentication Service Log File	222
	Configuring a Regular Expression for General Authentication Service Messages to Be Logged	222
	Configuring Subscriber Filtering for General Authentication Service	
	Tracing	222
	Configuring the General Authentication Service Tracing Flags	223
<b>Part 2</b>	<b>DHCP and DHCPv6 for Subscriber Management</b>	
<b>Chapter 5</b>	<b>DHCP for Subscriber Management</b>	<b>227</b>
	DHCP Overview	227
	Extended DHCP Local Server Overview	228
	Interaction Among the DHCP Client, Extended DHCP Local Server, and Address-Assignment Pools	230
	Providing DHCP Client Configuration Information	231
	Minimal Configuration for Clients	232
	DHCP Local Server and Address-Assignment Pools	232
	Extended DHCP Relay Agent Overview	234
	Interaction Among the DHCP Relay Agent, DHCP Client, and DHCP Servers	235
	DHCP Liveness Detection	236
	DHCP Relay Proxy Overview	236
	Interaction Among DHCP Relay Proxy, DHCP Client, and DHCP Servers	236
	Benefits of Using DHCP Relay Proxy	237
	Example: Minimum DHCP Relay Agent Configuration	237
	Example: DHCP Relay Agent Configuration with Multiple Clients and Servers	238
	DHCP Access Profiles for Subscriber Authentication and Accounting	
	Parameters	240
	Access Profiles for the DHCP Relay Agent and DHCP Local Server	
	Overview	240
	Attaching Access Profiles to DHCP Subscriber Interfaces or DHCP Client Interfaces	240
	Attaching an Access Profile to All DHCP Subscriber or All DHCP Client Interfaces	240
	Attaching an Access Profile to a Group of DHCP Subscribers or a Group of DHCP Clients	241
	Attaching an Access Profile to a Group of DHCP Subscriber Interfaces or a Group of DHCP Client Interfaces	242

Overrides for Default DHCP Local Server and DHCP Relay Configuration	
Settings	243
Overriding the Default DHCP Local Server Configuration Settings	
Overview	243
Overriding the Default DHCP Relay Configuration Settings	246
DHCP Behavior When Renegotiating While in Bound State	249
Sending Release Messages When Clients Are Deleted	250
Disabling Automatic Binding of Stray DHCP Requests	251
Enabling DHCP Relay Proxy Mode	252
Changing the Gateway IP Address (giaddr) Field to the giaddr of the DHCP	
Relay Agent	253
Replacing the DHCP Relay Request and Release Packet Source Address	253
Configuring the DHCP Relay Agent Source Address to Enable DHCP Packets	
to Pass Through a Firewall	254
Using Layer 2 Unicast Transmission instead of Broadcast for DHCP	
Packets	254
Disabling DHCP Relay Agent for Interfaces, for Groups, or Globally	255
Delaying DHCP Offer and Advertise Responses to Load Balance DHCP	
Servers	255
Load Balancing DHCP Local Servers by Delaying Responses to Clients	255
Benefits to Delaying DHCP Local Server Response	256
Configuring a Delay in Local Server Response to DHCP Discover and Solicit	
Messages	256
DHCP Options and Selective Traffic Processing	259
DHCP Options and Selective Traffic Processing Overview	260
Using DHCP Option Information to Selectively Process DHCP Client	
Traffic	262
Displaying a Count of DHCP Packets That Are Dropped or Forwarded During	
Selective Processing That Is Based on DHCP Option Strings	263
Example: Configuring DHCP Relay Agent Selective Traffic Processing Based	
on DHCP Option Strings	263
Example: Configuring DHCP and DHCPv6 Relay Agent Group-Level Selective	
Traffic Processing	267
DHCP Message Exchange Between DHCP Clients and DHCP Server in	
Different VRFs	272
Configuring DHCP Message Exchange Between DHCP Server and Clients	
in Different Virtual Routing Instances	273
Client-Side Support	274
Server-Side Support	275
DHCP Local Server Support	276
DHCP-Initiated Service Change Based on Remote ID	276
Configuring DHCP-Initiated Service Change Based on Remote ID	277
DHCPv4 and DHCPv6 Forward-Only Action for Relay Traffic with Unknown	
DHCP Server Address	279
Processing of DHCPv4 and DHCPv6 Destination Addresses	279
Processing Order and Actions	280

Using DHCP Option 82 Information . . . . .	282
Using DHCP Relay Agent Option 82 Information . . . . .	282
Configuring Option 82 Information . . . . .	283
Overriding Option 82 Information . . . . .	285
Including a Prefix in DHCP Options . . . . .	286
Including a Textual Description in DHCP Options . . . . .	288
Enable Processing of Untrusted Packets So Option 82 Information Can Be Used . . . . .	290
Extracting an Option 82 or Option 37 Substring to Create an Interface Set . . . . .	291
Default Services for DHCP Subscribers . . . . .	293
Default Subscriber Service Overview . . . . .	293
Configuring a Default Subscriber Service . . . . .	293
DHCP Client Attribute and Address Assignment . . . . .	294
DHCP Attributes Overview . . . . .	295
Benefits of Configuring DHCP Attributes . . . . .	296
Attributes That Can Be Applied to DHCP Clients . . . . .	296
Configuring DHCP Attributes for All Clients or a Group of Clients . . . . .	298
Configuring DHCP Client-Specific Attributes Applied When Clients Obtain an Address . . . . .	299
Configuring How the Extended DHCP Local Server Determines Which Address-Assignment Pool to Use . . . . .	300
Assign a Specific IP Address to a Client Using DHCP Option 50 and DHCPv6 IA_NA Option . . . . .	301
Specifying the Subnet for DHCP Client Address Assignment . . . . .	302
DHCP Local Server Handling of Client Information Request Messages . . . . .	302
Enabling Processing of Client Information Requests . . . . .	303
DNS Address Assignment Precedence . . . . .	304
Example: Extended DHCP Local Server Configuration with Optional Pool Matching . . . . .	304
DHCP Lease Times for IP Addresses . . . . .	305
DHCP Lease Timers . . . . .	306
Benefits of Configuring DHCP Timers in Address Pools . . . . .	306
DHCP Lease-Time Validation Overview . . . . .	307
Configuring a DHCP Lease-Time Threshold . . . . .	308
DHCP Asymmetric Leasing Overview . . . . .	309
Benefits of Asymmetric DHCP Lease Timing . . . . .	310
Configuring DHCP Asymmetric Leasing . . . . .	310
DHCP Leasequery Methods . . . . .	312
DHCP Leasequery and Bulk Leasequery . . . . .	313
Guidelines for Configuring Support for Leasequery and Bulk Leasequery Operations . . . . .	313
Configuring and Using DHCP Individual Leasequery . . . . .	314
Configuring and Using DHCP Bulk Leasequery . . . . .	316
Initiating DHCP Leasequery to Update the DHCP Relay Agent Lease Database . . . . .	320
Verifying and Managing DHCP Leasequery and Bulk Leasequery Configuration . . . . .	321

DHCP Client Authentication With An External AAA Authentication Service . . . .	322
Using External AAA Authentication Services with DHCP . . . . .	322
Creating Unique Usernames for DHCP Clients . . . . .	323
Configuring Passwords for Usernames . . . . .	326
Receiving DHCP Options From a RADIUS Server . . . . .	327
Centrally Configured Opaque DHCP Options . . . . .	328
Data Flow for RADIUS-Sourced DHCP Options . . . . .	330
Multiple VSA 26-55 Instances Configuration . . . . .	331
DHCP Options That Cannot Be Centrally Configured . . . . .	331
Exchange of DHCPv4 and DHCPv6 Parameters with the RADIUS Server	
Overview . . . . .	332
Differentiating Subscriber Classes with DHCPv6 Option 17 and VSA	
26-207 . . . . .	334
Excluding the VSAs from RADIUS Messages . . . . .	335
Dedicated Session Database and Vendor-Specific Attributes for DHCPv4	
and DHCPv6 Subscribers . . . . .	335
Client Options . . . . .	335
Exchange of DHCPv4 Client, DHCPv4 Server, and RADIUS-Sourced	
Options . . . . .	336
Exchange of DHCPv6 Client, DHCPv6 Server, and RADIUS-Sourced	
Options . . . . .	336
Monitoring DHCP Options Configured on RADIUS Servers . . . . .	337
Common DHCP Configuration for Interface Groups and Server Groups . . . . .	340
Grouping Interfaces with Common DHCP Configurations . . . . .	340
Guidelines for Configuring Interface Ranges for Groups of DHCP	
Interfaces . . . . .	341
Configuring Group-Specific DHCP Local Server Options . . . . .	342
Configuring Group-Specific DHCP Relay Options . . . . .	343
Configuring Active Server Groups to Apply a Common DHCP Relay Agent	
Configuration to Named Server Groups . . . . .	344
Number of DHCP Clients Per Interface . . . . .	347
Specifying the Maximum Number of DHCP Clients Per Interface . . . . .	347
Allowing Only One DHCP Client Per Interface . . . . .	348
Maintaining DHCP Subscribers During Interface Delete Events . . . . .	349
Maintaining Subscribers During Interface Delete Events . . . . .	349
Benefits of Maintaining Subscriber Bindings . . . . .	350
Configuring the Router to Maintain DHCP Subscribers During Interface Delete	
Events . . . . .	350
Configuring an ACX Series DHCP Local Server to Preserve Subscriber Binding	
Information . . . . .	351
Verifying and Managing DHCP Subscriber Binding During Interface Delete	
Events . . . . .	352
Dynamic Reconfiguration of Clients From a DHCP Local Server . . . . .	353
Understanding Dynamic Reconfiguration of Extended DHCP Local Server	
Clients . . . . .	353
Default Client/Server Interaction . . . . .	353
Dynamic Client/Server Interaction for DHCPv4 . . . . .	354
Dynamic Client/Server Interaction for DHCPv6 . . . . .	354

Manually Forcing the Local Server to Initiate the Reconfiguration Process . . . . .	355
Action Taken for Events That Occur During a Reconfiguration . . . . .	355
Configuring Dynamic Client Reconfiguration of Extended Local Server Clients Overview . . . . .	356
Configuring Dynamic Reconfiguration Attempts for DHCP Clients . . . . .	357
Configuring Deletion of the Client When Dynamic Reconfiguration Fails . .	358
Configuring Reconfiguration of the Client on Receipt of RADIUS-Initiated Disconnect . . . . .	358
Configuring a Token for DHCP Local Server Authentication . . . . .	359
Conserving IP Addresses Using DHCP Auto Logout . . . . .	360
DHCP Auto Logout Overview . . . . .	360
Auto Logout Overview . . . . .	360
How DHCP Identifies and Releases Clients . . . . .	361
Option 60 and Option 82 Requirements . . . . .	362
Automatically Logging Out DHCP Clients . . . . .	362
How DHCP Relay Agent Uses Option 82 for Auto Logout . . . . .	363
DHCPv6 Match Criteria for Identifying DHCPv6 Subscribers . . . . .	364
Automatically Logging Out DHCPv6 Clients . . . . .	364
DHCP Short Cycle Protection . . . . .	366
DHCP Short Cycle Protection Against Frequent Brief or Failed Client Sessions . . . . .	366
Conditions That Can Cause Failed or Short-Lived DHCP Client Sessions . . . . .	366
How DHCP Short-Cycle Protection Works . . . . .	367
Termination of the Lockout Condition . . . . .	368
Benefits of Using DHCP Short Cycle Protection . . . . .	368
Configuring DHCP Short-Cycle Protection . . . . .	369
Verifying and Managing DHCP Short-Cycle Protection . . . . .	371
DHCP Monitoring and Management . . . . .	373
Requesting DHCP Local Server to Initiate Reconfiguration of Client Bindings . . . . .	373
Viewing and Clearing DHCP Bindings . . . . .	374
Monitoring DHCP Relay Server Responsiveness . . . . .	376
Verifying and Managing DHCP Local Server Configuration . . . . .	376
Verifying and Managing DHCP Relay Configuration . . . . .	377
Tracing Extended DHCP Operations . . . . .	377
Configuring the Extended DHCP Log Filename . . . . .	379
Configuring the Number and Size of Extended DHCP Log Files . . . . .	379
Configuring Access to the Extended DHCP Log File . . . . .	380
Configuring a Regular Expression for Extended DHCP Messages to Be Logged . . . . .	381
Configuring the Extended DHCP Tracing Flags . . . . .	381
Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged . . . . .	381
Tracing Extended DHCP Operations for Specific Interfaces . . . . .	382

<b>Chapter 6</b>	<b>DHCPv6 for Subscriber Management</b>	<b>385</b>
	DHCPv6 Local Server	385
	DHCPv6 Local Server Overview	386
	Enabling DHCPv6 Rapid Commit Support	387
	Preventing Binding of Clients That Do Not Support Reconfigure Messages	387
	Configuring the DUID Type Supported by DHCPv6 Servers	389
	Example: Extended DHCPv6 Local Server Configuration	390
	DHCPv6 Relay Agent	391
	DHCPv6 Relay Agent Overview	391
	DHCPv6 Relay Agent Options	392
	Configuring DHCPv6 Relay Agent Options	392
	Inserting DHCPv6 Interface-ID Option (Option 18) In DHCPv6 Packets	394
	Inserting DHCPv6 Remote-ID Option (Option 37) In DHCPv6 Packets	395
	DHCPv6 Client MAC Address Validation to Prevent Session Hijacking	396
	Benefits	398
	DHCPv6 Monitoring and Management	398
	Requesting DHCPv6 Local Server to Initiate Reconfiguration of Client Bindings	398
	Verifying and Managing DHCPv6 Local Server Configuration	399
	Verifying and Managing DHCPv6 Relay Configuration	400
<b>Part 3</b>	<b>IPv6 for Subscriber Management</b>	
<b>Chapter 7</b>	<b>IPv6 for Subscriber Management</b>	<b>403</b>
	Introduction to IPv6 Addresses	403
	IPv6 Notation	404
	IPv6 Prefixes	404
	IPv6 Address Types	404
	Unicast Addresses	405
	Multicast Addresses	405
	Anycast Addresses	405
	Migration to IPv6 Using IPv4 and IPv6 Dual Stack	406
	Basic Architecture of a Subscriber Access Dual-Stack Network	406
	Terms Used in IPv6 Subscriber Management Documentation	407
	IPv6 Addressing Requirements for a Subscriber Access Network	409
	Alternatives to Using a Global IPv6 Address on the CPE WAN Link	409
	IPv6 WAN Link Addressing with NDRA	410
	Using NDRA to Provide IPv6 WAN Link Addressing Overview	410
	IPv6 Neighbor Discovery Protocol Overview	411
	Neighbor Discovery Messages	412
	Dynamic Router Advertisement Configuration Overview	412
	Configuring an Interval Range for Unsolicited Router Advertisements to IPv6 Neighbors	414
	Methods for Obtaining IPv6 Prefixes for NDRA	415
	Using AAA RADIUS Server to Obtain IPv6 Prefixes for NDRA	416
	Duplicate Prefix Protection for NDRA	416

IPv6 WAN Link Addressing with DHCPv6 IA_NA . . . . .	417
Methods for Obtaining IPv6 Global Addresses for DHCPv6 IA_NA . . . . .	417
Using a AAA RADIUS Server to Obtain IPv6 Addresses for DHCPv6 IA_NA . . . . .	417
Configuring an Address-Assignment Pool for Use by DHCPv6 IA_NA . . . . .	418
Subscriber LAN Addressing with DHCPv6 Prefix Delegation . . . . .	418
Using DHCPv6 Prefix Delegation Overview . . . . .	419
Using a Delegated Prefix on the CPE Loopback Interface . . . . .	420
DHCPv6 Prefix Delegation over PPPoE . . . . .	420
Methods for Obtaining IPv6 Prefixes for DHCPv6 Prefix Delegation . . . . .	421
Using a AAA RADIUS Server to Obtain IPv6 Prefixes for Prefix Delegation . . . . .	421
DHCPv6 Prefix Exclusion . . . . .	422
Configuring DHCPv6 Prefix Exclude Option . . . . .	423
Configuring an Address-Assignment Pool for Use by DHCPv6 Prefix Delegation . . . . .	424
Specifying the Delegated Address-Assignment Pool to Be Used for DHCPv6 Prefix Delegation . . . . .	424
WAN and LAN Addressing Using DHCPv6 IA_NA and DHCPv6 Prefix Delegation . . . . .	425
Using DHCPv6 IA_NA with DHCPv6 Prefix Delegation Overview . . . . .	425
Lease Times and Session Timeouts for DHCPv6 IA_NA and DHCPv6 Prefix Delegation . . . . .	426
Behavior When CPE Sends Separate Renew Requests for IA_NA and IA_PD Address Types . . . . .	426
DHCPv6 Options in a DHCPv6 Multiple Address Environment . . . . .	427
Methods for Obtaining Addresses for Both DHCPv6 Prefix Delegation and DHCPv6 IA_NA . . . . .	427
Address Pools for DHCPv6 Prefix Delegation and DHCPv6 IA_NA . . . . .	427
Using a AAA RADIUS Server to Obtain IPv6 Addresses and Prefixes . . . . .	428
Junos OS Predefined Variable for Multiple DHCPv6 Address Assignment . . . . .	428
Multiple DHCPv6 IA_NA and IA_PD Requests per Client Interface . . . . .	428
Example: Configuring a Dual Stack That Uses DHCPv6 IA_NA and DHCPv6 Prefix Delegation over PPPoE . . . . .	429
Designs for IPv6 Addressing in a Subscriber Access Network . . . . .	453
Selecting the Type of Addressing Used on the CPE . . . . .	453
Selecting the Method of Provisioning a Global IPv6 Address for the WAN Link . . . . .	453
Selecting the Method of Assigning Global IPv6 Addresses to Subscribers . . . . .	454
Selecting the Method of Obtaining IPv6 Prefixes . . . . .	454
Using a AAA RADIUS Server to Obtain Global IPv6 Addresses and IPv6 Prefixes . . . . .	455
Design 1: IPv6 Addressing with DHCPv6 IA_NA and DHCPv6 Prefix Delegation . . . . .	455
Design 2: IPv6 Addressing with NDRA and DHCPv6 Prefix Delegation . . . . .	456
Design 3: IPv6 Addressing with NDRA . . . . .	457

Design 4: IPv6 Addressing with DHCPv6 Prefix Delegation and No NDRA	
Prefix	457
Dual-Stack Access Models in a DHCP Network	458
IPv4 and IPv6 Dual Stack in a DHCP Access Network	458
Support for Demultiplexing Interfaces	459
AAA Service Framework in a Dual Stack over a DHCP Access Network	459
Collection of Accounting Statistics in a DHCP Access Network	460
Change of Authorization (CoA)	460
Dual-Stack Interface Stack in a DHCP Wholesale Network	460
Single-Session DHCP Dual-Stack Overview	461
Configuring Single-Session DHCP Dual-Stack Support	464
Verifying and Managing DHCP Dual-Stack Configuration	467
Dual-Stack Access Models in a PPPoE Network	468
IPv4 and IPv6 Dual Stack in a PPPoE Access Network	468
Support for Demultiplexing Interfaces	469
Determining the Status of CPE in a PPPoE Access Network	469
IPv6 Address Provisioning in the PPPoE Access Network	469
Authentication in a PPPoE Access Network	469
Negotiation of Network Control Protocols When Authorized Addresses	
Are Unavailable	469
Shared IPv4 and IPv6 Service Sessions on PPP Access Networks	470
Accounting for Shared IPv4 and IPv6 Service Sessions	470
Deactivating Shared IPv4 and IPv6 Service Sessions	470
AAA Service Framework in a Dual Stack over a PPPoE Access Network	470
Collection of Accounting Statistics in a PPPoE Access Network	471
Change of Authorization (CoA)	472
RADIUS Accounting Messages for Dual-Stack PPPoE Subscribers	472
Accounting Messages for PPPoE Using NDRA Prefixes	473
Accounting Messages for PPPoE Subscribers That Use DHCPv6 IA_NA	
Prefixes	477
Suppressing Accounting Information That Comes from AAA	483
Avoiding Negotiation of IPv6CP in the Absence of an Authorized	
Address	484
Best Practices for Configuring IPv4 and IPv6 Dual Stack in a PPPoE Access	
Network	485
Best Practice: Static PPPoE Interfaces with NDRA	485
Best Practice: DHCPv6 Prefix Delegation over a PPPoE Access Network	486
Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic	
Profiles with NDRA	486
Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic	
Profiles with DHCPv6	487
Best Practice: IPv4 Addressing for Logical Interfaces in PPPoE Dynamic	
Profiles	487
Best Practice: Configuring Authentication for DHCP Subscribers on a PPPoE	
Access Network	488
Dual Stack for PPPoE Access Networks Using DHCP	489
Configuring a DHCPv6 Local Server for DHCPv6 over PPPoE	489
Configuring a PPPoE Dynamic Profile for Use with DHCP Addressing in a	
Dual-Stack Network	490

Dual Stack for PPPoE Access Networks Using NDRA . . . . .	492
Configuring a PPPoE Dynamic Profile for Use with NDRA in a Dual-Stack Network . . . . .	493
Configuring a Static PPPoE Logical Interface for NDRA . . . . .	495
Configuring an Address-Assignment Pool Used for Router Advertisements . . . . .	496
Configuring Duplicate IPv6 Prefix Protection for Router Advertisement . . . . .	497
Configuring the IPv6 Link-Local Address for Dynamic Demux Interfaces over Static Demux VLAN Interfaces . . . . .	498
Example: Configuring a Dual Stack That Uses ND/RA Over PPPoE . . . . .	498
Example: Configuring a Dual Stack That Uses ND/RA and DHCPv6 Prefix Delegation Over PPPoE . . . . .	517
IP demultiplexing interfaces on Packet-Triggered Subscribers Services Overview . . . . .	542
Benefits of IP demultiplexing interfaces on Packet-Triggered Subscribers Services feature: . . . . .	542
Configuring Packet Triggered Subscribers Using IP Demux Interfaces in Dynamic Profiles . . . . .	543
Conservation of IPv4 Addresses for Dual-Stack PPP Subscribers Using On-Demand IPv4 Address Allocation . . . . .	544
Conserving IPv4 Addresses for Dual-Stack PPP Subscribers Using On-Demand IPv4 Address Allocation . . . . .	545
On-Demand IPv4 Address Negotiation and Release for Static PPP Subscribers Overview . . . . .	545
IPv4 Address Negotiation for Static PPP Subscribers . . . . .	545
IPv4 Address Release for Static PPP Subscribers . . . . .	547
On-Demand IPv4 Address Negotiation and Release for Dynamic PPP Subscribers Overview . . . . .	547
IPv4 Address Negotiation for Dynamic PPP Subscribers . . . . .	548
IPv4 Address Release for Dynamic PPP Subscribers . . . . .	549
IPCP Negotiation with Optional Peer IP Address . . . . .	550
How RADIUS Attributes Are Used During Authentication When On-Demand Address Allocation is Enabled . . . . .	551
Configuring Static On-Demand IPv4 Address Allocation for Dual-Stack PPP Subscribers . . . . .	552
Configuring Dynamic On-Demand IPv4 Address Allocation for Dual-Stack PPP Subscribers . . . . .	552
Configuring Global On-Demand IPv4 Address Allocation for Dual-Stack PPP Subscribers . . . . .	552
Enabling Immediate Interim Accounting Messages for On-Demand IPv4 Address Changes . . . . .	553
Enabling IPv4 Release Control VSA (26–164) in RADIUS Messages . . . . .	553
Dual Stack Subscribers Monitoring and Management . . . . .	554
Monitoring Active Subscriber Sessions . . . . .	554
Monitoring Both IPv4 and IPv6 Address in Correct Routing Instance . . . . .	555
Monitoring Dynamic Subscriber Sessions . . . . .	555
Monitoring Address Pools Used for Subscribers . . . . .	556
Monitoring Specific Subscriber Sessions . . . . .	557
Monitoring the Status of the PPPoE Logical Interface . . . . .	558

	Monitoring Service Sessions for Subscribers . . . . .	559
	Monitoring PPP Options Negotiated with the Remote Peer . . . . .	559
	Monitoring the RADIUS Attribute Used for NDRA . . . . .	560
<b>Part 4</b>	<b>Address-Assignment Pools for Subscriber Management</b>	
<b>Chapter 8</b>	<b>Address-Assignment Pools for Subscriber Management . . . . .</b>	<b>563</b>
	Address-Assignment Pools for Subscriber Management . . . . .	563
	Address-Assignment Pools Overview . . . . .	563
	Benefits of Address Assignment Pools . . . . .	565
	Address Allocation from Linked Address Pools . . . . .	565
	Address-Assignment Pool Configuration Overview . . . . .	570
	Configuring an Address-Assignment Pool Name and Addresses . . . . .	571
	Configuring a Named Address Range for Dynamic Address Assignment . . . . .	572
	Preventing Addresses from Being Allocated from an Address Pool . . . . .	573
	Configuring Address-Assignment Pool Usage Threshold Traps . . . . .	574
	Configuring Address-Assignment Pool Linking . . . . .	576
	Configuring Address-Assignment Pool Hold-Down . . . . .	577
	Configuring DHCP Local Address Pool Rapid Drain . . . . .	578
	Configuring Static Address Assignment . . . . .	581
	Configuring Duplicate IPv4 Address Protection for AAA . . . . .	582
	Example: Configuring an Address-Assignment Pool . . . . .	583
<b>Part 5</b>	<b>DNS Addresses for Subscriber Management</b>	
<b>Chapter 9</b>	<b>DNS Addresses for Subscriber Management . . . . .</b>	<b>589</b>
	DNS Name Server Addresses for Subscriber Management . . . . .	589
	DNS Name Server Address Overview . . . . .	589
	Configuring DNS Name Server Addresses for Subscriber Management . . . . .	590
	Overriding How the DNS Server Address Is Returned in a DHCPv6 Multiple Address Environment . . . . .	592
	DNS Resolver for IPv6 DNS Overview . . . . .	593
	Configuring a DNS Server Address for IPv6 Hosts . . . . .	593
<b>Part 6</b>	<b>Access Node Control Protocol and the ANCP Agent for Subscriber Services</b>	
<b>Chapter 10</b>	<b>Access Node Control Protocol and the ANCP Agent for Subscriber Services . . . . .</b>	<b>597</b>
	ANCP Agent Neighbors and Operations . . . . .	597
	ANCP and the ANCP Agent Overview . . . . .	598
	Overview . . . . .	598
	Topology Discovery . . . . .	599
	Subscriber Services . . . . .	599
	ANCP Interfaces and Access Loop Circuit Identifiers . . . . .	600
	Mapping Access Lines to Interfaces and Interface Sets . . . . .	601
	ANCP Neighbors . . . . .	602
	Partitions . . . . .	604
	Adjacency Update Messages . . . . .	604

Generic Response Messages and Result Codes . . . . .	605
ANCP Operations in Different Network Configurations . . . . .	606
1:1 and N:1 Traffic Shaping Models . . . . .	607
Business Services Traffic Shaping Model . . . . .	609
ANCP Network Using N:1 and 1:1 Configuration Models without Interface Sets . . . . .	610
Sequence of ANCP Events: Static VLAN or VLAN Demux Interfaces over Ethernet Without Interface Sets . . . . .	611
ANCP Network Using N:1 Configuration Model with Interface Sets . . . .	612
Sequence of ANCP Events: Static VLAN Interfaces over Ethernet with Interface Sets . . . . .	613
ANCP Network Using 1:1 Configuration Model with Interface Sets . . . .	614
Sequence of ANCP Events: Static VLAN Demux Interfaces over Aggregated Ethernet with Interface Sets . . . . .	615
Configuring the ANCP Agent . . . . .	616
Configuring ANCP Neighbors . . . . .	617
Associating an Access Node with Subscribers for ANCP Agent Operations . . . . .	619
Specifying the Interval Between ANCP Adjacency Messages . . . . .	620
Specifying the Maximum Number of Discovery Table Entries . . . . .	620
Configuring the ANCP Agent for Backward Compatibility . . . . .	621
Specifying How Long Processes Wait for the ANCP Agent Restart to Complete . . . . .	621
Configuring the ANCP Agent to Learn ANCP Partition IDs . . . . .	622
Example: Configuring an ANCP Network with Interface Sets and N:1 Static Demux VLANs over Aggregated Ethernet . . . . .	622
ANCP Agent Traffic Shaping and CoS . . . . .	645
Traffic Rate Reporting and Adjustment by the ANCP Agent . . . . .	645
Overview . . . . .	645
Traffic Rate Adjustment . . . . .	647
Recommended Traffic Shaping Rates . . . . .	649
ANCP Agent Keepalives for CoS . . . . .	649
Preservation of CoS Shaping Across ANCP Agent Restarts . . . . .	649
Configuring the ANCP Agent to Report Traffic Rates to CoS . . . . .	650
Setting a Recommended Shaping Rate for Traffic on ANCP Interfaces . . . .	652
Setting a Global Adjustment Factor per DSL Subscriber Line for ANCP Agent-Reported Traffic Rates . . . . .	654
Verifying and Monitoring CoS for ANCP Subscribers . . . . .	655
ANCP Agent and AAA . . . . .	656
ANCP Agent Interactions with AAA . . . . .	656
ANCP DSL Attributes Mapped to Juniper Networks DSL Vendor-Specific Attributes . . . . .	658
Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages . . . . .	660
Configuring Immediate Interim Accounting Updates to RADIUS in Response to ANCP Notifications . . . . .	661

ANCP Monitoring and Management . . . . .	662
Triggering ANCP OAM to Test the Local Loop . . . . .	662
Verifying and Monitoring ANCP Neighbors . . . . .	663
Clearing ANCP Neighbors . . . . .	663
Verifying and Monitoring ANCP Subscribers . . . . .	664
Clearing ANCP Subscribers . . . . .	664
Clearing and Verifying ANCP Statistics . . . . .	665
Tracing ANCP Events for Troubleshooting . . . . .	665
Configuring the ANCP Trace Log Filename . . . . .	666
Configuring the Number and Size of ANCP Log Files . . . . .	666
Configuring Access to the ANCP Log File . . . . .	667
Configuring a Regular Expression for ANCP Messages to Be Logged . . . . .	667
Configuring the ANCP Tracing Flags . . . . .	668
Configuring the Severity Level to Filter Which ANCP Messages Are Logged . . . . .	668

## Part 7

### Chapter 11

## Diameter Base Protocol and its Applications

<b>Diameter Base Protocol and its Applications . . . . .</b>	<b>671</b>
Diameter Base Protocol . . . . .	671
Diameter Base Protocol Overview . . . . .	671
Benefits of Using Diameter . . . . .	674
Messages Used by Diameter Applications . . . . .	674
Diameter AVPs and Diameter Applications . . . . .	681
Configuring Diameter . . . . .	695
Configuring the Origin Attributes of the Diameter Instance . . . . .	696
Configuring Diameter Peers . . . . .	696
Configuring the Diameter Transport . . . . .	698
Configuring Diameter Network Elements . . . . .	699
Gx-Plus for Provisioning Subscribers . . . . .	700
Gx-Plus for Provisioning Subscribers Overview . . . . .	701
Understanding Gx-Plus Interactions Between the Router and the PCRF . . . . .	702
Subscriber Login . . . . .	703
Fault Tolerance and Event Notification . . . . .	705
PCRF-Generated Discovery . . . . .	706
Subscriber Accounting . . . . .	706
Subscriber Usage Thresholds . . . . .	707
Subscriber Audit . . . . .	710
Subscriber Logout . . . . .	710
Configuring Gx-Plus . . . . .	711
Configuring the Gx-Plus Partition . . . . .	712
Configuring Gx-Plus Global Attributes . . . . .	713
Provisioning Subscribers with Gx-Plus . . . . .	714
Disabling PCRF Control of a Subscriber Session . . . . .	714

3GPP Policy and Charging Control for Wireline Provisioning and Accounting . . .	716
3GPP Policy and Charging Control Overview for Wireline Provisioning and Accounting . . . . .	716
Policy and Charging Enforcement Function Overview for Broadband Wireline Subscribers . . . . .	718
Wireline Access Environment . . . . .	719
Junos OS Environment . . . . .	720
Understanding Gx Interactions Between the Router and the PCRF . . . . .	722
Subscriber Login . . . . .	722
Subscriber Update . . . . .	726
Subscriber Logout . . . . .	727
Subscriber Disconnect . . . . .	728
Connectivity Fault Recovery . . . . .	729
Understanding Gy Interactions Between the Router and the OCS . . . . .	730
First Interrogation to the OCS . . . . .	731
Intermediate Interrogation to the OCS . . . . .	732
Final Interrogation to the OCS . . . . .	734
Connectivity Fault Recovery . . . . .	735
Abort Session Requests . . . . .	735
Gy File Backup Overview . . . . .	735
OCS SFTP-Backup . . . . .	736
Benefits of Gy File Backup: . . . . .	736
Understanding Rule Interactions Between the PCRF, PCEF, and OCS . . . . .	736
Login Interactions . . . . .	738
Update Interactions . . . . .	738
Quota Expiration and Validity-Time Interactions . . . . .	739
Connection and Monitoring Interactions . . . . .	739
Logout Interactions . . . . .	740
Understanding Upstream and Downstream Messages for the PCRF . . . . .	742
Common Upstream Messages . . . . .	743
Common Downstream Messages . . . . .	744
Configuring the OCS Partition . . . . .	745
Configuring the PCRF Partition . . . . .	751
Configuring OCS Global Parameters . . . . .	755
NASREQ for Authentication and Authorization . . . . .	755
Diameter Network Access Server Application (NASREQ) . . . . .	756
Benefits of Using the Diameter NASREQ Protocol . . . . .	757
Configuring the Diameter Network Access Server Application (NASREQ) . . . . .	757
JSRC for Subscriber Provisioning and Accounting . . . . .	759
Juniper Networks Session and Resource Control (SRC) and JSRC Overview . . . . .	759
Benefits of Using JSRC . . . . .	760
Hardware Requirements for JSRC for Subscriber Access . . . . .	760
Understanding JSRC-SAE Interactions . . . . .	761
Subscriber Login . . . . .	761
Subscriber Service Activation and Deactivation . . . . .	762
Subscriber Resynchronization . . . . .	762
Subscriber Session Terminated by the SAE . . . . .	762

Statistics Collection and Reporting per Service Rule . . . . .	763
Subscriber Logout . . . . .	763
JSRC Provisioning for Dual-Stack Subscribers . . . . .	763
Benefits of JSRC Dual-Stack Provisioning . . . . .	763
AA-Request Messages When Dual-Stack Support Configured . . . . .	764
Accounting-Request Messages When Dual-Stack Support Configured . . . . .	765
Network Family Activation and Deactivation Notification When Dual-Stack Support Configured . . . . .	765
JSRC Configuration Overview . . . . .	766
Configuring the JSRC Partition . . . . .	767
Assigning a Partition to JSRC . . . . .	768
Authorizing Subscribers with JSRC . . . . .	768
Provisioning Subscribers with JSRC . . . . .	769
Configuring JSRC for Dual-Stack Subscribers . . . . .	770
Excluding AVPs from Diameter Messages for JSRC . . . . .	771
Service Accounting with JSRC . . . . .	771
Configuring Service Accounting with JSRC . . . . .	772
JSRC and Subscribers on Static Interfaces . . . . .	773
Subscribers on Static Interfaces Overview . . . . .	774
Benefits of subscribers on static interfaces . . . . .	777
Subscribers over Static Interfaces Configuration Overview . . . . .	777
Example: Configuring Static Subscribers for Subscriber Access . . . . .	779
Specifying the Static Subscriber Global Access Profile . . . . .	780
Specifying the Static Subscriber Global Dynamic Profile . . . . .	781
Enabling Multiple Subscribers on a VLAN Logical Interface for All Static Subscribers . . . . .	781
Configuring the Static Subscriber Global Authentication Password . . . . .	782
Configuring the Static Subscriber Global Username . . . . .	782
Creating a Static Subscriber Group . . . . .	784
Specifying the Static Subscriber Group Access Profile . . . . .	785
Specifying the Static Subscriber Group Dynamic Profile . . . . .	785
Specifying the Static Subscriber Group Service Profile . . . . .	785
Enabling Multiple Subscribers on a VLAN Logical Interface for a Static Subscriber Group . . . . .	786
Configuring the Static Subscriber Group Authentication Password . . . . .	786
Configuring the Static Subscriber Group Username . . . . .	787
Monitoring and Management Diameter Information . . . . .	789
Verifying Diameter Node, Instance, and Route Information . . . . .	789
Verifying and Managing Diameter Application Information . . . . .	790
Verifying and Managing Diameter Peer Information . . . . .	791
Verifying Diameter Network Element Information . . . . .	792
Tracing Diameter Base Protocol Events for Troubleshooting . . . . .	793
Configuring the Diameter Base Protocol Trace Log Filename . . . . .	793
Configuring the Number and Size of Diameter Base Protocol Log Files . . . . .	794
Configuring Access to the Diameter Base Protocol Log File . . . . .	794
Configuring a Regular Expression for Diameter Base Protocol Messages to Be Logged . . . . .	795
Configuring the Diameter Base Protocol Tracing Flags . . . . .	795

Configuring the Severity Level to Filter Which Diameter Base Protocol Messages Are Logged . . . . .	795
Troubleshooting Diameter Networks . . . . .	796
Troubleshooting Diameter Network Configuration . . . . .	796
Troubleshooting Diameter Network Connectivity . . . . .	796
Monitoring and Managing Static Subscriber Information . . . . .	797
Forcing a Static Subscriber to Be Logged Out . . . . .	797
Resetting the State of an Interface for Static Subscriber Login . . . . .	797
Forcing a Group of Static Subscribers to Be Logged Out . . . . .	797
Resetting the State of an Interface Group for Static Subscriber Login . . . . .	797
Verifying Information about Subscriber Sessions on Static Interfaces . . . . .	798
Tracing Static Subscriber Events for Troubleshooting . . . . .	798
Configuring the Static Subscribers Trace Log Filename . . . . .	799
Configuring the Number and Size of Static Subscribers Log Files . . . . .	799
Configuring Access to the Static Subscribers Log File . . . . .	800
Configuring a Regular Expression for Static Subscriber Messages to Be Logged . . . . .	800
Configuring the Static Subscribers Tracing Flags . . . . .	800
Configuring the Severity Level to Filter Which Static Subscriber Messages Are Logged . . . . .	801

## Part 8

### Chapter 12

## Configuration Statements and Operational Commands

<b>Configuration Statements . . . . .</b>	<b>805</b>
aaa-logical-system (Domain Map) . . . . .	820
aaa-routing-instance (Domain Map) . . . . .	821
abated-utilization (Address-Assignment Pools) . . . . .	822
abated-utilization-v6 (Address-Assignment Pools) . . . . .	823
accept-max-tcp-connections (System Process) . . . . .	824
accept-sdr (PCRF Partition) . . . . .	825
access-identifier . . . . .	826
access-line (Access-Line Rate Adjustment) . . . . .	827
access-loop-id-local . . . . .	837
access-profile . . . . .	838
access-profile (Extensible Subscriber Services Manager) . . . . .	839
access-profile (Domain Map) . . . . .	839
access-profile (Static Subscribers) . . . . .	840
access-profile-name (Duplicate Accounting) . . . . .	841
accounting (Access Profile) . . . . .	842
accounting (Service Accounting) . . . . .	843
accounting-backup-options (Access Profile) . . . . .	844
accounting-order (Service Accounting) . . . . .	845
accounting-port . . . . .	847
accounting-retry (RADIUS) . . . . .	848
accounting-server . . . . .	849
accounting-session-id-format . . . . .	850
accounting-stop-on-access-deny . . . . .	851
accounting-stop-on-failure . . . . .	852
accounting-timeout (RADIUS) . . . . .	853

active-drain (Address Assignment Pools) .....	854
active-server-group .....	855
actual-transit-statistics (Dynamic Profiles) .....	857
address (Diameter Peer) .....	858
address (Diameter Transport) .....	858
address-assignment (Address-Assignment Pools) .....	859

- Requesting Technical Support on page xlix

## Documentation and Release Notes

---

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <https://www.juniper.net/documentation/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <https://www.juniper.net/books>.

## Using the Examples in This Manual

---

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

## Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

## Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

## Documentation Conventions

Table 1 on page [xlvii](#) defines notice icons used in this guide.

*Table 1: Notice Icons*

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page [xlviii](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
<b>Bold text like this</b>	Represents text that you type.	To enter configuration mode, type the <b>configure</b> command:  user@host> <b>configure</b>
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> <b>show chassis alarms</b>  No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> <li>Introduces or emphasizes important new terms.</li> <li>Identifies guide names.</li> <li>Identifies RFC and Internet draft titles.</li> </ul>	<ul style="list-style-type: none"> <li>A policy <i>term</i> is a named structure that defines match conditions and actions.</li> <li><i>Junos OS CLI User Guide</i></li> <li>RFC 1997, <i>BGP Communities Attribute</i></li> </ul>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name:  [edit] root@# <b>set system domain-name</b> <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> <li>To configure a stub area, include the <b>stub</b> statement at the [edit protocols ospf area area-id] hierarchy level.</li> <li>The console port is labeled <b>CONSOLE</b>.</li> </ul>
< > (angle brackets)	Encloses optional keywords or variables.	<b>stub</b> <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	<b>broadcast</b>   <b>multicast</b>  ( <i>string1</i>   <i>string2</i>   <i>string3</i> )
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	<b>rsvp { # Required for dynamic MPLS only</b>
[ ] (square brackets)	Encloses a variable for which you can substitute one or more values.	<b>community name members</b> [ <i>community-ids</i> ]
Indentation and braces ( { } )	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

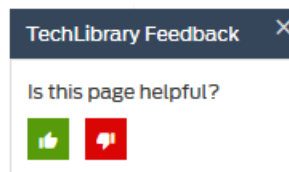

Table 2: Text and Syntax Conventions (continued)

Convention	Description	Examples
<b>GUI Conventions</b>		
<b>Bold text like this</b>	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> <li>In the Logical Interfaces box, select <b>All Interfaces</b>.</li> <li>To cancel the configuration, click <b>Cancel</b>.</li> </ul>
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select <b>Protocols&gt;Ospf</b> .

## Documentation Feedback

We encourage you to provide feedback so that we can improve our documentation. You can use either of the following methods:

- Online feedback system—Click TechLibrary Feedback, on the lower right of any page on the [Juniper Networks TechLibrary](#) site, and do one of the following:

- Click the thumbs-up icon if the information on the page was helpful to you.
- Click the thumbs-down icon if the information on the page was not helpful to you or if you have suggestions for improvement, and use the pop-up form to provide feedback.
- E-mail—Send your comments to [techpubs-comments@juniper.net](mailto:techpubs-comments@juniper.net). Include the document or topic name, URL or page number, and software version (if applicable).

## Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <https://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <https://www.juniper.net/support/warranty/>.

- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

## Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <https://www.juniper.net/customers/support/>
- Search for known bugs: <https://prsearch.juniper.net/>
- Find product documentation: <https://www.juniper.net/documentation/>
- Find solutions and answer questions using our Knowledge Base: <https://kb.juniper.net/>
- Download the latest versions of software and review release notes: <https://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <https://kb.juniper.net/InfoCenter/>
- Join and participate in the Juniper Networks Community Forum: <https://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <https://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://entitlementsearch.juniper.net/entitlementsearch/>

## Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <https://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <https://www.juniper.net/support/requesting-support.html>.

## AAA Service Framework Overview

---

The authentication, authorization, and accounting (AAA) Service Framework provides a single point of contact for all the authentication, authorization, accounting, address assignment, and dynamic request services that the router supports for network access. The framework supports authentication and authorization through external servers, such as RADIUS. The framework also supports accounting and dynamic-request change of authorization (CoA) and disconnect operations through external servers, and address assignment through a combination of local address-assignment pools and RADIUS.

When interacting with external back-end RADIUS servers, the AAA Service Framework supports standard RADIUS attributes and Juniper Networks vendor specific attributes (VSAs). The AAA Service Framework also includes an integrated RADIUS client that is compatible with RADIUS servers that conform to RFC-2865, *Remote Authentication Dial In User Service (RADIUS)*, RFC-2866, *RADIUS Accounting*, and RFC-3576, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*, and which can initiate requests.

You create the following types of configurations to manage subscriber access.

- **Authentication**—Authentication parameters defined in the access profile determine the authentication component of the AAA processing. For example, subscribers can be authenticated using an external authentication service such as RADIUS.
- **Accounting**—Accounting parameters in the access profile specify the accounting part of the AAA processing. For example, the parameters determine how the router collects and uses subscriber statistics. You can also configure AAA to enable the router to collect statistics on a per-service session basis for subscribers.
- **RADIUS-initiated dynamic requests**—A list of authentication server IP addresses in the access profile specify the RADIUS servers that can initiate dynamic requests to the router. Dynamic requests include CoA requests, which specify VSA modifications and service changes, and disconnect requests, which terminate subscriber sessions. The list of authentication servers also provide RADIUS-based dynamic service activation and deactivation during subscriber login.

- Address assignment—The AAA Service Framework assigns addresses to subscribers based on the configuration of local address-assignment pools. For example, the AAA framework collaborates with RADIUS servers to assign addresses from the specified pools.
- Subscriber secure policy—RADIUS VSAs and attributes provide RADIUS-initiated traffic mirroring on a per-subscriber basis.

## RADIUS for Subscriber Access Overview

---

- [RADIUS Server Options for Subscriber Access on page 5](#)
- [Global RADIUS Options for Subscriber Access on page 9](#)

## RADIUS Server Options for Subscriber Access

You can specify in an access profile the options that the router uses when communicating with RADIUS authentication and accounting servers for subscriber access.

The following list describes the RADIUS options you can configure:

- **access-loop-id-local**—The Agent-Remote-Id and Agent-Circuit-Id generated locally when these values are not present in the client database. The interface description of the logical interface is used as the Agent-Remote-Id and the interface description portion of the NAS-Port-Id using the format `<underlying-interface-name>:<outer-tag>-<inner-tag>` is used as the Agent-Circuit-Id.

**NOTE:** The NAS-Port-Id format changes (established by `[set access profile profile-name radius options interface-description-format]`) are applied before generating the Agent-Circuit-Id.

The NAS-Port-Id format (established by `[set access profile profile-name radius options interface-description-format]`) leverages the locally generated Agent-Remote-Id and Agent-Circuit-Id.

- **accounting-session-id-format**—The format the router uses to identify the accounting session. The identifier can be in one of the following formats:
  - **decimal**—The default format. For example, `435264`
  - **description**—In the format, `jnpr interface-specifier:subscriber-session-id`. For example, `jnpr fastEthernet 3/2.6:1010101010101`
- **calling-station-id-delimiter**—The character that the router uses as the separator between concatenated values in the Calling-Station-Id string (RADIUS attribute 31).
- **calling-station-id-format**—Optional information that the router includes in the Calling-Station-Id (RADIUS attribute 31).
- **client-accounting-algorithm** and **client-authentication-algorithm**—The method the router uses to access RADIUS accounting and RADIUS authentication servers. You can specify the following methods:
  - **direct**—The default method, in which there is no load balancing. For example, in the direct method, the router always accesses **server1** (the primary server) first, and uses **server2** and **server3** as backup servers.
  - **round-robin**—The method that provides load balancing by rotating router requests among the list of configured RADIUS servers. For example, if three RADIUS servers are configured to support the router, the router sends the first request to **server1**, and uses **server2** and **server3** as backup servers. The router then sends the second request to **server2**, and uses **server3** and **server1** as backups.

**NOTE:** When a RADIUS server in the round-robin list becomes unreachable, the next reachable server in the round-robin list is used for the current request. That same server is also used for the next request because it is at the top of the list of available servers. As a result, after a server failure, the server that is used takes up the load of two servers.

- **coa-dynamic-variable-validation**—The optional method that the router uses when processing CoA requests that include changes to a client profile dynamic variable that cannot be applied. The optional configuration specifies that when a CoA operation is unable to apply a requested change to a client profile dynamic variable, subscriber management does not apply any changes to client profile dynamic variables in the CoA request and then responds with a NACK. In the default method, subscriber management does not apply the incorrect update but does apply the other changes to the client profile dynamic variables, and then responds with an ACK message.
- **ethernet-port-type-virtual**—The physical port type of **virtual** that the router uses to authenticate clients. The port type is passed in RADIUS attribute 61 (NAS-Port-Type). By default the router passes a port type of **ethernet** in RADIUS attribute 61.
- **interface-description-format**—The information that is excluded from the interface description that the router passes to RADIUS for inclusion in the RADIUS attribute 87 (NAS-Port-Id). By default, the router includes the adapter, channel, and subinterface information in the interface description. You can specify:
  - **exclude-adapter**—Exclude the adapter.
  - **exclude-channel**—Exclude the channel information.
  - **exclude-subinterface**—Exclude the subinterface.
- **nas-identifier**—The value for the client RADIUS attribute 32 (NAS-Identifier), which is used for authentication and accounting requests. You can specify a string in the range 1 through 64 characters.
- **nas-port-extended-format**—The extended format for RADIUS attribute 5 (NAS-Port) and for the width of the fields in the NAS-Port attribute that the RADIUS client uses. You can specify:
  - **adapter-width *width***—Number of bits in the adapter field.
  - **port-width *width***—Number of bits in the port field.
  - **pw-width**—Number of bits in the pseudowire field.
  - **slot-width *width***—Number of bits in the slot field.
  - **stacked-vlan-width *width***—Number of bits in the SVLAN ID field.
  - **vlan-width *width***—Number of bits in the VLAN ID field.

**NOTE:** The total of the widths must not exceed 32 bits, or the configuration fails.

You can configure an extended format for the NAS-Port attribute for both Ethernet subscribers and ATM subscribers. For ATM subscribers, you can specify:

- **adapter-width**—Number of bits in the ATM adapter field, in the range 0 through 32
- **port-width**—Number of bits in the ATM port field, in the range 0 through 32
- **slot-width**—Number of bits in the ATM slot field, in the range 0 through 32

- **vci-width**—Number of bits in the ATM virtual circuit identifier (VCI) field, in the range 0 through 32
- **vpi-width**—Number of bits in the ATM virtual path identifier (VPI) field, in the range 0 through 32

**NOTE:** For ATM subscribers, the combined total of the widths of all fields must not exceed 32 bits, or the configuration fails. The router may truncate the values of individual fields depending on the bit width you specify.

- **nas-port-id-delimiter**—The character used as the separator between values in the NAS-Port-Id string.
- **nas-port-id-format**—Optional information included in RADIUS attribute 87 (NAS-Port-Id).
- **nas-port-type**—The port type used to authenticate subscribers.
- **override**—Override the value of RADIUS options or attributes.
  - **calling-station-id remote-circuit-id**—Override the information sent by the LAC to the LNS in L2TP Calling Number AVP 22, when the LAC is already configured to use the Calling-Station-ID value configured with the **calling-station-id-format** statement. You use the **remote-circuit-id-format** option in the access profile to configure the override value.

**NOTE:** For more information about configuring the override, see *Override the Calling-Station-ID Format for the Calling Number AVP*.

- **nas-ip-address tunnel-client-gateway-address**—Check the SDB to determine whether the session's LAC endpoint IP address is available. If so, override the value of the RADIUS NAS-IP-Address attribute (4) at the LNS with that value. Otherwise, use the original NAS IP address in attribute 4.
- **nas-port tunnel-client-nas-port**—Check the SDB to determine whether the LAC NAS port information is conveyed to the LNS in the Cisco Systems NAS Port Info AVP (100). If so, override the value of the RADIUS NAS-Port attribute (5) at the LNS with that value. Otherwise, use the original NAS port information in attribute 5.
- **nas-port-type tunnel-client-nas-port-type**—Check the SDB to determine whether the LAC NAS port information is conveyed to the LNS in the Cisco Systems NAS Port Info AVP (100). If so, override the value of the RADIUS NAS-Port-Type attribute (61) at the LNS with that value. Otherwise, use the original NAS-Port-Type in attribute 61.
- **remote-circuit-id-format**—Format (values) for the string that overrides the Calling-Station-ID format in L2TP Calling Number AVP 22. You configure the LAC to use the ACI, the ARI, or both the ACI and ARI it receives from the PADR packet. These values are referred to as the remote circuit ID values.

## NOTE:

- **remote-circuit-id-delimiter**—The character used as the separator between concatenated values in the override string for Calling Number AVP 22.
- **remote-circuit-id-fallback**—Fallback value used when you have configured the LAC to override the Calling-Station-ID values with the ACI, the ARI, or both the ACI and ARI, but these remote circuit ID values are not received in the PADR packet.

You can specify either of the following as the fallback value:

- **configured-calling-station-id**—Use the value configured with the **calling-station-id-format** statement.
- **default**—Use the underlying interface.
- **revert-interval**—The number of seconds that the router waits after a server has become unreachable. The router rechecks the connection to the server when the **revert-interval** expires. If the server is then reachable, it is used in accordance with the order of the server list. You can configure from 0 (off) through 604800 seconds. The default is 60 seconds.
- **service-activation**—Setting that determines whether newly authenticated subscriber can successfully log in when service activation failures related to configuration errors occur during authd processing of the activation request for the subscriber's address family. You can specify this behavior for services configured in dynamic profiles (**dynamic-profile**) or in Extensible Subscriber Services Manager (ESSM) operation scripts (**extensible-service**):
  - **optional-at-login**—Service activation is optional. Activation failure due to configuration errors does not prevent activation of the address family; it allows subscriber access. Service activation failures due to causes other than configuration errors cause network family activation to fail. The login attempt is terminated unless another address family is already active for the subscriber. This is the default behavior for the **extensible-service** service type.
  - **required-at-login**—Service activation is required. Activation failure for any reason causes network family activation to fail. The login attempt is terminated unless another address family is already active for the subscriber. This is the default value for the **dynamic-profile** service type.
- **vlan-nas-port-stacked-format**—The format that turns off RADIUS attribute 5 (NAS-Port) to include the S-VLAN ID, in addition to the VLAN ID, for subscribers on Ethernet interfaces.

## Global RADIUS Options for Subscriber Access

You can specify options that the router uses when communicating with all configured RADIUS servers for subscriber access.

The following list describes the global RADIUS options you can configure:

- **revert-interval**—The number of seconds that the router waits after a server has become unreachable. The router rechecks the connection to the server when the **revert-interval** expires. If the server is then reachable, it is used in accordance with the order of the server list. You can configure from 0 (off) through 604800 seconds. The default is 60 seconds.
- **request-rate**—The number of requests per second that the router can send to all configured RADIUS servers collectively. By limiting the flow of requests from the router to the RADIUS servers, you can prevent the RADIUS servers from being flooded with requests. You can configure from 100 through 4000 requests per second. The default is 500 requests per second.
- **timeout-grace**—The duration of a period during which unresponsive RADIUS authentication servers are not yet considered to be unreachable or down. You can vary the period depending on whether you want to redirect authentication requests more quickly to another server or provide the unresponsive server more time to recover and respond. You can configure a duration from 0 through 30 seconds; the default period is 10 seconds.

## RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework

The AAA Service Framework supports RADIUS attributes and vendor-specific attributes (VSAs). This support provides tunable parameters that the subscriber access management feature uses when creating subscribers and services.

RADIUS attributes are carried as part of standard RADIUS request and reply messages. The subscriber management access feature uses the RADIUS attributes to exchange specific authentication, authorization, and accounting information. VSAs allow the subscriber access management feature to pass implementation-specific information that provide extended capabilities, such as service activation or deactivation, and enabling and disabling filters.

When you use dynamic profiles, the AAA Service Framework supports the use of Junos OS predefined variables to specify the RADIUS attribute or VSA for the information obtained from the RADIUS server.

## RADIUS IETF Attributes Supported by the AAA Service Framework

Table 3 on page 11 describes the RADIUS IETF attributes that the Junos OS AAA Service Framework supports. Some attributes correspond to Juniper Networks predefined variables; see *Junos OS Predefined Variables That Correspond to RADIUS Attributes and VSAs*

**NOTE:** A “Yes” entry in the Dynamic CoA Support column indicates that the attribute can be dynamically configured by Access-Accept messages and dynamically modified by CoA-Request messages.

**Table 3: Supported RADIUS IETF Attributes**

Attribute Number	Attribute Name	Description	Dynamic CoA Support
1	User-Name	<ul style="list-style-type: none"> <li>Name of user to be authenticated.</li> <li>Configurable username override.</li> <li>Non-standard use for LLID preauthentication feature.</li> </ul>	No
2	User-Password	<ul style="list-style-type: none"> <li>Password of user to be authenticated by Password Authentication Protocol (PAP).</li> <li>Configurable password override.</li> <li>Non-standard use for LLID preauthentication feature.</li> </ul>	No
3	CHAP-Password	Value provided by a PPP (CHAP) user in response to the challenge.	No
4	NAS-IP-Address	IP address of the network access server (NAS) that is requesting authentication of the user.	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
5	NAS-Port	Physical port number of the NAS that is authenticating the user.  For a tunneled PPP user in an L2TP LNS session, there is no physical port. In this case, the port value is reported as 4194303.	No
6	Service-Type	Type of service the user has requested or the type of service to be provided.	No
7	Framed-Protocol	Framing type used for framed access.	No
8	Framed-IP-Address	<ul style="list-style-type: none"> <li>IP address to be configured for the user.</li> <li>0.0.0.0 or absence is interpreted as 255.255.255.254.</li> </ul>	No
9	Framed-IP-Netmask	<ul style="list-style-type: none"> <li>IP network to be configured for the user when the user is a router or switch to a network.</li> <li>Absence implies 255.255.255.255.</li> </ul>	No
11	Filter-Id	<p>Name of a subscriber firewall filter, formatted as follows:</p> <ul style="list-style-type: none"> <li>For an IPv4 input filter—IPv4-ingress:<i>ingress-filter-name</i></li> <li>For an IPv4 output filter—IPv4-egress:<i>egress-filter-name</i></li> <li>For an IPv6 input filter—IPv6-ingress:<i>ingress-filter-name</i></li> <li>For an IPv6 output filter—IPv6-egress:<i>egress-filter-name</i></li> </ul> <p>RADIUS accounting request messages, Acct-Start and Acct-Stop, can include more than one Filter-Id attribute, one of each of the listed types.</p> <p>However, RADIUS Access-Accept messages can include only one attribute instance. The value is always treated as an IPv4 input filter name.</p>	Yes
12	Framed-MTU	Maximum Transmission Unit configured for the user, when it is not negotiated by some other means (such as PPP).	No
18	Reply-Message	<ul style="list-style-type: none"> <li>Text that may be displayed to the user.</li> <li>Only the first instance of this attribute is used.</li> </ul>	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
22	Framed-Route	String that provides routing information to be configured for the user on the NAS in the format:  <code>&lt;addr&gt;[/&lt;maskLen&gt;] [&lt;nexthop&gt; [&lt;cost&gt;]] [tag &lt;tagValue&gt;] [distance &lt;distValue&gt;]</code>  Starting in Junos OS Release 18.2R1, if this attribute does not include the subnet mask, the MX Series router ignores the attribute but connects the session.	Yes
24	State	String enabling state information to be maintained between the device and the RADIUS server.	No
25	Class	Arbitrary value that the NAS includes in all accounting packets for the user if supplied by the RADIUS server.	No
27	Session-Timeout	Maximum number of consecutive seconds of service to be provided to the user before termination of the session.	No
28	Idle-Timeout	Maximum number of consecutive seconds of idle connection allowed to the user before termination of the session or prompt.	No
31	Calling-Station-ID	Phone number from which the call originated.	No
32	NAS-Identifier	NAS originating the request.	No
40	Acct-Status-Type	Whether this Accounting-Request marks the beginning of the user service (Start), the end (Stop), or the interim (Interim-Update).	No
41	Acct-Delay-Time	Number of seconds the client has been trying to send a particular record.	No
42	Acct-Input-Octets	Number of octets that have been received from the port during the time this service has been provided.	No
43	Acct-Output-Octets	Number of octets that have been sent to the port during the time this service has been provided.	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
44	Acct-Session-ID	<p>Unique accounting identifier that makes it easy to match start and stop records in a log file. The identifier can be in one of the following formats:</p> <ul style="list-style-type: none"> <li><b>decimal</b>—For example, 435264</li> <li><b>description</b>—In the generic format, <i>jnpr interface-specifier:subscriber-session-id</i>; For example, <i>jnpr fastEthernet 3/2.6:1010101010101</i></li> </ul>	No
45	Acct-Authentic	Method by which user was authentication: whether by RADIUS, the NAS itself, or another remote authentication protocol.	No
46	Acct-Session-Time	Number of seconds that the user has received service	No
47	Acct-Input-Packets	Number of packets that have been received from the port during the time this service has been provided to a framed user.	No
48	Acct-Output-Packets	Number of packets that have been sent to the port in the course of delivering this service to a framed user.	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
49	Acct-Terminate-Cause	Reason the service (a PPP session) was terminated. The service can be terminated for the following reasons: <ul style="list-style-type: none"> <li>• User Request (1)—User initiated the disconnect (log out).</li> <li>• Idle Timeout (4)—Idle timer has expired.</li> <li>• Session Timeout (5)—Client reached the maximum continuous time allowed on the service or session.</li> <li>• Admin Reset (6)—System administrator terminated the session.</li> <li>• Port Error (8)—PVC failed; no hardware or no interface.</li> <li>• NAS Error (9)—Negotiation failures, connection failures, or address lease expiration.</li> <li>• NAS Request (10)—PPP challenge timeout, PPP request timeout, tunnel establishment failure, PPP bundle failure, IP address lease expiration, PPP keep-alive failure, tunnel disconnect, or an unaccounted-for error.</li> </ul>	No
52	Acct-Input-Gigawords	Number of times the Acct-Input-Octets counter has wrapped around $2^{32}$ during the time this service has been provided. Can be present in Accounting-Request records only where the Acct-Status-Type is set to Stop or Interim-Update.	No
53	Acct-Output-Gigawords	Number of times the Acct-Output-Octets counter has wrapped around $2^{32}$ in the course of delivering this service. Can be present in Accounting-Request records only where the Acct-Status-Type is set to Stop or Interim-Update.	No
55	Event-Timestamp	Time that this event occurred on the NAS, in seconds, since January 1, 1970 00:00 UTC.	No
61	NAS-Port-Type	Type of physical port the NAS is using to authenticate the user.  For a tunneled PPP user in an L2TP LNS session, there is no physical port. In this case, the port type is <b>Virtual</b> .	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
64	Tunnel-Type	<ul style="list-style-type: none"> <li>Tunneling protocol to use (in the case of a tunnel initiator) or the tunneling protocol already in use (in the case of a tunnel terminator).</li> <li>Only L2TP tunnels are currently supported.</li> </ul>	No
65	Tunnel-Medium-Type	<ul style="list-style-type: none"> <li>Transport medium to use when creating a tunnel for protocols that can operate over multiple transports.</li> <li>Only IPv4 is currently supported.</li> </ul>	No
66	Tunnel-Client-Endpoint	Address of the initiator end of the tunnel (LAC).	No
67	Tunnel-Server-Endpoint	Address of the server end of the tunnel (LNS).	No
68	Acct-Tunnel-Connection	Identifier assigned to the tunnel session. Value is the same as the Call Serial Number AVP received from the LAC in the ICRQ message.	No
69	Tunnel-Password	Encrypted password used to authenticate to a remote server. Recommended over using VSA Tunnel-Password [26-9] because of the encryption. Do not use both this attribute and the VSA.	No
77	Connect-Info	<ul style="list-style-type: none"> <li>Information sent from the NAS that describes the subscriber's connection, such as transmit speed.</li> <li>Non-standard use for LLID preauthentication feature.</li> </ul>	No
82	Tunnel-Assignment -Id	Tunnel to which a session is assigned. When user profiles share the same values for Tunnel-Assignment-Id, Tunnel-Server-Endpoint, and Tunnel-Type, the LAC can group these users into the same tunnel. This grouping enables fewer tunnels to be created. (LAC)	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
83	Tunnel-Preference	<ul style="list-style-type: none"> <li>Included in each set of tunneling attributes to indicate the relative preference assigned to each tunnel when more than one set of tunneling attributes is returned by the RADIUS server to the tunnel initiator.</li> <li>Included in the Tunnel-Link-Start, the Tunnel-Link-Reject, and the Tunnel-Link-Stop packets (LAC only).</li> </ul>	No
85	Acct-Interim-Interval	<p>Number of seconds between each interim accounting update for this session.</p> <p>The router uses the following guidelines for interim accounting:</p> <ul style="list-style-type: none"> <li>Attribute value is within the acceptable range (from 600 through 86,400 seconds)—Accounting is updated at the specified interval.</li> <li>Attribute value of 0—No RADIUS accounting is performed.</li> <li>Attribute value is less than the minimum acceptable value—Accounting is updated at the minimum interval (600 seconds).</li> <li>Attribute value is greater than the maximum acceptable value—Accounting is updated at the maximum interval (86,400 seconds).</li> </ul> <p><b>NOTE:</b> Values are rounded up to the next higher multiple of 10 minutes. For example, a setting of 900 seconds (15 minutes) is rounded up to 20 minutes (1200 seconds).</p>	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
87	NAS-Port-Id	Text string that identifies the physical interface of the NAS that is authenticating the user.  For a tunneled PPP user in an L2TP LNS session, there is no physical port, and the NAS-Port-Id value has the following format: <i>media:local address:peer address:local tunnel id:peer tunnel id:local session id:peer session id:call serial number</i> . For example, Ip:198.51.100.1:192.168.0.2:3341:21031:16138:11846:2431. The local information refers to the LNS and the peer information refers to the LAC.	No
88	Framed-Pool	Name of an assigned address pool to use to assign an address for the user.	No
90	Tunnel-Client-Auth-Id	Name of the tunnel initiator (LAC) used during the authentication phase of tunnel establishment.	No
91	Tunnel-Server-Auth-Id	Name of the tunnel terminator (LNS) used during the authentication phase of tunnel establishment.	No
95	NAS-IPv6-Address	Address of the NAS that is requesting authentication of the user.	No
96	Framed-Interface-ID	Interface identifier that is configured for the user.	No
97	Framed-IPv6-Prefix	IPv6 prefix and address that are configured for the user. Prefix lengths of 128 are associated with host addresses. Prefix lengths less than 128 are associated with NDRA prefixes.	No
98	Login-IPv6-Host	System the user connects to when the Login-Service attribute is included.	No
99	Framed-IPv6-Route	IPv6 routing information that is configured for the user.	Yes
100	Framed-IPv6-Pool	Name of the assigned pool used to assign the address and IPv6 prefix for the user.	No

Table 3: Supported RADIUS IETF Attributes (continued)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
101	Error-Cause	Reason that the RADIUS server does not honor Disconnect-Request or CoA-Request messages. Depending on the value, can be included in COA or Disconnect NAK messages. <ul style="list-style-type: none"> <li>• 201—Residual Session Context Removed (Disconnect ACK only)</li> <li>• 202—Invalid EAP Packet (Ignored)</li> <li>• 401—Unsupported Attribute; request contains unsupported attribute.</li> <li>• 402—Missing Attribute; critical attribute missing from request</li> <li>• 403—NAS Identification Mismatch</li> <li>• 404—Invalid Request</li> <li>• 405—Unsupported Service</li> <li>• 406—Unsupported Extension</li> <li>• 407—Invalid Attribute Value</li> <li>• 501—Administratively Prohibited</li> <li>• 502—Request Not Routable (Proxy)</li> <li>• 503—Session Context Not Found</li> <li>• 504—Session Context Not Removable</li> <li>• 505—Other Proxy Processing Error</li> <li>• 506—Resources Unavailable</li> <li>• 507—Request Initiated</li> <li>• 508—Multiple Session Selection Unsupported</li> </ul>	Yes
123	Delegated-IPv6-Prefix	IPv6 prefix that is delegated to the user.	No
168	Framed-IPv6-Address	IPv6 address of the authenticated user. The Framed-IPv6-Address attribute is sent if the IPv6 address is assigned to the subscriber.	No
242	Ascend-Data-Filter	Binary data that specifies RADIUS policy definitions.	Yes

## Juniper Networks VSAs Supported by the AAA Service Framework

Table 4 on page 20 describes Juniper Networks VSAs supported by the Junos OS AAA Service Framework. The AAA Service Framework uses vendor ID 4874, which is assigned to Juniper Networks by the Internet Assigned Numbers Authority (IANA). Some VSAs correspond to Juniper Networks predefined variables; see *Junos OS Predefined Variables That Correspond to RADIUS Attributes and VSAs*.

**NOTE:** A “Yes” entry in the Dynamic CoA Support column indicates that the attribute can be dynamically configured by Access-Accept messages and dynamically modified by CoA-Request messages.

**Table 4: Supported Juniper Networks VSAs**

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-1	Virtual-Router	<p>Client logical system:routing instance name. Allowed only from AAA server for default logical system:routing instance.</p> <p>When this VSA is not included in the subscriber profile, the routing instance assigned to the subscriber—the one in which the subscriber session comes up—varies by subscriber type.</p> <p>For DHCP and PPPoE subscribers, it is the default routing instance.</p> <p>For L2TP tunnel subscribers, it is the routing instance in which the tunnel resides, whether default or non-default. If the tunnel routing instance is not default and you want the L2TP session to be in the default routing instance, you must use the Virtual-Router VSA to set the desired routing instance.</p>	string: <i>logical system:routing instance</i>	No
26-4	Primary-DNS	Client DNS address negotiated during IPCP.	integer: 4-byte <i>primary-dns-address</i>	No
26-5	Secondary-DNS	Client DNS address negotiated during IPCP	integer: 4-byte <i>secondary-dns-address</i>	No
26-6	Primary-WINS	Client WINS (NBNS) address negotiated during IPCP.	integer: 4-byte <i>primary-wins-address</i>	No
26-7	Secondary-WINS	Client WINS (NBNS) address negotiated during IPCP.	integer: 4-byte <i>secondary-wins-address</i>	No
26-8	Tunnel-Virtual-Router	Virtual router name for tunnel connection.	string: <i>tunnel-virtual-router</i>	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-9	Tunnel-Password	Tunnel password in cleartext.  Do not use both this VSA and the standard RADIUS attribute Tunnel-Password [69]. We recommend that you use the standard attribute because the password is encrypted when that attribute is used.	string: <i>tunnel-password</i>	No
26-10	Ingress-Policy-Name	Input policy name to apply to client interface.	string: <i>input-policy-name</i>	Yes
26-11	Egress-Policy-Name	Output policy name to apply to client interface.	string: <i>output-policy-name</i>	Yes
26-23	IGMP-Enable	Whether IGMP is enabled or disabled on a client interface.	integer: <ul style="list-style-type: none"> <li>0=disable</li> <li>1=enable</li> </ul>	Yes
26-24	PPPoE-Description	Client MAC address.	string: <i>pppoe client-mac-address</i>	No
26-25	Redirect-VRouter-Name	Client logical system:routing instance name indicating to which logical system:routing instance the request is redirected for user authentication.	string: <i>logical-system:routing-instance</i>	No
26-30	Tunnel-Nas-Port-Method	Method that determines whether the RADIUS server conveys to the LNS the physical NAS port number identifier and the type of the physical port, such as Ethernet or ATM. This information is conveyed only when the VSA value is 1.  The VSA is formatted such that the first octet indicates the tunnel and the remaining three bytes are the attribute value.	4-octet integer: <ul style="list-style-type: none"> <li>0 = none</li> <li>1 = Cisco CLID</li> </ul>	Yes
26-31	Service-Bundle	SSC service bundle.	string <i>bundle-name</i>	No
26-33	Tunnel-Max-Sessions	Maximum number of sessions allowed in a tunnel.	integer: 4-octet	No
26-34	Framed-IP-Route-Tag	Route tag to apply to returned framed-ip-address.	integer: 4-octet	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-42	Input-Gigapackets	Number of times the input-packets attribute rolls over its 4-octet field.	integer	No
26-43	Output-Gigapackets	Number of times the output-packets attribute rolls over its 4-octet field.	integer	No
26-47	Ipv6-Primary-DNS	Client primary IPv6 DNS address negotiated by DHCP.	hexadecimal string: <i>ipv6-primary-dns-address</i>	No
26-48	Ipv6-Secondary-DNS	Client secondary IPv6 DNS address negotiated by DHCP.	hexadecimal string: <i>ipv6-secondary-dns-address</i>	No
26-51	Disconnect-Cause	Disconnect cause when a tunneled subscriber is disconnected, and L2TP layer of the LNS initiates the termination. The PPP Disconnect Cause Code (L2TP AVP 46) is included in VSA 26-51 in the Accounting-Stop message that the router sends to the RADIUS server.	hexadecimal string: <i>disconnect-cause</i>	No
26-55	DHCP-Options	Client DHCP options.  Starting in Junos OS Release 17.4R1, includes only DHCPv4 options. In earlier releases, includes both DHCPv4 and DHCPv6 options.	string: <i>dhcp-options</i>	No
26-56	DHCP-MAC-Address	Client MAC address.	string: <i>mac-address</i>	No
26-57	DHCP-GI-Address	DHCP relay agent IP address.	integer: 4-octet	No
26-58	LI-Action	Traffic mirroring action.  For dynamic CoA, VSA 26-58 changes the action on the mirrored traffic identified by VSA 26-59.  CoA-Request messages that include any of the RADIUS-based mirroring attributes (VSAs 26-58, 26-59, 26-60, or 26-61) must always include all four VSAs.  If the CoA action is to stop mirroring (VSA 26-58 value is 0), then the values of the other three attributes in the CoA message must match the existing attribute values, or the action fails.	salt-encrypted integer  0=stop mirroring 1=start mirroring 2=no action	Yes

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-59	Med-Dev-Handle	<p>Identifier that associates mirrored traffic to a specific subscriber.</p> <p>For dynamic CoA, VSA 26-58 changes the action on the mirrored traffic identified by VSA 26-59.</p> <p>CoA-Request messages that include any of the RADIUS-based mirroring attributes (VSAs 26-58, 26-59, 26-60, or 26-61) must always include all four VSAs.</p>	salt-encrypted string	No
26-60	Med-Ip-Address	<p>IP address of content destination device to which mirrored traffic is forwarded.</p> <p>CoA-Request messages that include any of the RADIUS-based mirroring attributes (VSAs 26-58, 26-59, 26-60, or 26-61) must always include all four VSAs.</p>	salt-encrypted IP address	No
26-61	Med-Port-Number	<p>UDP port in the content destination device to which mirrored traffic is forwarded.</p> <p>CoA-Request messages that include any of the RADIUS-based mirroring attributes (VSAs 26-58, 26-59, 26-60, or 26-61) must always include all four VSAs.</p>	salt-encrypted integer	No
26-63	Interface-Desc	Text string that identifies the subscriber's access interface.	string: <i>interface-description</i>	No
26-64	Tunnel-Group	Name of the tunnel group (profile) assigned to a domain map.	string: <i>tunnel-group-name</i>	No
26-65	Activate-Service	Service to activate for the subscriber. Tagged VSA, which supports 8 tags (1-8).	string: <i>service-name</i>	Yes
26-66	Deactivate-Service	Service to deactivate for the subscriber.	string: <i>service-name</i>	Yes
26-67	Service-Volume	Amount of traffic, in MB, that can use the service; service is deactivated when the volume is exceeded. Tagged VSA, which supports 8 tags (1-8).	<p>integer</p> <ul style="list-style-type: none"> <li>range = 0 through 16777215 MB</li> <li>0 = no limit</li> </ul>	Yes

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-68	Service-Timeout	Number of seconds that the service can be active; service is deactivated when the timeout expires. Tagged VSA, which supports 8 tags (1-8).	integer <ul style="list-style-type: none"> <li>range = 0 through 16777215 seconds</li> <li>0 = no timeout</li> </ul>	Yes
26-69	Service-Statistics	Whether statistics for the service is enabled or disabled. Tagged VSA, which supports 8 tags (1-8).	integer <ul style="list-style-type: none"> <li>0 = disable</li> <li>1 = enable time statistics</li> <li>2 = enable time and volume statistics</li> </ul>	Yes
26-71	IGMP-Access-Name	Access list to use for the group (G) filter.	string: 32-octet	Yes
26-72	IGMP-Access-Src-Name	Access list to use for the source-group (S,G) filter.	string: 32-octet	Yes
26-74	MLD-Access-Name	Access list to use for the group (G) filter.	string: 32-octet	Yes
26-75	MLD-Access-Src-Name	Access list to use for the source-group (S,G) filter.	string: 32-octet	Yes
26-77	MLD-Version	MLD protocol version.	integer: 1-octet <ul style="list-style-type: none"> <li>1=MLD version 1</li> <li>2=MLD version 2</li> </ul>	Yes
26-78	IGMP-Version	IGMP protocol version.	integer: 1-octet <ul style="list-style-type: none"> <li>1=IGMP version 1</li> <li>2=IGMP version 2</li> <li>3=IGMP version 3</li> </ul>	Yes
26-83	Service-Session	Name of the service.	string: <i>service-name</i>	No
26-91	Tunnel-Switch-Profile	Tunnel switch profile that determines whether a subscriber session is switched to a second session to a remote LNS. Takes precedence over tunnel switch profiles applied in any other manner.	string: <i>profile-name</i>	No
26-92	L2C-Up-Stream-Data	Actual upstream rate access loop parameter (ASCII encoded) as defined in GSMP extensions for layer2 control (L2C) Topology Discovery and Line Configuration.	string: actual upstream rate access loop parameter (ASCII encoded)	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-93	L2C-Down-Stream-Data	Actual downstream rate access loop parameter (ASCII encoded) as defined in GSMP extensions for layer2 control (L2C) Topology Discovery and Line Configuration.	string: actual downstream rate access loop parameter (ASCII encoded)	No
26-94	Tunnel-Tx-Speed-Method	Method that determines the source from which the transmit speed is derived. Overrides global configuration in the CLI.	integer: 4-octet <ul style="list-style-type: none"> <li>• 0 = none</li> <li>• 1 = static Layer 2</li> <li>• 2 = dynamic layer 2. This method is not supported; the static Layer 2 method is used instead.</li> <li>• 3 = CoS. This method is not supported; the actual method is used instead.</li> <li>• 4 = actual</li> <li>• 5 = ANCP</li> <li>• 6 = PPPoE IA tags</li> </ul>	No
26-97	IGMP-Immediate-Leave	IGMP Immediate Leave.	integer: 4-octet <ul style="list-style-type: none"> <li>• 0=disable</li> <li>• 1=enable</li> </ul>	Yes
26-100	MLD-Immediate-Leave	MLD Immediate Leave.	integer: 4-octet <ul style="list-style-type: none"> <li>• 0=disable</li> <li>• 1=enable</li> </ul>	Yes
26-106	IPv6-Ingress-Policy-Name	Input policy name to apply to a user IPv6 interface.	string: <i>policy-name</i>	Yes
26-107	IPv6-Egress-Policy-Name	Output policy name to apply to a user IPv6 interface.	string: <i>policy-name</i>	Yes

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-108	CoS-Parameter-Type	CoS traffic-shaping parameter type and description: <ul style="list-style-type: none"> <li><b>T01:</b> Scheduler-map name</li> <li><b>T02:</b> Shaping rate</li> <li><b>T03:</b> Guaranteed rate</li> <li><b>T04:</b> Delay-buffer rate</li> <li><b>T05:</b> Excess rate</li> <li><b>T06:</b> Traffic-control profile</li> <li><b>T07:</b> Shaping mode</li> <li><b>T08:</b> Byte adjust</li> <li><b>T09:</b> Adjust minimum</li> <li><b>T10:</b> Excess-rate high</li> <li><b>T11:</b> Excess-rate low</li> <li><b>T12:</b> Shaping rate burst</li> <li><b>T13:</b> Guaranteed rate burst</li> </ul>	Two parts, delimited by white space: <ul style="list-style-type: none"> <li>Parameter type</li> <li>Parameter value</li> </ul> Examples: <ul style="list-style-type: none"> <li><b>T01 smap_basic</b></li> <li><b>T02 50m</b></li> <li><b>T03 1m</b></li> <li><b>T04 2000</b></li> <li><b>T05 200</b></li> <li><b>T06 tcp-gold</b></li> <li><b>T07 frame-mode</b></li> <li><b>T08 50</b></li> </ul>	Yes
26-109	DHCP-Guided-Relay-Server	IP address of DHCP server that DHCP relay agent uses to forward the discover PDUs.	integer: 4-byte <i>ip-address</i>	No
26-110	Acc-Loop-Cir-Id	Identification of the subscriber node connection to the access node.	string: up to 63 ASCII characters	No
26-111	Acc-Aggr-Cir-Id-Bin	Unique identification of the DSL line.	integer: 8-octet	No
26-112	Acc-Aggr-Cir-Id-Asc	Identification of the uplink on the access node, as in the following examples: <ul style="list-style-type: none"> <li>Ethernet access aggregation—<b>ethernet slot/port [:inner-vlan-id] [:outer-vlan-id]</b></li> <li>ATM aggregation—<b>atm slot/port:vpi.vci</b></li> </ul>	string: up to 63 ASCII characters	No
26-113	Act-Data-Rate-Up	Actual upstream data rate of the subscriber's synchronized DSL link.	integer: 4-octet	No
26-114	Act-Data-Rate-Dn	Actual downstream data rate of the subscriber's synchronized DSL link.	integer: 4-octet	No
26-115	Min-Data-Rate-Up	Minimum upstream data rate configured for the subscriber.	integer: 4-octet	No
26-116	Min-Data-Rate-Dn	Minimum downstream data rate configured for the subscriber.	integer: 4-octet	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-117	Att-Data-Rate-Up	Maximum upstream data rate that the subscriber can attain.	integer: 4-octet	No
26-118	Att-Data-Rate-Dn	Maximum downstream data rate that the subscriber can attain.	integer: 4-octet	No
26-119	Max-Data-Rate-Up	Maximum upstream data rate configured for the subscriber.	integer: 4-octet	No
26-120	Max-Data-Rate-Dn	Maximum downstream data rate configured for the subscriber.	integer: 4-octet	No
26-121	Min-LP-Data-Rate-Up	Minimum upstream data rate in low power state configured for the subscriber.	integer: 4-octet	No
26-122	Min-LP-Data-Rate-Dn	Minimum downstream data rate in low power state configured for the subscriber.	integer: 4-octet	No
26-123	Max-Interlv-Delay-Up	Maximum one-way upstream interleaving delay configured for the subscriber.	integer: 4-octet	No
26-124	Act-Interlv-Delay-Up	Subscriber's actual one-way upstream interleaving delay..	integer: 4-octet	No
26-125	Max-Interlv-Delay-Dn	Maximum one-way downstream interleaving delay configured for the subscriber.	integer: 4-octet	No
26-126	Act-Interlv-Delay-Dn	Subscriber's actual one-way downstream interleaving delay.	integer: 4-octet	No
26-127	DSL-Line-State	State of the DSL line.	integer: 4-octet <ul style="list-style-type: none"> <li>• 1 = Show uptime</li> <li>• 2 = Idle</li> <li>• 3 = Silent</li> </ul>	No
26-128	DSL-Type	Encapsulation used by the subscriber associated with the DSLAM interface from which requests are initiated.	integer: 4-octet	No
26-130	Qos-Set-Name	Interface set to apply to the dynamic profile.	string: <i>interface-set-name</i>	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-140	Service-Interim-Acct-Interval	Amount of time between interim accounting updates for this service. Tagged VSA, which supports 8 tags (1-8).	<ul style="list-style-type: none"> <li>range = 600 through 86400 seconds</li> <li>0 = disabled</li> </ul> <p><b>NOTE:</b> Values are rounded up to the next higher multiple of 10 minutes. For example, a setting of 900 seconds (15 minutes) is rounded up to 20 minutes (1200 seconds).</p>	Yes
26-141	Downstream-Calculated-QoS-Rate	Calculated (adjusted) downstream QoS rate in Kbps as set by the ANCP configuration.	range = 1000 through 4,294,967,295	No
26-142	Upstream-Calculated-QoS-Rate	Calculated (adjusted) upstream QoS rate in Kbps as set by the ANCP configuration.	range = 1000 through 4,294,967,295	No
26-143	Max-Clients-Per-Interface	Maximum allowable client sessions per interface. For DHCP clients, this value is the maximum sessions per logical interface. For PPPoE clients, this value is the maximum sessions (PPPoE interfaces) per PPPoE underlying interface.	integer: 4-octet	No
26-146	CoS-Scheduler-Pmt-Type	<p>CoS scheduler parameter type and description:</p> <ul style="list-style-type: none"> <li>Null: CoS scheduler name</li> <li><b>T01:</b> CoS scheduler transmit rate</li> <li><b>T02:</b> CoS scheduler buffer size</li> <li><b>T03:</b> CoS scheduler priority</li> <li><b>T04:</b> CoS scheduler drop-profile low</li> <li><b>T05:</b> CoS scheduler drop-profile medium-low</li> <li><b>T06:</b> CoS scheduler drop-profile medium-high</li> <li><b>T07:</b> CoS scheduler drop-profile high</li> <li><b>T08:</b> CoS scheduler drop-profile any</li> </ul>	<p>Three parts, delimited by white space:</p> <ul style="list-style-type: none"> <li>Scheduler name</li> <li>Parameter type</li> <li>Parameter value</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li><b>be_sched</b></li> <li><b>be_sched T01 12m</b></li> <li><b>be_sched T02 26</b></li> </ul>	Yes
26-151	IPv6-Acct-Input-Octets	IPv6 receive octets.	integer	No
26-152	IPv6-Acct-Output-Octets	IPv6 transmit octets.	integer	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-153	IPv6-Acct-Input-Packets	IPv6 receive packets.	integer	No
26-154	IPv6-Acct-Output-Packets	IPv6 transmit packets.	integer	No
26-155	IPv6-Acct-Input-Gigawords	IPv6 receive gigawords.	integer	No
26-156	IPv6-Acct-Output-Gigawords	IPv6 transmit gigawords.	integer	No
26-158	PPPoE-Padn	Route add for PPPoE sessions	string	No
26-160	Vlan-Map-Id	Trunk VLAN tag corresponding to the core-facing trunk physical interface.  Vlan-Map-Id (26-160), Inner-Vlan-Map-Id (26-184), and Core-Facing-Interface (26-185) collectively represent the network service provider-facing location for the subscriber for the Layer 2 cross-connect in a Layer 2 wholesale configuration.	integer	No
26-161	IPv6-Delegated-Pool-Name	Address pool used to locally allocate a delegated prefix (IA_PD).	string	No
26-162	Tx-Connect-Speed	Indication of transmit speed of the user's connection.	string	No
26-163	Rx-Connect-Speed	Indication of receive speed of the user's connection.	string	No
26-164	IPv4-Release-Control	Indicates to server status of on-demand address allocation and deallocation.	string	No
26-173	Service-Activate-Type	Indication of service activation type. This is a tagged attribute.	integer: 4-octet <ul style="list-style-type: none"><li>• 1 = dynamic-profile for residential services</li><li>• 2 = op-script for business services</li></ul>	No
26-174	Client-Profile-Name	Enables RADIUS to override an assigned client dynamic profile with the included profile.	string	No
26-177	Cos-Shaping-Rate	Effective downstream shaping rate for subscriber.	string	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-179	Service-Volume-Gigawords	Amount of traffic, in 4GB units, that can use the service; service is deactivated when the volume is exceeded. Tagged VSA, which supports 8 tags (1-8).	integer <ul style="list-style-type: none"> <li>range = 0 through 16777215 4GB units</li> <li>0 = no limit</li> </ul>	Yes
26-180	Update-Service	New values of service and time quotas for existing service. Tagged VSA, which supports 8 tags (1-8).	string: <i>service-name</i>	Yes
26-181	DHCPv6-Guided-Relay-Server	IPv6 addresses of DHCPv6 servers to which DHCPv6 relay agent forwards the Solicit and subsequent PDUs. Use multiple instances of the VSA to specify a list of servers.	hexadecimal string: <i>ipv6-address</i>	No
26-182	Acc-Loop-Remote-Id	Reports the ANCP Access-Loop-Remote-ID attribute.	string	No
26-183	Acc-Loop-Encap	Reports the ANCP Access-Loop-Encapsulation attribute.	hexadecimal string	No
26-184	Inner-Vlan-Map-Id	<p>Inner VLAN tag allocated from the ranges provisioned on the core-facing physical interface, used to swap (replace) the autosensed VLAN tag on the access interface.</p> <p>Vlan-Map-Id (26-160), Inner-Vlan-Map-Id (26-184), and Core-Facing-Interface (26-185) collectively represent the network service provider-facing location for the subscriber for the Layer 2 cross-connect in a Layer 2 wholesale configuration.</p>	integer	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-185	Core-Facing-Interface	Name of the core-facing physical interface that forwards the Layer 2 wholesale session's downstream and upstream traffic relative to the network service provider (NSP) router.  Vlan-Map-Id (26-160), Inner-Vlan-Map-Id (26-184), and Core-Facing-Interface (26-185) collectively represent the network service provider-facing location for the subscriber for the Layer 2 cross-connect in a Layer 2 wholesale configuration.	string	No
26-189	DHCP-First-Relay-IPv4-Address	IPv4 address of the first relay link of a client/server binding.	integer: 4-byte <i>ip-address</i>	No
26-190	DHCP-First-Relay-IPv6-Address	IPv6 address of the first relay link of a client/server binding.	hexadecimal string: <i>ipv6-address</i>	No
26-191	Input-Interface-Filter	Name of an input filter to be attached to a <b>family any</b> interface.	string	Yes
26-192	Output-Interface-Filter	Name of an output filter to be attached to a <b>family any</b> interface.	string	Yes
26-193	Pim-Enable	Enable or disable PIM on a BRAS user's interface.	integer: 4-octet <ul style="list-style-type: none"><li>• 0 = disable</li><li>• any nonzero value = enable</li></ul>	Yes
26-194	Bulk-CoA-Transaction-Id	A common identifier or tag to associate the series of related CoA Requests as a transaction. This attribute is untagged and value 0 is reserved.	integer: 4-octet	Yes
26-195	Bulk-CoA-Identifier	A unique identifier for each CoA Request message that is part of the same transaction as specified by the Bulk-CoA-Transaction-Id VSA. This attribute is untagged and the value 0 is reserved.	integer: 4-octet	Yes
26-196	IPv4-Input-Service-Set	Name of an IPv4 input service set to be attached.	string	Yes
26-197	IPv4-Output-Service-Set	Name of an IPv4 output service set to be attached.	string	Yes

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-198	IPv4-Input-Service-Filter	Name of an IPv4 input service filter to be attached.	string	Yes
26-199	IPv4-Output-Service-Filter	Name of an IPv4 output service filter to be attached.	string	Yes
26-200	IPv6-Input-Service-Set	Name of an IPv6 input service set to be attached.	string	Yes
26-201	IPv6-Output-Service-Set	Name of an IPv6 output service set to be attached.	string	Yes
26-202	IPv6-Input-Service-Filter	Name of an IPv6 input service filter to be attached.	string	Yes
26-203	IPv6-Output-Service-Filter	Name of an IPv6 output service filter to be attached.	string	Yes
26-204	Adv-Pcef-Profile-Name	Name of a PCEF profile to be attached.	string	Yes
26-205	Adv-Pcef-Rule-Name	Name of a PCC rule to activate.	string	Yes
26-206	Reauthentication-On-Renew	Reason that the client application is reauthenticated.	integer <ul style="list-style-type: none"> <li>• 0 = disable</li> <li>• 1 = Initiate reauthentication when DHCP renew request is received from the client</li> <li>• all other values = invalid</li> </ul>	No
26-207	DHCPv6-Options	DHCPv6 client and server options exchanged with the RADIUS server as TLV options.  In releases earlier than Junos OS Release 17.4.1R1, this VSA is not supported. DHCPv6 options are included instead in 26-55, DHCP-Options.	hexadecimal string	No
26-208	DHCP-Header	DHCPv4 packet header sent to the RADIUS server; used to instantiate dynamic subscriber interfaces.	hexadecimal string	No
26-209	DHCPv6-Header	DHCPv6 packet header sent to the RADIUS server; used to instantiate dynamic subscriber interfaces.	hexadecimal string	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-210	Acct-Request-Reason	Reason for sending an Accounting-Request message.	integer: 4-octet <ul style="list-style-type: none"> <li>0x0001 = Acct-Start-Ack; that is, receipt of an Acct response for the Acct-Start message</li> <li>0x0002 = Periodic/Timed interval interim</li> <li>0x0004 = IP active</li> <li>0x0008 = IP inactive</li> <li>0x0010 = IPv6 active</li> <li>0x0020 = IPv6 inactive</li> <li>0x0040 = Session active</li> <li>0x0080 = Session inactive</li> <li>0x0100 = Line speed change</li> <li>0x0200 = Address assignment change</li> <li>0x0400 = Completion of processing of CoA request</li> </ul>	No
26-211	Inner-Tag-Protocol-Id	Protocol identifier for the inner VLAN tag	hexadecimal string: <ul style="list-style-type: none"> <li>range = 0x600 through 0xffff.</li> <li>0x8100 = Inner VLAN tag for designated L2BSA subscribers</li> </ul>	No
26-212	Routing-Services	Determines whether the routing services capability is enabled or disabled.	integer: 4-octet <ul style="list-style-type: none"> <li>0x0000 = Disable installation of routing services.</li> <li>0x0001 = Enable installation of routing services.</li> </ul> Any value other than 0 or 1 is rejected.	No
26-213	Interface-Set-Targeting-Weight	Specify a weight for an interface set to associate it and its member links with an aggregated Ethernet member link for targeted distribution.	integer: 4-octet	No

Table 4: Supported Juniper Networks VSAs (continued)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-214	Interface-Targeting-Weight	Specify a weight for an interface to associate it with an interface set and thus with the set's aggregated Ethernet member link for targeted distribution. When an interface set does not have a weight, then the interface weight value for the first authorized subscriber interface is used for the set.	integer: 4-octet	No

## AAA Access Messages and Supported RADIUS Attributes and Juniper Networks VSAs for Junos OS

Table 5 on page 34 shows the RADIUS attributes and Juniper Networks VSAs support in AAA access messages. A checkmark in a column indicates that the message type supports that attribute.

## DSL Forum Vendor-Specific Attributes

Digital Subscriber Line (DSL) attributes are RADIUS vendor-specific attributes (VSAs) that are defined by the DSL Forum. The attributes transport DSL information that is not supported by standard RADIUS attributes and which convey information about the associated DSL subscriber and data rate. The attributes are defined in RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes* and RFC 5515, *Layer 2 Tunneling Protocol (L2TP) Access Line Information Attribute Value Pair (AVP) Extensions*.

**NOTE:** Junos OS uses the vendor ID 3561, which is assigned by the Internet Assigned Numbers Authority (IANA), for the DSL Forum VSAs.

Subscriber management does not process DSL values—the router simply passes the values received from the subscriber to the RADIUS server, without performing any parsing or manipulation. However, you can manage the content of DSL VSA values either by using the client configuration to restrict the DSL VSAs that the client sends, or by configuring the RADIUS server to ignore unwanted DSL VSAs.

Table 7 on page 46 describes the DSL Forum VSAs.

**Table 7: DSL Forum VSAs**

Attribute Number	Attribute Name	Description	Value
26-1	Agent-Circuit-Id	Identifier for the subscriber agent circuit ID (ACI) that corresponds to the DSLAM interface from which subscriber requests are initiated.  For auto-sensed VLANs, the ACI is extracted from DHCP discover, DHCPv6 solicit, or PPPoE PADI messages, stored in the VLAN shared database entry, and then presented in the RADIUS Access-Request message in this VSA.	string
26-2	Agent-Remote-Id	Unique identifier for the subscriber associated with the DSLAM interface from which requests are initiated.  For auto-sensed VLANs, the ARI is extracted from DHCP discover, DHCPv6 solicit, or PPPoE PADI messages, stored in the VLAN shared database entry, and then presented in the RADIUS Access-Request message in this VSA.	string
26-129	Actual-Data-Rate-Upstream	Actual upstream data rate of the subscriber's synchronized DSL link	integer: 4-octet
26-130	Actual-Data-Rate-Downstream	Actual downstream data rate of the subscriber's synchronized DSL link	integer: 4-octet
26-131	Minimum-Data-Rate-Upstream	Minimum upstream data rate configured for the subscriber	integer: 4-octet
26-132	Minimum-Data-Rate-Downstream	Minimum downstream data rate configured for the subscriber	integer: 4-octet
26-133	Attainable-Data-Rate-Upstream	Upstream data rate that the subscriber can attain	integer: 4-octet
26-134	Attainable-Data-Rate-Downstream	Downstream data rate that the subscriber can attain	integer: 4-octet
26-135	Maximum-Data-Rate-Upstream	Maximum upstream data rate configured for the subscriber	integer: 4-octet

Table 7: DSL Forum VSAs (continued)

Attribute Number	Attribute Name	Description	Value
26-136	Maximum-Data-Rate-Downstream	Maximum downstream data rate configured for the subscriber	integer: 4-octet
26-137	Minimum-Data-Rate-Upstream-Low-Power	Minimum upstream data rate in low power state configured for the subscriber	integer: 4-octet
26-138	Minimum-Data-Rate-Downstream-Low-Power	Minimum downstream data rate in low power state configured for the subscriber	integer: 4-octet
26-139	Maximum-Interleaving-Delay-Upstream	Maximum one-way upstream interleaving delay configured for the subscriber	integer: 4-octet
26-140	Actual-Interleaving-Delay-Upstream	Subscriber's actual one-way upstream interleaving delay	integer: 4-octet
26-141	Maximum-Interleaving-Delay-Downstream	Maximum one-way downstream interleaving delay configured for the subscriber	integer: 4-octet
26-142	Actual-Interleaving-Delay-Downstream	Subscriber's actual one-way downstream interleaving delay	integer: 4-octet
26-144	Access-Loop-Encapsulation	Encapsulation used by the subscriber associated with the DSLAM interface from which requests are initiated	string: 3-byte
26-254	IWF-Session	Indication that the interworking function (IWF) has been performed for the subscriber's session	No data field required

## DSL Forum VSAs Support in AAA Access and Accounting Messages for Junos OS

Table 8 on page 47 lists the DSL Forum VSAs supported by Junos OS in RADIUS Access-Request, Acct-Start, Acct-Stop, Interim-Acct, and CoA-Request messages. A checkmark in a column indicates that the message type supports that attribute. The DSL Forum vendor ID is 3561 (hexadecimal DE9), which is assigned by the IANA.

### RADIUS Support for Microsoft Corporation VSAs for DNS Server Addresses

Starting in Junos OS Release 15.1, the Junos OS AAA implementation supports RADIUS VSAs that identify the primary and secondary DNS servers for IANA private enterprise number 311 (Microsoft Corporation). For example, during PPP authentication, the router receives the VSAs from a RADIUS server and uses the attributes to provision customer premise equipment.

The two VSAs are shown in the following table, and are described in RFC 2548 (*Microsoft Vendor-specific RADIUS Attributes*)

**Table 9: Microsoft Vendor-Specific RADIUS Attributes for DNS Server Addresses**

Attribute Number	Attribute Name	Description	Value
26-28	MS-Primary-DNS-Server	IP address of the primary Domain Name Server.  This VSA can be included in Access-Accept and Accounting-Request packets.	integer: 4-octet <i>primary-dns-address</i>
26-29	MS-Secondary-DNS-Server	IP address of the secondary Domain Name Server.  This VSA can be included in Access-Accept and Accounting-Request packets.	integer: 4-octet <i>secondary-dns-address</i>

**See Also** • [DNS Address Assignment Precedence on page 304](#)

## Support for Cisco Systems VSAs

Cisco Systems, IANA private enterprise number 9, uses a single VSA, Cisco-AVPair (26-1). This VSA conveys different information based on the values it contains. In some subscriber access networks, which have a BNG connected to both a RADIUS server and a Cisco BroadHop application that is used as the Policy Control and Charging Rules Function (PCRF) server for provisioning services using RADIUS change of authorization (CoA) messages, you can use this VSA in RADIUS messages to activate and deactivate services. You cannot modify any attributes in authentication, accounting, or CoA responses in the RADIUS messages that the BNG sends. See [“Processing Cisco VSAs in RADIUS Messages for Service Provisioning” on page 142](#) for more information.

Any Cisco VSAs other than the ones used to provision the services are considered as unsupported attributes.

## Subscriber Management RADIUS Dictionary Files

The Juniper Networks RADIUS dictionary that is used by default for subscriber management is updated when software features that affect the file are added or changed. The dictionary is not updated for every Junos OS release. The dictionary includes Juniper Networks vendor-specific attributes that are used by Junos OS, JunosE OS, or both.

**NOTE:** The VSA names in the dictionary begin with the prefix “Jnpr-” or “Unisphere”. By convention, both prefixes are omitted from the Tech Library documentation to reduce confusion in feature discussions.

## Interface Text Descriptions for Inclusion in RADIUS Attributes

RADIUS attributes such as NAS-Port-ID (87) and Calling-Station-ID (31) include a description that identifies the physical interface that is used to authenticate subscribers. The default format for nonchannelized interfaces is as follows:

***interface-type-slot/adapter/port.subinterface[:svlan-vlan]***

For example, consider physical interface ge-1/2/0, with a subinterface of 100 and SVLAN identifier of 100. The interface description used in the NAS-Port-ID is ge-1/2/0.100:100.

Starting in Junos OS Release 17.3R1, a different format is used for channelized interfaces. For channelized interfaces, the default interface description is as follows:

***interface-type-slot/adapter/logical-port-number.subinterface[:svlan-vlan]***

The channel information (logical port number) is determined by this formula:

Logical port number = 100 + (actual-port-number x 20) + channel-number

For example, consider a channelized interface 3 on port 2 where the:

- Physical interface is xe-0/1/2:3.
- Subinterface is 4.
- SVLAN is 5.
- VLAN is 6.

Using the formula, the logical port number = 100 + (2 x 20) + 3 = 143. Consequently, the default interface description is xe-0/1/143.4-5.6.

You can optionally configure the interface description format in an access profile to exclude the adapter, channel, or subinterface information.

For example, if you exclude the subinterface from the nonchannelized interface description format, the description becomes ge-1/2/0:100. If you exclude the channel information from the channelized interface description format, the description becomes xe-0/1/2.4-5.6.

### Configuring Router or Switch Interaction with RADIUS Servers

You specify the RADIUS servers that the router or switch can use and you also configure how the router or switch interacts with the specified servers. You can configure the router or switch to connect to multiple RADIUS servers on IPv4 and IPv6 networks. You can configure the RADIUS server connectivity at the **[edit access]** hierarchy level or for a specific dynamic profile at the **[edit access profile]** hierarchy level.

To configure connectivity to a RADIUS server and to specify how the router or switch interacts with the server:

1. Specify the IP address of the RADIUS server.

The example in this step shows the configuration statement for two RADIUS servers, one with an IPv4 address and the other with an IPv6 address. All other examples in this topic show an IPv4 address. The configuration is similar for IPv6.

For an IPv4 RADIUS server:

```
[edit access]
user@host# edit radius-server 192.168.1.250
```

For an IPv6 RADIUS server:

```
user@host# edit radius-server 2001:DB8:0:f101::2
```

2. (Optional) Configure the RADIUS server accounting port number. The default accounting port number is 1813.

```
[edit access radius-server 192.168.1.250]  
user@host# set accounting-port 1813
```

3. (Optional) Configure the port number the router or switch uses to contact the RADIUS server. The default port number is 1812.

```
[edit access radius-server 192.168.1.250]  
user@host# set port 18914
```

4. Configure the required secret (password) that the local router or switch passes to the RADIUS client. Secrets enclosed in quotation marks can contain spaces.

```
[edit access radius-server 192.168.1.250]  
user@host# set secret $ABC123$ABC123
```

5. (Optional) Configure the maximum number of outstanding requests that a RADIUS server can maintain. An outstanding request is a request to which the RADIUS server has not yet responded. You can limit the number from 0 through 2000 outstanding requests per RADIUS server. The default setting is 1000 outstanding requests per server.

```
[edit access radius-server 192.168.1.250]  
user@host# set max-outstanding-requests 500
```

6. Configure the source address for the RADIUS server. Each RADIUS request sent to a RADIUS server uses the specified source address. The source address is a valid IPv4 or IPv6 address configured on one of the router or switch interfaces.

For an IPv4 source address:

```
[edit access radius-server 192.168.1.250]  
user@host# set source-address 192.168.1.100
```

For an IPv6 source address:

```
[edit access radius-server 2001:DB8:0:f101::2]  
user@host# set source-address 2001:DB8:0:f101::1
```

7. (Optional) Configure retry and timeout values for authentication and accounting messages.
  - a. Configure how many times the router or switch attempts to contact a RADIUS server when it has received no response. You can configure the router or switch to retry from 1 through 100 times. The default setting is 3 retry attempts.

```
[edit access radius-server 192.168.1.250]
user@host# set retry 4
```

- b. Configure how long the router or switch waits to receive a response from a RADIUS server before retrying the contact. By default, the router or switch waits 3 seconds. You can configure the timeout to be from 1 through 1000 seconds.

```
[edit access radius-server 192.168.1.250]
user@host# set timeout 20
```

**NOTE:** The maximum retry duration (the number of retries times the length of the timeout) cannot exceed 2700 seconds. An error message is displayed if you configure a longer duration.

**NOTE:** The retry and timeout settings apply to both authentication and accounting messages unless you configure both the **accounting-retry** statements and the **accounting-timeout** statement. In that case, the retry and timeout settings apply only to authentication messages.

8. (Optional) Configure retry and timeout values for accounting messages separate from the settings for authentication messages.

**NOTE:** You must configure both of these options. If you do not, then the value you configure is ignored in favor of the values configured with the **retry** and **timeout** statements.

- a. Configure how many times the router attempts to send accounting messages to the RADIUS accounting server when it has received no response. You can configure the router to retry from 0 through 100 times. The default setting is 0, meaning that this option is disabled.

```
[edit access radius-server 192.168.1.250]
user@host# set accounting-retry 6
```

- b. Configure how long the router waits to receive a response from a RADIUS accounting server before retrying the request. You can configure the timeout to be from 0 through 1000 seconds. The default setting is 0, meaning that this option is disabled.

```
[edit access radius-server 192.168.1.250]
user@host# set accounting-timeout 20
```

## Configuring Options that Apply to All RADIUS Servers

You can configure RADIUS options that apply to all RADIUS servers globally.

To configure RADIUS options globally:

1. Specify that you want to configure RADIUS options.

```
[edit access ]
user@host# edit radius-options
```

2. (Optional) Configure the number of requests per second that the router can send to all the RADIUS servers collectively.

```
[edit access radius-options]
user@host# set request-rate rate
```

3. (Optional) Configure the number of seconds that the router or switch waits after a server has become unreachable.

```
[edit access radius-options]
user@host# set revert-interval interval
```

4. (Optional) Configure the number of seconds during which a failing authentication server is not marked as down or unreachable.

```
[edit access radius-options]
user@host# set timeout-grace seconds
```

5. (Optional) Configure a NAS-Port value that is unique across all MX series routers in the network.

```
[edit access radius-options]
user@host# set unique-nas-port chassis-id-width chassis-id-width
user@host# set unique-nas-port chassis-id chassis-id
```

## Configuring a Timeout Grace Period to Specify When RADIUS Servers Are Considered Down or Unreachable

When a RADIUS authentication server fails to respond to any of the attempts for a given authentication request and times out, `authd` notes the time for reference, but it does not immediately mark the server as down (if other servers are available) or unreachable (if it is the only configured server). Instead, a configurable grace period timer starts at the reference time. The grace period is cleared if the server responds to a subsequent request before the period expires.

During the grace period, the server is not marked as down or unreachable. Each time the server times out for subsequent requests to that server, `authd` checks whether the grace period has expired. When the check determines that the grace period has expired and the server has still not responded to a request, the server is marked as unreachable or down.

Using a short grace period enables you to more quickly abandon an unresponsive server and direct authentication requests to other available servers. A long grace period gives a server more opportunities to respond and may avoid needlessly abandoning a resource. You might specify a longer grace period when you have only one or a small number of configured servers.

To configure the grace period during which an unresponsive RADIUS server is not marked as unreachable or down:

- Specify the duration of the grace period.

```
[edit access radius-options]  
user@host# set timeout-grace seconds
```

## Storage and Reporting of Interface Descriptions to Uniquely Identify Subscribers

- [Interface Description Storage and Reporting Overview on page 55](#)
- [Interface Description Storage and Reporting Configuration on page 59](#)

### Interface Description Storage and Reporting Overview

You can configure Junos OS to store subscriber access interface descriptions and report the interface description through RADIUS. This capability enables you to uniquely identify subscribers on a particular logical or physical interface. When you enable storing of the interface descriptions, RADIUS requests include the interface description in VSA 26-63, if the subscriber's access interface has been configured with an interface description. All interface descriptions must be statically configured using the Junos OS CLI. Storing and reporting of interface descriptions is supported for DHCP, PPP, and authenticated dynamic VLANs, and applies to any client session that either authenticates or uses the RADIUS accounting service. The description can contain letters, numbers, and hyphens (-), and can be up to 64 characters long.

### Interface Description Precedence

The interface description sent in the VSA depends on the configured interface. Two configuration models apply across topologies and protocols for subscriber management.

- Subscriber logical interface directly over a physical interface (non-underlying logical interfaces).
- Subscriber logical interface over an underlying logical interface and physical interface.

In both models, Junos OS selects the interface description to report based on order of precedence. Interfaces not configured with interface descriptions are excluded when selecting an interface by precedence. If no interface description is configured on any of the static interfaces in the subscriber interface hierarchy, VSA 26-63 is not sent in any of the RADIUS messages.

#### NOTE:

- For aggregated Ethernet physical interfaces, the interface description on the aggregated Ethernet interface, for example AEO or AE1, serves as the physical interface description.
- If the subscriber's access is a combination of dynamic and static interfaces, Junos OS uses the description on the static interface.

### Example: Reporting Interface Descriptions on Non-Underlying Logical Interfaces

This topic shows an example of subscriber access with non-underlying logical interfaces. In this case, the logical interface can be a VLAN or a VLAN demux interface. This example shows a DHCP subscriber logical interface over a VLAN without a demux interface. For non-underlying interfaces, Junos OS selects which interface description to report based on the following order of precedence:

1. Logical interface description
2. Physical interface description

Based on the order of precedence that Junos OS uses to select the interface description for non-underlying interfaces, Junos OS reports subscriber\_ifl\_descr as the interface description.

```
system {
  services {
    dhcp-local-server {
      group LSG1 {
        authentication {
          password $ABC123;
          username-include {
            user-prefix rich;
          }
        }
      }
    }
    interface ge-1/0/0.100;
```

```

    }
  }
}
interfaces {
  ge-1/0/0 {
    description subscriber_ifd_descr;
    vlan-tagging;
    unit 100 {
      description subscriber_ifl_descr;
      vlan-id 100;
      family inet {
        unnumbered-address lo0.0 preferred-source-address 198.51.100.20;
      }
    }
  }
}

```

### ***Reporting Interface Descriptions on Underlying Logical Interfaces***

Underlying logical interfaces can apply to both DHCP and PPP.

For DHCP, Junos OS selects which interface description to report based on the following order of precedence:

1. Underlying logical interface description
2. Underlying physical interface description

**NOTE:** For DHCP, Junos OS does not report the IP demux logical interface description.

For PPP over an underlying VLAN or VLAN demux interface, Junos OS selects which interface description to report based on the following order of precedence:

1. PPP interface description
2. Underlying VLAN without a demux interface or VLAN demux logical interface description
3. Underlying physical interface description

### ***Example: PPP over an Underlying VLAN Demux Interface***

The following example shows a PPP subscriber over an underlying VLAN demux interface. This configuration includes three possible interface descriptions. Based on the order of precedence that Junos OS uses to select the interface description for PPP, the interface description is reported as subscriber\_ppp\_ifl\_descr\_0.

```

interfaces {
  ge-1/0/0 {
    description subscriber_ifd_descr;
    hierarchical-scheduler maximum-hierarchy-levels 2;
  }
}

```

```

        flexible-vlan-tagging;
    }
    demux0 {
        unit 0 {
            vlan-tags outer 1 inner 1;
            description subscriber_under_ifl_descr_1_1;
            demux-options {
                underlying-interface ge-1/0/0;
            }
            family pppoe {
                duplicate-protection;
            }
        }
        unit 1 {
            vlan-tags outer 1 inner 2;
            description subscriber_under_ifl_descr_1_2;
            demux-options {
                underlying-interface ge-1/0/0;
            }
            family pppoe {
                duplicate-protection;
            }
        }
    }
    pp0 {
        unit 0 {
            description subscriber_ppp_ifl_descr_0;
            ppp-options {
                chap;
                pap;
            }
            pppoe-options {
                underlying-interface demux0.0;
                server;
            }
        }
        unit 1 {
            description subscriber_ppp_ifl_descr_1;
            ppp-options {
                chap;
                pap;
            }
            pppoe-options {
                underlying-interface demux0.1;
                server;
            }
        }
    }
}

```

### ***Example: Reporting Interface Descriptions on Dynamic VLANs***

If you create dynamic VLANs with authentication, Junos OS reports the interface description on the physical interface. In the following example, dynamic VLANs created

over the ge-1/2/0 interface are authenticated with an interface description of ge-1/2/0-bos-mktg-group.

```
ge-1/2/0 {
  description ge-1/2/0-bos-mktg-group;
  flexible-vlan-tagging;
  auto-configure {
    vlan-ranges {
      dynamic-profile vlan-prof {
        accept inet;
        ranges {
          any;
        }
      }
    }
    authentication {
      password $ABC123;
      username-include {
        user-prefix rich;
      }
    }
  }
}
```

### Interface Description Storage and Reporting Configuration

To enable or disable storage and reporting of interface descriptions:

- Enable storing and reporting of interface descriptions.

```
[edit access]
user@host# set report-interface-descriptions
```

- Disable storing and reporting of interface descriptions per RADIUS message type.

```
[edit access profile profile-name radius attributes]
user@host# set exclude interface-description [ access-request | accounting-start |
accounting-stop ]
```

## Configuring an Access Profile for Subscriber Management

Access profiles enable you to specify subscriber access authentication and accounting parameters. After you have created the access profile that specifies the subscriber authentication and accounting parameters, you must specify where the profile is used; this is known as attaching the profile. Authentication and accounting will not run unless you attach the profile.

To configure an access profile:

1. Specify an existing or new access profile name.

```
[edit access]
user@host# edit profile profile-name
```

2. Specify any desired subscriber access authentication and accounting parameters for the access profile.

See “[RADIUS Authentication and Accounting Basic Configuration](#)” on [page 112](#) and “[RADIUS Accounting for Subscriber Access](#)” on [page 131](#) for information about individual parameters.

3. Attach the profile.
  - a. Access the appropriate hierarchy level. For example:

```
[edit]
user@host# edit logical-systems LS1 routing-instances R11
```

- [edit]
  - [edit routing-instances *routing-instance-name*]
  - [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]
  - [edit interfaces *interface-name* auto-configure vlan-ranges]
  - [edit interfaces *interface-name* auto-configure stacked-vlan-ranges]
- b. Specify the name of the access profile that you want to attach. For example:

```
[edit logical-systems logical-system-name routing-instances routing-instance-name]
user@host# set access-profile vz-bos-metro-fios-basic
```

## Configuring RADIUS Server Parameters for Subscriber Access

Include the **radius** statement at the **[edit access profile *profile-name*]** hierarchy level to specify the RADIUS parameters for the subscriber access manager feature. The following list provides an overview of the parameters you can configure:

- The IP addresses of one or more RADIUS authentication and accounting servers.
- Options for the RADIUS servers, such as the following:
  - Format (decimal or description) used for the accounting session
  - Method (round-robin or direct) the router or switch uses to communicate with the servers
  - NAS identifier to use for RADIUS requests
  - Revert time setting that specifies when the router or switch reverts to using the primary RADIUS server
  - Delimiter character and format for the NAS-Port-ID (RADIUS attribute 87) and Calling-Station-ID (RADIUS attribute 31)
- The RADIUS attributes to be ignored or excluded from RADIUS messages.

To configure RADIUS server parameters:

1. Specify that you want to configure RADIUS support.

```
[edit access profile isp-bos-metro-fiber-basic]
user@host# edit radius
```

2. Specify the addresses of RADIUS authentication and accounting servers.

See [“Specifying RADIUS Authentication and Accounting Servers for Subscriber Access” on page 113](#).

3. Configure the RADIUS server options.

See [“Configuring RADIUS Server Options for Subscriber Access” on page 61](#).

4. Configure RADIUS attributes that are ignored or excluded from RADIUS messages.

See [“Filtering RADIUS Attributes and VSAs from RADIUS Messages” on page 65](#).

## Configuring RADIUS Server Options for Subscriber Access

You can specify options that the router or switch uses when communicating with RADIUS authentication and accounting servers for subscriber access.

To configure RADIUS authentication and accounting server options:

1. Specify that you want to configure RADIUS.

```
[edit access profile isp-bos-metro-fiber-basic]  
user@host# edit radius
```

2. Specify that you want to configure RADIUS options.

```
[edit access profile isp-bos-metro-fiber-basic radius]  
user@host# edit options
```

3. (Optional) Configure the method the router or switch uses to access RADIUS accounting servers.

```
[edit access profile isp-bos-metro-fiber-basic radius options]  
user@host# set client-accounting-algorithm round-robin
```

4. (Optional) Configure the method the router or switch uses to access RADIUS authentication servers.

```
[edit access profile isp-bos-metro-fiber-basic radius options]  
user@host# set client-authentication-algorithm round-robin
```

5. (Optional) Configure the format the router or switch uses to identify the accounting session.

```
[edit access profile isp-bos-metro-fiber-basic radius options]  
user@host# set accounting-session-id-format decimal
```

6. (Optional) Specify that the Agent-Remote-Id and Agent-Circuit-Id are generated locally when these values are not present in the client database.

```
[edit access profile isp-bos-metro-fiber-basic radius options]  
user@host# set access-loop-id-local
```

7. (Optional) Specify the information that is excluded from the interface description that the router or switch passes to RADIUS for inclusion in RADIUS attribute 87 (NAS-Port-ID).

```
[edit access profile isp-bos-metro-fiber-basic radius options]  
user@host# set interface-description-format (exclude-adapter | exclude-channel |  
exclude-sub-interface)
```

8. (Optional) Configure the value for the client RADIUS attribute 32 (NAS-Identifier), which is used for authentication and accounting requests.

```
[edit access profile isp-bos-metro-fiber-basic radius options]  
user@host# set nas-identifier 56
```

9. (Optional) Configure the RADIUS client to use the extended format for RADIUS attribute 5 (NAS-Port) and specify the width of the fields in the NAS-Port attribute. The total of the widths must not exceed 32 bits, or the configuration fails.

- For Ethernet subscribers:

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-extended-format ae-width 10 slot-width 4 adapter-width
2 port-width 4 pw-width 12 stacked-vlan-width 10 vlan-width 2
```

The width value appears in the Cisco NAS-Port-Info AVP (100).

- For ATM subscribers:

```
[edit access profile retailer01 radius options]
user@host# set nas-port-extended-format atm slot-width 3 adapter-width 2
port-width 3 vpi-width 8 vci-width 16
```

10. (Optional) Configure the delimiter character that the router inserts between values in RADIUS attribute 87 (NAS-Port-Id).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-id-delimiter %
```

11. (Optional) Configure the information that the router includes in RADIUS attribute 87 (NAS-Port-Id).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-id-format agent-circuit-id agent-remote-id
```

12. (Optional) Configure the delimiter character that the router inserts between values in RADIUS attribute 31 (Calling-Station-Id).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set calling-station-id-delimiter "%"
```

13. (Optional) Configure the information that the router includes in RADIUS attribute 31 (Calling-Station-Id).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set calling-station-id-format agent-circuit-id agent-remote-id
```

14. (Optional) Configure the port type that is included in RADIUS attribute 61 (NAS-Port-Type). This specifies the port type the router uses to authenticate subscribers.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-type ethernet wireless-ieee80211
```

**NOTE:** This statement is ignored if you configure the `ethernet-port-type-virtual` in the same access profile.

15. (Optional) Configure the router or switch to use a port type of `virtual` to authenticate clients.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set ethernet-port-type-virtual
```

**NOTE:** This statement takes precedence over the `nas-port-type` statement if you include both in the same access profile.

16. (Optional) Configure the number of seconds that the router or switch waits after a server has become unreachable.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set revert-interval 259200
```

17. (Optional) Specify that RADIUS attribute 5 (NAS-Port) includes the S-VLAN ID, in addition to the VLAN ID, for subscribers on Ethernet interfaces.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set vlan-nas-port-stacked-format
```

18. (Optional) Configure the router to use the optional behavior when processing CoA requests that include changes to client profile dynamic variables.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set coa-dynamic-variable-validation
```

19. (Optional) Configure the router to use the optional behavior that inserts the random challenge generated by the NAS into the Request Authenticator field of Access-Request packets, rather than sending the random challenge as the CHAP-Challenge attribute (RADIUS attribute 60) in Access-Request packets. This optional behavior requires that the value of the challenge must be 16 bytes; otherwise the statement is ignored and the challenge is sent as the CHAP-Challenge attribute.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set chap-challenge-in-request-authenticator
```

20. (Optional) Configure whether subscribers can successfully log in even when service activation failures related to configuration errors occur during family activation request processing by authd for a newly authenticated subscriber.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set service-activation dynamic-profile optional-at-login
```

21. (Optional) Configure the LAC to override the configured Calling-Station-ID format for the value sent in the L2TP Calling Number AVP 22. By default, the LAC sends the underlying interface. Alternatively, you might have configured a Calling-Station-ID format that includes different information in the AVP; in this case, AVP 22 establishes the value of the RADIUS Calling-Station-ID attribute (31) sent to the server. You can override the Calling-Station-ID format and configure the LAC to use the ACI, the ARI, or both the ACI and ARI that are received from the L2TP client in the PADR packet. You can also specify a delimiter to use between components of the AVP string and a fallback value to use when the configured override components are not received in the PADR packet.

**NOTE:** See *Override the Calling-Station-ID Format for the Calling Number AVP* for more information.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set override calling-station-id remote-circuit-id
user@host# set remote-circuit-id-format (agent-circuit-id | agent-remote-id |
agent-circuit-id agent-remote-id)
user@host# set remote-circuit-id-delimiter delimiter
user@host# set remote-circuit-id-fallback (configured-calling-station-id | default)
```

## Filtering RADIUS Attributes and VSAs from RADIUS Messages

Standard attributes and vendor-specific attributes (VSAs) received in RADIUS messages take precedence over internally provisioned attribute values. Filtering attributes consists of choosing to *ignore* certain attributes when they are received in Access Accept packets and to *exclude* certain attributes from being sent to the RADIUS server. Ignoring attributes received from the RADIUS server enables your locally provisioned values to be used instead. Excluding attributes from being sent is useful, for example, for attributes that do not change for the lifetime of a subscriber. It enables you to reduce the packet size without loss of information.

You can specify standard RADIUS attributes and VSAs that the router or switch subsequently *ignores* when they are received in RADIUS Access-Accept messages. You can also specify attributes and VSAs that the router or switch *excludes* from specified RADIUS message types. Exclusion means that the router or switch does not include the attribute in specified messages that it sends to the RADIUS server.

Starting in Junos OS Release 18.1R1, you can configure the router or switch to ignore or exclude RADIUS standard attributes and VSAs by specifying the standard attribute number or the IANA-assigned vendor ID and the VSA number, respectively. With this flexible configuration method, you can configure any standard attribute and VSA supported by your platform to be ignored or excluded. The configuration has no effect if you configure unsupported attributes, vendors, and VSAs.

The legacy method allows you to configure only those attributes and VSAs for which the statement syntax includes a specific option. Consequently, you can use the legacy method to ignore only a subset of all attributes that can be received in Access-Accept messages.

To configure the attributes ignored or excluded by your router or switch:

1. Specify that you want to configure RADIUS in the access profile.

```
[edit access profile profile-name]  
user@host# edit radius
```

2. Specify that you want to configure how RADIUS attributes are filtered.

```
[edit access profile profile-name radius]  
user@host# edit attributes
```

3. (Optional) Specify one or more attributes you want your router or switch to ignore when the attributes are in Access-Accept messages.

- Legacy method: Specify dedicated option for attribute:

```
[edit access profile profile-name radius attributes]  
user@host# set ignore attribute-name
```

- Flexible method: Specify standard attribute number or the IANA-assigned vendor ID and the VSA number:

```
[edit access profile profile-name radius attributes]  
user@host# set ignore standard-attribute number  
user@host# set ignore vendor-id id-number vendor-attribute vsa-number
```

4. (Optional) Configure an attribute that you want your router or switch to exclude from one or more specified RADIUS message types. You cannot configure a list of attributes, but you can specify a list of message types for each attribute.

- Legacy method: Specify dedicated option for attribute and message type:

```
[edit access profile profile-name radius attributes]  
user@host# set exclude attribute-name [packet-type]
```

- Flexible method: Specify standard attribute number or the IANA-assigned vendor ID, the VSA number, and the message type:

```
[edit access profile profile-name radius attributes]  
user@host# set exclude standard-attribute number packet-type [packet-type]  
user@host# set exclude vendor-id id-number vendor-attribute vsa-number  
packet-type [packet-type]
```

The following example compares the legacy and flexible configuration methods to ignore the standard RADIUS attribute, Framed-IP-Netmask (9), and the Juniper Networks VSAs, Ingress-Policy-Name (26-10) and Egress-Policy-Name (26-11).

- Legacy method:

```
[edit access profile prof-ign radius attributes]
user@host# set ignore framed-ip-netmask input-filter output-filter
```

- Flexible method:

```
[edit access profile prof-ign radius attributes]
user@host# set ignore standard-attribute 9
user@host# set ignore vendor-id 4874 vendor-attribute [ 10 11 ]
```

The following example compares the legacy and flexible configuration methods to exclude the standard RADIUS attribute, Framed-IP-Netmask (9), and the Juniper Networks VSAs, Ingress-Policy-Name (26-10) and Egress-Policy-Name (26-11).

- Legacy method:

```
[edit access profile prof-exc radius attributes]
user@host# set exclude framed-ip-netmask accounting-stop
user@host# set exclude input-filter [ accounting-start accounting-stop ]
user@host# set exclude output-filter [ accounting-start accounting-stop ]
```

- Flexible method: Specify standard attribute number or the IANA-assigned vendor ID, the VSA number, and the message type:

```
[edit access profile prof-exc radius attributes]
user@host# set exclude standard-attribute 9 packet-type accounting-stop
user@host# set exclude vendor-id 4874 vendor-attribute 10 packet-type
[ accounting-start accounting-stop ]
user@host# set exclude vendor-id 4874 vendor-attribute 11 packet-type
[ accounting-start accounting-stop ]
```

What happens if you specify an attribute with both methods in the same profile? The effective configuration is the logical OR of the two methods. Consider the following example for the standard attribute, accounting-delay-time (41):

```
[edit access profile prof-3 radius attributes]
user@host# set exclude accounting-delay-time [ accounting-off accounting-on ]
user@host# set exclude standard-attribute 41 packet-type [ accounting-start
accounting-stop ]
```

The result is that the attribute is excluded from all four message types: Accounting-Off, Accounting-On, Accounting-Start, and Accounting-Stop. The effect is the same as if either of the following configurations is used:

- ```
[edit access profile prof-3 radius attributes]
user@host# set exclude accounting-delay-time [ accounting-off accounting-on
accounting-start accounting-stop ]
```

- `[edit access profile prof-3 radius attributes]`  
`user@host# set exclude standard-attribute 41 packet-type [ accounting-off`  
`accounting-on accounting-start accounting-stop ]`

## Configuring a Calling-Station-ID with Additional Options

You can configure an alternative value for the Calling-Station-ID (RADIUS IETF attribute 31) in an access profile on the MX Series router.

By default, the Calling-Station-ID includes the **agent-circuit-id** string. Optionally, you can configure the Calling-Station-ID to include one or more of the following options, in any combination:

- Agent circuit identifier (**agent-circuit-id**)—Identifier of the subscriber's access node and the digital subscriber line (DSL) on the access node. The agent circuit identifier (ACI) string is stored in either the DHCP option 82 field of DHCP messages for DHCP traffic, or in the DSL Forum Agent-Circuit-ID VSA [26-1] of PPPoE Active Discovery Initiation (PADI) and PPPoE Active Discovery Request (PADR) control packets for PPPoE traffic.
- Agent remote identifier (**agent-remote-id**)—Identifier of the subscriber on the digital subscriber line access multiplexer (DSLAM) interface that initiated the service request. The agent remote identifier (ARI) string is stored in either the DHCP option 82 field for DHCP traffic, or in the DSL Forum Agent-Remote-ID VSA [26-2] for PPPoE traffic.
- Interface description (**interface-description**)—Value of the interface.
- Interface text description (**interface-text-description**)—Text description of the interface. The interface text description is configured separately, using either the **set interfaces interface-name description description** statement or the **set interfaces interface-name unit unit-number description description** statement
- MAC address (**mac-address**)—MAC address of the source device for the subscriber.
- NAS identifier (**nas-identifier**)—Name of the NAS that originated the authentication or accounting request. NAS-Identifier is RADIUS IETF attribute 32.
- Stacked VLAN (**stacked-vlan**)—Stacked VLAN ID.
- VLAN (**vlan**)—VLAN ID.

If you configure the format of the Calling-Station-ID with more than one optional value, a hash character (#) is the default delimiter that the router uses as a separator between the concatenated values in the resulting Calling-Station-ID string. Optionally, you can configure an alternative delimiter character for the Calling-Station-ID to use. The following example shows the order of output when you configure multiple optional values:

```
nas-identifier#interface description#interface text
description#agent-circuit-id#agent-remote-id#mac address#stacked vlan#vlan
```

To configure an access profile to provide optional information in the Calling-Station-ID:

1. Specify the access profile you want to configure.

```
[edit]
user@host# edit access profile profile-name
```

- Specify that you want to configure RADIUS options.

```
[edit access profile profile-name]
user@host# edit radius options
```

- Specify the nondefault character to use as the delimiter between the concatenated values in the Calling-Station-ID.

By default, subscriber management uses the hash character (#) as the delimiter in Calling-Station-ID strings that contain more than one optional value.

```
[edit access profile profile-name radius options]
user@host# set calling-station-id-delimiter delimiter-character
```

- Configure the value for the NAS-Identifier (RADIUS attribute 32), which is used for authentication and accounting requests.

```
[edit access profile profile-name radius options]
user@host# set nas-identifier identifier-value
```

- Specify that you want to configure the format of the Calling-Station-ID.

```
[edit access profile profile-name radius options]
user@host# edit calling-station-id-format
```

- (Optional) Include the interface text description in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set interface-text-description
```

- (Optional) Include the interface description value in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set interface-description
```

- (Optional) Include the agent circuit identifier in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set agent-circuit-id
```

- (Optional) Include the agent remote identifier in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set agent-remote-id
```

10. (Optional) Include the configured NAS identifier value in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set nas-identifier
```

11. (Optional) Include the stacked VLAN ID in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set stacked-vlan
```

12. (Optional) Include the VLAN ID in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set vlan
```

13. (Optional) Include the MAC address in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set mac-address
```

**Example:**  
**Calling-Station-ID with**  
**Additional Options in**  
**an Access Profile**

The following example creates an access profile named `retailer01` that configures a Calling-Station-ID string that includes the NAS-Identifier (**fox**), interface description, agent circuit identifier, and agent remote identifier options.

```
[edit access profile retailer01 radius options]
nas-identifier "fox";
calling-station-id-delimiter "*";
calling-station-id format {
  nas-identifier;
  interface-description;
  agent-circuit-id;
  agent-remote-id;
}
```

The resulting Calling-Station-ID string is formatted as follows:

**fox\*ge-1/2/0.100:100\*as007\*ar921**

where:

- The NAS-Identifier value is **fox**.
- The Calling-Station-ID delimiter character is **\*** (asterisk).
- The interface description value is **ge-1/2/0.100:100**.
- The agent circuit identifier value is **as007**.
- The agent remote identifier value is **ar921**.

Consider an example where all options are configured, but no values are available for the Agent-Circuit-ID, the Agent-Remote-Id, or the stacked VLAN identifier. The other values are as follows:

- NAS identifier—solarium
- interface description—ge-1/0/0.1073741824:101
- interface text description—example-interface
- MAC address—00:00:5E:00:53:00
- VLAN identifier—101

These values result in the following Calling-Station-ID:

```
solarium#ge-1/0/0.1073741824:101#example-interface###00-00-5E-00-53-00##101
```

#### Release History Table

| Release | Description                                                                                                                                                                                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18.1R1  | Starting in Junos OS Release 18.1R1, you can configure the router or switch to ignore or exclude RADIUS standard attributes and VSAs by specifying the standard attribute number or the IANA-assigned vendor ID and the VSA number, respectively. |

## Session Options for Subscriber Access

Session options enable you to specify several characteristics for DHCP, L2TP, and terminated PPP subscriber sessions. Session options are configured in access profiles

that determine the parameters for subscriber access, authentication, authorization, and accounting.

- [Understanding Session Options for Subscriber Access on page 72](#)
- [Configuring Subscriber Session Timeout Options on page 77](#)

## Understanding Session Options for Subscriber Access

You can use access profiles to configure several characteristics of the sessions that are created for DHCP, L2TP, and terminated PPP subscribers. You can place limits on subscriber access based on how long the session has been up, how long the user has been inactive, or both. You can limit subscriber sessions by username per access profile. You can also set parameters that modify a subscriber's username at login based on the subscriber's access profile.

- [Subscriber Session Timeouts on page 72](#)
- [Limits on Subscriber Sessions per Username and Access Profile on page 75](#)
- [Section on page ?](#)
- [Subscriber Username Modification on page 76](#)

### Subscriber Session Timeouts

---

You can limit subscriber access by configuring a session timeout or an idle timeout. Use a session timeout to specify a fixed period of time that the subscriber is permitted to have access. Use an idle timeout to specify a maximum period of time that the subscriber can be idle. You can use these timeouts separately or together. By default, neither timeout is present.

**NOTE:** For all subscriber types other than DHCP (such as L2TP-tunneled and PPP-terminated subscribers), the session timeout value limits the subscriber session. For DHCP subscribers, the session timeout value is used to limit the lease when no other lease time configuration is present. The lease expires when the timeout value expires. If this value is not supplied by either the CLI or RADIUS, the DHCP lease does not expire.

---

The idle timeout is based on accounting statistics for the subscriber. The router determines subscriber inactivity by monitoring data traffic, both upstream from the user (ingress) and downstream to the user (egress). Control traffic is ignored. The subscriber is not considered idle as long as data traffic is detected in either direction.

Optionally, you can specify that only subscriber ingress traffic is monitored; egress traffic is ignored. This configuration is useful in cases where the LNS sends traffic to the remote peer even when the peer is not up, such as when the LNS does not have PPP keepalives enabled and therefore cannot detect that the peer is not up. In this situation, because

by default the LAC monitors both ingress and egress traffic, it detects the egress traffic from the LNS and either does not log out the subscriber or delays detection of inactivity until the egress traffic ceases. When you specify that only ingress traffic is monitored, the LAC can detect that the peer is inactive and then initiate logout.

When either timeout period expires, the non-DHCP subscribers are gracefully logged out, similarly to a RADIUS-initiated disconnect or a CLI-initiated logout. DHCP subscribers are disconnected. The Acct-Terminate-Cause [RADIUS attribute 49] value includes a reason code of 5 for a session timeout and a code of 4 for an idle timeout.

You can configure these limitations to subscriber access on a per-subscriber basis by using the RADIUS attributes Session-Timeout [27] and Idle-Timeout [28]. RADIUS returns these attributes in Access-Accept messages in response to Access-Request messages from the access server.

Service providers often choose to apply the same limitations to large numbers of subscribers. You can reduce the RADIUS provisioning effort for this scenario by defining the limitations for subscribers in an access profile on a per-routing-instance basis. If you do so, RADIUS attributes subsequently returned for a particular subscriber logged in with the profile override the per-routing-instance values.

**BEST PRACTICE:** We recommend that you do not configure a session timeout for subscribers receiving voice services. Because the session timeout is based only on time and not user activity, it is likely to interrupt subscribers actively using a voice service and terminate their calls unexpectedly (from the subscriber viewpoint). This result is a particular concern for emergency services calls.

**BEST PRACTICE:** We recommend that you do not configure an idle timeout for DHCP subscribers. When the timeout expires with no activity and the connection is terminated, the protocol has no means to inform the client. Consequently, these subscribers are forced to reboot their CPE device the next time they attempt to access the Internet.

Contrast the behavior when an idle timeout is configured for PPP subscribers. In this case, timeout expiration causes PPP to terminate the link with the peer. Depending on the CPE device, this termination enables the peer to automatically retry the connection either on demand or immediately. In either case, no subscriber intervention is required.

The available range for setting a timeout is the same whether you configure it in the CLI or through the RADIUS attributes:

- Session timeouts can be set for 1 minute through 527,040 minutes in the CLI and the corresponding number of seconds (60 through 31,622,400) in the Session-Timeout attribute [27].

- Idle timeouts can be set for 10 minutes through 1440 minutes in the CLI and the corresponding number of seconds (600 through 86,400) in the Idle-Timeout attribute [28].

The router interprets the values in the attributes to conform to the supported ranges. For example, for Session-Timeout [27]:

- A value of zero is treated as no timeout.
- A value in the range 1 through 59 is raised to 60 seconds.
- A value that exceeds 31,622,400 is reduced to 31,622,400 seconds.

For Idle-Timeout [28]:

- A value of zero is treated as no timeout.
- A value in the range 1 through 599 is raised to 600 seconds.
- A value that exceeds 86,400 is reduced to 86,400 seconds.

In configurations using dynamically created subscriber VLANs, the idle timeout also deletes the inactive subscriber VLANs when the inactivity threshold has been reached. In addition to deleting inactive dynamic subscriber VLANs, the idle timeout also removes dynamic VLANs when no client sessions were ever created (for example, in the event no client sessions are created on the dynamic VLAN or following the occurrence of an error during session creation or client authentication where no client sessions are created on the dynamic VLAN).

Session and idle timeouts for deleting dynamic subscriber VLANs are useful only in very limited use cases; typically neither timeout is configured for this purpose.

A possible circumstance when they might be useful is when the dynamic VLANs have no upper layer protocol that helps determine when the VLAN is removed with the **remove-when-no-subscribers** statement; for example, when the VLAN is supporting IP over Ethernet without DHCP in a business access model with fixed addresses. However, business access is generally a higher-tier service than residential access and as such typically is not subject to timeouts due to inactivity as might be desired for residential subscribers.

An idle timeout might be appropriate in certain Layer 2 wholesale situations, where the connection can be regenerated when any packet is received from the CPE.

When using the idle timeout for dynamic VLAN removal, keep the following in mind:

- The idle timeout period begins after a dynamic subscriber VLAN interface is created or traffic activity stops on a dynamic subscriber VLAN interface.
- If a new client session is created or a client session is reactivated successfully, the client idle timeout resets.
- The removal of inactive subscriber VLANs functions only with VLANs that have been authenticated.

### Limits on Subscriber Sessions per Username and Access Profile

Legitimate subscribers might share their login credentials with unauthorized persons, expending service provider resources without benefit to the provider. Starting in Junos OS Release 18.4R1, you can control or prevent the sharing of login credentials by limiting the number of active subscriber sessions that are allowed for a specific username associated with an access profile. You can also achieve this control with RADIUS, but configuring the limit locally on the BNG eliminates dependency on an external server.

When you configure a limit, active sessions for the username/access profile combination are tracked. The number of tracked sessions is checked when authd receives a new session login request. If the number of tracked session matches the limit, the new login attempt is rejected and counted as a blocked request.

When authd receives a logout or client termination request for a session, the tracked-sessions count is decremented for that username/access profile entry. If this continues until there are no active sessions for the combination, the entry is removed from the session limit table. All associated username/access profile entries are removed from the table if you delete the access profile or the session-limit from your configuration.

The total number of sessions for a username can exceed the configured limit for a particular access profile, because the same username can be used with multiple access profiles.

**NOTE:** For stacked subscriber sessions such as PPP with autoconfigured VLANs, both usernames in the stack are used for authentication and consequently both are counted against the session limit.

The configured limit applies to existing active subscribers, but existing sessions are not torn down if number of active sessions exceeds the limit for a subscriber with that username and access profile combination.

Consider a situation where five sessions are currently active for a given username/access profile combination when you configure a limit of two.

1. The active sessions count is recorded as five in the session limit table entry for the combination.
2. A new subscriber with the same username and access profile tries to log in. The attempt is blocked because the limit of two sessions is already exceeded (five > two).
3. An existing subscriber logs out, decrementing the active sessions count to four.
4. A new subscriber with the same username and access profile tries to log in. The attempt is blocked because the limit of two sessions is still exceeded (four > two).
5. Three existing subscribers log out, reducing the active sessions count to one.
6. A new subscriber with the same username and access profile tries to log in. The attempt is allowed because the limit of two sessions has not yet been reached (one < two).

The session limit design prevents a denial-of-service event where a malicious user makes multiple login attempts with the correct username and access profile, but the wrong password. The numerous login attempts might exceed the configured session limit, but this does not occur because the tracked-sessions count is incremented only when the subscriber session state transitions to the active state, which the malicious logins do not achieve.

### Subscriber Username Modification

For Layer 2 wholesale applications, some network service providers employ username modification to direct subscribers to the appropriate retail enterprise network. This modification is also called username *stripping*, because some of the characters in the username are stripped away and discarded. The remainder of the string becomes the new, modified username. The modified username is used by an external AAA server for session authentication and accounting. The modification parameters are applied according to a subscriber access profile that also determines the subscriber and session context; that is, the logical system:routing instance (LS:RI) used by the subscriber. Only the default (master) logical system is supported. Because the wholesaler differentiates between multiple retailers by placing each in a different LS:RI, the usernames are appropriately modified for each retailer.

You can select up to eight characters as delimiters to mark the boundary between the discarded and retained portions of the original username; there is no default delimiter. The portion of the name to the right of the selected delimiter is discarded along with the delimiter. By configuring multiple delimiters, a given username structure can result in different modified usernames. You can configure the direction in which the original name is parsed to determine which delimiter marks the boundary. By default, the parse direction is from left to right.

Consider the following examples:

- You specify one delimiter, @. The username is user1@example.com. In this case, the parse direction does not matter. In either case, the single delimiter is found and example.com is discarded. The modified username is user1.

| parse direction | identify delimiter                                                                  | modified username |
|-----------------|-------------------------------------------------------------------------------------|-------------------|
| left-to-right   |  | user1             |
| right-to-left   |  | user1             |

804376

- You specify one delimiter, @. The username is user1@test@example.com. In this case, the parse direction results in different usernames.
  - Parse direction is left-to-right—The left-most @ is identified as the delimiter and test@example.com is discarded. The modified username is user1.
  - Parse direction is right-to-left—The right-most @ is identified as the delimiter and example.com is discarded. The modified username is user1@test.

| parse direction | identify delimiter                                                                                                   | modified username |
|-----------------|----------------------------------------------------------------------------------------------------------------------|-------------------|
| left-to-right   | user1@ <b>test</b> @example.com<br> | user1             |
| right-to-left   | user1@test@ <b>example</b> .com<br> | user1@test        |

8043377

- You specify two delimiters, @ and /. The username is user1@bldg1/example.com. The parse direction results in different usernames.
  - Parse direction is left-to-right—The @ is identified as the delimiter and bldg1/example.com is discarded. The modified username is user1.
  - Parse direction is right-to-left—The / is identified as the delimiter and example.com is discarded. The modified username is user1@bldg1.

| parse direction | identify delimiter                                                                                                    | modified username |
|-----------------|-----------------------------------------------------------------------------------------------------------------------|-------------------|
| left-to-right   | user1@ <b>bldg1</b> /example.com<br> | user1             |
| right-to-left   | user1@bldg1/ <b>example</b> .com<br> | user1@bldg1       |

8043378

You can configure a subscriber access profile so that a portion of each subscriber login string is stripped and subsequently used as a modified username by an external AAA server for session authentication and accounting. The modified username appears, for example, in RADIUS Access-Request, Acct-Start, and Acct-Stop messages, as well as RADIUS-initiated disconnect requests and change of authorization (CoA) requests.

**See Also** • [RADIUS IETF Attributes Supported by the AAA Service Framework on page 11](#)

## Configuring Subscriber Session Timeout Options

Subscriber session timeout options enable you to place limits on subscriber access based on how long the session has been up, how long the user has been inactive, or both. The subscriber session options apply to both L2TP-tunneled and PPP-terminated subscriber sessions. For DHCP subscribers, the session timeout limits the DHCP lease time.

**NOTE:** To configure the timeout attributes in RADIUS, refer to the documentation for your RADIUS server.

To configure limitations on subscriber sessions, configure the session options in the client profile that applies to the subscriber:

- Terminate the subscriber when the configured session timeout expires, regardless of activity.

```
[edit access profile profile-name session-options]
user@host# set client-session-timeout minutes
```

- Terminate the subscriber when there is no ingress or egress data traffic for the duration of the configured idle timeout.

```
[edit access profile profile-name session-options]
user@host# set client-idle-timeout minutes
```

- Terminate the subscriber when there is no ingress data traffic for the duration of the configured idle timeout; ignore egress traffic.

```
[edit access profile profile-name session-options]
user@host# set client-idle-timeout minutes
user@host# set client-idle-timeout-ingress-only
```

For example, to configure session timeout options in the **acc-prof** client profile, specifying an idle timeout of 15 minutes, that only ingress traffic is monitored, and that the session times out after 120 minutes:

```
[edit]
access {
  profile {
    acc-prof {
      session-options {
        client-idle-timeout 15;
        client-idle-timeout-ingress-only;
        client-session-timeout 120;
      }
    }
  }
}
```

## Limiting the Number of Active Sessions per Username and Access Profile

You can control the degree to which legitimate subscribers can share their login credentials by limiting the number of active subscriber sessions that are allowed for a specific username associated with an access profile.

To limit the number of active sessions per username and access profile:

- ```
[edit access profile profile-name]
user@host# set session-limit-per-username number
```

For example, to set the maximum number of active sessions per username to five for the access profile **isp-weg-4**:

```
[edit access profile isp-weg-4]
user@host# set session-limit-per-username 5
```

You can use the `show network-access aaa statistics session-limit-per-username` command to view statistics for active sessions and blocked requests.

You can use the `clear network-access aaa statistics session-limit-per-username username` command as an aid to debugging by clearing the blocked request statistics for any of the following cases:

- For all usernames across all access profiles.
- For a specific username across all access profiles.
- For a specific username in a specific access profile.
- For all usernames in a specific access profile.

## Configuring Username Modification for Subscriber Sessions

You can use subscriber session options to set parameters that modify a subscriber's username at login based on the subscriber's access profile. This modification is also called username *stripping*, because some of the characters in the username are stripped away and discarded. The remainder of the string becomes the new, modified username. The modified username is used by an external AAA server for session authentication and accounting. This capability can be useful, for example, in Layer 2 wholesale implementations, where the network service providers employ username modification to direct subscribers to the appropriate retail enterprise network.

The modification parameters are applied according to a subscriber access profile that also determines the subscriber and session context; that is, the logical system:routing instance (LS:RI) used by the subscriber. Only the default (master) logical system is supported. Because the wholesaler differentiates between multiple retailers by placing each in a different LS:RI, the usernames are appropriately modified for each retailer.

You can select up to eight characters as delimiters to mark the boundary between the discarded and retained portions of the original username; there is no default delimiter. The portion of the name to the right of the selected delimiter is discarded along with the delimiter. By configuring multiple delimiters, a given username structure can result in different modified usernames. You can configure the direction in which the original name is parsed to determine which delimiter marks the boundary. By default, the parse direction is from left to right.

To configure username modification:

1. Define a profile consisting of a set of AAA options for authorizing and configuring a subscriber or set of subscribers with a subscriber access profile.
  - a. Specify the name of the subscriber access profile that includes the username stripping configuration.

```
[edit access aaa-options aaa-options-name]
user@host# access-profile profile-name
```

- b. (Optional) Specify the logical-system:routing-instance (LS:RI) that the subscriber session uses for AAA (RADIUS) interactions like authenticating and accounting. For example, this may correspond to the LS:RI for a retail ISP that provides services to the subscriber.

```
[edit access aaa-options aaa-options-name]
user@host# aaa-context aaa-context-name
```

- c. (Optional) Specify the logical-system:routing-instance (LS:RI) in which the subscriber interface is placed. For example, this may correspond to the LAC-facing interface on the LNS that is accessed by all requests from a subscriber residence.

```
[edit access aaa-options aaa-options-name]
user@host# subscriber-context subscriber-context-name
```

2. Configure the session options in the access profile that specify how usernames are stripped.
  - a. Specify one or more delimiters to mark the boundary between the discarded and retained portions of the original username.

```
[edit access profile profile-name session-options strip-user-name]
user@host# set delimiter [ delimiter ]
```

- b. (Optional) Specify the direction in which the original username is examined to find a delimiter. The default direction is left-to-right.

```
[edit access profile profile-name session-options strip-user-name]
user@host# set parse-direction (left-to-right | right-to-left)
```

3. (Optional) Specify that the AAA options are on a per-interface basis when dynamic subscribers are authenticated.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit" ppp-options]
user@host# set aaa-options aaa-options-name
```

4. (Optional) Specify that the AAA options are part of the PPP options in a group profile that applies to tunneled PPP subscribers at the LNS.

```
[edit access group-profile profile-name ppp]
user@host# set ppp-options aaa-options aaa-options-name
```

In the following example, the AAA options profile, `aaa1`, specifies a subscriber access profile, `entA`, for subscribers in the default logical system and routing instance 1. The access profile, `entA`, specifies that usernames are examined from left to right until the delimiter, `@`, is found. The AAA options profile is applied to tunneled PPP subscribers that belong to the group profile, `FD1`.

```
[edit access aaa-options aaa1]
user@host# access-profile entA
```

```

user@host# aaa-context master:1
[edit access profile entA session-options strip-user-name]
user@host# set delimiter @
user@host# set parse-direction left-to-right
[edit access group-profile FD1 ppp]
user@host# set ppp-options aaa-options aaa1

```

Given that configuration, suppose a subscriber attempts to log in with the username, user1@example.com. When this name is examined, the delimiter and the string example.com are discarded, leaving a modified username of user1. Note that the result is the same if the parse direction is set to examine the name from right to left, because only one delimiter is defined and only one is present in the original username.

parse direction	identify delimiter	modified username
left-to-right		user1
right-to-left		user1

804376

Now suppose the subscriber logs in with the username, user1@test@example.com. For a username like this, the parsing direction makes a difference in the modified username. The configuration determines that the first instance of the delimiter @ is found first, because the name is parsed from left to right. This delimiter and the string test@example.com are discarded, leaving user1 as the modified username.

What happens when the configuration sets a different parsing direction?

```

[edit access profile entA session-options strip-user-name]
user@host# set delimiter @
user@host# set parse-direction right-to-left

```

In this case, for the username user1@test@example.com, the second instance of the delimiter is identified and it is discarded with the string @example.com. The modified username is user1@test.

parse direction	identify delimiter	modified username
left-to-right		user1
right-to-left		user1@test

804377

You can achieve the same results of different modified usernames based on parse direction by configuring more than one delimiter as in the following configuration, where you specify two delimiters, @ and /.

```

[edit access profile entA session-options strip-user-name]
user@host# set delimiter [@ /]
user@host# set parse-direction left-to-right

```

For the username `user1@bldg1/example.com`, parsing left to right identifies the `@` delimiter first and the modified username is `user1`. Parsing right to left instead, identifies the `/` delimiter first and strips it away with the string `example.com`, leaving a modified username of `user1@bldg1`.

parse direction	identify delimiter	modified username
left-to-right	 <code>user1@bldg1/example.com</code>	<code>user1</code>
right-to-left	 <code>user1@bldg1/example.com</code>	<code>user1@bldg1</code>

## Removing Inactive Dynamic Subscriber VLANs

Subscriber session timeouts enable you to place limits on subscriber access based on how long the session has been up, how long the user has been inactive, or both. In configurations using dynamically created subscriber VLANs, the idle timeout also:

- Deletes the inactive subscriber VLANs when the inactivity threshold has been reached.
- Removes dynamic VLANs when no client sessions were ever created (for example, in the event no client sessions are created on the dynamic VLAN or following the occurrence of an error during session creation or client authentication where no client sessions are created on the dynamic VLAN).

**NOTE:** Session timeouts are typically not used for deleting dynamic subscriber VLANs. The timeout might be useful only in very limited use cases. One case might be when the dynamic VLANs have no upper layer protocol that helps determine when the VLAN is removed with the `remove-when-no-subscribers` statement; for example, when the VLAN is supporting IP over Ethernet without DHCP in a business access model with fixed addresses.

**NOTE:** To configure the idle timeout attribute in RADIUS, refer to the documentation for your RADIUS server.

To remove inactive dynamic subscriber VLANs:

1. Edit session options for the router access profile.

```
[edit]
user@host# edit access profile profile-name session-options
```

2. Configure the maximum period a subscriber session can remain idle.

```
[edit access profile profile-name session-options]
user@host# set client-idle-timeout minutes
```

#### Release History Table

Release	Description
18.4R1	Starting in Junos OS Release 18.4R1, you can control or prevent the sharing of login credentials by limiting the number of active subscriber sessions that are allowed for a specific username associated with an access profile.

### Manual Configuration of the NAS-Port-ID RADIUS Attribute

Subscriber management uses the NAS-Port-ID (RADIUS attribute 87) to provide an interface description that identifies the physical interface that is used to authenticate subscribers. The NAS-Port-ID is included in RADIUS Access-Request, Acct-Start, Acct-Stop, Acct-On, and Acct-Off messages.

You can configure access profiles to specify additional information in the NAS-Port-ID. The additional information can be any combination of the interface description (the

default value), the Agent Circuit ID, the Agent Remote ID, and the NAS identifier. You can also specify an optional delimiter character, which separates the values in a NAS-Port-ID. The default delimiter character is the hash character (#).

A default NAS-Port-ID for nonchannelized interfaces consists of the following **interface-description** string:

***interface-type-slot/adapter/port.subinterface[:svlan-vlan]***

For example: ge-1/2/0.100:100.

Starting in Junos OS Release 17.3R1, a logical port number is added to the default format for only channelized interfaces. For channelized interfaces, the default format for a NAS-Port-ID consists of the following **interface-description** string:

***interface-type-slot/adapter/logical-port-number.subinterface[:svlan-vlan]***

For example, xe-0/1/143.4-5.6.

You can optionally configure the interface description format in an access profile to exclude the adapter, channel, or subinterface information.

You might optionally configure an access profile that specifies that the NAS-Port-ID includes the NAS identifier, the Agent Circuit ID, and the Agent Remote ID, in addition to the default interface description. For this configuration, the NAS-Port-ID consists of the following string:

**nas-identifier#interface-description#agent-circuit-id#agent-remote-id**

For example:

**retailer25#ge-1/2/0.100:100#ACI 12/1/22/1230:1.1.23#ARI 55/2/23.9999:10.11.1923**

**NOTE:** The NAS-Port-ID displays the configured values in the following order (where # is the delimiter):

**nas-identifier#interface-description#agent-circuit-id#agent-remote-id**

---

- [RADIUS Server Options for Subscriber Access on page 5](#)
  - [Interface Text Descriptions for Inclusion in RADIUS Attributes on page 50](#)

## Configuring a NAS-Port-ID with Additional Options

The NAS-Port-ID (RADIUS attribute 87) identifies the physical interface that subscriber management uses to authenticate subscribers. By default, the NAS-Port-ID includes the **interface-description** value that describes the physical interface. You can include the following optional values in the NAS-Port-ID:

- **agent-circuit-id**
- **agent-remote-id**
- **interface-description**
- **interface-text-description**
- **nas-identifier**
- **postpend-vlan-tags**

**NOTE:** If you specify any optional values, the default **interface-description** value is no longer automatically included. You must explicitly specify the **interface-description** value if you want it to appear in the NAS-Port-ID.

When you specify optional values, the router arranges the values in the following default order, where the **#** character is the default delimiter:

**nas-identifier # interface-description # interface-text-description # agent-circuit-id # agent-remote-id # postpend-vlan-tags**

You can use the **order** option to configure the explicit order in which the specified optional values appear in the NAS-Port-ID string.

To configure optional values in the NAS-Port-ID string:

1. Specify the access profile you want to configure.

```
[edit]
user@host# edit access profile retailer25
```

2. Specify that you want to configure RADIUS options.

```
[edit access profile retailer25]
user@host# edit radius options
```

3. Specify the character to use as the delimiter between the different attribute values in the NAS-Port-ID. By default, subscriber management uses the hash character (**#**).

```
[edit access profile retailer25 radius options]
user@host# set nas-port-delimiter %
```

- Specify that you want to configure the format of the NAS-Port-ID.

```
[edit access profile retailer25 radius options]
user@host# edit nas-port-id-format
```

- (Optional) Specify the optional values you want to include in the NAS-Port-ID string. The optional values appear in the default order.

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set interface-description nas-identifier agent-remote-id agent-circuit id
```

- (Optional) To specify an explicit non-default order in which the optional values appear in the NAS-Port-ID string, include the **order** option before each optional value. Specify the values in the order you want them to appear.

See “Configuring the Order in Which Optional Values Appear in the NAS-Port-ID” on page 86.

- See Also**
- [Configuring RADIUS Server Options for Subscriber Access on page 61](#)
  - [Configuring RADIUS Server Parameters for Subscriber Access on page 61](#)

## Configuring the Order in Which Optional Values Appear in the NAS-Port-ID

In addition to specifying the values that you want to include in the NAS-Port-ID, you can use the **order** option to specify the explicit order in which you want the values to appear.

By default, the router arranges the specified values in the following order, where the # character is the delimiter:

```
nas-identifier # interface-description # interface-text-description #
agent-circuit-id # agent-remote-id # postpend-vlan-tags
```

**NOTE:** The default order and the customized order are mutually exclusive. The configuration fails if you try to specify both.

To configure the specific order in which you want the optional values to appear in the NAS-Port-ID:

- Specify that you want to configure the format of the NAS-Port-ID.

```
[edit access profile retailer25 radius options]
user@host# edit nas-port-id-format
```

- Include the **order** option before each optional value that you want to include in the NAS-Port-ID. Specify the optional values in the order in which you want them to appear.

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set order interface-description order nas-identifier order agent-remote-id
order interface-text-description
```

This configuration configures the following NAS-Port-ID string, where the % character is the delimiter:

```
interface-description % nas-identifier % agent-remote-id % interface-text-description
```

3. (Optional) To add an optional value to an existing NAS-Port-ID string:

Use the **order** option and the name of the optional value to add the new value to the existing NAS-Port-ID. The new value is added at the end of the string. For example:

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set order agent-circuit-id
```

This configuration modifies the example in the previous step by adding the **agent-circuit-id** to the end of the NAS-Port-ID string:

```
interface-description % nas-identifier % agent-remote-id % interface-text-description
% agent-circuit-id
```

**NOTE:** If you attempt to add an optional value that already exists in the NAS-Port-ID string, the new specification is ignored and the existing value remains in the order in which it was originally configured.

If you want to modify the existing order, delete the existing specification and define the new order.

## Enabling Unique NAS-Port Attributes (RADIUS Attribute 5) for Subscribers

Typically, the router derives the RADIUS NAS-Port attribute (attribute 5) value from a subscriber's physical port, as shown in the following list.

- Subscribers over Ethernet interfaces—combination of **slot/adaptor/port/SVLAN ID/VLAN ID**
- Subscribers over ATM interfaces—combination of **slot/adaptor/port/VPI/VCI**

However, in some customer environments, a NAS-Port attribute that is based on the physical port might not be unique, and multiple subscribers might have the same NAS-Port value. To avoid the duplicate use of a NAS-Port attribute, you can configure the router to provide unique NAS-Port attributes. The unique NAS-Port attribute consists of 32 bits (the most significant bit [MSB] is always 0), which make up two parts— a unique number that the router internally generates, and an optional unique chassis ID that you specify.

If you create the NAS-Port value based on the internally generated number only, the resulting NAS-Port value is unique within the router only. If your implementation requires NAS-Port values to be unique across all MX series routers in the network, you must also configure the unique chassis ID.

Uniqueness across all routers—To configure a NAS-Port attribute that is unique across all routers in the network, you use the following procedure:

- Configure the chassis ID width (1–7 bits)—You must use the same width for all routers in the network.
- Configure the chassis ID—You must ensure that you configure a unique ID for each router.
- The router uses the remainder of the 31 bits (minus the MSB and the number of bits used for the chassis ID width) for the internally generated number.

Uniqueness within the local router—To configure a NAS-Port attribute that is unique within the local router only, you use the following procedure:

- Do not configure the chassis ID width or chassis ID.
- The router uses all 31 bits for the internally generated number. The resulting NAS-Port attribute is unique only within the router and cannot be guaranteed to be unique for any other routers in the network.

To configure unique NAS-Port attribute values for subscribers:

**NOTE:** Before configuring the unique NAS-Port attribute, ensure that neither the `nas-port-extended-format` statement or the `vlan-nas-port-stacked-format` statement is configured at the `[edit access profile profile-name radius options]` hierarchy level. Otherwise, the commit operation will fail.

---

1. Specify that you want to configure RADIUS options at the `[edit access]` hierarchy level.

```
[edit access]
user@host# edit radius-options
```

2. Specify that you want to enable unique NAS-Port attribute support.

```
[edit access radius-options]
user@host# edit unique-nas-port
```

**NOTE:** This step configures the router to generate a unique number, which creates a NAS-Port value that is unique within the router.

3. (Optional) If you want to provide NAS-Port values that are unique across all MX series routers in the network, complete the following additional steps.
  - Specify the number of bits used in the chassis ID portion of the NAS-Port attribute. You can specify 1-7 bits. You must use the same chassis ID width for all routers across the network.

```
[edit access radius-options unique-nas-port]
user@host# set chassis-id-width chassis-id-width
```

- Specify the value you want to use for chassis ID portion of the NAS-Port attribute. The chassis ID can be in the range from 0-127 bits. You must configure a unique chassis ID for each MX router in the network.

```
[edit access radius-options unique-nas-port]
user@host# set chassis-id chassis-id
```

## RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN Overview

On MX Series routers with Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces, you can configure the NAS-Port-Type (61) RADIUS IETF attribute, and an extended format for the NAS-Port (5) RADIUS IETF attribute, on a per-interface, per-VLAN, or per-stacked VLAN basis. The router passes the NAS-Port and NAS-Port-Type attributes to the RADIUS server during the authentication, authorization, and accounting (AAA) process.

This overview covers the following topics:

- [NAS-Port-Type RADIUS Attribute on page 90](#)
- [NAS-Port RADIUS Attribute on page 90](#)
- [NAS-Port Options Configuration and Subscriber Network Access Models on page 90](#)
- [NAS-Port Options Definition on page 90](#)

### NAS-Port-Type RADIUS Attribute

---

The NAS-Port-Type attribute specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber. When you use the **nas-port-type** statement to configure the NAS-Port-Type, you can specify one of several predefined port types, or a user-defined port type value in the range 0 through 65535.

### NAS-Port RADIUS Attribute

---

The NAS-Port attribute specifies the physical port number of the NAS that is authenticating the user, and is formed by a combination of the physical port's slot number, port number, adapter number, VLAN ID, and S-VLAN ID. The NAS-Port extended format, which you configure with the **nas-port-extended-format** statement, specifies the number of bits (bit width) for each field in the NAS-Port attribute: slot, adapter, port, VLAN, and S-VLAN.

To include stacked VLAN IDs, in addition to VLAN IDs, in the NAS-Port extended format, use the **stacked** option as part of the **nas-port-extended-format** statement. If you do not configure the **stacked** option, stacked VLAN IDs are not included in the extended format.

### NAS-Port Options Configuration and Subscriber Network Access Models

---

Configuring the NAS-Port-Type and the extended format for NAS-Port on a per-VLAN, per-stacked VLAN, or per-physical interface basis is useful in network configurations that use the following subscriber access models:

- 1:1 access model (per-VLAN basis)—In a 1:1 access model, dedicated customer VLANs (C-VLANs) provide a one-to-one correspondence between an individual subscriber and the VLAN encapsulation.
- N:1 access model (per-S-VLAN basis)—In an N:1 access model, service VLANs are dedicated to a particular service, such as video, voice, or data, instead of to a particular subscriber. Because a service VLAN is typically shared by many subscribers within the same household or in different households, the N:1 access model provides a many-to-one correspondence between individual subscribers and the VLAN encapsulation.
- 1:1 or N:1 access model (per-physical interface basis)—You can configure the NAS-Port-Type and NAS-Port format on a per-physical interface basis for both the 1:1 access model and the N:1 access model.

### NAS-Port Options Definition

---

As an alternative to globally configuring the NAS-Port-Type and NAS-Port extended format in an access profile, you can configure these attributes on a per-interface, per-VLAN, or per-stacked VLAN basis. To do so, you must create a *NAS-Port options definition*, which includes some or all of the following components:

- NAS-Port-Type value—Specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.
- NAS-Port extended format—Configures the number of bits (bit width) for each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN. Optionally,

you can also use the **stacked** option as part of the **nas-port-extended-format** statement to include S-VLAN IDs, in addition to VLAN IDs, in the extended format. If you do not configure the **stacked** option, stacked VLAN IDs are not included in the extended format.

- VLAN ranges or S-VLAN ranges—Defines the VLAN range of subscribers or stacked VLAN range of subscribers to which each NAS-Port options definition applies.

### Guidelines for Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN

The following guidelines apply when you configure the NAS-Port-Type attribute and the extended format for the NAS-Port attribute on a per-VLAN, per-stacked VLAN, or per-physical interface basis:

- You can create a maximum of 16 NAS-Port options definitions per physical interface. Each definition can include either a maximum of 32 VLAN ranges or a maximum of 32 stacked VLAN ranges, but cannot include a combination of VLAN ranges and stacked VLAN ranges.
- Configuring the NAS-Port-Type attribute and NAS-Port extended format on a per-VLAN, per-stacked VLAN, or per-physical interface basis overrides the global settings for these attributes configured in an access profile.
- If the NAS-Port-Type attribute and the NAS-Port extended format are not configured on a per-VLAN basis (in a 1:1 access model) or on a per-stacked VLAN basis (in an N:1 access model), the router uses the global settings configured for these attributes in an access profile for all RADIUS request messages.

## Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN

On MX Series routers with MPC/MIC interfaces, you can configure the NAS-Port-Type (61) RADIUS IETF attribute, and an extended format for the NAS-Port (5) RADIUS IETF attribute, on a per-physical interface, per-VLAN, or per-stacked VLAN (S-VLAN) basis. The router passes the NAS-Port-Type and NAS-Port attributes to the RADIUS server during the authentication, authorization, and accounting (AAA) process.

To configure the NAS-Port-Type and NAS-Port extended format on a per-physical interface, per-VLAN, or per-stacked VLAN basis, you must create a NAS-Port options definition, which includes the following components:

- NAS-Port-Type value—Specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.
- NAS-Port extended format—Configures the number of bits (bit width) for each field in the NAS-Port attribute, which specifies the physical port number of the NAS that is authenticating the subscriber. Fields in the NAS-Port attribute include: slot, adapter, port, VLAN, and S-VLAN. Optionally, you can also use the **stacked** option as part of the **nas-port-extended-format** statement to include S-VLAN IDs, in addition to VLAN IDs, in the extended format. If you do not configure the **stacked** option, stacked VLAN IDs are not included in the extended format.
- VLAN ranges or S-VLAN ranges—Defines the VLAN range of subscribers or stacked VLAN range of subscribers to which each NAS-Port options definition applies.

**NOTE:** You can create a maximum of 16 NAS-Port options definitions per physical interface. Each definition can include a maximum of 32 VLAN ranges or 32 stacked VLAN ranges, but *cannot* include a combination of VLAN ranges and stacked VLAN ranges.

To configure the NAS-Port-Type and NAS-Port extended format on a per-physical interface, per-VLAN, or per-stacked VLAN basis:

1. Specify the physical interface you want to configure.
2. Enable VLAN tagging, stacked VLAN tagging, or flexible VLAN tagging on the interface.
  - For VLAN tagging, see *Enabling VLAN Tagging*.
  - For stacked VLAN tagging, see *Configuring Stacked VLAN Tagging*.
  - For flexible VLAN tagging, also referred to as mixed tagging, see *Enabling VLAN Tagging*.
3. Specify that you want to configure RADIUS options for a physical interface, VLAN, or S-VLAN.

```
[edit interfaces interface-name]
```

```
user@host> edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type, and the VLAN ranges or stacked VLAN ranges to which the named NAS-Port options definition applies.
  - For per-physical interface configurations, see “Configuring the RADIUS NAS-Port-Type per Physical Interface” on page 95.
  - For per-VLAN configurations, see “Configuring the RADIUS NAS-Port-Type per VLAN” on page 96.
  - For per-stacked VLAN configurations, see “Configuring the RADIUS NAS-Port-Type per Stacked VLAN” on page 98.
6. Configure the NAS-Port extended format, and the VLAN ranges or stacked VLAN ranges to which the named NAS-Port options definition applies.
  - For per-physical interface configurations, see “Configuring the RADIUS NAS-Port Extended Format per Physical Interface” on page 99.
  - For per-VLAN configurations, see “Configuring the RADIUS NAS-Port Extended Format per VLAN” on page 101.
  - For per-stacked VLAN configurations, see “Configuring the RADIUS NAS-Port Extended Format per Stacked VLAN” on page 102.

## Manual Configuration of the NAS-Port-Type RADIUS Attribute

Subscriber management uses the NAS-Port-Type (RADIUS attribute 61) to identify the type of physical port that is used to authenticate subscribers. By default, subscriber management uses a NAS-Port-Type of **ethernet**.

You can optionally configure access profiles to provide the value for the NAS-Port-Type attribute, which enables you to explicitly specify the NAS port type that is used for a given connection. For example, you might configure an access profile that specifies that a NAS port type of **wireless** is used for all Ethernet connections that are managed by that access profile.

**NOTE:** The **ethernet-port-type-virtual** configuration statement takes precedence over the **nas-port-type** statement when you include both statements in the same access profile. When you include the **ethernet-port-type-virtual** statement, subscriber management uses the RADIUS attribute value of 5, which specifies a NAS port type of **virtual**.

Table 10 on page 94 shows the supported port type values for RADIUS attribute 61 (NAS-Port-Type) that you can include in an access profile.

**Table 10: RADIUS NAS-Port-Type Values**

Statement Option	NAS-Port-Type Value	Description
<i>value</i>	0–65535	Number that indicates either the IANA-assigned value for the RADIUS port type or a custom number-to-port type defined by the user
adsl-cap	12	Asymmetric DSL, carrierless amplitude phase (CAP) modulation
adsl-dmt	13	Asymmetric DSL, discrete multitone (DMT)
async	0	Asynchronous
cable	17	Cable
ethernet	15	Ethernet
fdi	21	Fiber Distributed Data Interface
g3-fax	10	G.3 Fax
hdlc-clear-channel	7	HDLC Clear Channel
iapp	25	Inter-Access Point Protocol (IAPP)
isdl	14	ISDN DSL
isdn-sync	2	ISDN Synchronous
isdn-v110	4	ISDN Async V.110
isdn-v120	3	ISDN Async V.120
plafs	6	Personal Handyphone System (PHS) Internet Access Forum Standard
sdsl	11	Symmetric DSL
sync	1	Synchronous
token-ring	20	Token Ring
virtual	5	Virtual
wireless	18	Other wireless

Table 10: RADIUS NAS-Port-Type Values (continued)

Statement Option	NAS-Port-Type Value	Description
wireless-1x-ev	24	Wireless 1xEV
wireless-cdma2000	22	Wireless code division multiple access (CDMA) 2000
wireless-ieee80211	19	Wireless 802.11
wireless-umts	23	Wireless universal mobile telecommunications system (UMTS)
x25	8	X.25
x75	9	X.75
xdsl	16	DSL of unknown type

**See Also** • [Configuring RADIUS Server Options for Subscriber Access on page 61](#)

## Configuring the RADIUS NAS-Port-Type per Physical Interface

As an alternative to globally configuring the NAS-Port-Type (61) RADIUS attribute in an access profile, you can configure the NAS-Port-Type on a per-physical interface basis as part of a NAS-Port options definition. The NAS-Port-Type specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.

Configuring NAS-Port options definitions on a per-physical interface basis is useful in network configurations that use a 1:1 access model or an N:1 access model.

To configure the NAS-Port-Type RADIUS attribute per physical interface:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a physical interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-type port-type
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-physical interface configurations typically require you to create a VLAN range that consists of all VLAN IDs on the physical interface. To do so, use the **any** option with the **vlan-ranges** statement.

The following example shows a per-interface NAS-Port options definition named **subscribers-east** that configures the **wireless-umts** NAS-Port-Type for a VLAN range consisting of all VLAN IDs on Gigabit Ethernet physical interface ge-1/0/0.

```
[edit interfaces ge-1/0/0 radius-options]
nas-port-options subscribers-east {
  nas-port-type wireless-umts;
  vlan-ranges {
    any;
  }
}
```

## Configuring the RADIUS NAS-Port-Type per VLAN

As an alternative to globally configuring the NAS-Port-Type (61) RADIUS attribute in an access profile, you can configure the NAS-Port-Type on a per-VLAN basis as part of a NAS-Port options definition. The NAS-Port-Type specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.

Configuring NAS-Port options definitions on a per-VLAN basis is useful in network configurations that use a 1:1 access model.

To configure the NAS-Port-Type RADIUS attribute per VLAN:

1. Specify the interface you want to configure.

```
[edit]
```

```
user@host# edit interfaces interface-name
```

2. Enable VLAN tagging on the interface.

```
[edit interfaces interface-name]  
user@host# set vlan-tagging
```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a VLAN interface.

```
[edit interfaces interface-name]  
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]  
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]  
user@host# set nas-port-type port-type
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]  
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-VLAN configurations typically require you to create a VLAN range that consists of a single VLAN ID on the physical interface. To do so, set the **low-tag** and **high-tag** options in the **vlan-ranges** statement to the same value, as shown in the following example.

The following example shows a per-VLAN NAS-Port options definition named subscribers-west that configures the **ethernet** NAS-Port-Type for VLAN ID 3 on Gigabit Ethernet physical interface ge-1/1/0.

```
[edit interfaces ge-1/1/0 radius-options]  
nas-port-options subscribers-west {  
  nas-port-type ethernet;  
  vlan-ranges {  
    3-3;  
  }  
}
```

## Configuring the RADIUS NAS-Port-Type per Stacked VLAN

As an alternative to globally configuring the NAS-Port-Type (61) RADIUS attribute in an access profile, you can configure the NAS-Port-Type on a per-stacked VLAN basis as part of a NAS-Port options definition. The NAS-Port-Type specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.

Configuring NAS-Port options definitions on a per-stacked VLAN basis is useful in network configurations that use an N:1 access model.

To configure the NAS-Port-Type RADIUS attribute per stacked VLAN:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable stacked VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set stacked-vlan-tagging
```

Setting stacked VLAN tagging enables you to configure dual VLAN tags for all logical interfaces on the physical interface. You must enable stacked VLAN tagging before you can configure the stacked VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a stacked VLAN interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-type port-type
```

6. Configure the stacked VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set stacked-vlan-ranges (any | low-outer-tag-high-outer-tag),any
```

Per-stacked VLAN configurations require you to create a stacked VLAN range of subscribers to which the NAS-Port options definition applies. You must configure the low and high outer tags (VLAN IDs) in the range 1 through 4094, and the inner tag (S-VLAN ID) as **any** to represent all S-VLAN ID tags.

7. Repeat Steps 3 through 6 to configure additional NAS-Port options definitions on this interface.

The following example creates two NAS-Port options definitions, subscribers-north and subscribers-south, configured on a per-stacked VLAN basis on Gigabit Ethernet physical interface ge-1/1/0.

The subscribers-north definition configures a NAS-Port-Type user-defined value (4711) for a stacked VLAN range with outer VLAN ID 1 and all inner S-VLAN IDs. The subscribers-south definition configures a NAS-Port-Type user-defined value (4722) for a stacked VLAN range with outer VLAN IDs in the range 2 through 10, and all inner S-VLAN IDs.

```
[edit interfaces ge-2/0/1 radius-options]
nas-port-options subscribers-north {
  nas-port-type 4711;
  stacked-vlan-ranges {
    1-1,any;
  }
}
nas-port-options subscribers-south {
  nas-port-type 4722;
  stacked-vlan-ranges {
    2-10,any;
  }
}
```

## Configuring the RADIUS NAS-Port Extended Format per Physical Interface

As an alternative to globally configuring the extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-physical interface basis as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN.

Configuring NAS-Port options definitions on a per-physical interface basis is useful in network configurations that use a 1:1 access model or an N:1 access model.

To configure an extended format for the NAS-Port RADIUS attribute per physical interface:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a physical interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port extended format.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-extended-format slot-width width adapter-width width
port-width width vlan-width width
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-physical interface configurations typically require you to create a VLAN range that consists of all VLAN IDs on the physical interface. To do so, use the **any** option with the **vlan-ranges** statement.

The following example shows a per-interface NAS-Port options definition named **boston-subscribers** that configures a NAS-Port extended format consisting of an 8-bit slot field, 8-bit adapter field, 8-bit port field, and 4-bit VLAN field. The **boston-subscribers** definition applies to a VLAN range consisting of all VLAN IDs on Gigabit Ethernet physical interface **ge-2/0/1**.

```
[edit interfaces ge-2/0/1 radius-options]
nas-port-options boston-subscribers {
  nas-port-extended-format {
    slot-width 8;
    adapter-width 8;
    port-width 8;
    vlan-width 4;
  }
  vlan-ranges {
```

```

    any;
  }
}

```

## Configuring the RADIUS NAS-Port Extended Format per VLAN

As an alternative to globally configuring the extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-VLAN basis as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN.

Configuring NAS-Port options definitions on a per-VLAN basis is useful in network configurations that use a 1:1 access model.

To configure an extended format for the NAS-Port RADIUS attribute per VLAN:

1. Specify the interface you want to configure.

```

[edit]
user@host# edit interfaces interface-name

```

2. Enable VLAN tagging on the interface.

```

[edit interfaces interface-name]
user@host# set vlan-tagging

```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a VLAN interface.

```

[edit interfaces interface-name]
user@host# edit radius-options

```

4. Create a named NAS-Port options definition.

```

[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name

```

5. Configure the NAS-Port extended format.

```

[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-extended-format slot-width width adapter-width width
port-width width vlan-width width

```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-VLAN configurations typically require you to create a VLAN range that consists of a single VLAN ID on the physical interface. To do so, set the **low-tag** and **high-tag** options in the **vlan-ranges** statement to the same value, as shown in the following example.

The following example shows a per-VLAN NAS-Port options definition named *paris-subscribers* that configures a NAS-Port extended format consisting of a 4-bit slot field, 2-bit adapter field, 4-bit port field, and 2-bit VLAN field. The *paris-subscribers* definition applies to VLAN ID 1 on Gigabit Ethernet physical interface *ge-1/0/1*.

```
[edit interfaces ge-1/0/1 radius-options]
nas-port-options paris-subscribers {
  nas-port-extended-format {
    slot-width 4;
    adapter-width 2;
    port-width 4;
    vlan-width 2;
  }
  vlan-ranges {
    1-1;
  }
}
```

## Configuring the RADIUS NAS-Port Extended Format per Stacked VLAN

As an alternative to globally configuring the extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-stacked VLAN basis as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN.

Configuring NAS-Port options definitions on a per-stacked VLAN basis is useful in network configurations that use an N:1 access model.

To configure an extended format for the NAS-Port RADIUS attribute per stacked VLAN:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable stacked VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set stacked-vlan-tagging
```

Setting stacked VLAN tagging enables you to configure dual VLAN tags for all logical interfaces on the physical interface. You must enable stacked VLAN tagging before

you can configure the stacked VLAN ranges to which the NAS-Port options definition applies.

- Specify that you want to configure RADIUS options for a stacked VLAN interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

- Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

- Configure the NAS-Port extended format.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-extended-format slot-width width adapter-width width
port-width width vlan-width width stacked
```

To include S-VLAN IDs, in addition to VLAN IDs, in the NAS-Port extended format, include the **stacked** option in the **nas-port-extended-format** statement.

- Configure the stacked VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set stacked-vlan-ranges (any | low-outer-tag-high-outer-tag),any
```

Per-stacked VLAN configurations require you to create a stacked VLAN range of subscribers to which the NAS-Port options definition applies. You must configure the low and high outer tags (VLAN IDs) in the range 1 through 4094, and the inner tag (S-VLAN ID) as **any** to represent all S-VLAN ID tags.

- Repeat Steps 3 through 6 to configure additional NAS-Port options definitions on this interface.

The following example creates two NAS-Port options definitions, *chicago-subscribers* and *barcelona-subscribers*, configured on a per-stacked VLAN basis on Gigabit Ethernet physical interface *ge-3/2/1*.

The *chicago-subscribers* definition configures a NAS-Port extended format consisting of a 8-bit slot field, 8-bit adapter field, 8-bit port field, 4-bit stacked VLAN field, and 4-bit VLAN field. Because the **stacked** option is configured in this definition, S-VLAN IDs, in addition to VLAN IDs, are included in the extended format. The *chicago-subscribers* definition applies to a stacked VLAN range with outer VLAN ID 1, and all inner S-VLAN IDs.

The barcelona-subscribers definition configures a NAS-Port extended format consisting of a 8-bit slot field, 8-bit adapter field, 8-bit port field, 4-bit stacked VLAN field, and 4-bit VLAN field. Because the **stacked** option is *not* configured in this definition, S-VLAN IDs are not included in the extended format. The barcelona-subscribers definition applies to a stacked VLAN range with outer VLAN IDs in the range 2 through 10, and all inner S-VLAN IDs.

```
[edit interfaces ge-3/2/1 radius-options]
nas-port-options chicago-subscribers {
  nas-port-extended-format {
    slot-width 8;
    adapter-width 8;
    port-width 8;
    stacked-vlan-width 4;
    vlan-width 4;
    stacked;
  }
  stacked-vlan-ranges {
    1-1,any;
  }
}
nas-port-options barcelona-subscribers {
  nas-port-extended-format {
    slot-width 8;
    adapter-width 8;
    port-width 8;
    stacked-vlan-width 4;
    vlan-width 4;
  }
  stacked-vlan-ranges {
    2-10,any;
  }
}
```

## Configuring the RADIUS NAS-Port Extended Format for ATM Interfaces

As an alternative to globally configuring an extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-physical interface basis for both Ethernet subscribers and ATM subscribers as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field of the NAS-Port attribute, including: slot, adapter, port, ATM virtual path identifier (VPI), and ATM virtual circuit identifier (VCI).

To configure the NAS-Port extended format for an ATM interface, include one or both of the following options in the **nas-port-extended-format** statement along with the other options as appropriate for your needs:

- **vpi-width**—Number of bits in the ATM VPI field, in the range 1 through 32
- **vci-width**—Number of bits in the ATM VCI field, in the range 1 through 32

**NOTE:** For ATM subscribers, the combined total of the widths of all fields must not exceed 32 bits, or the configuration fails. The router may truncate the values of individual fields depending on the bit width you specify.

To configure an extended format for the NAS-Port RADIUS attribute for an ATM interface:

1. Specify the ATM interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Specify that you want to configure RADIUS options for a physical interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

3. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

4. Configure the NAS-Port extended format.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-extended-format slot-width width adapter-width width
port-width width vpi-width width vci-width width
```

The following example shows a NAS-Port options definition named *boston-subscribers* for ATM interface *at-1/0/4* that configures a NAS-Port extended format with an ATM

slot width of 6 bits, ATM adapter width of 3 bits, ATM port width of 4 bits, ATM VPI width of 12 bits, and ATM VCI width of 24 bits.

```
[edit interfaces at-1/0/4 radius-options]
nas-port-options boston-subscribers {
  nas-port-extended-format {
    slot-width 6;
    adapter-width 3;
    port-width 4;
    vpi-width 12;
    vci-width 24;
  }
}
```

## RADIUS Logical Line Identifier (LLID) Overview

The logical line identification (LLID) feature helps service providers maintain a reliable and up-to-date customer database for those subscribers who frequently move from one physical line to another. The LLID is designed to provide the service provider with a configurable calling station ID for the subscriber access line. A calling station ID is derived from the physical line location and the subscriber client's information. The line information derived from the facility of the service provider is not friendly for the access line wholesaler to manage access line ownership when subscribers frequently move physical locations. The LLID feature is based on a virtual port — the LLID — rather than the physical line used by the subscriber. The LLID provides AAA driven line information management with a service provider (usually a wholesaler).

The LLID is an alphanumeric string that is based on the subscriber user name and circuit ID. The LLID logically identifies the subscriber line, and is mapped to the subscriber's physical line in the service provider customer database. When the subscriber moves to a different location and different physical line, the database is updated to map the LLID to the new physical line. Because the subscriber's LLID remains constant, it provides service providers with a secure and reliable means for tracking subscribers and maintaining an accurate customer database. Subscriber management supports the LLID feature for PPP subscribers over PPPoE, PPPoA, and LAC.

To assign an LLID to a subscriber, the router issues two RADIUS access requests. The first request is a preauthentication request, which obtains the LLID from a RADIUS preauthentication server. The second request is the standard authentication request sent to the RADIUS authentication server.

The following sequence of steps describes how subscriber management obtains and uses the LLID. The procedure assumes that preauthentication is enabled on the router and that the RADIUS preauthentication and authentication servers are configured.

1. The PPP subscriber sends an Authentication-Request message to the router.
2. The router sends an Access-Request message to the RADIUS preauthentication server to obtain an LLID for the subscriber.
3. The preauthentication server returns the LLID to the router in the Calling-Station-Id attribute (RADIUS attribute 31) in the Access-Accept message.

**NOTE:** This step includes a non-standard use of the Calling-Station-Id attribute. This attribute is typically present in RADIUS request messages, such as an Access-Request, not in response messages. Also, the router ignores all RADIUS attributes, other than the Calling-Station-Id, that are returned in the preauthentication Access-Accept message. In addition, any radius options that are configured on the router, such as `calling-station-id-format`, have no effect on the Calling-Station-Id attribute in the preauthentication request.

4. The router encodes the Calling-Station-Id (the LLID) in a second Access-Request message and sends the message to the RADIUS authentication server. This authentication request is the standard use of the Calling-Station-Id attribute.
5. The RADIUS authentication server returns an Access-Accept message to the router. The Access-Accept message includes attributes for the subscriber session.

**NOTE:** Once the preauthenticated subscriber has been successfully authenticated by the RADIUS authentication server, all subsequent RADIUS request messages, such as Accounting-Request messages, will include the LLID in the Calling-Station-Id attribute.

**NOTE:** For tunneled PPP subscribers, the router, acting as an L2TP access concentrator (LAC), encodes the LLID into Calling Number AVP (L2TP attribute 22) and sends the attribute to the L2TP network server (LNS) in an Incoming-Call-Request (ICRQ) packet. After a successful preauthentication request, the router always encodes the LLID in the L2TP Calling Number AVP.

## RADIUS Attributes for LLID Preauthentication Requests

Table 11 on page 108 lists the RADIUS IETF attributes used in a preauthentication request to obtain a subscriber's LLID, and describes the information that is included in the attributes. In some cases, preauthentication uses an attribute for information that is different than the IETF description—the table indicates any non-standard use of RADIUS attributes.

**Table 11: RADIUS Attributes for LLID Preauthentication Requests**

Attribute Number	Attribute Name	Description
1	User-Name	<p>(Non-standard use of attribute.) Identifying information for the user associated with the LLID, in the following format.</p> <p><b>nas-port:nas-ip-address:nas-port-id</b></p> <p>Example: <b>nas-port:198.51.100.117:ge-1/0/5:100</b></p> <p><b>NOTE:</b> The router strips any dynamically generated information from the User-Name attribute during preauthentication.</p>
2	User-Password	<p>(Non-standard use of attribute.) Password of the user to be authenticated.</p> <p>Example: Always set to <b>juniper</b></p>

Table 11: RADIUS Attributes for LLID Preauthentication Requests (continued)

Attribute Number	Attribute Name	Description
4	NAS-IP-Address	IP address of the network access server (NAS) that is requesting authentication of the user  Example: <b>198.51.100.117</b>
5	NAS-Port	Physical port number of the NAS that is authenticating the user. Always interpreted as a bit field
6	Service-Type	Type of service the user requested or the type of service to be provided.  Example: <b>gold-service</b>
61	NAS-Port-Type	Type of physical port the NAS is using to authenticate the user. You can use the <b>ethernet-port-type-virtual</b> statement to configure this to <b>virtual</b> (type 5).
77	Connect-Info	(Non-standard use of attribute.) The user name.  Example: <b>jdoe@xyzcorp.example.com</b>
87	NAS-Port-Id	Text string that identifies the physical interface of the NAS that is authenticating the user. Includes any dynamically generated information.  Example: <b>ge 1/0/5:100</b>

## Configuring Logical Line Identification (LLID) Preauthentication

The logical line identification (LLID) feature enables service providers to track subscribers on the basis of a virtual port — the LLID — rather than by the physical port used by the subscriber. The LLID is assigned by a RADIUS preauthentication server, which you configure in an access profile.

To configure the router to support preauthentication for the LLID feature:

**NOTE:** You cannot configure the preauthentication statements in this procedure if you have configured the **radius attributes exclude** statement to exclude the Calling-Station-ID attribute from RADIUS Access-Request messages.

1. Specify the access profile you want to use for the subscriber preauthentication support.

```
[edit]
user@host# edit access profile profile-name
```

- Specify the order in which the router uses the supported preauthentication methods. **radius** is the only supported authentication method.

```
[edit access profile profile-name]
user@host# set preauthentication-order radius
```

- Specify that you want to configure RADIUS support.

```
[edit access profile profile-name]
user@host# edit radius
```

- Specify the IP address of the RADIUS server used for preauthentication.

```
[edit access profile profile-name radius]
user@host# set preauthentication-server 192.168.100.10
```

**NOTE:** The preauthentication feature uses the **retry** and **timeout** parameters that are configured for the RADIUS authentication server.

- (Optional) Display AAA preauthentication statistics.

```
user@host> show network-access aaa statistics preauthentication
Preauthentication module statistics
Requests received: 2118
Multistack requests: 0
Accepts: 261
Rejects: 975
Challenges: 0
Requests timed out: 882
```

- (Optional) Verify configuration of the RADIUS preauthentication server.

```
user@host1> show radius pre-authentication servers
```

RADIUS Pre-Authentication Configuration						
IP Address	Udp Port	Retry Count	Timeout	Maximum Sessions	Dead Time	Secret
203.0.113.168	1812	3	3	255	0	radius

## Configuring a Port and Password for LLID Preauthentication Requests

You can configure a router that operates as the RADIUS client to contact a RADIUS server for authentication and preauthentication requests on two different UDP ports and using different secret passwords. Similar to configuring the port numbers for authentication and accounting requests, you can define a unique port number that the router uses to

contact the RADIUS server for logical line identification (LLID) preauthentication requests. You can also define a unique password for preauthentication requests. If you do not configure a separate UDP port or secret for preauthentication purposes, the same UDP port and secret that you configure for authentication messages is used.

To configure a unique UDP port number to be used to contact the RADIUS server for preauthentication requests, include the **preauthentication-port *port-number*** statement at the **[edit access radius-server *server-address*]** or **[edit access profile *profile-name* radius-server *server-address*]** hierarchy level.

- To specify the UDP port for all of the access profiles:

```
[edit access]
radius-server server-address {
  preauthentication-port port-number;
}
```

- To specify the UDP port for a specific access profile:

```
[edit access]
profile profile-name {
  radius-server server-address {
    preauthentication-port port-number;
  }
}
```

To configure the password to be used to contact the RADIUS preauthentication server, include the **preauthentication-secret *password*** statement at the **[edit access radius-server *server-address*]** or **[edit access profile *profile-name* radius-server *server-address*]** hierarchy level.

- To specify the password for all of the access profiles:

```
[edit access]
radius-server server-address {
  preauthentication-secret password;
}
```

- To specify the password for a specific access profile:

```
[edit access]
profile profile-name {
  radius-server server-address {
    preauthentication-secret password;
  }
}
```

## Verifying and Managing LLID Preauthentication Configuration

**Purpose** Display statistics and configuration information related to logical line identification (LLID) preauthentication.

- Action**
- To display LLID preauthentication statistics:

```
user@host> show network-access aaa statistics preauthentication
```

- To display information about preauthentication servers:

```
user@host> show network-access aaa radius-servers
```

---

## RADIUS Authentication and Accounting Basic Configuration

- [Configuring Authentication and Accounting Parameters for Subscriber Access on page 112](#)
- [Specifying the Authentication and Accounting Methods for Subscriber Access on page 112](#)
- [Specifying RADIUS Authentication and Accounting Servers for Subscriber Access on page 113](#)
- [Example: Configuring RADIUS-Based Subscriber Authentication and Accounting on page 114](#)
- [Configuring Local Authentication and Authorization for Subscribers on page 117](#)

### Configuring Authentication and Accounting Parameters for Subscriber Access

You use an access profile to configure authentication and accounting support for the subscriber access management feature. The access profile enables you to specify the type of methods used for authentication and accounting. You can also configure how subscriber access management collects and uses accounting statistics.

To configure authentication and accounting for subscriber access:

1. Specify the authentication and accounting methods to use.  
[See “Specifying the Authentication and Accounting Methods for Subscriber Access” on page 112.](#)
2. Specify how accounting statistics are collected.  
[See “Configuring Per-Subscriber Session Accounting” on page 134.](#)

### Specifying the Authentication and Accounting Methods for Subscriber Access

You can specify the authentication and accounting methods that subscriber access management uses.

You can configure multiple authentication and accounting methods—the **authentication-order** and **accounting order** statements specify the order in which the subscriber access management feature uses the methods. For example, an authentication entry of **radius password** specifies that RADIUS authentication is performed first; if it times out (for example, if the RADIUS server is unreachable), then local authentication (**password**) is attempted. However, if a method rejects the authentication attempt, no

subsequent method is attempted. If **password** is configured as the first method to be attempted, authentication is always either accepted or rejected; in either case, no other method is attempted.

You can specify the following authentication methods with the **authentication-order** statement:

- **radius**—RADIUS-based authentication using an external RADIUS server.
- **password**—Local authentication using locally configured and stored usernames and passwords.

Subscriber access management does not support the **password** option until Junos OS Release 18.2R1. Starting in Junos OS Release 18.2R1, you can use the **password** option to provide local authentication for individual subscribers, typically when you do not have external authentication and authorization servers, or when you want to use local authentication as a backup to external authentication. In this case, you configure the actual subscriber password with the **password** option of the **subscriber username** statement in the access profile. In earlier releases you must always specify the **radius** authentication method.

You can specify the following accounting methods:

- **radius**—RADIUS-based accounting using an external RADIUS server.

To configure the authentication and accounting methods for subscriber access management:

1. Specify the authentication methods and the order in which they are used.

```
[edit access profile profile-name]
user@host# set authentication-order method
```

2. Specify the accounting method.

```
[edit access profile profile-name]
user@host# set accounting order radius
```

- See Also**
- [Configuring Local Authentication and Authorization for Subscribers on page 117](#)
  - [Configuring Per-Subscriber Session Accounting on page 134](#)

## Specifying RADIUS Authentication and Accounting Servers for Subscriber Access

You can specify one or more RADIUS authentication or accounting servers to use for subscriber access management.

To configure RADIUS authentication and accounting support:

1. Specify that you want to configure RADIUS support.

```
[edit access profile isp-bos-metro-fiber-basic]
user@host# edit radius
```

2. Specify the IP address of the RADIUS server used for authentication.

```
[edit access profile isp-bos-metro-fiber-basic radius]
user@host# set authentication-server 192.168.1.251
```

3. Specify the IP address of the RADIUS server used for accounting.

```
[edit access profile isp-bos-metro-fiber-basic radius]
user@host# set accounting-server 192.168.1.250
```

To configure multiple RADIUS authentication or accounting servers:

- Specify the IP addresses of all RADIUS servers used for authentication or accounting.

```
[edit access profile isp-bos-metro-fiber-basic radius]
user@host# set authentication-server 192.168.1.251 192.168.1.252
user@host# set accounting-server 192.168.1.250 192.168.1.251
```

**See Also** • [Configuring RADIUS Server Parameters for Subscriber Access on page 61](#)

## Example: Configuring RADIUS-Based Subscriber Authentication and Accounting

This example shows a RADIUS-based authentication and accounting configuration.

```
[edit access]
radius-server {
  192.168.1.250 {
    port 1812;
    accounting-port 1813;
    accounting-retry 6;
    accounting-timeout 20;
    retry 3;
    secret $ABC123$ABC123;
    source-address 192.168.1.100;
    timeout 45;
  }
  192.168.1.251 {
    port 1812;

                unnumbered-address lo0.0;
            }
        }
    }
}
```

## Configuring Local Authentication and Authorization for Subscribers

Starting in Junos OS Release 18.2R1, you can configure local authentication and limited local authorization for subscribers. Local authentication supports all subscriber types that are currently supported by subscriber management and services on MX Series routers. Local authentication and authorization is useful in the following circumstances:

- When you do not want to use external authentication and authorization servers.
- When you want local authentication and authorization to provide a backup method in the event RADIUS authentication fails.
- When you are migrating a network from E Series routers running JunosE software to MX Series routers running Junos OS.

Enable local authentication and authorization for subscribers by configuring the **password** option to be configured as an **authentication-order** method for the access profile. Then configure a password for each subscriber you want to authenticate locally. When a subscriber associated with the access profile logs in, the login username is compared to the configured username. If that matches, then the login password is compared to the configured password. Local authentication failures result from credential mismatches; that is, either the subscriber username or password do not match.

Local authentication can take the form of either of the following:

- User password authentication—The configured password is used to verify the subscriber's login password.
- Challenge handshake authentication (CHAP)—The configured password acts as the challenge secret to verify the subscriber's challenge password and challenge response credential.

You can also optionally configure several attributes, such as address pool, logical system, or routing instance, to be authorized locally for the subscriber when authentication is successful. If you do not configure an address or address pool for local authorization, address assignment is based on network matching or the first address pool assigned to the routing instance.

**NOTE:** Local authentication and authorization support a chassis-wide maximum of 100 subscribers. If subscribers are configured in access profiles where **authentication-order password** is not configured, local authentication does not occur, but these subscribers count against the system limit of 100 subscribers for local authentication.

To configure local authentication and authorization:

1. Enable local authentication.

```
[edit access profile profile-name]
user@host# set authentication-order password
```

If you want only local authentication to be used, then configure **password** as the only authentication method. If you want local authentication to back up RADIUS authentication in the event the method times out, then you must configure **radius** as the first method and **password** as the second method, like so:

```
[edit access profile profile-name]  
user@host# set authentication-order [radius password]
```

If you configure **password** as the first method, authentication is always either accepted or rejected. In either case, a second method is never attempted.

2. Configure the local password for the subscriber.

```
[edit access profile profile-name]  
user@host# set subscriber username password password
```

3. (Optional) Configure an IPv4 address for the subscriber.

```
[edit access profile profile-name]  
user@host# set subscriber username framed-ip-address ipv4-address
```

4. (Optional) Configure an address pool to assign an IPv4 address for the subscriber.

```
[edit access profile profile-name]  
user@host# set subscriber username framed-pool ipv4-pool-name
```

5. (Optional) Configure an address pool to assign a router advertisement IPv6 prefix or a DHCPv6 IA\_NA/128 address for the subscriber.

```
[edit access profile profile-name]  
user@host# set subscriber username framed-ipv6-pool ipv6-pool-name
```

6. (Optional) Configure an address pool to locally allocate a delegated IPv6 prefix.

```
[edit access profile profile-name]  
user@host# set subscriber username delegated-pool delegated-pool-name
```

7. (Optional) Configure a logical system and if desired a routing instance assigned to the subscriber.

```
[edit access profile profile-name]  
user@host# set subscriber username target-logical-system logical-system-name  
    <target-routing-instance (default | routing-instance-name)>
```

8. (Optional) Configure a routing instance for the subscriber.

```
[edit access profile profile-name]
user@host# set subscriber username target-routing-instance (default |
routing-instance-name)
```

You can use the following **show** commands to display information about local authentication:

- **show network-access aaa statistics authentication detail**—Displays failure statistics for local authentication.
- **show network-access requests statistics**—Displays both local authentication and local reauthentication statistics such as requests received and the number of success and failure responses.
- **show network-access aaa statistics re-authentication**—Displays reauthentication statistics, but they are aggregated from both local authentication and RADIUS.

## RADIUS Reauthentication As an Alternative to RADIUS CoA for DHCP Subscribers

---

RADIUS Change of Authorization (CoA) messages, specified in RFC 5176, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*, are used to activate or deactivate client services and to change certain client session characteristics without logging out the client, thus avoiding interruption to the subscriber. In some circumstances, it may be preferable to use *reauthentication* of the subscriber as the method to alter client session services and characteristics without interruption.

For example, the following customer deployment modes both require changes in attributes during the life of a session.

- Residential subscribers—Residential subscribers may change service plans throughout the life of a session by online service selection or direct calling to the provider. The change in service plan is propagated to the DHCP local server by changing the value of the DHCP client Agent Remote ID. The Agent Remote ID is conveyed in option 82, suboption 2, for DHCPv4 clients and in option 37 for DHCPv6 clients.

When reauthentication is configured, the change in service plan is detected, triggering reauthentication; the new service plan and any changed attributes are returned by the RADIUS server and implemented for the subscriber.

- Business subscribers—Business subscribers often need changes in attributes (particularly framed routes) during any given session. The desired change in attributes is not initiated by a change in service plans.

When reauthentication is configured, negotiation of the lease renewal triggers reauthentication. Any changes in attributes or services are provided in the Access-Accept message from the RADIUS server and implemented for the subscriber.

Two alternatives to using reauthentication can both change many more session characteristics than are possible with reauthentication. CoA requests change characteristics without disrupting the subscriber. Logging the subscriber out and then back in can change many more session characteristics but is obviously disruptive.

- [Benefits of Reauthentication on page 120](#)
- [Functionality on page 121](#)
- [Dual-Stack Subscribers on page 123](#)
- [Packet Flow on page 125](#)
- [RADIUS Attributes Supported for Reauthentication on page 127](#)

### Benefits of Reauthentication

- Update or modify subscriber session attributes and service plans without using a CoA request.
- Simplify activation of services resulting from frequent subscriber-initiated changes.
- Enable reauthentication per family in dual-stack, single-session configurations.
- Control reauthentication through CLI configuration or a RADIUS VSA.

## Functionality

Reauthentication is supported for both DHCPv4 and DHCPv6. It can be triggered when the DHCP local server receives a renew, rebind, discover, or solicit message from a DHCP client. The discover and solicit messages support reauthentication starting in Junos OS Release 18.1R1. Support for the discover and solicit messages means that if a CPE with a bound client reboots and the client sends one of those messages to bring the session back up, reauthentication enables authd to obtain any updates that have been made for the subscriber.

Reauthentication behavior is determined as follows:

- The **reauthenticate lease-renewal** statement specifies reauthentication is triggered when any of the four supported messages is received.
- The **reauthenticate remote-id-mismatch** statement specifies reauthentication is triggered only when the received message includes a change in the value of the DHCP client's Agent Remote ID. The attribute value includes the name of the subscriber service plan, so a change in value signifies a change in service for the subscriber.
- The Juniper Networks **reauthentication-on-renew** VSA (26-206), when returned with a value of 1 in the Access-Accept message from the RADIUS server for the subscriber at login, triggers reauthentication on receipt of any of the four messages. A value of 0 disables reauthentication. The VSA value is stored in the session database whenever it is received. After this VSA has enabled reauthentication, it is checked at each reauthentication attempt. If the value has changed to 0—that is, if a subsequent Access-Accept returned the VSA with a value of 0—the reauthentication process stops for that subscriber.

The CLI configuration (**reauthenticate** statement) and Reauthenticate-On-Renew behavior is additive. Disabling reauthentication with the VSA has an effect only when the **reauthenticate** statement is not configured. When the **reauthenticate** statement is configured with either option, it overrides a VSA value of 0. In the absence of the CLI configuration, the VSA can enable reauthentication by itself.

The reauthentication process is almost identical to the original authentication process. When reauthentication is triggered, the `jdhcpd` process on the local server submits an authentication request to `authd`, which in turn submits an Access-Request message to the RADIUS server to request a second authentication.

**NOTE:** The reauthentication request fails for any authentication order other than `radius` or `none`. The `authd` process returns a negative acknowledgment (NAK) for any such request.

This Access-Request includes RADIUS state and class attributes that were returned in the original Access-Accept message. These attributes enable the RADIUS server to distinguish the reauthentication request from login (authentication) requests.

The RADIUS server returns an Access-Accept message to `authd` with new attributes for the subscriber. The `authd` process sends an acknowledgment (ACK) with the changes

to `jdhcpd`, which sends a DHCP offer to the DHCP client with changed attributes. The DHCP negotiation continues as usual, as shown in [Figure 1 on page 126](#), and the subscriber session continues with the new attribute values. When the reauthentication includes a change in service plan, the RADIUS server returns the new plan with any other changed attributes, if it accepts the request, as shown in [Figure 2 on page 127](#). If the CPE hosting the DHCP client reboots during the process of changing a service plan, reauthentication with the new plan is supported with no disruption in service.

If the RADIUS server rejects a reauthentication request or times out, `authd` sends a NAK to `jdhcpd`, which reviews the included error code. If the error code indicates a timeout, `jdhcpd` sends an ACK to the DHCP client and the subscriber session is maintained with the original attributes and service. For any other error code, `jdhcpd` sends a DHCPv4 NAK or DHCPv6 REPLY (with the lifetime value set to 0) as a logical NAK, initiates subscriber logout, and deletes the subscriber from the session database.

[Table 12 on page 122](#) describes how `authd` processes requests when a different request type is already in progress for the same subscriber.

**Table 12: Processing Multiple Request Types**

Request in Progress	Additional Request Received for Same Subscriber	Action
Reauthentication	CoA	<code>authd</code> responds to the CoA with a NAK.
CoA	Reauthentication	<code>authd</code> queues the reauthentication request until the CoA is processed, then processes the reauthentication request.
Reauthentication	Disconnect	<code>authd</code> responds to the disconnect with a NAK.
Disconnect	Reauthentication	<code>authd</code> responds to the reauthentication request with a NAK and continues logging out the subscriber.

**BEST PRACTICE:** Because the network family does not terminate or reinitiate as part of reauthentication, the subscriber content is not reevaluated with regards to subscriber secure policy mirroring. Do not use as a trigger for subscriber secure policy mirroring any attribute that can change during reauthentication processing.

When reauthentication results in a change in a DHCPv6 subscriber's IP or IPv6 address after a client is bound, the DHCPv6 server evaluates the address change request. The server returns a status code to the client in the identity association (IA) of the reply PDU. Starting in Junos OS Release 18.4R1, when the DHCPv6 server discovers an issue with the address, a status code for `NotOnLink` is supported in addition to the previously supported codes for `NoAddrsAvail` and `NoPrefixAvail`. These status codes are defined as follows:

- `NoAddrsAvail` (2)—The server cannot assign any addresses for the IA in the client request. It returns the IA with no addresses and `NoAddrsAvail`.

- NotOnLink (4)—The server determines that the prefix for one or more addresses in any IA in the client request is not appropriate for the link connecting to the client. This code is also used in the event of a reauthentication failure (RADIUS Access-Reject).
- NoPrefixAvail (6)—The server has no prefixes available for the IA in the client request.

If the client receives the NotOnLink status code, it can send another request without any addresses or it can restart the negotiation process. If it sends a request, the DHCPv6 local server ignores the request, expecting a new renegotiation to begin.

## Dual-Stack Subscribers

In releases earlier than Junos OS Release 18.1R1, dual-stack DHCP subscribers are treated as independent client sessions. Each stack renews and obtains new services independently.

Starting in Junos OS Release 18.1R1, per-family authentication and reauthentication are supported for dual-stack, single-session subscribers. A dual-stack, single-session subscriber is typically a household with its own VLAN in a 1:1 access model. The household is represented as a single subscriber with a single session in the session database, but it has two separate DHCP bindings, one for each family, DHCPv4 and DHCPv6. Consequently, authd sends separate Access-Requests as each family in the session logs in or attempts to reauthenticate:

- Per-family authentication occurs when a discover or solicit message is received while a subscriber session is in the DHCP init state.
- Per-family reauthentication occurs when reauthentication and on-demand address allocation are both configured and a renew, rebind, discover, or solicit message is received for the family session while it is in the DHCP bound state.

**NOTE:** On-demand address allocation causes an address to be allocated separately for each family as it logs in. On-demand address allocation must be configured for dual-stack, single-session subscribers or per-family authentication and reauthentication cannot be enabled. For reauthentication, this is true whether it is configured in the CLI or with the Reauthenticate-On-Renew VSA (26-206).

Authentication and reauthentication are both processed per family. The first family to trigger the process is attended to before the other (second) family triggers authentication or reauthentication. Messages from the second family are ignored until the first family is bound. Then the second family request is processed.

If only one family of the dual-stack single session logs in, then only one authentication is processed. Reauthentications are processed for only the one client family.

The authd process classifies attributes as belonging to the DHCPv4 or DHCPv6 family and tags them accordingly. For both authentication and reauthentication, depending on which family initiates the request, authd includes either the DHCP-Options VSA (26-55) or the DHCPv6-Options VSA (26-65). Depending on its configuration, the RADIUS server

might return information for only the family that initiated the request (the *requesting family*) or for both families.

When authd receives attributes in the Access-Accept message, the family tags enable authd to determine which attributes correspond to the requesting family or the other (*nonrequesting*) family. Only attributes for the requesting family are written to the session database.

For reauthentication requests, authd compares the returned attributes to the session database to determine whether any changes were made on the RADIUS server. Again, only changes that correspond to the requesting family are written to the session database, overwriting the old values.

Changes during reauthentication are processed as follows:

- **Attribute (other than address)**—When authd determines that one or more of these attributes has changed for the requesting family, it stores the new values in the session database. After authd notifies jdhcpd, it sends an ACK to the DHCP client with the new attribute values.
- **Address or address pool**—When authd detects a change for the requesting family, it notifies the DHCP local server, which in turn sends a NAK (DHCPv4) or logical NAK (DHCPv6) to the DHCP client.

If the requesting family is the only family that is bound, jdhcpd gracefully logs out the subscriber. If the nonrequesting family is also bound, jdhcpd deactivates the requesting family, but leaves the nonrequesting family binding intact, with no disruption in service to the nonrequesting family. The deactivation of the requesting family has no effect on a subsequent triggering of reauthentication by the nonrequesting family.

When the deactivated family subsequently sends a discover or solicit message to log back in, an Access-Request is sent for reauthentication as usual, and the new address received in the Access-Accept is applied to the subscriber.

If the RADIUS server responds to an authentication or reauthentication request with an Access-Reject message, authd notifies the DHCP local server, which in turn sends a NAK (DHCPv4) or logical NAK (DHCPv6) to the DHCP client. The requesting family is terminated gracefully; the family is deactivated and the subscriber is logged out. Then the nonrequesting family is deactivated and logged out, but the client is not notified about the termination.

If liveness detection is running on the nonrequesting family, the client detects loss of connection when the family is terminated, and subsequently sends a discover or solicit message to the DHCP local server. However, if liveness detection is not running, the client does not detect loss of connection until the rebinding time (T2, option 59) expires and service is lost. Depending on the duration of the lease, this could take a long time.

**BEST PRACTICE:** Configure liveness detection for both address families to reduce the time to detect loss of connection. See [DHCP Liveness Detection Overview](#) for information about configuring liveness detection.

---

## Packet Flow

The following figure describes the sequence for initial negotiation of a subscriber session between a DHCP client, a DHCP server, and the RADIUS server. The client's service plan is specified in the second substring in the remote ID contained in DHCPv4 option 82, suboption 2, or DHCPv6 option 37.

### Initial Negotiation

---

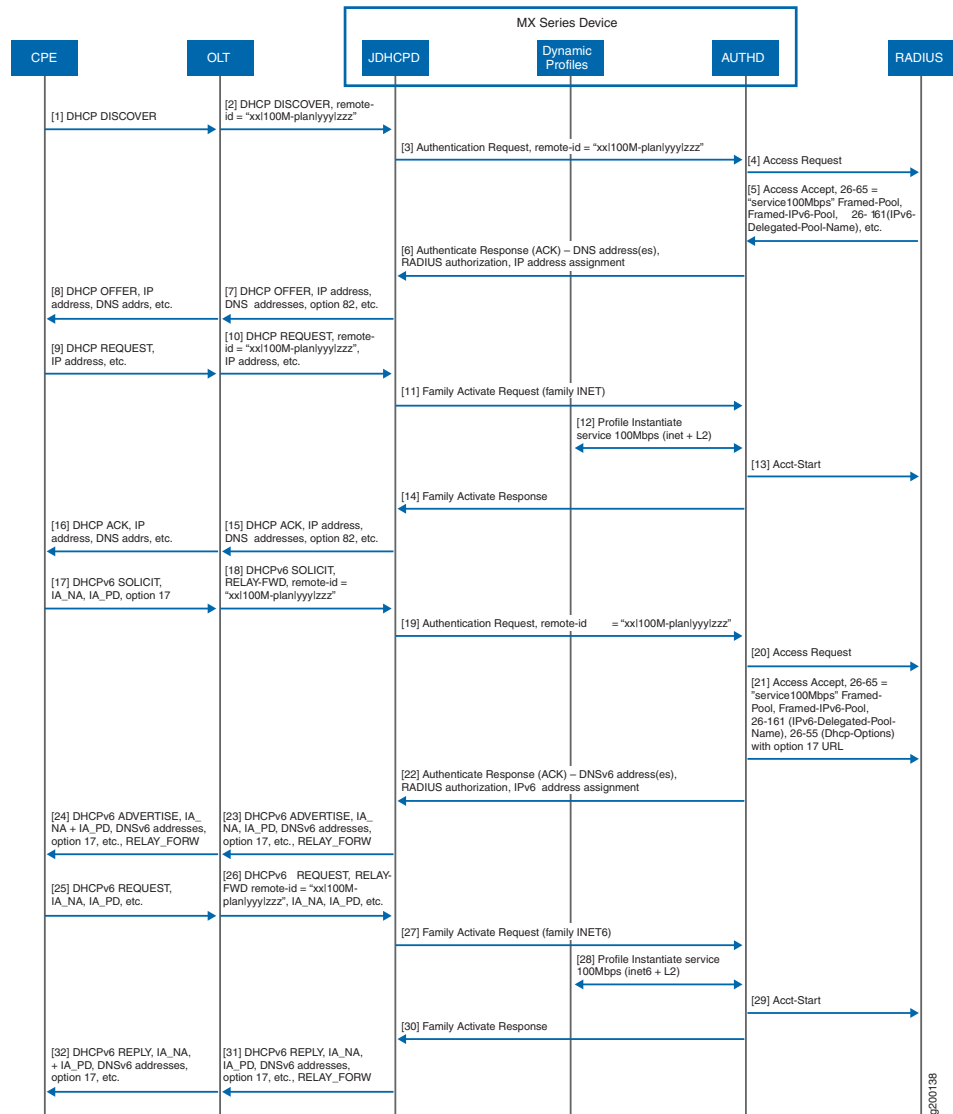

[Figure 1 on page 126](#) illustrates the sequence of steps in the initial negotiation between a DHCP client, a DHCP server, and the RADIUS server. The following terms are used in the figure:

CPE—Customer premises equipment (functions as the DHCP client or subscriber).

OLT—Optical line terminator—for example, a DSL access multiplexer (DSLAM) or other aggregation device.

MX Series device—Functions as the DHCP server.

Figure 1: Initial Negotiation

## Service Plan Change

Figure 2 on page 127 illustrates the sequence of steps in a change of service plans, from a 100 Mbps plan to a 1 Gbps plan.:

Figure 2: Service Plan

## RADIUS Attributes Supported for Reauthentication

Table 13 on page 127 lists the RADIUS standard attributes and VSAs that can be processed during reauthentication when received in the RADIUS Access-Accept message, and describes how authd handle changes in attributes. Attribute processing is consistent with CoA request processing. The characteristics of the reauthenticating subscriber session change only if new values or new attributes are received in the Access-Accept message.

Table 13: RADIUS attributes supported by reauthentication

Attribute Number	Attribute Name	Result of Processing
8	Framed-IP-Address	A new value is stored in the subscriber session database; old data is overwritten.
22	Framed-Route	A new value is stored in the subscriber session database; old data is appended.
24	State	A new value is stored in the subscriber session database; old data is overwritten.

Table 13: RADIUS attributes supported by reauthentication (continued)

Attribute Number	Attribute Name	Result of Processing
25	Class	A new value is stored in the subscriber session database; old data is overwritten.
26-4	Primary-DNS	A new value is stored in the subscriber session database; old data is overwritten.
26-5	Secondary-DNS	A new value is stored in the subscriber session database; old data is overwritten.
26-6	Primary-WINS	A new value is stored in the subscriber session database; old data is overwritten.
26-7	Secondary-WINS	A new value is stored in the subscriber session database; old data is overwritten.
26-55	DHCP-Options	Value is sent to the DHCP local server for processing the changes to the subscriber's DHCP configuration.
26-65	Activate-Service	<p>The authd process compares the list of services in the VSA to the services that are already active for that subscriber session.</p> <ul style="list-style-type: none"> <li>• If the list on the VSA contains services not yet active, authd activates those services for the subscriber.</li> <li>• If any service already active for the subscriber session is not listed in the VSA, then authd deactivates that service.</li> </ul> <p>For example, suppose services A and B are active on the session, but the VSA includes only services B and C. Service A is not on the VSA list and is deactivated. Service C is on the list but not currently active, so authd activates C. Service B is both already active and on the list, so it remains active.</p>
26-161	IPv6-Delegated-Pool-Name	A new value is stored in the subscriber session database; old data is overwritten.
26-206	Reauthenticate-On-Renew	<p>If the value is 1 (enable), authd adds the value to the subscriber session database if it is not already present.</p> <p>If the value is 0 (disable) and a value of 1 is already present in the database, authd sets the database value to 0.</p> <p>If the value in the message is missing or invalid, and a value is already present in the database, authd deletes the value from the database.</p>
26-207	DHCPv6-Options	Value is sent to the DHCPv6 local server for processing the changes to the subscriber's DHCP configuration.
88	Framed-Pool	A new value is stored in the subscriber session database; old data is overwritten.
97	Framed-IPv6-Prefix	A new value is stored in the subscriber session database; old data is overwritten.
100	Framed-IPv6-Pool	A new value is stored in the subscriber session database; old data is overwritten.
123	Delegated-IPv6-Prefix	A new value is stored in the subscriber session database; old data is overwritten.
168	Framed-IPv6-Address	A new value is stored in the subscriber session database; old data is overwritten.

Release History Table

Release	Description
18.4R1	Starting in Junos OS Release 18.4R1, when the DHCPv6 server discovers an issue with the address, a status code for NotOnLink is supported in addition to the previously supported codes for NoAddrsAvail and NoPrefixAvail.
18.1R1	The discover and solicit messages support reauthentication starting in Junos OS Release 18.1R1.

## Configuring RADIUS Reauthentication for DHCP Subscribers

You can configure reauthentication as an alternative to RADIUS CoA messages as a means to change characteristics of the subscriber session, such as activating or changing service plans or changing DHCP subscriber attributes. When configured, reauthentication is triggered when the DHCP local server receives a renew, rebind, discover, or solicit message from a DHCP client. The message triggers `jdhcpd` to request reauthentication from `authd`, which in turn reissues the RADIUS Access-Request for a second subscriber authentication. Reauthentication is available for DHCPv4, DHCPv6, and dual-stack subscribers.

Starting in Junos OS Release 18.1R1, reauthentication can be triggered by discover and solicit messages in addition to the previously supported renew and rebind messages. The release also introduces reauthentication support for dual-stack, single-session subscribers.

You can use the **reauthenticate** statement to configure reauthentication to occur in response to all DHCP renew, rebind, discover, or solicit messages or only in response to those messages when they include a different Agent Remote ID for the DHCP client. The Agent Remote ID carries information about the subscriber's service plan, so a change in ID value corresponds to a change in the subscriber service plan. The Agent Remote ID is conveyed in option 82, suboption 2 for DHCPv4 clients and in option 37 for DHCPv6 clients.

You can also use the Juniper Networks VSA, Reauthentication-On-Renew (26-206) as an alternative to the CLI configuration to enable reauthentication. The VSA is conveyed in the RADIUS Access-Accept message at subscriber login, and must be configured on your RADIUS server. The **reauthenticate** statement overrides the VSA when the VSA is present with a value of disable.

Configure reauthentication for non-dual-stack, single session DHCP subscribers:

- (Optional) Specify reauthentication is triggered by receipt of every renew, rebind, discover, and solicit message.

For DHCPv4 subscribers:

```
[edit system services dhcp-local-server]
user@host# set reauthenticate lease-renewal
```

For DHCPv6 subscribers:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set reauthenticate lease-renewal
```

- (Optional) Specify reauthentication is triggered only when the Agent Remote ID has changed in the received discover or solicit message.

For DHCPv4 subscribers:

```
[edit system services dhcp-local-server]
user@host# set reauthenticate remote-id-mismatch
```

For DHCPv6 subscribers:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set reauthenticate remote-id-mismatch
```

Configure reauthentication for dual-stack, single session DHCP subscribers:

1. Configure addresses to be allocated on demand for subscribers in the dual-stack group.

```
[edit system services dhcp-local-server dual-stack-group name]
user@host# set on-demand-address-allocation
```

2. (Optional) Specify reauthentication is triggered for every subscriber in the dual-stack group by receipt of every renew, rebind, discover, and solicit message.

```
[edit system services dhcp-local-server dual-stack-group name]
user@host# set reauthenticate lease-renewal
```

3. (Optional) Specify reauthentication is triggered for every subscriber in the dual-stack group only when the Agent Remote ID has changed in the received discover or solicit message.

```
[edit system services dhcp-local-server dual-stack-group name]
user@host# set reauthenticate remote-id-mismatch
```

A change in the Agent Remote ID can also initiate a service change during renew and rebind operations when the `remote-id-mismatch` statement is configured. You cannot configure both the `remote-id-mismatch` statement and the `reauthenticate` statement at the global level, `[edit system services dhcp-local-server]`. However, DHCP precedence rules do permit you to configure both statements when they are at different levels. For example, you can configure `reauthenticate` at the global level and `remote-id-mismatch`

for DHCPv6 at the `[edit system services dhcp-local-server dhcpv6]` hierarchy level or for a specific group at the `[edit system services dhcp-local-server group name]` hierarchy level, and so on.

#### Release History Table

Release	Description
18.1R1	Starting in Junos OS Release 18.1R1, reauthentication can be triggered by discover and solicit messages in addition to the previously supported renew and rebind messages. The release also introduces reauthentication support for dual-stack, single-session subscribers.

## RADIUS Accounting Statistics for Subscriber Access Overview

The AAA Service Framework enables you to configure how the router collects and uses accounting statistics for subscriber management.

For example, you can specify when statistics collection is terminated, the order in which different accounting methods are used, the types of statistics collected, and how often statistics are collected. You can also configure the router to request that the RADIUS server immediately update the accounting statistics when certain events occur, such as when a subscriber logs in or when a change of authorization (CoA) occurs.

Subscriber management provides two levels of subscriber accounting—subscriber session and service session. In subscriber session accounting, the router collects statistics for the entire subscriber session. In service session accounting, the router collects statistics for specific service sessions for the subscriber.

**NOTE:** Subscriber management counts forwarded packets only. Dropped traffic (for example, as a result of a filter action) and control traffic are not included in the accounting statistics.

The router uses the RADIUS attributes and Juniper Networks VSAs listed in [Table 14 on page 132](#) to provide the accounting statistics for subscriber and service sessions. If the session has both IPv4 and IPv6 families enabled, the router reports statistics for both families.

**NOTE:**

RADIUS reports subscriber statistics as an aggregate of both IPv4 statistics and IPv6 statistics.

- For an IPv4-only configuration, the standard RADIUS attributes report the IPv4 statistics and the IPv6 VSA results are all reported as 0.
- For an IPv6-only configuration, the standard RADIUS attributes and the IPv6 VSA statistics are identical, both reporting the IPv6 statistics.
- When both IPv4 and IPv6 are configured, the standard RADIUS attributes report the combined IPv4 and IPv6 statistics. The IPv6 VSAs report IPv6 statistics.

**Table 14: RADIUS Attributes and VSAs Used for Per-Subscriber Session Accounting**

Attribute Number	Attribute Name	Type of Statistics
26-151	IPv6-Acct-Input-Octets	IPv6
26-152	IPv6-Acct-Output-Octets	IPv6
26-153	IPv6-Acct-Input-Packets	IPv6

**Table 14: RADIUS Attributes and VSAs Used for Per-Subscriber Session Accounting (continued)**

Attribute Number	Attribute Name	Type of Statistics
26-154	IPv6-Acct-Output-Packets	IPv6
26-155	IPv6-Acct-Input-Gigawords	IPv6
26-156	IPv6-Acct-Output-Gigawords	IPv6
47	Acct-Input-Packets	IPv4 and IPv6 aggregation
48	Acct-Output-Packets	IPv4 and IPv6 aggregation
52	Acct-Input-Gigawords	IPv4 and IPv6 aggregation
53	Acct-Output-Gigawords	IPv4 and IPv6 aggregation

## RADIUS Acct-On and Acct-Off Messages

Subscriber management supports RADIUS Acct-On and Acct-Off messages to indicate the current state of RADIUS accounting support.

RADIUS Acct-On messages indicate that accounting is being supported. Subscriber management issues Acct-On messages in the following situations:

- Accounting is enabled through configuration (for example, an accounting server is configured).
- A new access profile is configured and committed for a logical system/routing instance context. However, no Acct-On message is sent if the accounting server exists prior to the access profile and if it is simply modified.
- The router performs a cold reboot.
- The router performs a warm reboot and there are no subscribers currently logged in.
- The Authd process restarts and there are no active subscribers.

RADIUS Acct-Off messages indicate that accounting is not supported. Subscriber management issues Acct-Off messages in the following situations:

- The Authd process is terminated and there are no active subscribers.
- The router is shut down and accounting servers are currently configured (this action also logs out all current subscribers).
- The router is rebooted and redundancy is disabled.

- [AAA Accounting Messages and Supported RADIUS Attributes and Juniper Networks VSAs for Junos OS on page 41](#)

## Configuring Per-Subscriber Session Accounting

To configure accounting for a subscriber session, you use an access profile, and specify how the subscriber access management feature collects and uses the accounting statistics. The router uses the RADIUS attributes and Juniper Networks VSAs discussed in [“RADIUS Accounting Statistics for Subscriber Access Overview” on page 132](#) to provide the accounting statistics for the subscriber session.

To configure accounting for a subscriber session:

1. At the **[edit access profile *profile-name*]** hierarchy level, specify that you want to configure accounting.

```
[edit access profile profile-name]  
user@host# edit accounting
```

2. (Optional) Configure AAA to issue an Acct-Stop message if the AAA server denies access to the subscriber.

```
[edit access profile profile-name accounting]  
user@host# set accounting-stop-on-access-deney
```

3. (Optional) Configure AAA to send an Acct-Stop message if the subscriber fails AAA but is granted access by the AAA server.

```
[edit access profile profile-name accounting]  
user@host# set accounting-stop-on-failure
```

4. (Optional) Configure the router or switch to send an Acct-Update message to the RADIUS accounting server when a CoA occurs.

```
[edit access profile profile-name accounting]  
user@host# set coa-immediate-update
```

5. (Optional) Configure subscriber management to send the RADIUS accounting report to both the wholesaler and the retailer accounting servers.

```
[edit access profile profile-name accounting]  
user@host# set duplication
```

6. (Optional) Configure the duplication filtering action you want the router to perform when the RADIUS duplication accounting operation is enabled.

```
[edit access profile profile-name accounting]
```

```
user@host# set duplication-filter interim-duplicated exclude-attributes
```

7. (Optional) Configure the router to send the RADIUS accounting report to multiple accounting servers listed in access profiles in a nondefault VRF (LS:RI).

```
[edit access profile profile-name accounting duplication-vrf]
user@host# set vrf-name vrf-name
user@host# set access-profile-name profile-name
```

8. (Optional) Configure the router or switch to send an Acct-Update message to the RADIUS accounting server when the router or switch receives a response (for example, an ACK or timeout) to the Acct-Start message.

```
[edit access profile profile-name accounting]
user@host# set immediate-update
```

9. (Optional) Configure the order in which multiple accounting methods are used.

```
[edit access profile profile-name accounting]
user@host# set order [ accounting-order ]
```

10. (Optional) Configure the types of statistics to gather. You can specify that the router or switch collect both volume and time statistics or only time statistics for subscriber sessions. When you change the type of statistics being collected, current subscribers continue to use the previous collection specification. Subscribers who log in after the change use the new specification.

```
[edit access profile profile-name accounting]
user@host# set statistics (time | volume-time)
```

11. (Optional) Override the default behavior and specify that, after a CoA action that changes the RADIUS Class attribute, accounting reports for the subscriber's service sessions continue to use the original Class attribute that was assigned when the service sessions were created. The new Class attribute value is used in accounting reports for the subscriber session only. By default, the accounting reports for both the subscriber session and the subscriber's service sessions use the new Class attribute value.

```
[edit access profile profile-name accounting]
user@host# set coa-no-override service-class-attribute
```

12. (Optional) Configure the number of minutes between accounting updates. You can configure an interval from 10 through 1440 minutes. All values are rounded up to the next higher multiple of 10. For example, the values 811 through 819 are all accepted by the CLI, but are all rounded up to 820.

```
[edit access profile profile-name accounting]
user@host# set update-interval minutes
```

13. (Optional) Configure AAA to send an immediate interim accounting update to the RADIUS server when AAA receives a rate change notification from the ANCP agent on the router.

```
[edit access profile profile-name accounting]
user@host# set ancp-speed-change-immediate-update
```

14. (Optional) Configure the authd process to wait for an Acct-On-Ack response message from RADIUS before sending any new authentication and accounting updates to the RADIUS server. This configuration ensures that when a new subscriber session starts, the authentication and accounting information for the new session does not get deleted when RADIUS clears previously existing session state information.

```
[edit access profile profile-name accounting]
user@host# set wait-for-acct-on-ack
```

15. (Optional) Configure the authd process to send accounting messages when the RADIUS server status changes for an access profile. It sends an Acct-On message when the first RADIUS server is added to the access profile and sends an Acct-Off message when the last RADIUS server is removed from the access profile. This configuration enables you to monitor whether the access profile has an active RADIUS server.

```
[edit access profile profile-name accounting]
user@host# set send-acct-status-on-config-change
```

## Enabling the Reporting of Accurate Subscriber Accounting Statistics to the CLI

You can configure the router to display accurate statistics for subscriber sessions on dynamic interfaces. By default, aggregate statistics (byte and packet counts) for interfaces displayed by the **show interfaces extensive** command do not accurately reflect customer traffic. These counters include overhead bytes that represent the encapsulation overhead added to the actual subscriber data bytes. The aggregate counters also include dropped packets in the total, so the values represent transit statistics rather than the actual subscriber traffic on the interface.

Inclusion of the overhead bytes and dropped packets can have a significant effect on the final reported values. You can exclude dropped packets from the count by including the **interface-transmit-statistics** statement for an interface, but this has no effect on the overhead bytes.

To display accurate subscriber statistics, include the **actual-transmit-statistics** statement for the logical interface in the dynamic profile. This statement enables the **show subscribers** command to display aggregate byte and packet counts for a specified subscriber session or for all subscriber sessions on a specified interface. The displayed statistics match the values that are reported to RADIUS for the subscribers. The statistics are collected after traffic shaping is applied and they do not include overhead bytes, control packets, or dropped packets.

**NOTE:** Starting in Junos OS Release 18.4R1, you must enable **actual-transit-statistics** to collect subscriber statistics. If you do not configure this statement, subscriber statistics are not collected; the **show subscribers accounting-statistics** command displays a value of 0 for subscriber statistics; and the subscriber statistics are reported to RADIUS with values of zero.

**NOTE:** Service accounting statistics are not included.

To configure the reporting of accurate subscriber session statistics:

- Enable actual transit statistics.

```
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit
$junos-interface-unit]
user@host# set actual-transit-statistics
```

You can display the subscriber accounting statistics in two ways:

- Display subscriber statistics by session ID with the **show subscribers id *session-id* accounting-statistics** command.
- Display subscriber statistics by dynamic interface for all session IDs with the **show subscribers interfaces *interface-name* accounting-statistics** command.

## Understanding RADIUS Accounting Duplicate Reporting

When you configure RADIUS accounting, by default the router sends the accounting reports to the accounting servers in the context in which the subscriber was last authenticated. You can configure RADIUS accounting to send duplicate accounting reports to other servers in the same context or in other contexts.

- [Layer 3 Wholesale Scenarios on page 138](#)
- [Other Scenarios on page 139](#)
- [Filters for Duplicate Accounting Reports on page 139](#)

### Layer 3 Wholesale Scenarios

In a Layer 3 wholesale network environment, the wholesaler and retailer might use different RADIUS accounting servers, and both might want to receive accounting reports. In this situation, you can configure RADIUS accounting duplicate reporting, which sends reports to both the wholesaler and the retailer accounting servers. The target to which the duplicate accounting records are sent must be in the default:default logical system:routing instance combination (LS:RI) , also called the *default VRF*.

[Table 15 on page 138](#) shows where subscriber management sends the accounting reports when you enable duplicate reporting. Subscriber management sends duplicate reports based on the access profile in which you configure the **duplication** statement at the **[edit access profile *profile-name* accounting]** hierarchy level, where the subscriber resides, and how the subscriber is authenticated.

**NOTE:** You can also enable accounting duplicate reporting based on the domain map configuration—you configure subscribers to authenticate with a nondefault routing instance and a target logical system:routing instance of default:default. The accounting reports are then sent to both the authentication context and the default:default context.

**Table 15: Duplicate RADIUS Accounting Reporting**

Access Profile in Which Duplication Is Configured	Where Subscriber Is Authenticated	Subscriber's Target Logical System/Routing Instance	Accounting Servers Where Accounting Reports Are Sent
retailer A	wholesaler	retailer A	wholesaler and retailer A
retailer A	retailer A	retailer A	wholesaler (default/default context)  <b>NOTE:</b> This is the domain map configuration described in the Note preceding this table.

*Table 15: Duplicate RADIUS Accounting Reporting (continued)*

Access Profile in Which Duplication Is Configured	Where Subscriber Is Authenticated	Subscriber's Target Logical System/Routing Instance	Accounting Servers Where Accounting Reports Are Sent
wholesaler	wholesaler and retailer A	retailer A	wholesaler and retailer A
wholesaler and retailer B	wholesaler and retailer A	retailer B	wholesaler, retailer A, and retailer B
not configured (default)	any	any	single report sent to accounting servers in the context in which subscriber was last authenticated

### Other Scenarios

For scenarios that are not in a Layer 3 wholesale network environment, you might want to send duplicate accounting records to a different set of RADIUS servers that reside in either the same or a different routing context. Unlike the Layer 3 wholesale scenario, the target for the duplicate RADIUS accounting records does not have to be the default VRF. You can specify a single nondefault VRF—that is, other than the default:default LS:RI combination—as the target. Additionally, you can specify up to five access profiles in the target VRF that list the RADIUS accounting servers that receive the duplicate reports.

For example, you might have a lawful intercept scenario where the subscriber is authenticated in the default domain. An authorized law enforcement organization needs duplicate accounting records for the subscriber to be sent to a mediation device that resides in the organization's networking domain, which lies in a nondefault VRF.

Subscriber management sends duplicate reports to the VRF that you specify with the **vrf-name** statement at the **[edit access profile *profile-name* accounting duplication-vrf]** hierarchy level. Include the **access-profile-name** statement at the same level to designate the access profiles that in turn specify the RADIUS servers that receive the duplicate reports.

### Filters for Duplicate Accounting Reports

Subscriber management provides a duplication filter feature that enables you to specify which accounting servers receive the RADIUS accounting interim reports when RADIUS accounting duplicate reporting is active. You configure the filters in the AAA access profile, and the router then applies the filters to subscribers associated with that profile.

Subscriber management supports the following filtering for RADIUS accounting duplicate reporting:

- Duplicated accounting interim messages— The router filters duplicate accounting messages. The accounting messages are sent only to RADIUS accounting servers in the subscriber's access profile.

- Original accounting interim messages—The router filters accounting messages destined for original RADIUS accounting servers, which are accounting servers in the subscriber's access profile. The accounting messages are sent only to duplication accounting servers (servers in a duplication access profile other than the subscriber's access profile).
- Excluded RADIUS attributes—The router filters the RADIUS attributes in the accounting messages based on the **exclude** statement configuration in the access profile under the duplication context. You can use the exclude filter alone, or with the duplicated or original accounting message filters.

## Configuring Duplication Filters for RADIUS Accounting Duplicate Reporting

You can use duplication filters to specify the RADIUS accounting servers that receive RADIUS accounting interim reports when accounting duplicate reporting is enabled. You configure the filters in a AAA access profile, and the router applies the filters to subscribers associated with that profile.

To configure duplication filters for accounting duplicate reporting:

1. At the **[edit access profile *profile-name*]** hierarchy level, specify that you want to configure accounting.

```
[edit access profile profile-name]  
user@host# edit accounting
```

2. Configure the duplication filter you want the router to use.

The following examples show the three types of filters and describe the results for each filter:

- Specify that the router does not send the accounting interim messages to duplicate RADIUS accounting servers.

Duplicate RADIUS accounting servers are those that are not in the subscriber's access profile. The router still sends the accounting interim messages to accounting servers that reside in the subscriber's access profile.

```
[edit access profile profile-name accounting]  
user@host# set duplication-filter interim-duplicated
```

- Specify that the router does not send the accounting interim messages to original RADIUS accounting servers.

Original accounting servers are those that reside in the subscriber's AAA routing context. The router still sends the accounting interim messages to duplicate accounting servers, which are those servers that do not reside in a duplication context other than the subscriber's access profile.

```
[edit access profile profile-name accounting]  
user@host# set duplication-filter interim-original
```

- Specify how the router uses the **exclude** statement configuration to filter RADIUS attributes from accounting interim messages.

The router uses the configuration for the **exclude** statement in the duplication access profile to determine which RADIUS attributes are not included in the accounting interim messages.

```
[edit access profile profile-name accounting]
user@host# set duplication-filter exclude-attributes
```

## Configuring Per-Service Session Accounting

Subscriber management enables you to configure the router to collect statistics on a per-service session basis for subscribers. Per-service session accounting requires two operations. First, RADIUS must be configured to provide the name of the service, the accounting interval to use, and the type of statistics to collect (either time statistics or a combination of time and volume statistics). Second, if RADIUS VSA 26-69 is configured for time and volume statistics, you must also configure a firewall or fast update firewall filter that counts service packets—the service packet information provides the volume statistics.

The router uses the RADIUS attributes and Juniper Networks VSAs discussed in “[RADIUS Accounting Statistics for Subscriber Access Overview](#)” on page 132 to provide the accounting statistics for the subscriber session.

**NOTE:** The collection of time-only service statistics is supported for all service sessions. However, time and volume statistics are provided for only firewall and fast update firewall service sessions.

To configure the router to provide per-service accounting statistics:

1. Ensure that the required RADIUS VSAs are configured.

See [Table 16 on page 141](#) for the VSAs that the router uses for per-service accounting.

2. Configure the classic firewall filter or fast update filter to count the service packets.

See “[Configuring Service Packet Counting for Volume Statistics](#)” on page 144.

**Table 16: Juniper Networks VSAs Used for Per-Service Session Accounting**

Attribute Number	Attribute Name	Description	Value
26-69	Service-Statistics	Enable or disable statistics for the service	<ul style="list-style-type: none"> <li>0 = disable</li> <li>1 = enable time statistics</li> <li>2 = enable time and volume statistics</li> </ul>

Table 16: Juniper Networks VSAs Used for Per-Service Session Accounting (continued)

Attribute Number	Attribute Name	Description	Value
26-83	Service-Session	Service string sent in accounting stop and start messages from the router to the RADIUS server	string: service-name, with parameter values that are sent from RADIUS server in attribute 26-65.
26-140	Service-Interim-Acct-Interval	Amount of time between interim accounting updates for this service	<ul style="list-style-type: none"> <li>• range = 600–86400 seconds</li> <li>• 0 = disabled</li> </ul> <p><b>NOTE:</b> Values are rounded up to the next higher multiple of 10 minutes. For example, a setting of 900 seconds (15 minutes) is rounded up to 20 minutes (1200 seconds).</p>

**See Also** • [Example: Configuring RADIUS-Based Subscriber Authentication and Accounting on page 114](#)

## Processing Cisco VSAs in RADIUS Messages for Service Provisioning

You can use Cisco VSAs in RADIUS messages to provision and manage services in a subscriber access network. In the topology for this deployment, the broadband network gateway (BNG) is connected to:

- A RADIUS server, such as the Steel-Belted Radius Carrier (SBRC), that is used to authentication and accounting.
- A Cisco BroadHop application that is used as the Policy Control and Charging Rules Function (PCRF) server for provisioning services using RADIUS change of authorization (CoA) messages.

Cisco BroadHop does not support Juniper VSAs. It uses the Cisco VSA, Cisco-AVPair (26-1, IANA private enterprise number 9) with different values to activate and deactivate the services.

To activate a service, use the Cisco-AVPair VSA (26-1) with each of the following values:

- Value of the `.subscriber:command=activate-service` parameter.
- Value of the `subscriber:service-name=service-name` parameter.

To deactivate a service, use the Cisco-AVPair VSA (26-1) with each of the following values:

- Value of the `subscriber:command=deactivate-service` parameter.
- Value of the `subscriber:service-name=service-name` parameter.

You cannot modify any attributes in authentication, accounting, or CoA responses in the RADIUS messages that the BNG sends. Any Cisco VSAs other than the ones used to provision the services are considered as unsupported attributes.

To configure service accounting for an access profile for a subscriber:

1. Specify that you want to configure service accounting.

```
[edit access profile profile-name service]
user@host# edit accounting
```

2. (Optional) Enable interim service accounting updates and configure the amount of time that the router or switch waits before sending a new service accounting update. You can configure an interval from 10 through 1440 minutes. All values are rounded up to the next higher multiple of 10. For example, the values 811 through 819 are all accepted by the CLI, but are all rounded up to 820.

```
[edit access profile profile-name service accounting]
user@host# set update-interval minutes
```

3. (Optional) Configure the types of statistics to gather. You can specify that the router or switch collect both volume and time statistics or only time statistics for subscriber sessions. When you change the type of statistics being collected, current subscribers continue to use the previous collection specification. Subscribers who log in after the change use the new specification.

```
[edit access profile profile-name service accounting]
user@host# set statistics (time | volume-time)
```

You can also define the UDP port number to configure the port on which the router that functions as the RADIUS dynamic-request server must receive requests from RADIUS servers. By default, the router listens on UDP port 3799 for dynamic requests from remote RADIUS servers. You can configure the UDP port number to be used for dynamic requests for a specific access profile or for all of the access profiles on the router. To define the UDP port number, include the **dynamic-request-port *port-number*** statement at the **[edit access profile *profile-name* radius-server *server-address*]** or the **[edit access radius-server *server-address*]** hierarchy level.

To specify the UDP port globally for all access profiles:

```
[edit access radius-server server-address]
user@host# set dynamic-request-port port-number
```

To specify the UDP port for a specific access profile:

```
[edit access profile profile-name radius-server server-address]
user@host# set dynamic-request-port port-number
```

**See Also** • [Standard and Vendor-Specific RADIUS Attributes on page 10](#)

## Configuring Service Packet Counting for Volume Statistics

Subscriber management uses service packet counting to report volume statistics for subscribers on a per-service session basis. To configure service packet counting, you specify the accounting action, and subscriber management then applies the results to a specific named counter (`_junos-dyn-service-counter`) for use by RADIUS.

The accounting action you configure specifies the counting mechanism that subscriber management uses when capturing statistics—either inline counters or deferred counters. Inline counters are captured when the event occurs, and do not include any additional packet processing that might occur after the event. Deferred counters (also called accurate accounting) are not incremented until the packet is queued for transmission, and therefore include the entire packet processing. Deferred counters provide a more accurate count of the packets than inline counters, and are more useful for subscriber accounting and billing.

You configure the accounting mechanism by specifying either the **service-accounting-deferred** action (for deferred counters) or the **service-accounting** action (for inline counters) at the `[edit firewall family family-name filter filter-name term term-name then]` hierarchy level.

The two accounting mechanisms are mutually exclusive, both on a per-term basis and a per-filter basis. Also, both accounting actions are mutually exclusive with the count action on a per-term basis.

**NOTE:** You can define deferred counters for the `inet` and `inet6` families for classic filters only. Fast update filters do not support deferred counters.

To enable service packet counting:

1. Configure any match conditions that you want to count using the service accounting action. For example:

```
[edit firewall family inet filter filtername term term-name]
user@host# set from source-address address
```

2. Specify the accounting action for the filter.

To use deferred counters:

```
[edit firewall family inet filter filtername term term-name]
user@host# set then service-accounting-deferred
```

To use inline counters:

```
[edit firewall family inet filter filtername term term-name]
user@host# set then service-accounting
```

When the match conditions for the filter are met, the packet is counted and applied to the well-known service counter (`_junos-dyn-service-counter`) for use by the RADIUS server. This counter provides the volume statistics for per-service accounting.

**TIP:** You cannot use the `service-accounting` action or the `service-accounting-deferred` action in the same term as a count action.

  - *Firewall Filter Terminating Actions*
  - *Firewall Filter Nonterminating Actions*

## Configuring Service Accounting

Service accounting is disabled by default. You can configure service accounting by using RADIUS attributes received from the external RADIUS server or by using the CLI to configure accounting locally on the router. If you configure both, the RADIUS setting takes precedence over the CLI setting.

In some networks, you must use the CLI to enable and disable service accounting and to specify the interim accounting interval. For example, the BNG might be connected to both a RADIUS server and a third-party device using an application that uses RADIUS CoAs for service provisioning but does not support Juniper Networks VSAs. For more information about this use case, see [“Processing Cisco VSAs in RADIUS Messages for Service Provisioning” on page 142](#).

[Table 17 on page 145](#) indicates the type of service accounting statistics that are collected when various combinations of local CLI and RADIUS service accounting configuration are present:

**Table 17: Type of Service Accounting Statistics Collected Based On CLI and RADIUS Configurations**

CLI Configuration Present for Service Statistics	RADIUS Configuration Present for Service Statistics	Service Statistics Collected
–	–	None
–	✓	RADIUS configuration
✓	–	CLI configuration
✓	✓	RADIUS configuration
✓	Explicitly disabled with a value of 0	None

Table 18 on page 146 indicates the service interim accounting interval value that is used when various combinations of local CLI and RADIUS service accounting configuration are present:

**Table 18: Service Interim Accounting Interval Value Based on CLI and RADIUS Configurations**

CLI Configuration Present for Service Interim Accounting Interval	RADIUS Configuration Present for Service Interim Accounting Interval	Service Interim Accounting Interval Value Used
–	–	No service interim accounting
–	✓	RADIUS value
✓	–	CLI value
✓	✓	RADIUS value
✓	Explicitly disabled with a value of 0	No service interim accounting

Table 19 on page 146 shows the results for two example combinations of CLI and RADIUS configurations.

**Table 19: Example of Values Used for Different Configurations**

CLI	RADIUS	Value Used
<b>update-interval = 400</b>	Acct-Interim-Interval (85) = 600	600
<b>statistics = time</b>	Service-Statistics (26-69) not set	time
<b>update-interval = 400</b>	Acct-Interim-Interval (85) not set	400
<b>statistics = time</b>	Service-Statistics (26-69) = 2, time and volume	time and volume

To configure service accounting for an access profile for a subscriber:

1. Specify that you want to configure service accounting.

```
[edit access profile profile-name service]
user@host# edit accounting
```

2. (Optional) Enable interim service accounting updates and configure the amount of time that the router or switch waits before sending a new service accounting update. You can configure an interval from 10 through 1440 minutes. All values are rounded up to the next higher multiple of 10. For example, the values 811 through 819 are all accepted by the CLI, but are all rounded up to 820.

```
[edit access profile profile-name service accounting]
user@host# set update-interval minutes
```

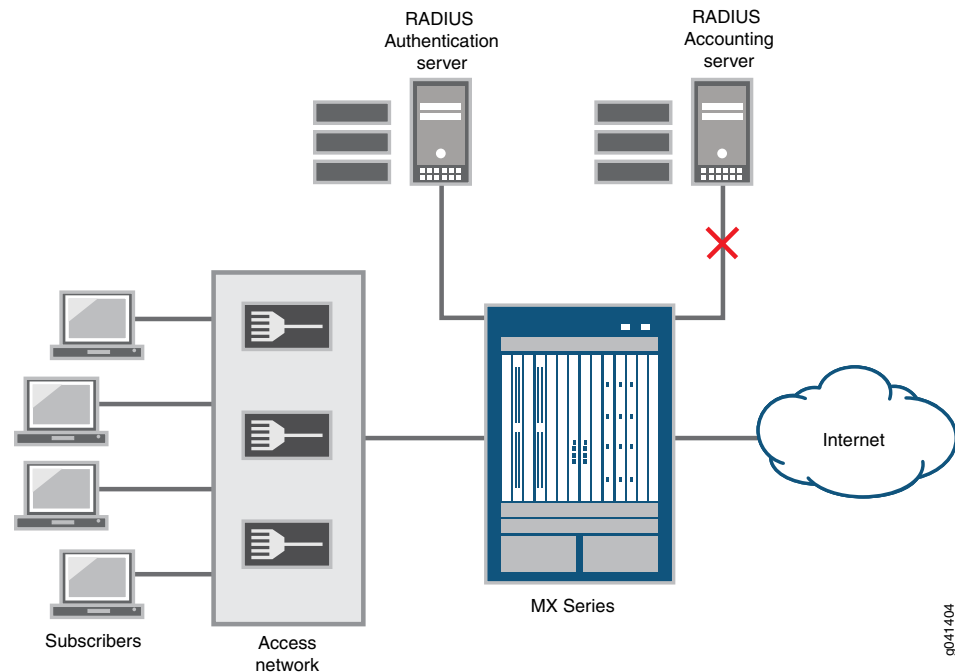

3. (Optional) Configure the types of statistics to gather. You can specify that the router or switch collect both volume and time statistics or only time statistics for subscriber sessions. When you change the type of statistics being collected, current subscribers continue to use the previous collection specification. Subscribers who log in after the change use the new specification.

```
[edit access profile profile-name service accounting]
user@host# set statistics (time | volume-time)
```

## Preservation of RADIUS Accounting Information During an Accounting Server Outage

If the router loses contact with the RADIUS accounting server, as represented in [Figure 3 on page 147](#), whether due to a server outage or a problem in the network connecting to the server, you can lose all the billing information that would have been received by the server. RADIUS accounting backup preserves the accounting data that accumulates during the outage. If you have not configured RADIUS accounting backup, the accounting data is lost for the duration of the outage from the time when the router has exhausted its attempts to resume contact with the RADIUS server. The configurable retry value determines the number of times the router attempts to contact the server.

*Figure 3: Topology with Loss of Access to Accounting Server*

g041404

By default, the router must wait until the revert timer expires before it can attempt to contact the non-responsive server again. However, when you configure accounting backup, the revert timer is disabled and the router immediately retries its accounting requests as soon as the router fails to receive accounting acknowledgments. Accounting backup follows this sequence:

1. The router fails to receive accounting acknowledgments from the server.
2. The router immediately attempts to contact the accounting server and marks the server as offline if the router does not receive an acknowledgment before exhausting the number of retries.
3. The router next attempts to contact in turn each additional accounting server configured in the RADIUS profile.

If a server is reached, then the router resumes sending accounting requests to this server.

4. If none of the servers responds or if no other servers are in the profile, the router declares a timeout and begins backing up the accounting data. It withholds all accounting stop messages and does not forward new accounting requests to the server.
5. During the outage, the router sends a single pending accounting stop message to the servers at periodic intervals.
6. If one of the servers acknowledges receipt, then the router sends all the pending stop messages to that server in batches at the same interval until all the stored stop messages have been sent. However, any new accounting requests are sent immediately rather being held and sent periodically.

The router replays accounting stop messages to the server in the correct order because it preserves both the temporal order among subscribers and the causal order between service and session stop requests for each subscriber. Only accounting stop messages are backed up, because they include the start time and duration of sessions and all the accounting statistics. This makes it unnecessary to withhold the accounting start messages, which eventually time out. Interim updates are not backed up and time out as well; if the session remains active, then the next interim update after the server connection is restored provides the interim accounting information.

You can configure the number of accounting stop messages that the router can queue pending restoration of contact with the accounting server. To preserve current accounting data in preference to collecting new accounting data, subscriber logins fail as soon as the maximum number of messages has been withheld. Subscriber logins resume immediately when the pending queue drops below the queue limit.

**NOTE:** Service accounting stop messages are withheld for a maximum of ten services per subscriber. If a subscriber attempts to activate an eleventh service while that accounting server is offline, the activation fails.

---

The router can hold the pending accounting messages for up to 24 hours. When the configurable maximum holding period passes, all accounting stop messages still in the pending queue are flushed, even if the accounting server has come back online. A consequence of this is that subscriber logins resume immediately if they were failing because the maximum pending limit had been reached.

All pending messages are also flushed in either of the following circumstances:

- If you remove the last accounting server from the access profile, because then there is no place to send the messages.
- If you remove the accounting backup configuration.

While the router is withholding accounting stop messages, you can force the router to attempt contact with the accounting server immediately, rather than allowing it to wait until the periodic interval has expired. When you do so, the router first replays a batch of stop messages to the server, with one of the following outcomes:

- If the router receives an acknowledgment of receipt, then it marks the server as online and begins replaying all remaining pending stop messages in batches.
- If the router does not receive the acknowledgment, then it resumes sending a single pending accounting stop message at the periodic interval.

When a subscriber logs out while the accounting server is offline, the accounting stop requests for the subscriber and the session are queued and replayed to the server when it comes online. In this case, the subscriber session and service session information is retained, so that the router can send a correct accounting request when the server comes back online.

In the event of a graceful Routing Engine switchover while the accounting server is offline, the pending stop messages can be replayed from the active Routing Engine when the server is online again.

**NOTE:** When RADIUS accounting backup is configured, you must use different servers for RADIUS authentication and accounting. Subscriber authentication fails when the same server is configured for both authentication and accounting.

If the RADIUS server acts on behalf of other back-end RADIUS accounting or authentication servers and forwards requests to them, subscribers can be authenticated but accounting requests are not sent out.

Use the `show network-access aaa statistics` command to view backup accounting statistics.

---

## Configuring Back-up Options for RADIUS Accounting

You can configure RADIUS accounting backup to preserve accounting data when the accounting server is unavailable because of a server or network outage. When backup is configured, RADIUS accounting stop messages are withheld and queued to be sent when connectivity is restored. You can specify the maximum number of stop messages that can be queued. When this maximum is reached, subsequent new subscriber logins fail because there is no remaining capacity to preserve accounting data for new sessions.

You can also configure how long the queued messages can be held. When this period expires, all pending accounting stops are flushed from the queue, even if the accounting server has come back online.

**NOTE:** Configuring accounting backup disables the revert timer. An error message is generated if you attempt to configure the `revert-interval` statement at the [edit access profile *profile-name* options] or [edit access radius-options] hierarchy levels.

**CAUTION:** Before you configure RADIUS accounting backup, ensure that RADIUS accounting and RADIUS authentication are configured on different servers. Subscriber authentication fails when the same server is configured for both authentication and accounting.

1. Enable accounting backup to use the default values.

```
[edit access ]
user@host# set accounting-backup-options
```

2. (Optional) Configure the number of accounting stops that the router can preserve while the accounting server is offline.

```
[edit access accounting-backup-options]
user@host# set max-pending-accounting-stops number
```

3. (Optional) Configure how long the router holds pending accounting stops before flushing them.

```
[edit access accounting-backup-options]
user@host# set max-withhold-time hold-time
```

For example, the following statements configure the backup options for all subscriber accounting; these statements specify that the router holds no more than 32,000 pending accounting stops—at which point all subsequent subscriber logins fail—and holds them no longer than 6 hours—at which point all pending messages are flushed and subscriber logins resume if they were failing:

```
[edit access accounting-backup-options]
user@host# set max-pending-accounting-stops 32000
user@host# set max-withhold-time 360
```

Use the `show network-access aaa statistics` command to view backup accounting statistics.

## Forcing the Router to Contact the Accounting Server Immediately

In the event of an accounting server outage while RADIUS accounting backup is enabled, by default the router waits for a time interval to expire before contacting the offline server. Rather than waiting for that interval to pass, you can force the router to immediately contact the server by issuing the `request network-access aaa replay pending-accounting-stops` command. The router sends a batch of pending accounting stop requests to the server. If the router receives an acknowledgment from the server, then the router continues to replay the pending messages to the server in batches at the periodic interval. If the router does not get that acknowledgment, then it resumes sending a single pending accounting stop message at the periodic interval.

To force the router to immediately contact the offline accounting server:

- Request the messages to be replayed.

```
user@host> request network-access aaa replay pending-accounting-stops
```

## Monitoring Pending RADIUS Accounting Stop Messages

**Purpose** Display information about RADIUS accounting stop messages that are being withheld due to an inability to contact the RADIUS accounting server.

**Action** When you want to know whether the number of pending accounting-stop messages is nearing the maximum, you can display a simple count of pending requests:

```
user@host> show network-access aaa statistics pending-accounting-stops
Pending accounting stops: 10,000
```

You can use other commands to display more information about the accounting messages. The next example displays information for all services in the accounting session for the user, `vjshah29@example.com`. Although this example shows only one user, this command actually displays the information for all subscribers for whom accounting is being backed up.

```
user@host> show accounting pending-accounting-stops detail
Type: pppoe
Username: vjshah29@example.com
AAA Logical system/Routing instance: default:default
Access-profile: ce-ppp-profile
Session ID: 84
Accounting Session ID: 84
```

```

IP Address: 192.168.0.25
IPv6 Prefix: 2001:db8:2010:9999:18::/48
Authentication State: AuthAcctStopAckWait
Accounting State: Acc-Stop-Stats-Pending
Service name: cos-service
  Service State: SvcInactive
  Session ID: 94
  Session uptime: 00:08:02
  Accounting status: on/time
  Service accounting session ID: 84:94-1352294677
  Service accounting state: Acc-Stop-Stats-Pending
  Accounting interim interval: 600
Service name: filter-service
  Service State: SvcInactive
  Session ID: 93
  Session uptime: 00:08:02
  Accounting status: on/volume+time
  Service accounting session ID: 84:93-1352294677
  Service accounting state: Acc-Stop-Stats-Pending
  Accounting interim interval: 600
Service name: filter-service6
  Service State: SvcInactive
  Session ID: 95
  Session uptime: 00:08:02
  Accounting status: on/volume+time
  Service accounting session ID: 84:95-1352294677
  Service accounting state: Acc-Stop-Stats-Pending
  Accounting interim interval: 600

```

You can display summary information for all users with a particular access profile. In the following example, only a single user, `vjshah29@example.com`, has the specified access profile, `ce-ppp-profile`:

```
user@host> show accounting pending-accounting-stops ce-ppp-profile
```

Type:	Username:	Session ID:	Service ID:	Service
pppoe	vjshah29@example.com	84		
pppoe	vjshah29@example.com	84	94	cos-service
pppoe	vjshah29@example.com	84	93	filter-service
pppoe	vjshah29@example.com	84	95	filter-service6

You can also display summary information for all subscribers that have accounting-stop messages pending, regardless of access profile. The next example displays information for two users. Because the subscriber `larry@example.com` is not shown in the previous example, he must have a different access profile than `vjshah29@example.com`, even though he has received the same services.

```
user@host> show accounting pending-accounting-stops terse
```

Type:	Username:	Session ID:	Service ID:	Service
pppoe	vjshah29@example.com	84		
pppoe	vjshah29@example.com	84	94	cos-service
pppoe	vjshah29@example.com	84	93	filter-service

## Suspending RADIUS Accounting and Baselining Accounting Statistics Overview

In certain enterprise provider deployments, maintaining and preserving accounting records might be necessary during a control plane upgrade of a RADIUS accounting server, during an upgrade of the billing system for subscribers, or when RADIUS servers are brought down for maintenance. RADIUS accounting subscriber and service accounting are typically used in such customer topologies for volume-based usage of subscriber traffic and computation of costs. Subscribers might also be billed based on the service level and usage, rather than being charged a set rate regardless of usage.

Starting in Junos OS Release 15.1R4, you can temporarily suspend system-wide accounting until you manually resume accounting. During the suspension period, current subscribers remain logged in, but the subscribers can log out and new subscriber sessions can be initiated. RADIUS Acct-Start, Interim-Update, and Acct-Stop accounting request messages are not generated while accounting is suspended; the router does not send any accounting messages to the RADIUS server. For example, if a subscriber logs out during the suspension, no Acct-Stop request is sent to the server.

After accounting is suspended, all accounting requests are dropped, even if the router is configured to hold the pending accounting messages for up to 24 hours. When accounting resumes, new accounting requests might go into the pending queue, but the requests pending when accounting stopped are no longer available.

**NOTE:** We do not recommend that operators suspend accounting as a standard practice for system upgrades. However, some operators might find it useful in service provider environments when an upgrade of the server infrastructure is critical and needed immediately.

While accounting is suspended, statistics counters continue to update. You can optionally request a baseline operation to be performed for subscriber and service session time and volume counters. In this case, when accounting is resumed, statistics are reported relative to the baseline values. You can begin the baselining operation only after the suspension starts and before the upgrade begins. You can successfully issue the baseline request only once per suspension. The CLI reports an error if you issue the command again.

**NOTE:** Statistics are baselined only for subscribers that have interim accounting enabled.

The following RADIUS attributes might be affected for subscribers who are logged in when the baseline is requested and are still logged in when accounting resumes:

- Acct-Session-Time
- Acct-Input-Octets
- Acct-Output-Octets
- Acct-Input-Packets
- Acct-Output-Packets
- Acct-Input-Gigawords
- Acct-Output-Gigawords
- IPv6-Acct-Input-Octets
- IPv6-Acct-Output-Octets
- IPv6-Acct-Input-Packets
- IPv6-Acct-Output-Packets
- IPv6-Acct-Input-Gigawords
- IPv6-Acct-Output-Gigawords

- [Sample Scenarios of Subscriber Accounting Suspension and Baselineing on page 156](#)

### **Sequence of Events During the Suspension, Baselineing, and Resumption of Accounting**

---

The following sequence of events occur when you suspend accounting, generate a baseline, and restart accounting processes:

1. Issue the **request network-access aaa accounting suspend** command to suspend accounting.
  - a. A system logging message is generated to indicate that accounting has been suspended.
  - b. All accounting, including accounting-backup-options, is suspended for all accounting servers in all routing contexts.
2. Issue the **request network-access aaa accounting baseline** command to generate a baseline.
  - a. A system logging message is generated to indicate that baselining has started for accounting statistics.
  - b. Time and volume statistics for each subscriber are set to the baseline value. The amount of time that is taken to complete the baseline process is indeterminate, depending on the number of statistical details.
  - c. A system logging message is generated to indicate that baselining has completed.

3. Issue the **request network-access aaa accounting resume** command when baselining is complete to restart accounting processes.
  - a. A system logging message is generated to indicate that accounting has resumed.
  - b. All previously configured accounting options are reenabled.

The baseline operation attempts to baseline the time and volume counters for each subscriber. Subscriber counters are set to baseline values only if interim accounting is enabled for the subscriber by using the **set update-interval *minutes*** statement at the **[edit access profile *profile-name* accounting]** hierarchy level. If interim accounting is not enabled for a subscriber, the counters of that corresponding subscriber are not mapped to baseline values.

After the baseline request is executed, an unspecified period of time elapses to baseline all subscriber records. During this interval, statistics for one subscriber can accumulate when the statistical information of another subscriber is being baselined. Sometimes, after baselining starts, counters for some services might be inaccurate and inconsistent due to traffic delivered to a subscriber while the counters of that subscriber are baselined. When the baseline command has been executed, accounting cannot be resumed until the baseline is complete. If you issue the command while accounting is not suspended or while baselining is in progress, the command fails. The command reports an error if the Accounting License is not installed.

### Guidelines for Accounting Suspension and Baselining of Statistics

Keep the following points in mind when you suspend accounting and specify a baseline for statistics:

- Accounting suspension in an environment where thresholds (or quotas) are applicable is not supported. This includes environments where Gx-Plus and Juniper Networks Session and Resource Control (SRC) thresholds or RADIUS session volume quotas are effective for any subscriber. The accounting suspend request fails if any subscriber has thresholds or quotas.
- Activation for threshold (or quota) services is not allowed while accounting is suspended.
- Accounting baselining is not supported when accounting is not suspended.
- You cannot specify more than one baseline request during an accounting suspension.
- Baselining for subscribers that are not configured with interim accounting is not supported.
- The time it takes for the baseline operation to complete is indeterminate. It depends on the amount and depth of statistics being collected and is proportional to the number of subscriber and service sessions that are active at the time the baseline is started. The command fails if you attempt to resume accounting while baselining is still in progress.
- You cannot use the commands to suspend, baseline, or resume accounting during a unified ISSU process. If you attempt to perform a unified ISSU while the baseline is in process, when the chassis daemon state changes to the DAEMON\_ISSU\_PREPARE

state, the authentication and Packet Forwarding Engine processes suspend baselining on a session boundary and resume after the Routing Engine switchover to the release to which the device is upgraded.

- If a graceful Routing Engine switchover (GRES) occurs while accounting is suspended or baselining is in progress, the state of suspension or baselining is preserved after the restart of the router. In such a scenario, accounting is suspended after the reboot of the router and the subscribers for which counters are remaining to be baselined are baselined after the router is online.

### Sample Scenarios of Subscriber Accounting Suspension and Baselining

Consider the following scenario:

1. Interim accounting is configured for subscriber X. It is not configured for subscribers Y and Z.
2. The last interim accounting request sent before accounting is suspended includes statistics for subscriber X; 50,000 octets of traffic have so far been sent for this subscriber. Although 20,000 octets have been sent for subscriber Y and 10,000 octets for subscriber Z, that information has not yet been reported because they do not have interim accounting configured.
3. Accounting is suspended.
4. Baselining begins. The current count for subscriber X is 50,000 octets; this becomes the baseline value for the subscriber. No baseline value is established for subscribers Y and Z, because they do not have interim accounting configured.
5. While baselining is in progress, traffic continues to be sent for the three subscribers: 150,000 octets for subscriber X, 80,000 octets for subscriber Y, and 20,000 octets for subscriber Z.
6. Subscriber Z logs out. No Acct-Stop request is sent because accounting is suspended. Consequently, the final accounting statistics are lost for this subscriber.
7. Baselining completes.
8. Accounting resumes.
9. Subscriber X logs out. Although 200,000 total octets were sent for subscriber X, the Acct-Stop record reports only 150,000 octets: 200,000 total octets minus the 50,000 octet baseline.
10. Subscriber Y logs out. Because 100,000 total octets were sent for subscriber Y and there is no baseline value, the Acct-Stop record reports the total of 100,000 octets.

Table 20 on page 156 summarizes this scenario.

**Table 20: Summary of Accounting Suspension and Baselining Scenario**

Subscriber	Interim Accounting configured	Octets Before Suspension	Octets After Baselining Starts	Total Octets	Octets in Acct-Stop When Accounting Resumes
X	Yes	50,000	150,000	200,000	150,000

Table 20: Summary of Accounting Suspension and Baseline Scenario (continued)

Subscriber	Interim Accounting configured	Octets Before Suspension	Octets After Baseline Starts	Total Octets	Octets in Acct-Stop When Accounting Resumes
Y	No	20,000	80,000	100,000	100,000
Z	No	10,000	20,000	30,000	n/a

## Configuring RADIUS Accounting Suspension and Baseline Accounting Statistics

You can temporarily suspend system-wide accounting for the duration of a system upgrade or maintenance action, until you manually resume accounting. During the suspension period, current subscribers remain logged in, but the subscribers can log out and new subscriber sessions can be initiated. RADIUS Acct-Start, Interim-Update, and Acct-Stop messages are not generated while accounting is suspended; the router does not send any accounting messages to the RADIUS server. For example, if a subscriber logs out during the suspension, no Acct-Stop is sent to the server.

**NOTE:** We do not recommend that operators suspend accounting as a standard practice for system upgrades. However, some operators might find it useful in service provider environments when an upgrade of the server infrastructure is critical and needed immediately.

To configure the suspension of accounting processes, create a baseline of the statistics after accounting is halted, and resume accounting after the baselining process is completed:

1. Suspend subscriber accounting.

```
user@host> request network-access aaa accounting suspend
```

A syslog message is generated to indicate that accounting is suspended. All accounting (including accounting-backup-options) is suspended for all accounting servers and all routing contexts.

2. (Optional) Begin baselining accounting statistics for subscribers that have interim accounting configured.

```
user@host> request network-access aaa accounting baseline
```

The router implements the baseline by reading and storing the statistics when the baseline is set. The baseline values are subtracted when you retrieve baseline-relative statistics after accounting resumes. A syslog message is generated to indicate the start of baselining. Time and volume statistics for each subscriber are set to the baseline value. The amount of time that is taken to complete the baseline process might vary, depending on the number of statistical details. A syslog message is generated when the baselining of statistics completes.

- Resume accounting after baselining completes.

```
user@host> request network-access aaa accounting resume
```

A syslog message is generated to indicate that accounting has resumed. All the previously configured accounting options are reenabled.

#### Release History Table

Release	Description
15.1R4	Starting in Junos OS Release 15.1R4, you can temporarily suspend system-wide accounting until you manually resume accounting.

## Verifying and Managing Subscriber AAA Information

**Purpose** View or clear subscriber access statistics and information.

**Action** • To display subscriber AAA statistics:

```
user@host> show network-access aaa statistics
```

```
user@host> show network-access aaa statistics authentication
```

- To display RADIUS server status and information:

```
user@host> show network-access aaa radius-servers
```

- To display subscriber access AAA information:

```
user@host> show network-access aaa subscribers
```

- To display subscriber session information:

```
user@host> show network-access aaa subscribers session-id session-id
```

- To clear subscriber access statistics and to log out specific subscribers:

```
user@host> clear network-access aaa subscriber
```

You can specify the subscriber with the **username** *username* option or the **session-id** *identifier* option. In either case, specify **reconnect** to attempt to reconnect the subscriber session after it is completely logged out.

- To clear blocked request statistics to debug session limits for all usernames across all access profiles:

```
user@host> clear network-access aaa subscriber session-limit-per-username
```

- To clear blocked request statistics to debug session limits for a specific username across all access profiles:

```
user@host> clear network-access aaa subscriber session-limit-per-username username
username
```

- To clear blocked request statistics to debug session limits for all usernames in a specific access profile:

```
user@host> clear network-access aaa subscriber session-limit-per-username
access-profile profile-name
```

- To clear blocked request statistics to debug session limits for a specific username in a specific access profile:

```
user@host> clear network-access aaa subscriber session-limit-per-username username
username access-profile profile-name
```

- To clear AAA accounting statistics:

```
user@host> clear network-access aaa statistics accounting
```

- To clear AAA address-assignment statistics for a client:

```
user@host> clear network-access aaa statistics address-assignment client
```

- To clear AAA address-assignment pool statistics:

```
user@host> clear network-access aaa statistics address-assignment pool pool-name
```

- To clear AAA authentication statistics:

```
user@host> clear network-access aaa statistics authentication
```

## Session Termination Causes and RADIUS Termination Cause Codes

- [Understanding Session Termination Causes and RADIUS Termination Cause Codes on page 160](#)
- [Mapping Session Termination Causes to Custom Termination Cause Codes on page 161](#)

## Understanding Session Termination Causes and RADIUS Termination Cause Codes

When a RADIUS Acct-Stop message is issued as a result of the termination of a subscriber session or service session, the RADIUS Acct-Terminate-Cause attribute (49) reports the cause or reason for the termination. This attribute is included only in RADIUS Acct-Stop messages. The termination cause is conveyed as a code value in the attribute. *RFC 2866, RADIUS Accounting*, defines the standard mapping between 18 code values and termination causes.

Junos OS defines a set of internal termination cause codes that are mapped to the RFC-defined code values. Default mappings exist for AAA, DHCP, L2TP, PPP, and VLAN subscriber and service sessions. When a subscriber or service session is terminated, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute.

You can use the logged information to help monitor and troubleshoot the events. For example, the AAA termination causes include session and service terminations as well as access denials. You might want to route the access failures to a team that monitors attempts to hack the network, the timeout failures to a AAA server team, and resource failures to a team that manages the routers.

Because there are many different Junos OS internal identifiers for termination causes and only 18 standard code values defined in the RFC, by default a given code value can map to multiple identifiers. Instead of using the default code values, you can optionally map any of the internally defined termination causes to any 32-bit number (1 through 4,294,967,295). The flexibility of customized mapping greatly increases the possibilities for fine-grained analytics and failure tracking.

**NOTE:** A single mapping for RADIUS account termination is shared by all clients.

Table 21 on page 160 lists the RFC-defined standard RADIUS Acct-Terminate-Cause codes and the corresponding causes.

**Table 21: RFC-Defined Code Values and Termination Causes**

Code Value	Termination Cause	Description
1	User Request	User initiated the disconnect (logout).
2	Lost Carrier	DCD was dropped on the port.
3	Lost Service	Service can no longer be provided; for example, the user's connection to a host was interrupted.
4	Idle Timeout	Idle timer expired.
5	Session Timeout	Subscriber reached the maximum continuous time allowed for the service or session.

*Table 21: RFC-Defined Code Values and Termination Causes (continued)*

Code Value	Termination Cause	Description
6	Admin Reset	System administrator reset the port or session.
7	Admin Reboot	System administrator terminated the session on the NAS; for example, prior to rebooting the NAS.
8	Port Error	NAS detected an error on the port that required ending the session.
9	NAS Error	NAS detected an error (other than on the port) that required ending the session.
10	NAS Request	NAS ended the session for a non-error reason.
11	NAS Reboot	NAS ended the session due to a non-administrative reboot.
12	Port Unneeded	NAS ended the session because the resource usage fell below the low threshold; for example, the bandwidth-on-demand algorithm determined that the port was no longer needed.
13	Port Preempted	NAS ended the session to allocate the port to a higher-priority use.
14	Port Suspended	NAS ended the session to suspend a virtual session.
15	Service Unavailable	NAS was unable to provide the requested service.
16	Callback	NAS is terminating the current session in order to perform callback for a new session.
17	User Error	Error in the user input caused the session to be terminated.
18	Host Request	Login host terminated the session normally.

## Mapping Session Termination Causes to Custom Termination Cause Codes

By default, Junos OS uses the RFC-defined termination cause codes for the internal identifiers that identify the causes of session termination and that are reported in the RADIUS Acct-Terminate-Cause attribute (49). Internal identifiers are available for AAA, DHCP, L2TP, PPP, and VLAN subscriber and service session failures. When a subscriber or service session is terminated or denied, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute. The Acct-Terminate-Cause attribute is included in RADIUS Acct-Stop messages. You can use the logged information to help monitor and troubleshoot terminated sessions.

You can optionally create customized mappings between any of the internal termination cause identifiers for the protocol and termination cause codes. You can specify any 32-bit

value for the code, enabling you to track and analyze particular termination events at a more fine-grained level.

To configure customized mappings between a termination cause and a RADIUS cause code:

1. Edit the **access** hierarchy.

```
[edit]
user@host# edit access
```

2. Edit the **terminate-code** statement.

**NOTE:** Termination cause codes do not appear as options on platforms where they are not supported.

```
[edit access]
user@host# edit terminate-code
```

3. Specify the protocol option (**aaa (deny | service-shutdown | shutdown) | dhcp | l2tp | ppp | vlan**) that you want to modify.

```
[edit access terminate-code]
user@host# edit protocol-option
```

4. Specify an existing termination cause that you want to remap.

```
[edit access terminate-code protocol-option]
user@host# edit term-reason
```

**NOTE:** Attempts to remap a termination cause to its default code value are rejected by the CLI. You must delete a custom mapping to restore the default mapping.

5. Specify the RADIUS termination cause code value (from 1 through 4,294,967,295) that you want to map to the termination cause.

```
[edit access terminate-code protocol-option term-reason]
user@host# set radius term-cause
```

Use the **show network-access aaa terminate-code** command to display the mapping between AAA termination causes and cause code values.

## AAA Termination Causes and Code Values

When a AAA event terminates a subscriber or service session, causing a RADIUS Acct-Stop message to be issued, the RADIUS Acct-Terminate-Cause attribute (49) reports the cause or reason for the termination. This attribute is included only in RADIUS Acct-Stop messages. The termination cause is conveyed as a code value in the attribute. *RFC 2866, RADIUS Accounting*, defines the standard mapping between 18 code values and termination causes.

Junos OS defines a set of internal termination cause codes that are mapped to the RFC-defined code values. When a subscriber or service session is terminated, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute. You can use the logged information to help monitor and troubleshoot terminated sessions.

[Table 22 on page 163](#) lists the default mapping between the internal identifier for AAA termination causes and the code values that represent them in the RADIUS Acct-Terminate-Cause attribute (49).

**NOTE:** You can remap the internal identifiers to a custom code value in the range 1 through 4,294,967,295 by using the `terminate-code` statement at the `[edit access]` hierarchy level. You can view the current mapping by issuing the `show network-access terminate-code aaa detail` command.

**Table 22: Default Mapping Between AAA Termination Causes and Code Values**

Internal AAA Termination Cause	RADIUS Acct-Terminate-Cause Attribute	
	Code Value	RADIUS Termination Cause
deny-authentication-denied	17	Subscriber access denied due to authentication failure.
deny-no-resources	10	Subscriber access denied for reasons such as no RADIUS server exists.

**Table 22: Default Mapping Between AAA Termination Causes and Code Values (continued)**

Internal AAA Termination Cause	RADIUS Acct-Terminate-Cause Attribute	
	Code Value	RADIUS Termination Cause
deny-server-request-timeout	17	Subscriber access denied because the BNG retried the Access-Request to the authentication server for the configured number of retries without receiving a response.
service-shutdown-network-logout	6	Service session termination initiated by deactivation of a family (network), typically triggered by termination of the corresponding Layer 3 access protocol.
service-shutdown-remote-reset	10	Service session termination initiated by an external authority, such as a CoA service deactivation.
service-shutdown-subscriber-logout	Inherited from the parent subscriber session.	Overrides the default value.  This code is displayed only when you map it to a custom value.
service-shutdown-time-limit	5	Service session termination initiated because the service time limit was reached.
service-shutdown-volume-limit	10	Service session termination initiated because the service traffic volume limit was reached.
shutdown-administrative-reset	6	Admin Reset
shutdown-idle-timeout	4	Idle Timeout
shutdown-remote-reset	10	NAS Request
shutdown-session-timeout	5	Session Timeout

- [Session Termination Causes and RADIUS Termination Cause Codes on page 159](#)

**DHCP Termination Causes and Code Values**

When a DHCP event terminates a subscriber session, causing a RADIUS Acct-Stop message to be issued, the RADIUS Acct-Terminate-Cause attribute (49) reports the

cause or reason for the termination. This attribute is included only in RADIUS Acct-Stop messages. The termination cause is conveyed as a code value in the attribute. *RFC 2866, RADIUS Accounting*, defines the standard mapping between 18 code values and termination causes.

Junos OS defines a set of internal termination cause codes that are mapped to the RFC-defined code values. When a subscriber session is terminated, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute. You can use the logged information to help monitor and troubleshoot terminated sessions.

[Table 23 on page 165](#) lists the default mapping between the internal identifier for DHCP termination causes and the code values that represent them in the RADIUS Acct-Terminate-Cause attribute (49).

**NOTE:** You can remap the internal identifiers to a custom code value in the range 1 through 4,294,967,295 by using the `terminate-code` statement at the `[edit access]` hierarchy level. You can view the current mapping by issuing the `show network-access terminate-code dhcp detail` command.

**Table 23: Default Mapping Between DHCP Termination Causes and Code Values**

Internal DHCP Termination Cause	RADIUS Acct-Terminate-Cause Attribute	
	Code Value	RADIUS Termination Cause
client request	1	User Request
lost-carrier	2	Lost Carrier
nak	15	Service Unavailable
nas logout	10	NAS Request
no offers	4	Idle Timeout

**Related Documentation**

- [Session Termination Causes and RADIUS Termination Cause Codes on page 159](#)

## L2TP Termination Causes and Code Values

When an L2TP event terminates a subscriber session, causing a RADIUS Acct-Stop message to be issued, the RADIUS Acct-Terminate-Cause attribute (49) reports the cause or reason for the termination. This attribute is included only in RADIUS Acct-Stop messages. The termination cause is conveyed as a code value in the attribute. *RFC 2866, RADIUS Accounting*, defines the standard mapping between 18 code values and termination causes.

Junos OS defines a set of internal termination cause codes that are mapped to the RFC-defined code values. When a subscriber session is terminated, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute. You can use the logged information to help monitor and troubleshoot terminated sessions.

Table 24 on page 166 lists the default mapping between the internal identifier for L2TP termination causes and the code values that represent them in the RADIUS Acct-Terminate-Cause attribute (49).

**NOTE:** You can remap the internal identifiers to a custom code value in the range 1 through 4,294,967,295 by using the `terminate-code` statement at the `[edit access]` hierarchy level. You can view the current mapping by issuing the `show network-access terminate-code l2tp detail` command.

**Table 24: Default Mapping Between L2TP Termination Causes and Code Values**

## PPP Termination Causes and Code Values

When a PPP event terminates a subscriber session, causing a RADIUS Acct-Stop message to be issued, the RADIUS Acct-Terminate-Cause attribute (49) reports the cause or reason for the termination. This attribute is included only in RADIUS Acct-Stop messages. The termination cause is conveyed as a code value in the attribute. *RFC 2866, RADIUS Accounting*, defines the standard mapping between 18 termination causes and code values.

Junos OS defines a set of internal termination cause codes that are mapped to the RFC-defined code values. When a subscriber session is terminated, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute. You can use the logged information to help monitor and troubleshoot terminated sessions.

[Table 25 on page 186](#) lists the default mapping between the internal identifier for PPP termination causes and the code values that represent them in the RADIUS Acct-Terminate-Cause attribute (49).

**NOTE:** You can remap the internal identifiers to a custom code value in the range 1 through 4,294,967,295 by using the `terminate-code` statement at the `[edit access]` hierarchy level. You can view the current mapping by issuing the `show network-access terminate-code ppp detail` command.

Table 25 on page 186 lists the default PPP terminate mappings. The table indicates the supported PPP terminate reasons and the RADIUS Acct-Terminate-Cause attributes they are mapped to by default.

**Related Documentation**

- [Session Termination Causes and RADIUS Termination Cause Codes on page 159](#)

**VLAN Termination Causes and Code Values**

When a VLAN event terminates a subscriber session, causing a RADIUS Acct-Stop message to be issued, the RADIUS Acct-Terminate-Cause attribute (49) reports the

cause or reason for the termination. This attribute is included only in RADIUS Acct-Stop messages. The termination cause is conveyed as a code value in the attribute. *RFC 2866, RADIUS Accounting*, define the standard mapping between 18 code values and termination causes.

Junos OS defines a set of internal termination cause codes that are mapped to the RFC-defined code values. When a subscriber session is terminated, the router logs a message for the internal termination cause and logs another message for the RADIUS Acct-Terminate-Cause attribute. You can use the logged information to help monitor and troubleshoot terminated sessions.

Table 26 on page 194 lists the default mapping between the internal identifier for VLAN termination causes and the code values that represent them in the RADIUS Acct-Terminate-Cause attribute (49).

**NOTE:** You can remap the internal identifiers to a custom code value in the range 1 through 4,294,967,295 by using the `terminate-code` statement at the `[edit access]` hierarchy level. You can view the current mapping by issuing the `show network-access terminate-code vlan detail` command.

**Table 26: Default Mapping Between VLAN Termination Causes and Code Values**

Internal VLAN Termination Cause	RADIUS Acct-Terminate-Cause Attribute	
	Code Value	RADIUS Termination Cause
vlan admin-logout	6	VLAN session termination initiated by the subscriber being administratively logged out.
vlan admin-reconnect	16	VLAN session termination initiated by the subscriber being administratively reconnected.
vlan other	9	VLAN session termination initiated by an otherwise undefined cause.
vlan out-of-band-access-interface-down	2	VLAN out-of-band session termination initiated by the access-facing interface going down.
vlan out-of-band-admin-access-interface-down	6	VLAN out-of-band session termination initiated by the access-facing interface being brought down administratively.

**Table 26: Default Mapping Between VLAN Termination Causes and Code Values (continued)**

Internal VLAN Termination Cause	RADIUS Acct-Terminate-Cause Attribute	
	Code Value	RADIUS Termination Cause
vlan out-of-band-admin-core-interface-down	6	VLAN out-of-band session termination initiated by the core-facing interface being brought down administratively.
vlan out-of-band-ancp-port-down	1	VLAN out-of-band session termination initiated by the receipt of an ANCP Port Down message.
vlan out-of-band-ancp-port-vlan-id-change	1	VLAN out-of-band session termination initiated by a change in the port VLAN ID, which is treated as a logical Port Down message.
vlan out-of-band-core-interface-down	2	VLAN out-of-band session termination initiated by the core-facing interface going down.
vlan out-of-band-l2-wholesale-no-free-vlans	15	VLAN out-of-band session termination initiated by the lack of any remaining available VLAN IDs.
vlan profile-request-error	9	VLAN session termination initiated by an error when requesting the dynamic profile associated with the VLAN range.
vlan sdb-error	9	VLAN session termination initiated by an error in the session database.
vlan subscriber-activate-error	9	VLAN session termination initiated by an error while attempting to activate the subscriber services for the session.

## Domain Mapping Overview

Domain mapping enables you to configure a map that specifies access options and session-specific parameters. The map is based on the domain name of subscriber sessions — the router applies the mapped options and parameters to sessions for subscribers that have the specified domains. For example, you might configure a domain map that is based on the domain name **example.com**. The options and parameters in that domain map are then applied when subscribers with the specified domain name (for example, **bob@example.com**, **raj@example.com**, and **juan@example.com**) request a AAA service.

**NOTE:** A subscriber's username is typically made up of two parts — the user's name followed by the user's domain name, which are separated by a delimiter character. The domain name is always to the right of the domain delimiter. For example, in the username, **juan@example.com**, the user's name, **juan** is followed by the domain name **example.com**, and the two are separated by the **@** delimiter character.

However, some systems use a username format in which the domain name *precedes* the user's name. To avoid confusion with the typical domain name usage, this type of preceding domain name is referred to as a realm name, and the realm name is to the left of the realm delimiter. For example, in the username, **top321-example.com/mary**, the **top321-example.com** part is the realm name, **mary** is the user's name, and the **/** character is the delimiter character.

The domain map provides efficiency, and enables you to make changes for a large number of subscribers in one operation. For example, if an address assignment pool becomes exhausted due to the number of subscribers obtaining addresses from the pool, you can create a domain map that specifies that subscribers in a particular domain obtain addresses from a different pool. In another use of the domain map, you might create a new dynamic profile and then configure the domain map to specify which subscribers (by their domain) use that dynamic profile.

**NOTE:** Subscriber management is supported in the default logical system only. The documentation for the subscriber management domain mapping feature describes using the **aaa-logical-system** and **target-logical-system** statements to configure mapping to a non-default logical system. These statements are for future extensions of subscriber management.

[Table 27 on page 199](#) describes the access options and parameters you can configure in the domain map.

*Table 27: Domain Map Options and Parameters*

Option	Description
AAA logical system/routing instance	<p>Logical system/routing instance in which AAA sends authentication and accounting requests for the subscriber sessions.</p> <p>Subscriber management is supported in the default logical system only.</p>
Access profile	Access profile applied to subscriber sessions.
Address pool	Address pool used to allocate addresses to subscribers.
Domain and realm name rules	Rules for domain and realm name usage, including domain name stripping, supported delimiters, and parse direction (delimiters and the parse direction are configured globally).
Dynamic profile	Dynamic profile applied to subscriber sessions.
PADN parameters	PPPoE route information for subscriber sessions.
Target logical system/routing instance	<p>Logical system/routing instance to which the subscriber interface is attached.</p> <p>Subscriber management is supported in the default logical system only.</p>
Tunnel profile	Tunnel profile applied to subscriber sessions.

### Types of Domain Maps and Their Order of Precedence

Starting in Junos OS Release 16.1, subscriber management uses a specific order when searching for a domain map that matches the subscriber domain name. The following list shows that order:

- **Exact match domain map**—The subscriber domain name is an exact match to a configured domain map.
- **Wildcard domain map**—The subscriber domain name is a partial match to a wildcard domain map.
- **default domain map**—The subscriber domain name is neither an exact match nor a partial wildcard match to a domain map.

**NOTE:** If the subscriber username does not have a domain name, then no search is performed and the subscriber is associated with the none domain map, if configured.

### Wildcard Domain Map

---

Starting in Junos OS Release 16.1, the wildcard domain map feature enables you to specify a domain name that is used by subscribers when there is no exact match to the subscriber's domain name. For example, if you create a wildcard domain map with the name **xyz\*.example.com**, subscribers with the domain names **xyz.example.com**, **xyz-1234.example.com**, **xyz-eastern.example.com**, and **xyz-northern.example.com** are all mapped to that wildcard domain if there was no exact match for the subscribers' domain names. You can insert the asterisk wildcard character anywhere within the domain map to create the desired matching specification. Wildcard domain mapping is also used in cases where subscriber names are derived from the DHCPv4 Agent Remote ID (option 82 suboption 2) or the DHCPv6 Remote-ID (option 37).

### Default Domain Map

---

You can configure a default domain map that the router uses for subscribers whose domain or realm name does not explicitly match any existing domain map, and also is not a partial match to a wildcard domain map. Specify the name **default** as the **domain map domain-map-name**.

For example, you might configure the default domain map to provide limited feature support for guest subscribers, such as a specific address pool used for guests or the routing instance that provides AAA services. When the router is unable to provide an exact or wildcard match for the guest subscriber, the router then uses the rules specified in the default domain map configuration to handle the guest subscriber's request.

### Domain Map for Subscriber Usernames With No Domain or Realm Name

---

In some cases a subscriber username might not include a domain name or realm name—you can configure a specific domain map that the router uses for these subscribers. Specify the name **none** as the **domain map domain-map-name**.

### Understanding Domain Maps and Logical System/Routing Instance Contexts

---

You can use a domain map to manage the logical system/routing instance that subscriber management uses for AAA and subscriber contexts. Subscriber management is supported in the default logical system only, so you manage the contexts by configuring the routing instance. The following list describes the two types of contexts:

- **Subscriber context**—The logical system/routing instance in which the subscriber interface is placed. For most dynamic subscriber sessions, the initial subscriber session context is the default logical system and default routing instance. One exception is LNS, in which the initial context for a dynamic LNS session (PPP over L2TP) is the same as the peer interface (the LAC facing interface). Therefore, for LNS sessions, if the peer interface uses a non-default routing instance, then the initial context of the subscriber session also uses that non-default routing instance.
- **AAA context**—The logical system/routing instance that the subscriber session uses for RADIUS interactions, such as authentication and accounting requests. By default, the AAA context is the same as the initial subscriber context. Therefore, for all subscriber sessions other than dynamic LNS sessions, authentication and authorization is

performed in the default logical system/routing instance context, unless the default routing instance is explicitly changed.

You can optionally configure a domain map to use a specific subscriber or AAA context. For example, if a dynamic LNS session is initially created in a non-default routing instance (because the initial subscriber context uses the non-default routing instance), you might use the **target-routing-instance** statement to configure the domain map to place the subscriber in the default routing instance. Or, for security reasons, you might want to have all RADIUS interactions in a particular context. In this case, you would use the **aaa-routing-instance** statement to configure the domain map to change the initial AAA context to the new routing instance.

Using domain maps to manage AAA and subscriber contexts is also useful in layer 3 wholesale environments. For example, you might want to place dynamic VLAN interfaces in different non-default routing instances, while maintaining all RADIUS interactions in the default routing instance. In this example, the initial AAA context is in the default routing instance, but RADIUS authorization places the subscriber VLAN session in a non-default routing instance. You can then include the **aaa-routing-instance** statement in the domain map, to specify that the AAA context uses the default routing instance for the dynamic VLAN session. The subscriber session is unchanged and remains in the non-default routing instance.

### Benefits of Using Domain Maps

- Domain maps simplify managing subscribers at scale by enabling you to make changes for a large number of subscribers in one operation.
- Domain maps provide granularity in applying changes to specific groups of subscribers based on your map definitions.

## Configuring a Domain Map

To configure a domain map for subscriber management:

1. Create the domain map. For the map name, specify the domain name that you want the domain map to use. (Use **default** for the name of the default domain map.)

```
[edit access]
user@host# edit domain map domain-map-name
```

- For example, to create a domain map to be mapped to subscribers with the domain name **example.com**:

```
[edit access]
user@host# edit domain map example.com
```

- To create a wildcard domain map to be mapped to subscribers whose domain name is not an exact match, but is a partial match:

```
[edit access]
user@host# edit domain map premiumTier*
```

See [“Configuring a Wildcard Domain Map” on page 203](#).

- To create a default domain map to be mapped to subscribers with non-matching domain names:

```
[edit access]
user@host# edit domain map default
```

- To create a domain map to be mapped to subscribers without a domain or realm name:

```
[edit access]
user@host# edit domain map none
```

2. (Optional) Specify the access profile used to apply access rules for the domain map.  
See [“Specifying an Access Profile in a Domain Map” on page 204](#).

3. (Optional) For dynamic profiles, clarify the provided dynamic configuration for the subscriber session.

See [“Specifying a Dynamic Profile in a Domain Map” on page 206](#).

4. (Optional) Specify the address pool used to allocate address for the domain map.

See [“Specifying an Address Pool in a Domain Map” on page 205](#).

5. (Optional) Configure the target logical system/routing instance for the subscriber context.

See [“Specifying an AAA Logical System/Routing Instance in a Domain Map” on page 206](#).

6. (Optional) Configure the target logical system/routing instance in which AAA requests are sent for the domain map.

See [“Specifying a Target Logical System/Routing Instance in a Domain Map” on page 207](#).

7. (Optional) Configure rules for domain names; for example; delimiters, parsing direction, and domain stripping. Delimiters and parsing direction are configured globally for all domain maps. Domain stripping is enabled in the domain map.

See [“Configuring Domain and Realm Name Usage for Domain Maps” on page 210](#).

8. (Optional) Configure rules to remove the domain portion from the username for authentication, accounting, and display purposes.

See [“Enabling Domain Name Stripping” on page 213](#).

9. (Optional) Configure rules to strip the user portion of the username for authentication only. You can also use a directional option to configure a left-to-right (default) or right-to-left application.

See [strip-username](#).

10. (Optional) Specify a password to use for all subscriber authentications. This option affects only the username/password sent in the access-request to external policy/RADIUS servers.

See [override-password](#).

11. (Optional) Assign a tunnel profile that provides tunnel definitions for the domain map.

See [“Specifying a Tunnel Profile in a Domain Map” on page 208](#).

12. (Optional) Assign a tunnel switch profile to be applied by the domain map.

See [“Specifying a Tunnel Switch Profile in a Domain Map” on page 208](#).

13. (Optional) Configure the PADN parameters used for PPPoE route information for the domain map.

See [“Configuring PADN Parameters for a Domain Map” on page 209](#).

## Configuring a Wildcard Domain Map

Subscriber management supports a wildcard domain map feature that enables you to configure a domain mapping that is based on a partial wildcard match. When there is no exact match between the subscriber domain name and a configured domain map, subscriber management next looks for a partial match between the subscriber domain name and a wildcard domain map.

To create the wildcard domain map, you include the asterisk wildcard character when you configure the domain map name, such as, **domain map example\***. You can insert the wildcard character anyplace within the domain map, and the wildcard can represent zero or any number of characters. The asterisk is the only supported wildcard character.

For example, the configuration statement **domain map example\*northern.com** creates a wildcard domain map that is a partial match for all domain names beginning with **example** and ending with **northern.com**, such as **examplenorthern.com**, **example-northern.com**, and **example1234northern.com**. However if you move the wildcard character in the domain map name to **domain map example-northern\*.com**, this creates a more restrictive match that requires the partial matching domain names to start with **example-northern**, such as **example-northern555.com** or **example-northern-alpha.com**.

Wildcard domain mapping is also useful when subscriber management derives subscriber usernames from the DHCPv4 Agent Remote ID (option 82 suboption 2) or the DHCPv6 Remote-ID (option 37). In these cases, the resultant username is in the format **subscriberID|service-plan|accountID|unused**; for example, **EricSmith|premiumTier1|314159265|0000** (where the | character is the delimiter). In this

example, subscriber management parses the username left-to-right, and identifies the subscriber's domain as **premiumTier1|314159265|0000**. To create a wildcard domain map that is used for this subscriber, you might configure **domain map premiumTier1\***.

The following example describes how four subscribers are mapped to different domains.

For this example, there are three domain maps configured; the **default** domain map, a domain map named **example3000.com**, and a wildcard domain map named **example\***. The subscribers are mapped as shown in the following list:

- **eric@example3000.com**—There is an exact domain map match, so the subscriber is mapped to domain **example3000.com**.
- **jack@example1001.com**—There is no exact match, but there is a partial match to the wildcard domain, so the subscriber is mapped to the wildcard domain **example\***.
- **ginger@example-western.com**—There is no exact match, but there is a partial match to the wildcard domain, so the subscriber is also mapped to the wildcard domain **example\***.
- **sunshine@test.com**—There is no exact match, nor is there a partial match to the wildcard domain, so the subscriber is mapped to the **default** domain.

To configure a wildcard domain map:

1. Specify the domain map name, including the wildcard character.

```
[edit access]
user@host# edit domain map premiumTier*
```

2. Specify the optional characteristics for the wildcard domain map.

See [“Configuring a Domain Map” on page 201](#).

## Specifying an Access Profile in a Domain Map

You use access profiles to specify the access rules and options (for example, the RADIUS authentication server and attributes) that the router applies to subscriber sessions. The domain map feature enables you to apply a specific access profile for subscribers in a particular domain.

Access profiles can be specified or modified in several different ways. If conflicts occur, the router applies the access profiles based on the precedence rules shown in [Table 28 on page 204](#).

**Table 28: Precedence Rules for Applying Access Profiles**

Precedence (High to Low)	How the Access Profile Is Applied
1	Specified by the RADIUS Redirect-VRouter-Name attribute (VSA 26-25)
2	Specified in the domain map configuration stanza

*Table 28: Precedence Rules for Applying Access Profiles (continued)*

Precedence (High to Low)	How the Access Profile Is Applied
3	Indirectly specified in the domain map configuration stanza by the AAA logical system/routing instance mapping
4	Specified in the client configuration stanza
5	Specified in the logical system/routing instance configuration stanza

To include an access profile in a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the access profile you want to include in the domain map.

```
[edit access domain map domain-map-name]
user@host# set access-profile profile-name
```

## Specifying an Address Pool in a Domain Map

You can use the domain map feature to specify the address pool that the router uses to allocate address for subscriber sessions. The address pool can include both IPv4 and IPv6 address ranges.

Address pools can be specified or modified in several different ways. If conflicts occur, the router applies the address pool based on the precedence rules shown in [Table 29 on page 205](#).

*Table 29: Precedence Rules for Determining the Address Pool to Use*

Precedence (High to Low)	How the Address Pool Reference Is Provided
1	Specified by the RADIUS Framed-Pool attribute (RADIUS attribute 88)
2	Configured in the domain map configuration stanza
3	Specified in the client configuration stanza (by address match rules)

To specify the address pool used for a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
```

```
user@host# edit domain map domain-map-name
```

- Specify the address pool you want to use for the domain map.

```
[edit access domain map domain-map-name]  
user@host# set address-pool pool-name
```

## Specifying a Dynamic Profile in a Domain Map

A dynamic profile defines the set of characteristics that provide dynamic access and services for subscriber sessions (such as class-of-service, protocols, and interface support). The domain map feature enables you to apply a specific dynamic profile based on subscriber domains.

Dynamic profiles are configured at the **[edit dynamic-profiles]** hierarchy, and can be specified or modified in several different ways. If conflicts occur, the router applies the dynamic profiles based on the precedence rules shown in [Table 30 on page 206](#).

*Table 30: Precedence Rules for Applying Dynamic Profiles*

Precedence (High to Low)	How the Dynamic Profile Is Applied
1	Specified by the RADIUS Virtual-Router attribute (VSA 26-1) or the Redirect-VRouter-Name attribute (VSA 26-25)
2	Specified in the domain map configuration stanza
3	Specified in the client configuration stanza

To include a dynamic profile in a domain map:

- Specify the domain map you want to configure.

```
[edit access]  
user@host# edit domain map domain-map-name
```

- Specify the dynamic profile you want to include in the domain map.

```
[edit access domain map domain-map-name]  
user@host# set dynamic-profile profile-name
```

## Specifying an AAA Logical System/Routing Instance in a Domain Map

By default, a domain map uses the subscriber logical system/routing instance as the context in which the **authd** daemon sends AAA authentication and accounting requests. You can optionally configure the domain map to direct AAA requests to a particular context, based on the subscriber domain name. Specifying a non-default AAA context enables you to manage workflow and traffic load, and to efficiently make changes for a large number of subscribers. For example, after upgrading your RADIUS services, you

might configure a domain map to specify that all subscribers in the domain **example.com** are now authenticated by a RADIUS server in a particular AAA context.

**NOTE:** Changing the AAA context does not change the subscriber context. You use the **target-logical-system** statement to explicitly configure the logical system/routing instance for subscribers.

To configure the logical system/routing instance context used for AAA requests:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the routing instance. If a non-default routing instance is currently configured, you can use the **default** option to specify that the domain map use the default routing instance. The AAA logical system is automatically set to the default.

```
[edit access domain map domain-map-name]
user@host# set aaa-routing-instance (routing-instance-name | default)
```

**NOTE:** Subscriber management is supported in the default logical system only.

## Specifying a Target Logical System/Routing Instance in a Domain Map

By default, the router places a subscriber in the logical system/routing instance context of the interface on which the subscriber negotiations start. You can later change the routing instance of the subscriber's context through the use of either a domain map or the RADIUS authentication server.

Subscriber management is supported in the default logical system only, however you can configure the domain map to use a non-default routing instance. Also, if a non-default routing instance is already configured, you can configure the domain map to use the default routing instance.

To configure the logical system/routing instance context used for a subscriber's interface :

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

- Specify the target routing instance (the default logical system is used by default). If a non-default routing instance is currently configured, you can use the **default** option to specify that the domain map use the default routing instance.

```
[edit access domain map domain-map-name]
user@host# set target-routing-instance (routing-instance-name | default)
```

**NOTE:** Subscriber management is supported in the default logical system only.

## Specifying a Tunnel Profile in a Domain Map

Tunnel profiles specify tunnel definitions (for example, a set of L2TP tunnels and their attributes) that the router applies to subscriber sessions. The domain map feature enables you to apply a specific tunnel profile to subscribers in a particular domain.

**NOTE:** A tunnel profile specified by a RADIUS server in the Tunnel-Group attribute (VSA 26-64) takes precedence over the tunnel profile specified in the domain map.

To include a tunnel profile in a domain map:

- Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

- Specify the tunnel profile you want to include in the domain map.

```
[edit access domain map domain-map-name]
user@host# set tunnel-profile profile-name
```

**See Also** • [Configuring a Tunnel Profile for Subscriber Access](#)

## Specifying a Tunnel Switch Profile in a Domain Map

Tunnel switch profiles determine whether packets in an L2TP subscriber session from a LAC are switched to another session that has a different destination LNS. The tunnel switch profile can also specify how certain L2TP AVPs are handled when the packets are switched to a second tunnel. The domain map feature enables you to apply a specific tunnel switch profile to subscribers in a particular domain.

**NOTE:** A tunnel switch profile specified by a RADIUS server in the Tunnel Switch-Profile VSA (26-91) takes precedence over the tunnel switch profile specified in the domain map. If the Tunnel-Group VSA (26-64) is received in addition to the Tunnel Switch-Profile VSA (26-91), the Tunnel Switch-Profile VSA (26-91) takes precedence over the Tunnel-Group VSA (26-64), ensuring that the subscribers are tunnel switched rather than LAC tunneled.

To include a tunnel switch profile in a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the tunnel switch profile you want to include in the domain map.

```
[edit access domain map domain-map-name]
user@host# set tunnel-switch-profile profile-name
```

**See Also** • *Configuring L2TP Tunnel Switching*

## Configuring PADN Parameters for a Domain Map

You can configure PPPoE to receive PPPoE Active Discovery Network (PADN) messages when a subscriber connects to a PPPoE server. The PADN information associates the PPPoE session with a set of routes that the session can use. You can configure the route information in a domain map, which enables you to apply specific PADN information to subscribers in a particular domain. You can configure a maximum of 16 routes in a domain map.

To configure PADN parameters in a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the PADN route information you want to include in the domain map. For each route, include the destination IP address, subnet mask, and route metric.

```
[edit access domain map domain-map-name]
user@host# set padn destination-address mask destination-mask metric route-metric
```

## Configuring Domain and Realm Name Usage for Domain Maps

You can configure how the router determines the domain names that are used for the domain mapping feature. At the global level, you can specify rules that are used for domain maps. The global rules enable you to specify additional characters that the router can recognize as domain or realm name delimiters and to specify the direction the router uses to parse domain or realm names. The purpose of parsing a domain or realm name is to identify a single, unique name that the router uses as the subscriber's domain name, regardless of whether the source of the name is in the typical domain name format (joseph@example.com) or in the realm name format (example.com\marilyn). The router uses the resulting domain name for operations such as domain map lookup and processing. At the domain map level, you can also enable domain name stripping. Domain name stripping specifies that the router remove the parsed domain or realm name from the subscriber username prior to performing any additional processing for the domain map.

To configure domain name usage rules for domain maps:

1. (Optional) For domain or realm names, configure the parsing order, which specifies whether the router searches for the domain name or the realm name first.  
[See “Specifying the Parsing Order for Domain and Realm Names” on page 211.](#)
2. (Optional) For domain or realm names, configure the delimiters you want the router to recognize for domain maps.  
[See “Specifying Domain and Realm Name Delimiters” on page 210.](#)
3. (Optional) For domain or realm names, configure the parse direction you want the router to use when determining domain names for domain maps.  
[See “Specifying the Parsing Direction for Domain and Realm Names” on page 212.](#)
4. (Optional) For domain names, configure the router to remove the parsed domain or realm name from usernames in the domain map before using AAA services.  
[See “Enabling Domain Name Stripping” on page 213.](#)

## Specifying Domain and Realm Name Delimiters

A delimiter is the character that separates a subscriber username from the domain or realm name. Delimiters are commonly used for domain or realm name parsing or domain name stripping. You can specify a maximum of eight delimiters that the router uses to recognize domain or realm names for a domain map. If you do not configure any delimiters, the router uses the @ character by default for domain names. There is no default delimiter for realm names.

For example, your network might include the subscribers **bob@test.com**, **pete!example.com**, and **test.net\maria**. In this case, you would configure the router to

recognize the characters @ and ! as domain name delimiters, and the \ character as a realm name delimiter.

Keep the following guidelines in mind when specifying delimiters:

- You cannot use the semicolon (;) as a delimiter.
- If you configure optional domain name delimiters, you must also specify the @ character (the default delimiter) if you want to continue to use it as a delimiter.
- If you configure optional domain name delimiters and then unconfigure them, the router sets the domain map delimiter back to the default @ character.

To configure domain and realm name delimiters for domain maps:

1. Specify that you want to configure domain attributes.

```
[edit]
user@host# edit access domain
```

2. Specify the characters you want to use as domain name delimiters. Do not include spaces between the delimiters.

```
[edit access domain]
user@host# set delimiter @!
```

3. Specify the characters you want to use as realm name delimiters. Do not include spaces between the delimiters.

```
[edit access domain]
user@host# set realm-delimiter \
```

## Specifying the Parsing Order for Domain and Realm Names

The router parses the username domain or realm name in order to identify a single, unique name that the router uses as the subscriber's domain name, regardless of whether the source of the name is in the typical domain name format (joseph@example.com) or in the realm name format (example.com\marilyn). You can specify whether the router first searches the subscriber username for a domain name or for a realm name. If the router does not find the specified name (for example, you specify **realm-first** and there is no realm name in the username), then the router searches for the second type of name (domain name, in this case). If the router does not find either a realm-name or a domain name, then there is no domain that can be used for domain mapping operations.

To configure the domain name parsing direction for domain maps:

1. Specify that you want to configure domain attributes.

```
[edit]
user@host# edit access domain
```

2. Specify the parsing order you want the router to use, either the domain name first or the realm name first.

```
[edit access domain]  
user@host# set parse-order domain-first
```

## Specifying the Parsing Direction for Domain and Realm Names

You can specify the direction in which the router performs the parsing operation it uses to identify subscriber domain or realm names for domain maps. During the parsing operation, the router searches the username until it recognizes a delimiter. It then considers anything to the right of the delimiter as the domain. By default, the router parses from right to left, starting at the right-most character in the username.

The router uses a subscriber's domain name to perform domain map lookup and processing operations. You can configure how the router identifies a unique domain name when the user's name is presented in a traditional domain name format or a realm name. In the traditional domain name format, the user's name is followed by the domain name; for example, joe@example.com. In the realm name format, the user's name is preceded by the domain name, referred to as the realm name; for example, example.com@joe. The purpose of parsing a domain or realm name is to identify a single name that the router uses as the subscriber's domain name, regardless if the source of the name is the user's original domain name or realm name. The router uses the resulting domain name for operations such as domain map lookup and processing. At the domain map level, you can also enable domain name stripping.

The domain parsing direction you use is important when there are nested domain names. For example, for the username **user1@test.com@example.com**, right-to-left parsing produces a domain name of **example.com**. For the same username, left-to-right parsing produces a domain name of **test.com@example.com**.

To configure the domain name parsing direction for domain maps:

1. Specify that you want to configure domain attributes.

```
[edit]  
user@host# edit access domain
```

2. Specify the parsing direction you want the router to use if the username uses the typical domain name format, in which the domain name follows the user's name.

```
[edit access domain]  
user@host# set parse-direction left-to-right
```

3. Specify the parsing direction you want the router to use if the username uses the realm name format, in which the realm name precedes the user's name.

```
[edit access domain]  
user@host# set realm-parse-direction right-to-left
```

## Enabling Domain Name Stripping

You can configure the router to strip the domain name from usernames before any AAA services are used. Domain name stripping is done for domain maps. The router uses the delimiters and parsing direction you globally configure to determine the domain name that is removed. For example, if the router uses the default delimiter and parsing direction **right-to-left**, the username **user1@example.com** is stripped to be **user1**.

To configure the router to strip the domain name from usernames in a domain map:

1. Specify the domain map for the stripping operation.

```
[edit]
user@host# edit access domain map domain-map-name
```

2. Enable domain name stripping.

```
[edit access domain map domain-map-name]
user@host# set strip-domain
```

### Release History Table

Release	Description
16.1	Starting in Junos OS Release 16.1, subscriber management uses a specific order when searching for a domain map that matches the subscriber domain name.
16.1	Starting in Junos OS Release 16.1, the wildcard domain map feature enables you to specify a domain name that is used by subscribers when there is no exact match to the subscriber's domain name.

## AAA Configuration Testing and Troubleshooting

Subscriber management supports a test feature that enables you to check the AAA configuration of a subscriber. You might use the test feature to verify the subscriber's AAA settings and to help troubleshoot or isolate subscriber login problems. The AAA test process creates a pseudo session that authenticates the subscriber, allocates an address for the subscriber, and issues an accounting start packet. The process then issues an accounting stop request, releases the address, and terminates the pseudo session.

The AAA test results provide details about the attributes that subscriber management assigns to the subscriber during login. The attributes might be assigned by RADIUS, a dynamic profile, static interface configuration, or might be statically assigned. You can test the AAA configuration for DHCP, PPP, and authd-lite subscribers. For L2TP clients, the AAA test process displays all tunnel parameters but does not create an actual tunnel session.

**NOTE:** The `test aaa` commands support all RADIUS-sourced attributes, both IETF standard attributes and Juniper Networks VSAs. Received attributes are displayed in the output. For information about standard RADIUS attributes, see [“RADIUS IETF Attributes Supported by the AAA Service Framework” on page 11](#). For information about Juniper Networks VSAs, see [“Juniper Networks VSAs Supported by the AAA Service Framework” on page 19](#).

.....

**NOTE:** The test aaa commands do not support volume-time accounting (Juniper Networks VSA 26-69 with a value of 2). If volume-time accounting is configured for the test subscriber, the test command replaces the statistics with time-only accounting statistics.

.....

## Testing a Subscriber AAA Configuration

**Purpose** Display the AAA attributes that subscriber management assigns to the subscriber during login.

The following example tests the AAA configuration for a PPP subscriber. You can use the **test aaa dhcp user** command to perform a similar test for DHCP subscribers and the **test aaa authd-lite user** command to test authd-lite subscribers.

Action user@host>test aaa ppp user user45@test.net password \$ABC123

For some networks, such as a Layer 2 network with VLAN-OOB subscribers, RADIUS is configured to provide the subscriber address in a client profile with the Client-Profile-Name VSA (26–174). In the default configuration, the test fails when it does not receive a subscriber address directly from RADIUS. To successfully test these subscribers, you must include the **no-address-request** option. The command output displays the client

profile name in the Dynamic Profile field and the name of the routing instance conveyed by the Virtual-Router VSA (26-1) in the Routing Instance field.

```
user@host>test aaa ppp user thomastank no-address-request
```

```

## Tracing General Authentication Service (authd) Events for Troubleshooting

The Junos OS trace operations feature tracks general authentication service operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems. The operations and events are those associated with the authd process, which manages the subscriber AAA infrastructure.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename, `authd`. You can specify a different filename, but you cannot change the directory (`/var/log`) in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). For more information about how log files are created, see the [System Log Explorer](#).

3. By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

The following topics describe how to configure all aspects of tracing general authentication service operations:

- [Configuring the General Authentication Service Trace Log Filename on page 221](#)
- [Configuring the Number and Size of General Authentication Service Log Files on page 221](#)
- [Configuring Access to the General Authentication Service Log File on page 222](#)
- [Configuring a Regular Expression for General Authentication Service Messages to Be Logged on page 222](#)
- [Configuring Subscriber Filtering for General Authentication Service Tracing on page 222](#)
- [Configuring the General Authentication Service Tracing Flags on page 223](#)

## Configuring the General Authentication Service Trace Log Filename

By default, the name of the file that records trace output for general authentication service is **authd**. You can specify a different name by including the **file** statement at the **[edit system processes general-authentication-service]** hierarchy level:

To configure the filename for general authentication service tracing operations:

- Specify the name of the file used for the trace output.

```
[edit system processes general-authentication-service traceoptions]
user@host# set file aap_logfile_1
```

## Configuring the Number and Size of General Authentication Service Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output, by including the **files** and **size** options with the **traceoptions** statement.

```
[edit system processes general-authentication-service traceoptions]
```

```
user@host# set file aap_logfile_1 files 20 size 2097152
```

## Configuring Access to the General Authentication Service Log File

By default, log files can be accessed only by the user who configures the tracing operation. You can allow all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system processes general-authentication-service traceoptions]  
user@host# set file aap_logfile_1 world-readable
```

To explicitly set the default behavior, in which the log file can only be read by the user who configured tracing:

- Configure the log file to be no-world-readable.

```
[edit system processes general-authentication-service traceoptions]  
user@host# set file aap_logfile_1 no-world-readable
```

## Configuring a Regular Expression for General Authentication Service Messages to Be Logged

By default, the trace operation output includes all lines relevant to the logged events. You can refine the output by including regular expressions (regex) that will be matched.

To configure regular expressions to match:

- Configure the regular expression.

```
[edit system processes general-authentication-service traceoptions]  
user@host# set file aap_logfile_1 match regular-expression
```

## Configuring Subscriber Filtering for General Authentication Service Tracing

Starting in Junos OS Release 14.1, you can apply filters to the general authentication service to limit tracing to particular subscribers or domains. Subscriber filtering simplifies troubleshooting in a scaled environment by enabling you to focus on a reduced set of trace results.

For subscriber usernames that have the expected form of *user@domain*, you can filter on the user, the domain, or both. You can use an asterisk (\*) as a wildcard to substitute for characters at the beginning or end of either term to match a greater number of subscribers.

**NOTE:** You cannot filter results using a wildcard in the middle of the user or domain terms. For example, the following uses of the wildcard are not supported: tom\*25@example.com, tom125@ex\*.com.

When you enable filtering by username, traces that have insufficient information to determine the username are automatically excluded.

To configure subscriber filtering:

- Specify the filter.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user user@domain
```

Consider the following examples of using the wildcard for filtering:

- Filter results for the specific subscriber with the username, tom@example.com.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user tom@example.com
```

- Filter results for all subscribers whose username begins with tom.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user tom*
```

- Filter results for all subscribers whose username ends with tom.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user *tom
```

- Filter results for subscribers with the username tom at all domains beginning with ex.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user tom@ex*
```

- Filter results for all subscribers at all domains that end with ample.com.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user *ample.com
```

- Filter results for all subscribers whose username begins with tom at domains that end with example.com.

```
[edit system processes general-authentication-service traceoptions]
user@host# set filter user tom*.*example.com
```

## Configuring the General Authentication Service Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system services subscriber-management traceoptions]  
user@host# set flag flag
```

## DHCP Overview

---

- [Extended DHCP Local Server Overview on page 228](#)
- [Extended DHCP Relay Agent Overview on page 234](#)
- [DHCP Relay Proxy Overview on page 236](#)
- [Example: Minimum DHCP Relay Agent Configuration on page 237](#)
- [Example: DHCP Relay Agent Configuration with Multiple Clients and Servers on page 238](#)

## Extended DHCP Local Server Overview

Junos OS includes an extended DHCP local server that enhances traditional DHCP server operation by providing additional address assignment and client configuration functionality and flexibility in a subscriber-aware environment. The extended DHCP local server enables service providers to take advantage of external address-assignment pools and integrated RADIUS-based configuration capabilities in addition to the continued support of traditional local address pools. The address-assignment pools are considered external because they are external to the DHCP local server. The pools are managed independently of the DHCP local server, and can be shared by different client applications, such as DHCP or PPPoE access. [Table 31 on page 229](#) provides a comparison of the extended DHCP local server and a traditional DHCP local server.

The extended DHCP local server provides an IP address and other configuration information in response to a client request. The server supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide DHCP client authentication. You can configure the dynamic profile and authentication support on a global basis or for a specific group of interfaces.

**Table 31: Comparing the Extended DHCP Local Server to the Traditional DHCP Local Server**

Feature	Extended DHCP Local Server	Traditional DHCP Local Server
Local address pools	X	X
External, centrally-managed address pools	X	—
Local configuration	X	X
External configuration using information from address-assignment pools or RADIUS servers	X	—
Dynamic-profile attachment	X	—
RADIUS-based subscriber authentication, and configuration using RADIUS attributes and Juniper Networks VSAs	X	—
IPv6 client support	X	—
Default minimum client configuration	X	X

You can also configure the extended DHCP local server to support IPv6 clients. Both DHCP local server and DHCPv6 local server support the specific address request feature, which enables you to assign a particular address to a client.

**NOTE:** If you delete the DHCP server configuration, DHCP server bindings might still remain. To ensure that DHCP bindings are removed, issue the `clear dhcp server binding` command before you delete the DHCP server configuration.

This overview covers:

- [Interaction Among the DHCP Client, Extended DHCP Local Server, and Address-Assignment Pools on page 230](#)
- [Providing DHCP Client Configuration Information on page 231](#)
- [Minimal Configuration for Clients on page 232](#)
- [DHCP Local Server and Address-Assignment Pools on page 232](#)

### **Interaction Among the DHCP Client, Extended DHCP Local Server, and Address-Assignment Pools**

---

The pattern of interaction between the DHCP local server, the DHCP client, and address-assignment pools is the same regardless of whether you are using a router or a switch. However, there are some differences in the details of usage.

- On routers—In a typical carrier edge network configuration, the DHCP client is on the subscriber's computer or customer premises equipment (CPE), and the DHCP local server is configured on the router.
- On switches—In a typical network configuration, the DHCP client is on an access device, such as a personal computer, and the DHCP local server is configured on the switch.

The following steps provide a high-level description of the interaction among the DHCP local server, DHCP client, and address-assignment pools:

1. The DHCP client sends a discover packet to one or more DHCP local servers in the network to obtain configuration parameters and an IP address for the subscriber (or DHCP client).
2. Each DHCP local server that receives the discover packet then searches its address-assignment pool for the client address and configuration options. Each local server creates an entry in its internal client table to keep track of the client state, then sends a DHCP offer packet to the client.
3. On receipt of the offer packet, the DHCP client selects the DHCP local server from which to obtain configuration information and sends a request packet indicating the DHCP local server selected to grant the address and configuration information.
4. The selected DHCP local server sends an acknowledgement packet to the client that contains the client address lease and configuration parameters. The server also installs the host route and ARP entry, and then monitors the lease state.

### Providing DHCP Client Configuration Information

When the extended DHCP application receives a response from an external authentication server, the response might include information in addition to the IP address and subnet mask. The extended DHCP application uses the information from the authentication grant for the response the DHCP application sends to the DHCP client. The DHCP application can either send the information in its original form or the application might merge the information with local configuration specifications. For example, if the authentication grant includes an address pool name and a local configuration specifies DHCP attributes for that pool (such as, DNS server address), the extended DHCP application merges the authentication results and the attributes in the reply that the server sends to the client.

A local configuration is optional — a client can be fully configured by the external authentication service. However, if the external authentication service does not provide client configuration, you might need to configure the local address-assignment pool to provide the configuration information, such as DNS server, for the client. When a local configuration specifies options, the extended DHCP application adds the local configuration options to the offer PDU the server sends to the client. If the two sets of options overlap, the options in the authentication response from the external service take precedence.

When you use RADIUS to provide the authentication, the additional information might be in the form of RADIUS attributes and Juniper Networks VSAs. [Table 32 on page 231](#) lists the information that RADIUS might include in the authentication grant. See [“RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework” on page 11](#) for a complete list of RADIUS attributes and Juniper Networks VSAs that the extended DHCP applications supports for subscriber access management or DHCP management.

**Table 32: Information in Authentication Grant**

Attribute Number	Attribute Name	Description
RADIUS attribute 8	Framed-IP-Address	Client IP address
RADIUS attribute 9	Framed-IP-Netmask	Subnet mask for client IP address (DHCP option 1)
Juniper Networks VSA 26-4	Primary-DNS	Primary domain server (DHCP option 6)
Juniper Networks VSA 26-5	Secondary-DNS	Secondary domain server (DHCP option 6)
Juniper Networks VSA 26-6	Primary-WINS	Primary WINS server (DHCP option 44)
Juniper Networks VSA 26-7	Secondary-WINS	Secondary WINS server (DHCP option 44)

*Table 32: Information in Authentication Grant (continued)*

Attribute Number	Attribute Name	Description
RADIUS attribute 27	Session-Timeout	Lease time
RADIUS attribute 88	Framed-Pool	Address assignment pool name
Juniper Networks VSA 26-109	DHCP-Guided-Relay-Server	DHCP relay server

### Minimal Configuration for Clients

The extended DHCP local server provides a minimal configuration to the DHCP client if the client does not have DHCP option 55 configured. The server provides the subnet mask of the address-assignment pool that is selected for the client. In addition to the subnet mask, the server provides the following values to the client if the information is configured in the selected address-assignment pool:

- **router**—A router located on the client's subnet. This statement is the equivalent of DHCP option 3.
- **domain name**—The name of the domain in which the client searches for a DHCP server host. This is the default domain name that is appended to hostnames that are not fully qualified. This is equivalent to DHCP option 15.
- **domain name server**—A Domain Name System (DNS) name server that is available to the client to resolve hostname-to-client mappings. This is equivalent to DHCP option 6.

### DHCP Local Server and Address-Assignment Pools

In the traditional DHCP server operation, the client address pool and client configuration information reside on the DHCP server. With the extended DHCP local server, the client address and configuration information reside in external address-assignment pools (external to the DHCP local server). The external address-assignment pools are managed by the **authd** process, independently of the DHCP local server, and can be shared by different client applications.

The extended DHCP local server also supports advanced pool matching and the use of named address ranges. You can also configure the local server to use DHCP option 82 information in the client PDU to determine which named address range to use for a particular client. The client configuration information, which is configured in the address-assignment pool, includes user-defined options, such as boot server, grace period, and lease time.

Configuring the DHCP environment that includes the extended DHCP local server requires two independent configuration operations, which you can complete in any order. In one operation, you configure the extended DHCP local server on the router and specify how the DHCP local server determines which address-assignment pool to use. In the other operation, you configure the address-assignment pools used by the DHCP local server. The address-assignment pools contain the IP addresses, named address ranges, and configuration information for DHCP clients.

.....

**NOTE:** The extended DHCP local server and the address-assignment pools used by the server must be configured in the same logical system and routing instance.

.....

## Extended DHCP Relay Agent Overview

You can configure extended DHCP relay options on the router or on the switch and enable the router (or switch) to function as a DHCP relay agent. A DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP server.

DHCP relay supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication or DHCP client authentication. You can attach dynamic profiles and configure authentication support on a global basis or for a specific group of interfaces.

**NOTE:** The PTX Series Packet Transport Routers do not support authentication for DHCP relay agents.

---

On the routers, you can use DHCP relay in carrier edge applications such as video/IPTV to obtain configuration parameters, including an IP address, for your subscribers.

On the switches, you can use DHCP relay to obtain configuration parameters including an IP address for DHCP clients.

**NOTE:** The extended DHCP relay agent options configured with the `dhcp-relay` statement are incompatible with the DHCP/BOOTP relay agent options configured with the `bootp` statement. As a result, you cannot enable both the extended DHCP relay agent and the DHCP/BOOTP relay agent on the router at the same time.

For information about the DHCP/BOOTP relay agent, see *Configuring Routers, Switches, and Interfaces as DHCP and BOOTP Relay Agents*.

---

You can also configure the extended DHCP relay agent to support IPv6 clients. See [“DHCPv6 Relay Agent Overview” on page 391](#) for information about the DHCPv6 relay agent feature.

To configure the extended DHCP relay agent on the router (or switch), include the `dhcp-relay` statement at the **[edit forwarding-options]** hierarchy level.

You can also include the `dhcp-relay` statement at the following hierarchy levels:

- **[edit logical-systems *logical-system-name* forwarding-options]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options]**
- **[edit routing-instances *routing-instance-name* forwarding-options]**
- [Interaction Among the DHCP Relay Agent, DHCP Client, and DHCP Servers on page 235](#)
- [DHCP Liveness Detection on page 236](#)

### Interaction Among the DHCP Relay Agent, DHCP Client, and DHCP Servers

The pattern of interaction among the DHCP Relay agent, DHCP client, and DHCP servers is the same regardless of whether the software installation is on a router or a switch. However, there are some difference in the details of usage.

On routers—In a typical carrier edge network configuration, the DHCP client is on the subscriber's computer, and the DHCP relay agent is configured on the router between the DHCP client and one or more DHCP servers.

On switches—In a typical network configuration, the DHCP client is on an access device such as a personal computer and the DHCP relay agent is configured on the switch between the DHCP client and one or more DHCP servers.

The following steps describe, at a high level, how the DHCP client, DHCP relay agent, and DHCP server interact in a configuration that includes two DHCP servers.

1. The DHCP client sends a discover packet to find a DHCP server in the network from which to obtain configuration parameters for the subscriber (or DHCP client), including an IP address.
2. The DHCP relay agent receives the discover packet and forwards copies to each of the two DHCP servers. The DHCP relay agent then creates an entry in its internal client table to keep track of the client's state.
3. In response to receiving the discover packet, each DHCP server sends an offer packet to the client. The DHCP relay agent receives the offer packets and forwards them to the DHCP client.
4. On receipt of the offer packets, the DHCP client selects the DHCP server from which to obtain configuration information. Typically, the client selects the server that offers the longest lease time on the IP address.
5. The DHCP client sends a request packet that specifies the DHCP server from which to obtain configuration information.
6. The DHCP relay agent receives the request packet and forwards copies to each of the two DHCP servers.
7. The DHCP server requested by the client sends an acknowledgement (ACK) packet that contains the client's configuration parameters.
8. The DHCP relay agent receives the ACK packet and forwards it to the client.
9. The DHCP client receives the ACK packet and stores the configuration information.
10. If configured to do so, the DHCP relay agent installs a host route and Address Resolution Protocol (ARP) entry for this client.
11. After establishing the initial lease on the IP address, the DHCP client and the DHCP server use unicast transmission to negotiate lease renewal or release. The DHCP relay agent "snoops" on all of the packets unicast between the client and the server that pass through the router (or switch) to determine when the lease for this client has expired or been released. This process is referred to as *lease shadowing* or *passive snooping*.

### DHCP Liveness Detection

---

Liveness detection for DHCP subscriber or DHCP client IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients are expected to respond to liveness detection requests within a specified amount of time. If the responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented.

**NOTE:** DHCP liveness detection either globally or per DHCP group.

---

### DHCP Relay Proxy Overview

DHCP relay proxy mode is an enhancement to extended DHCP relay. DHCP relay proxy supports all DHCP relay features while providing additional features and benefits.

Normally, extended DHCP relay operates as a helper application for DHCP operations. Except for the ability to add DHCP relay agent options and the gateway address (giaddr) to DHCP packets, DHCP relay is transparent to DHCP clients and DHCP servers, and simply forwards messages between DHCP clients and servers.

When you configure DHCP relay to operate in proxy mode, the relay is no longer transparent. In proxy mode, DHCP relay conceals DHCP server details from DHCP clients, which interact with a DHCP relay in proxy mode as though it is the DHCP server. For DHCP servers there is no change, because proxy mode has no effect on how the DHCP server interacts with the DHCP relay.

**NOTE:** You cannot configure both DHCP relay proxy and extended DHCP local server on the same interface.

---

### Interaction Among DHCP Relay Proxy, DHCP Client, and DHCP Servers

---

The DHCP relay agent is configured on the router (or switch), which operates between the DHCP client and one or more DHCP servers.

The following steps provide a high-level description of how DHCP relay proxy interacts with DHCP clients and DHCP servers.

1. The DHCP client sends a discover packet to locate a DHCP server in the network from which to obtain configuration parameters for the subscriber.
2. The DHCP relay proxy receives the discover packet from the DHCP client and forwards copies of the packet to each supporting DHCP server. The DHCP relay proxy then creates a client table entry to keep track of the client state.
3. In response to the discover packet, each DHCP server sends an offer packet to the client, which the DHCP relay proxy receives. The DHCP relay proxy does the following:
  - a. Selects the first offer received as the offer to sent to the client

- b. Replaces the DHCP server address with the address of the DHCP relay proxy
  - c. Forwards the offer to the DHCP client.
4. The DHCP client receives the offer from the DHCP relay proxy.
5. The DHCP client sends a request packet that indicates the DHCP server from which to obtain configuration information—the request packet specifies the address of the DHCP relay proxy.
6. The DHCP relay proxy receives the request packet and forwards copies, which include the address of selected server, to all supporting DHCP servers.
7. The DHCP server requested by the client sends an acknowledgement (ACK) packet that contains the client configuration parameters.
8. The DHCP relay proxy receives the ACK packet, replaces the DHCP server address with its own address, and forwards the packet to the client.
9. The DHCP client receives the ACK packet and stores the configuration information.
10. If configured to do so, the DHCP relay proxy installs a host route and Address Resolution Protocol (ARP) entry for the DHCP client.
11. After the initial DHCP lease is established, the DHCP relay proxy receives all lease renewals and lease releases from the DHCP client and forwards them to the DHCP server.

---

### Benefits of Using DHCP Relay Proxy

DHCP relay proxy provides the following benefits:

- DHCP server isolation and DoS protection—DHCP clients are unable to detect the DHCP servers, learn DHCP server addresses, or determine the number of servers that are providing DHCP support. Server isolation also provides denial-of-service (DoS) protection for the DHCP servers.
- Multiple lease offer selection—DHCP relay proxy receives lease offers from multiple DHCP servers and selects a single offer to send to the DHCP client, thereby reducing traffic in the network. Currently, the DHCP relay proxy selects the first offer received.
- Support for both numbered and unnumbered Ethernet interfaces—For DHCP clients connected through Ethernet interfaces, when the DHCP client obtains an address, the DHCP relay proxy adds an access internal host route specifying that interface as the outbound interface. The route is automatically removed when the lease time expires or when the client releases the address.
- Logical system support—DHCP relay proxy can be configured in a logical system, whereas a non-proxy mode DHCP relay cannot.

### Example: Minimum DHCP Relay Agent Configuration

This example shows the minimum configuration you need to use the extended DHCP relay agent on the router or switch:

```
[edit forwarding-options]
dhcp-relay {
  server-group {
    test 203.0.113.21;
  }
  active-server-group test;
  group all {
    interface fe-0/0/2.0;
  }
}
```

**NOTE:** The interface type in this topic is just an example. The **fe-** interface type is not supported by EX Series switches.

This example creates a server group and an active server group named **test** with IP address 203.0.113.21. The DHCP relay agent configuration is applied to a group named **all**. Within this group, the DHCP relay agent is enabled on interface fe-0/0/2.0.

### Example: DHCP Relay Agent Configuration with Multiple Clients and Servers

This example shows an extended DHCP relay agent configuration for a network that includes multiple DHCP clients and DHCP servers. Additional details follow the example.

```
[edit forwarding-options]
dhcp-relay {
  server-group {
    sp-1 {
      203.0.113.21;
      203.0.113.22;
    }
    sp-2 {
      203.0.113.31;
      203.0.113.32;
      203.0.113.33;
    }
  }
  active-server-group sp-1;
  overrides layer2-unicast-replies;
  group clients_a {
    relay-option-82 circuit-id;
    interface fe-1/0/1.1;
    interface fe-1/0/1.2;
    interface fe-1/0/1.3;
  }
  group clients_b {
    relay-option-82 {
      circuit-id {
        prefix routing-instance-name;
      }
    }
    interface fe-1/0/1.4;
    interface fe-1/0/1.5;
  }
}
```

```

    interface fe-1/0/1.6;
  }
  group eth_dslam_relay {
    active-server-group sp-2;
    overrides {
      trust-option-82;
      layer2-unicast-replies;
    }
    interface fe-1/0/1.7;
    interface fe-1/0/1.8;
    interface fe-1/0/1.9;
  }
}

```

This example creates two server-groups: **sp-1**, which includes DHCP server addresses 203.0.113.21 and 203.0.113.22, and **sp-2**, which includes DHCP server addresses 203.0.113.31, 203.0.113.32, and 203.0.113.33. The active server group to which the DHCP relay agent configuration applies is **sp-1**. A global override is set that causes the DHCP relay agent to use Layer 2 unicast transmission to send DHCP reply packets from the DHCP server to DHCP clients during the discovery process.

The example also creates three groups of subscribers and their associated Fast Ethernet interfaces: **clients\_a**, **clients\_b**, and **eth\_dslam\_relay**. These groups are configured to meet different needs, as follows:

- The **clients\_a** and **clients\_b** groups consist of basic subscribers. The service provider for these groups inserts option 82 information in the DHCP packets that are destined for the DHCP server.
- The subscribers in **eth\_dslam\_relay** are connected to an Ethernet digital subscriber line access multiplexer (DSLAM) that functions as a Layer 2 DHCP relay agent. The active server group for **eth\_dslam\_relay** is **sp-2**. Overrides are set for the **eth\_dslam\_relay** group that enable the DHCP relay agent to trust option 82 information and to use Layer 2 unicast transmission to send DHCP reply packets to DHCP clients during discovery.

## DHCP Access Profiles for Subscriber Authentication and Accounting Parameters

---

- [Access Profiles for the DHCP Relay Agent and DHCP Local Server Overview on page 240](#)
- [Attaching Access Profiles to DHCP Subscriber Interfaces or DHCP Client Interfaces on page 240](#)

### Access Profiles for the DHCP Relay Agent and DHCP Local Server Overview

Starting in Junos OS Release 14.2, access profiles enable you to specify subscriber access authentication and accounting parameters. After access profiles are created, you can attach them at the **[edit system services dhcp-local-server]** hierarchy level on a DHCP local server for DHCP or DHCPv6 subscribers and at the **[edit forwarding-options dhcp-relay]** hierarchy level on a DHCP relay agent for DHCP or DHCPv6 subscribers, group of subscribers, or group of interfaces.

If you configured a global access profile at the **[edit access profile *profile-name*]** hierarchy level for all DHCP or DHCPv6 clients on a router that functions as a DHCP local server or a DHCP relay agent, the access profile configured at the **[edit system services dhcp-local-server]** hierarchy level on a DHCP local server for DHCP or DHCPv6 subscribers and at the **[edit forwarding-options dhcp-relay]** hierarchy level on a DHCP relay agent for DHCP or DHCPv6 subscribers take precedence over the global access profile.

Configuring an access profile for DHCP subscribers at the DHCP relay agent level or the DHCP local server level provide you with the flexibility and effectiveness of enabling DHCP authentication and accounting for specific subscribers instead of enabling them at a global level. If no access profile is configured at the DHCP relay agent level or the DHCP local server level, the global access profile becomes effective.

### Attaching Access Profiles to DHCP Subscriber Interfaces or DHCP Client Interfaces

Starting in Junos OS Release 14.2, you can attach an access profile to a DHCP subscriber interface, to a DHCP client interface, to a group of subscriber interfaces, and to a specific subscriber or groups of subscribers. When a DHCP subscriber or DHCP client logs in, the specified access profile is instantiated and the services defined in the profile are applied to the interface, subscriber, or the group of interfaces or subscribers.

This topic contains the following sections:

- [Attaching an Access Profile to All DHCP Subscriber or All DHCP Client Interfaces on page 240](#)
- [Attaching an Access Profile to a Group of DHCP Subscribers or a Group of DHCP Clients on page 241](#)
- [Attaching an Access Profile to a Group of DHCP Subscriber Interfaces or a Group of DHCP Client Interfaces on page 242](#)

#### Attaching an Access Profile to All DHCP Subscriber or All DHCP Client Interfaces

To attach an access profile to all DHCP subscribers or all DHCP client interfaces:

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set access-profile profile-name
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# set access-profile profile-name
```

### Attaching an Access Profile to a Group of DHCP Subscribers or a Group of DHCP Clients

You use the group feature to group together a set of subscriber access profiles and then apply a common DHCP configuration to the named subscriber profile group. The extended DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent all support groups.

Before you begin:

- Configure the group by entering the **group group-name** statement at the **[edit system services dhcp-local-server]** or the **[edit forwarding-options dhcp-relay]** hierarchy level. For DHCPv6 subscriber profiles, use the **dhcpv6** option at this hierarchy level.

To attach an access profile to a group of subscribers:

- At the DHCP configuration hierarchy, specify the name of the group and the access profile to attach to the group.
  - For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set group boston access-profile profile-name
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# set group quebec access-profile profile-name
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set group boston access-profile profile-name
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
```

```
user@host# set group quebec access-profile profile-name
```

## Attaching an Access Profile to a Group of DHCP Subscriber Interfaces or a Group of DHCP Client Interfaces

Before you begin:

- Configure the interface group.

See “[Grouping Interfaces with Common DHCP Configurations](#)” on page 340.

To attach an access profile to a group of interfaces:

- At the DHCP configuration hierarchy, specify the name of the interface group and the access profile to attach to the group.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set group boston interface interface-name access-profile profile-name
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# set group quebec interface interface-name access-profile profile-name
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set group boston interface interface-name access-profile profile-name
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set group quebec interface interface-name access-profile profile-name
```

Release History Table

Release	Description
14.2	Starting in Junos OS Release 14.2, access profiles enable you to specify subscriber access authentication and accounting parameters.
14.2	Starting in Junos OS Release 14.2, you can attach an access profile to a DHCP subscriber interface, to a DHCP client interface, to a group of subscriber interfaces, and to a specific subscriber or groups of subscribers.

### Overriding the Default DHCP Local Server Configuration Settings Overview

Subscriber management enables you to override certain default DHCP local server configuration settings. You can override the configuration settings at the global level, for a named group of interfaces, or for a specific interface within a named group.

- To override global default DHCP local server configuration options, include the **overrides** statement and its subordinate statements at the **[edit system services dhcp-local-server]** hierarchy level.
- To override DHCP local server configuration options for a named group of interfaces, include the statements at the **[edit system services dhcp-local-server group group-name]** hierarchy level.
- To override DHCP local server configuration options for a specific interface within a named group of interfaces, include the statements at the **[edit system services dhcp-local-server group group-name interface interface-name]** hierarchy level.
- To configure overrides for DHCPv6 local server at the global level, group level, or per-interface, use the corresponding statements at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

To override default DHCP local server configuration settings:

1. (DHCPv4 and DHCPv6) Specify that you want to configure override options.

- DHCPv4 overrides.

Global override:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

Group-level override:

```
[edit system services dhcp-local-server]
user@host# edit group group-name overrides
```

Per-interface override:

```
[edit system services dhcp-local-server]
user@host# edit group group-name overrides interface interface-name
```

DHCPv6 overrides.

Global override:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

Group level override:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit group group-name overrides
```

Per-interface override:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit group group-name overrides interface interface-name
```

2. (Optional) Override the maximum number of DHCP clients allowed per interface.

See [“Specifying the Maximum Number of DHCP Clients Per Interface” on page 347](#).

3. (Optional) Configure DHCP client auto logout.

See [“Automatically Logging Out DHCP Clients” on page 362](#).

4. (Optional) Enable processing of information requests from clients.

See [“Enabling Processing of Client Information Requests” on page 303](#).

5. (Optional) Specify that DHCP NAK and FORCERENEW messages support option 82 information.

See [“Configuring DHCP Message Exchange Between DHCP Server and Clients in Different Virtual Routing Instances”](#) on page 273.

6. (Optional, DHCPv6 only) Specify a delegated pool name to use for DHCPv6 multiple address assignment.

See [“Specifying the Delegated Address-Assignment Pool to Be Used for DHCPv6 Prefix Delegation”](#) on page 424.

7. (Optional, DHCPv6 only) Enable DHCPv6 rapid commit support.

See [“Enabling DHCPv6 Rapid Commit Support”](#) on page 387.

8. (Optional, DHCPv6 only) Specify that DHCPv6 local server return DNS server addresses as IA\_NA or IA\_PD suboptions rather than as a global DHCPv6 option.

See [“Overriding How the DNS Server Address Is Returned in a DHCPv6 Multiple Address Environment”](#) on page 592.

9. (Optional, DHCPv6 only) Automatically log out existing client when new client solicits on same interface.

See [“Automatically Logging Out DHCPv6 Clients”](#) on page 364.

10. (Optional) Specify that when the DHCP or DHCPv6 local server receives a Discover or Solicit message that has a client ID that matches the existing client entry, the local server deletes the existing client entry.

See [“DHCP Behavior When Renegotiating While in Bound State”](#) on page 249.

11. (Optional, DHCPv4 and DHCPv6) Specify that a short lease be sent to the client.

See [“Configuring DHCP Asymmetric Leasing”](#) on page 310.

12. (Optional, DHCPv4 and DHCPv6) Specify DHCP attributes globally or for groups.

See [“Configuring DHCP Attributes for All Clients or a Group of Clients”](#) on page 298.

13. Load balance traffic by allowing some local servers to respond to specific clients while preventing other local servers from responding immediately to these clients.

See [“Delaying DHCP Offer and Advertise Responses to Load Balance DHCP Servers”](#) on page 255.

## Overriding the Default DHCP Relay Configuration Settings

You can override the default DHCP relay configuration settings at the global level, for a named group of interfaces, or for a specific interface within a named group.

- To override global default DHCP relay agent configuration options, include the **overrides** statement and its subordinate statements at the **[edit forwarding-options dhcp-relay]** hierarchy level.
- To override DHCP relay configuration options for a named group of interfaces, include the statements at the **[edit forwarding-options dhcp-relay group *group-name*]** hierarchy level.
- To override DHCP relay configuration options for a specific interface within a named group of interfaces, include the statements at the **[edit forwarding-options dhcp-relay group *group-name* interface *interface-name*]** hierarchy level.
- To configure overrides for DHCPv6 relay at the global level, group level, or per-interface, use the corresponding statements at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

To override default DHCP relay agent configuration settings:

1. (DHCPv4 and DHCPv6) Specify that you want to configure override options.

- DHCPv4 overrides.

Global override:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

Group-level override:

```
[edit forwarding-options dhcp-relay]
user@host# edit group group-name overrides
```

Per-interface override:

```
[edit forwarding-options dhcp-relay]
user@host# edit group group-name interface interface-name overrides
```

- DHCPv6 overrides.

Global override:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

Group-level override:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group group-name overrides
```

Per-interface override:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group group-name interface interface-name overrides
```

2. (DHCPv4 only) Enable DHCP relay proxy mode.

See [“Enabling DHCP Relay Proxy Mode” on page 252](#).

3. (DHCPv4 only) Overwrite the giaddr in DHCP packets that the DHCP relay agent forwards.

See [“Changing the Gateway IP Address \(giaddr\) Field to the giaddr of the DHCP Relay Agent” on page 253](#).

4. (DHCPv4 only) Replace the IP source address in DHCP relay request and release packets with the gateway IP address (giaddr).

See [“Replacing the DHCP Relay Request and Release Packet Source Address” on page 253](#).

5. (DHCPv4 only) Override the DHCP relay agent information option (option 82) in DHCP packets.  
See [“Overriding Option 82 Information” on page 285](#).
6. (DHCPv4 only) Override the setting of the broadcast bit in DHCP request packets and use the Layer 2 unicast transmission method.  
See [“Using Layer 2 Unicast Transmission instead of Broadcast for DHCP Packets” on page 254](#).
7. (DHCPv4 only) Trust DHCP client packets that have a giaddr of 0 and that contain option 82 information.  
See [“Enable Processing of Untrusted Packets So Option 82 Information Can Be Used” on page 290](#).
8. (DHCPv4 and DHCPv6) Override the maximum number of DHCP clients allowed per interface.  
See [“Specifying the Maximum Number of DHCP Clients Per Interface” on page 347](#).
9. (DHCPv4 only) Configure client auto logout.  
See [“DHCP Auto Logout Overview” on page 360](#).
10. (DHCPv4 and DHCPv6) Enable or disable support for DHCP snooped clients on interfaces.  
See *Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent*.
11. (DHCPv4 and DHCPv6) Delay authentication of subscribers until the DHCP client sends a Request packet.  
See the [delay-authentication](#).
12. (DHCPv4 and DHCPv6) Send release messages to the DHCP server when clients are deleted.  
See [“Sending Release Messages When Clients Are Deleted” on page 250](#).
13. (Optional) Specify that when the DHCP or DHCPv6 relay agent receives a Discover or Solicit message that has a client ID that matches the existing client entry, the relay agent deletes the existing client entry.  
See [“DHCP Behavior When Renegotiating While in Bound State” on page 249](#).
14. (DHCPv6 only) Automatically log out existing client when new client solicits on same interface.  
See [“Automatically Logging Out DHCPv6 Clients” on page 364](#).

15. (DHCPv4 only) Disable the DHCP relay agent on specific interfaces.  
See [“Disabling DHCP Relay Agent for Interfaces, for Groups, or Globally” on page 255.](#)
16. (DHCPv4 and DHCPv6) Disable automatic binding of stray DHCP requests.  
See [“Disabling Automatic Binding of Stray DHCP Requests” on page 251.](#)
17. (DHCPv4 and DHCPv6) Assign a single-session DHCP dual-stack group to a specified group of subscribers. You must assign the group to both legs of the DHCP dual stack.  
See [“Configuring Single-Session DHCP Dual-Stack Support” on page 464.](#)
18. (Optional, DHCPv4 and DHCPv6) Specify that a short lease be sent to the client.  
See [“Configuring DHCP Asymmetric Leasing” on page 310.](#)

## DHCP Behavior When Renegotiating While in Bound State

All DHCP models (DHCPv4 and DHCPv6 local server and relay agent) use the same default behavior when receiving a DHCPv4 Discover or DHCPv6 Solicit message while in a bound state. In the default behavior, DHCP maintains the existing client entry when receiving a new Discover or Solicit message that has a client ID that matches the existing client.

You can use the **delete-binding-on-renegotiation** statement to configure DHCP local server and relay agent to override the default behavior. You can configure the override on a global or group basis. In the override configuration, when DHCP is in a bound state and receives a Discover or Solicit message with a matching client entry, DHCP tears down the existing entry and sends (DHCP local server) or forwards (relay agent) a new Offer (DHCPv4) or Advertise (DHCPv6) message.

**NOTE:** In Junos OS releases prior to 15.1, DHCPv6 local server uses the opposite default behavior, and tears down the existing client entry when receiving a Solicit message while in a bound state.

For example, to configure DHCPv4 local server to override the default renegotiation behavior globally:

1. Specify that you want to configure a DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Specify that you want to configure an override action.

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

3. Specify that you want DHCP local server to override the default renegotiation behavior.

```
[edit system services dhcp-local-server overrides]
user@host# set delete-binding-on-renegotiation
```

For example, to configure DHCPv6 relay agent to override the default renegotiation behavior for an interface group:

1. Specify that you want to configure DHCPv6 relay agent.

```
[edit forwarding-options]
user@host# edit dhcp-relay dhcpv6
```

2. Specify that the configuration is for an interface group.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group boston
```

3. Specify that you want to configure an override action.

```
[edit forwarding-options dhcp-relay dhcpv6 group]
user@host# edit overrides
```

4. Specify that you want DHCPv6 relay agent to override the default renegotiation behavior.

```
[edit forwarding-options dhcp-relay dhcpv6 group overrides]
user@host# set delete-binding-on-renegotiation
```

## Sending Release Messages When Clients Are Deleted

By default, when DHCP relay and relay proxy delete a client, they do not send a release message to the DHCP server. You can override the default behavior and configure DHCP relay and relay proxy to send a release message whenever they delete a client. The release message sent by DHCP relay and relay proxy includes option 82 information.

**NOTE:** You must include the `send-release-on-delete` statement to configure DHCP relay and relay proxy to send the release message when the `client-discover-match` statement is included.

You can use the `[edit forwarding-options dhcp-relay dhcpv6]` hierarchy level to override the default behavior for DHCPv6 relay agent.

To send a release message:

1. Specify that you want to configure override options.

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

2. Specify that you want DHCP relay and relay proxy (or DHCPv6 relay agent) to send a release message when clients are deleted.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set send-release-on-delete
```

## Disabling Automatic Binding of Stray DHCP Requests

DHCP requests that are received but have no entry in the database are known as stray requests. By default, DHCP relay, DHCP relay proxy, and DHCPv6 relay agent attempt to bind the requesting client by creating a database entry and forwarding the request to the DHCP server. If the server responds with an ACK, the client is bound and the ACK is forwarded to the client. If the server responds with a NAK, the database entry is deleted and the NAK is forwarded to the client. This behavior occurs regardless of whether authentication is configured.

You can override the default configuration at the global level, for a named group of interfaces, or for a specific interface within a named group. Overriding the default causes DHCP relay, DHCP relay proxy, and DHCPv6 relay agent to drop all stray requests instead of attempting to bind the clients.

**NOTE:** Automatic binding of stray requests is enabled by default.

- To disable automatic binding behavior, include the **no-bind-on-request** statement when you configure DHCP overrides at the global, group, or interface level.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set no-bind-on-request
```

- To override the default behavior for DHCPv6 relay agent, configure the override at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

```
[edit forwarding-options dhcp-relay dhcpv6 overrides]
user@host# set no-bind-on-request
```

The following two examples show a configuration that disables automatic binding of stray requests for a group of interfaces and a configuration that disables automatic binding on a specific interface.

To disable automatic binding of stray requests on a group of interfaces:

1. Specify the named group.

```
[edit forwarding-options dhcp-relay]
user@host# edit group boston
```

2. Specify that you want to configure overrides.

```
[edit forwarding-options dhcp-relay group boston]
user@host# edit overrides
```

3. Disable automatic binding for the group.

```
[edit forwarding-options dhcp-relay group boston overrides]
user@host# set no-bind-on-request
```

To disable automatic binding of stray requests on a specific interface:

1. Specify the named group of which the interface is a member.

```
[edit forwarding-options dhcp-relay]
user@host# edit group boston
```

2. Specify the interface on which you want to disable automatic binding.

```
[edit forwarding-options dhcp-relay group boston]
user@host# edit interface fe-1/0/1.2
```

3. Specify that you want to configure overrides.

```
[edit forwarding-options dhcp-relay group boston interface fe-1/0/1.2]
user@host# edit overrides
```

4. Disable automatic binding on the interface.

```
[edit forwarding-options dhcp-relay group boston interface fe-1/0/1.2 overrides]
user@host# set no-bind-on-request
```

## Enabling DHCP Relay Proxy Mode

You can enable DHCP relay proxy mode on all interfaces or a group of interfaces.

To enable DHCP relay proxy mode:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Enable DHCP relay proxy mode.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set proxy-mode
```

## Changing the Gateway IP Address (giaddr) Field to the giaddr of the DHCP Relay Agent

You can configure the DHCP relay agent to change the gateway IP address (giaddr) field in packets that it forwards between a DHCP client and a DHCP server.

To overwrite the giaddr of every DHCP packet with the giaddr of the DHCP relay agent before forwarding the packet to the DHCP server:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that the giaddr of DHCP packets is overwritten.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set always-write-giaddr
```

## Replacing the DHCP Relay Request and Release Packet Source Address

You can configure the DHCP relay agent to replace request and release packets with the gateway IP address (giaddr) before forwarding the packet to the DHCP server.

To replace the source address with giaddr:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that you want to replace the IP source address in DHCP relay request and release packets with the gateway IP address (giaddr).

```
[edit forwarding-options dhcp-relay overrides]
user@host# set replace-ip-source-with giaddr
```

## Configuring the DHCP Relay Agent Source Address to Enable DHCP Packets to Pass Through a Firewall

In network configurations where a firewall on the broadband network gateway (BNG) is between the DHCP relay agent and the DHCP server, only the BNG loopback address passes through the firewall. In that case, DHCP unicast packets are discarded. To enable DHCP unicast packets to pass through the BNG firewall, configure the source address in DHCP packets and DHCP messages to be the configured loopback address.

In addition to configuring the IP source address, on the DHCPv4 relay server, configure Link Selection (suboption 5) in option 82 information to cause the DHCP server to locate the correct address pool for the DHCP client when the server receives a forwarded packet, and Server ID Override (suboption 11) in option 82 information to set the server ID option in the DHCP packet.

To configure DHCPv4 relay agent to use the loopback address as the source address:

1. Configure the DHCPv4 relay agent to set the IP source address of DHCP packets to the configured loopback address.

```
[edit forwarding options dhcp-relay overrides]
user@host# set relay-source lo0
```

2. Configure the DHCPv4 relay agent to add Server ID and Link Selection suboptions to option 82 information:

```
[edit forwarding options dhcp-relay relay-option-82]
user@host# set server-id-override
```

To configure DHCPv6 relay agent to use the loopback address as the source address:

1. Configure the DHCPv6 relay agent to set the IP source address of DHCP packets to the configured loopback address.

```
[edit forwarding options dhcp-relay dhcpv6 overrides]
user@host# set relay-source lo0
```

## Using Layer 2 Unicast Transmission instead of Broadcast for DHCP Packets

You can configure the DHCP relay agent to override the setting of the broadcast bit in DHCP request packets. DHCP relay agent then instead uses the Layer 2 unicast transmission method to send DHCP Offer reply packets and DHCP ACK reply packets from the DHCP server to DHCP clients during the discovery process.

To override the default setting of the broadcast bit in DHCP request packets:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
```

```
user@host# edit overrides
```

2. Specify that the DHCP relay agent uses the Layer 2 unicast transmission method.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set layer2-unicast-replies
```

## Disabling DHCP Relay Agent for Interfaces, for Groups, or Globally

You can disable DHCP relay on all interfaces or a group of interfaces.

To disable DHCP relay agent:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Disable the DHCP relay agent.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set disable-relay
```

## Delaying DHCP Offer and Advertise Responses to Load Balance DHCP Servers

- [Load Balancing DHCP Local Servers by Delaying Responses to Clients on page 255](#)
- [Configuring a Delay in Local Server Response to DHCP Discover and Solicit Messages on page 256](#)

### Load Balancing DHCP Local Servers by Delaying Responses to Clients

In a network environment with multiple DHCP local servers and numerous DHCP clients, you might want to load balance traffic by allowing some local servers to respond to specific clients while preventing other local servers from responding immediately to these clients. Starting in Junos OS Release 16.1R1, you can configure a client-specific delay in response on DHCP local servers. When a DHCPv4 client sends a discover message or a DHCPv6 client sends a solicit message to the server network, all the corresponding (Same

family) DHCP servers on the network receive the request at the same time, but servers that are configured with a delay do not respond to the client until the delay timer expires.

When the delay timer expires, the local server sends an offer or advertise message to the client. If the client is already bound, that means that a different server, one that has either no delay or a shorter delay, responded with an offer or advertise message to the client. In this case the server configured with the delay releases the client.

However, if the client does not receive a response from any server, it sends a second discover or solicit message. If the configured server receives the second message from the client before the original delay times out, it immediately sends a response to the client. This behavior enables the configured server to act as a redundant or back-up server for the server that was intended to handle the client.

[Table 33 on page 256](#) lists the characteristics that you can use to identify DHCP clients for which responses are delayed and the corresponding DHCPv4 and DHCPv6 options you specify in the configuration.

**Table 33: Characteristics to Identify Clients for Delayed Responses**

Client Characteristic	DHCPv4	DHCPv6
Agent Circuit ID—A string that identifies the local circuit between the client and the DHCP relay agent, uniquely identifying the particular client.	Option 82, suboption 1	Option 18
Agent Remote ID—A string that uniquely identifies a client based on characteristics of the client, such as caller ID or user name.	Option 82, suboption 2	Option 37
User Class Identifier—A string representing a class or group to which the client belongs. For example, different user classes might identify a marketing group versus an accounting group.	Option 77	Option 15
Vendor Class Identifier—The IANA registered enterprise number for the vendor of the equipment running the client.	Option 60	Option 16

#### Benefits to Delaying DHCP Local Server Response

- Enable load to be distributed among many DHCP servers by causing certain clients to be preferably served by other servers.
- Enable redundancy among servers by allowing a server to respond in the event the preferred server does not.

### Configuring a Delay in Local Server Response to DHCP Discover and Solicit Messages

You can configure a DHCPv4 or DHCPv6 local server to delay responding to discover and solicit messages, respectively, from clients. The server responds to the client only when the delay timer expires. You can configure the delay at global, group, and interface levels. To determine which clients are sent a delayed response, configure the server to identify specific hexadecimal or ASCII strings received in the message from the client. The local server compares the configured string with the value received DHCP options in the client

message and delays the response depending on whether the received value matches the configured value, does not match it, or starts with the configured value.

To configure a delayed response to an offer message received from a DHCPv4 client:

**NOTE:** This procedure shows the global configuration. You can also configure the delay at the [edit system services dhcp-local-server group *group-name* interface *interface-name* overrides] and [edit system services dhcp-local-server group *group-name* overrides] hierarchy levels.

1. Specify how long the DHCPv4 local server delays before responding to the client.

```
[edit system services dhcp-local-server overrides]
user@host# set delay-offer delay-time seconds
```

2. Specify the option received in the DHCPv4 offer message that identifies the client to receive a delayed response.

```
[edit system services dhcp-local-server overrides]
user@host# edit delay-offer based-on (option-60 | option-77 | option-82)
```

3. Specify how to match the received option.

- Match when the received ASCII or hexadecimal string is exactly the same as the configured string.

```
[edit system services dhcp-local-server overrides based-on (option-60 | option-77
| option-82)]
user@host# set equals ascii ascii-string
user@host# set equals hexadecimal hexadecimal-string
```

- Match when the received ASCII or hexadecimal string is not exactly the same as configured string.

```
[edit system services dhcp-local-server overrides based-on (option-60 | option-77
| option-82)]
user@host# set not-equals ascii ascii-string
user@host# set not-equals hexadecimal hexadecimal-string
```

- Match when the received ASCII or hexadecimal string starts with the configured string.

```
[edit system services dhcp-local-server overrides based-on (option-60 | option-77
| option-82)]
user@host# set starts-with ascii ascii-string
user@host# set starts-with hexadecimal hexadecimal-string
```

To configure a delayed response to an advertise message received from a DHCPv6 client:

**NOTE:** This procedure shows the global configuration. You can also configure the delay at the [edit system services dhcp-local-server dhcpv6 group *group-name* interface *interface-name* overrides] and [edit system services dhcp-local-server dhcpv6 group *group-name* overrides] hierarchy levels.

1. Specify how long the DHCPv6 local server delays before responding to the client.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set delay-advertise delay-time seconds
```

2. Specify the option received in the DHCPv6 advertise message that identifies the client to receive a delayed response.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# edit delay-advertise based-on (option-15 | option-16 | option-18 |
option-37)
```

3. Specify how to match the received option.

- Match when the received ASCII or hexadecimal string is exactly the same as the configured string.

```
[edit system services dhcp-local-server dhcpv6 overrides based-on (option-15 |
option-16 | option-18 | option-37)]
user@host# set equals ascii ascii-string
user@host# set equals hexadecimal hexadecimal-string
```

- Match when the received ASCII or hexadecimal string is not exactly the same as configured string.

```
[edit system services dhcp-local-server dhcpv6 overrides based-on (option-15 |
option-16 | option-18 | option-37)]
user@host# set not-equals ascii ascii-string
user@host# set not-equals hexadecimal hexadecimal-string
```

- Match when the received ASCII or hexadecimal string starts with the configured string.

```
[edit system services dhcp-local-server dhcpv6 overrides based-on (option-15 |
option-16 | option-18 | option-37)]
user@host# set starts-with ascii ascii-string
user@host# set starts-with hexadecimal hexadecimal-string
```

## DHCP Options and Selective Traffic Processing Overview

Subscriber management enables you to provide selective traffic processing based on information that is provided in the DHCP and DHCPv6 options string included in the traffic. Starting in Junos OS Release 15.1, the selective traffic processing feature lets you manage multivendor networks with the extended DHCP and DHCPv6 relay agent. You can enable the extended DHCP and DHCPv6 relay agent to compare option-specific strings received in DHCP client packets against a list of ASCII or hexadecimal strings that you configure on the router. The selective traffic processing feature allows you to identify traffic based on the option in the DHCP client packets, filter the traffic, and specify the action that the DHCP relay takes for the traffic. You can use DHCP options 60 and 77 and DHCPv6 options 15 and 16 to identify client traffic. You configure the action the router takes for the selected traffic, such as forwarding the traffic to a specific DHCP server, or dropping the traffic. DHCP relay agent selective traffic processing also allows you to specify a default action, which the router uses when no other action satisfies the configuration.

Using selective traffic processing is helpful in network environments where DHCP clients access services that are provided by multiple vendors and by multiple DHCP servers. For example, a DHCP client might gain Internet access from a particular DHCP server provided by one vendor, and access an IPTV service from a different DHCP server owned by a second vendor. Using the option-specific information in the DHCP client packets enables DHCP relay agent to differentiate between the two servers and to take the correct action for the subscriber.

You might also use selective processing to distinguish between services to different DHCP subscribers on the same interface. For example, a household might include two IP devices that obtain their IP addresses from the service provider's DHCP server. The service provider might want to bind one of the devices to the incoming interface, sharing that address with other households. At the same time the service provider might want the second device to have its own filter and CoS capabilities. For this second device, the service provider can use selective processing to create a dynamic IP demux interface.

You can configure selective processing support globally or for a named group of interfaces. You can also configure the support for the extended DHCP relay agent on a per logical system and per routing instance basis.

To configure selective processing, you specify the DHCP or DHCPv6 option attribute that identifies the traffic, the match criteria used to filter the traffic, and the action to perform with the filtered traffic.

You can use the following DHCP options to selectively process client traffic:

- DHCPv4 option 60 (Vendor Class Identifier)
- DHCPv4 option 77 (User Class Identifier)
- DHCPv6 option 15 (User Class Option)
- DHCPv6 option 16 (Vendor Class Option)

You can configure exact match or partial match criteria to filter client traffic, and specify either the **ascii** option (to define a nonempty ASCII string of 1 through 255 alphanumeric characters) or the **hexadecimal** option (to define a hexadecimal string of 1 through 255 hexadecimal characters [0 through 9, a through f, and A through F]).

**BEST PRACTICE:** Because of the format of DHCP option 77 and DHCPv6 option 16, we recommend you configure hexadecimal matching only with these two options instead of ASCII matching.

You can configure an unlimited number of match strings. If you configure a string as both exact match (**equals**) and a partial match (**starts-with**) criteria, the exact match takes precedence. Wildcard characters are not supported in exact match or partial match strings.

Use the following match criteria to filter client traffic:

- **equals**—Your specified string is an exact match to the option string in client traffic.
- **starts-with**—Your specified string is a subset of the option string in client traffic, starting with the left-most character. For example, your configuration of the string “test” is a subset of “test123” in the client’s option string, and matches the **starts-with** criteria.
- **default-action**—The option string in client traffic does not satisfy any match criteria, or no match criteria are configured.

**NOTE:** The **default-action** is optional. If the match criteria are not satisfied or not configured and there is no **default-action** configured, DHCP relay processes the traffic in the normal manner.

You can specify the following actions for the filtered client traffic:

- **drop**—Discard the traffic.
- **forward-only**—Forward the traffic, without creating a new subscriber session.

**NOTE:** When you use the **forward-only** action, the only configured **overrides** operation supported is the **trust-option-82** option. DHCP relay agent ignores all other **overrides** options that are configured.

- **local-server-group**—Forward the traffic to the specified group of DHCP local servers that provides the requested client service. This option is not supported for DHCPv6 relay agent.
- **relay-server-group**—Forward the traffic to the specified group of DHCP servers that provides the requested client service.

## Using DHCP Option Information to Selectively Process DHCP Client Traffic

Starting in Junos OS Release 15.1, you can configure the DHCP relay agent to selectively process client traffic. Selective processing uses DHCP or DHCPv6 option information to identify, filter, and process client traffic. To configure DHCPv6 support you use the procedure at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

To configure DHCP relay agent to use option information to selectively process DHCP client traffic:

1. Specify that you want to configure DHCP relay agent support.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Specify that you want to use the DHCP option feature to selectively process incoming DHCP traffic.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option
```

3. Specify the DHCP or DHCPv6 option number DHCP relay uses to identify and process the client traffic. You can specify options 60 and 77 for DHCP relay agent, and options 15 and 16 for DHCPv6 relay agent.

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set option-number option-number
```

For example, to identify traffic that has DHCP option 60 information:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set option-number 60
```

4. (Optional) Configure the default action that DHCP relay uses when the incoming client traffic does not satisfy any configured match or partial match criteria.

For example, to configure DHCP relay to drop traffic by default:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set default-action drop
```

5. (Optional) Configure an exact match condition that filters the client traffic and specifies the associated action for DHCP relay agent to take.

For example, to select traffic that has an option 60 ASCII string of **video25**, and then forward that traffic to a named local server group:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set equals ascii video25 local-server-group servergroup-east-video
```

6. (Optional) Configure a partial match condition that filters the client traffic and specifies the associated action.

For example, to select traffic that has an option 60 hexadecimal string that starts with **766964656F** (left to right), and then forward that traffic without creating a new session:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# edit starts-with hexadecimal 766964656F forward-only
```

## Displaying a Count of DHCP Packets That Are Dropped or Forwarded During Selective Processing That Is Based on DHCP Option Strings

To display the number of DHCP or DHCPv6 client packets that are dropped or forwarded during selective processing, use the following operational commands:

- `show dhcp relay statistics`
- `show dhcpv6 relay statistics`

## Example: Configuring DHCP Relay Agent Selective Traffic Processing Based on DHCP Option Strings

This example shows how to configure DHCP relay agent to use DHCP option strings to selectively identify, filter, and process client traffic.

- [Requirements on page 263](#)
- [Overview on page 263](#)
- [Configuration on page 264](#)
- [Verification on page 266](#)

### Requirements

This example uses the following hardware and software components:

- MX Series 5G Universal Routing Platforms or EX Series Switches

Before you configure DHCP relay agent selective processing support, be sure you:

- Configure DHCP relay agent.

See [“Extended DHCP Relay Agent Overview” on page 234](#).

- (Optional) Configure a named DHCP local server group if you want to forward client traffic to a server group.

See [“Grouping Interfaces with Common DHCP Configurations” on page 340](#).

### Overview

In this example, you configure DHCP relay agent to use DHCP option strings in client packets to selectively identify, filter, and process client traffic. To configure selective processing, you perform the following procedures:

1. Identify the client traffic—Specify the DHCP option that DHCP relay agent uses to identify the client traffic you want to process. The option you specify matches the option in the client traffic.
2. Configure a default action—Specify the default processing action, which DHCP relay uses for identified client traffic that does not satisfy any configured match criteria.
3. Create match filters and associate an action with each filter—Specify match criteria that filter the client traffic. The criteria can be an exact match or a partial match with the option string in the client traffic. Associate a processing action with each match criterion.

### Configuration

To configure DHCP relay agent selective processing based on DHCP option information, perform these tasks:

- [Configuring DHCP Relay Agent To Selectively Process Client Traffic Based on DHCP Option Strings on page 264](#)
- [Results on page 265](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the command into the CLI at the **[edit]** hierarchy level.

```
set forwarding-options dhcp-relay relay-option option-number 60
set forwarding-options dhcp-relay relay-option equals ascii video-gold forward-only
set forwarding-options dhcp-relay relay-option equals ascii video-bronze local-server-group
  servergroup-15
set forwarding-options dhcp-relay relay-option starts-with hexadecimal ffff
  local-server-group servergroup-east
set forwarding-options dhcp-relay relay-option default-action drop
```

#### *Configuring DHCP Relay Agent To Selectively Process Client Traffic Based on DHCP Option Strings*

#### Step-by-Step Procedure

To configure DHCP relay selective processing:

1. Specify that you want to configure DHCP relay agent support.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Specify the DHCP option that DHCP relay agent uses to identify incoming client traffic.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option option-number 60
```

3. Configure a default action, which DHCP relay agent uses when the incoming client traffic does not satisfy any configured match criteria.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option default-action drop
```

4. Configure an exact match condition and associated action that DHCP relay uses to process the identified client traffic.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option equals ascii video-gold forward-only
```

5. Configure a second exact match condition and associated action that DHCP relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option equals ascii video-bronze local-server-group
servergroup-15
```

6. Configure a partial match criteria and associated action that DHCP relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option starts-with hexadecimal ffff local-server-group
servergroup-east
```

## Results

From configuration mode, confirm the results of your configuration by issuing the **show** statement at the **[edit forwarding-options]** hierarchy level. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit forwarding-options]
user@host# show
dhcp-relay {
  relay-option {
    option-number 60;
    equals {
      ascii video-gold {
        forward-only;
      }
    }
    equals {
      ascii video-bronze {
        local-server-group servergroup-15;
      }
    }
    default-action {
```

```
        drop;
    }
    starts-with {
        hexadecimal ffff {
            local-server-group servergroup-east;
        }
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

---

### Verification

To verify the status of DHCP relay agent selective traffic processing, perform this task:

- [Verifying the Status of DHCP Relay Agent Selective Traffic Processing on page 266](#)

#### *Verifying the Status of DHCP Relay Agent Selective Traffic Processing*

**Purpose** Verify the DHCP relay agent selective traffic processing status.

**Action** Display statistics for DHCP relay agent.

```
user@host> show dhcp relay statistics
```

```
Packets dropped:
  Total                  30

Packets forwarded:
  Total                  4
  BOOTREQUEST            2
  BOOTREPLY              2
```

**Meaning** The **Packets forwarded** field in the **show dhcp relay statistics** command output displays the number of client packets that have been forwarded as a result of the selective traffic processing configuration. In this example, the output indicates the total number of packets that DHCP relay agent has forwarded, as well as a breakdown for the number of **BOOTREQUEST** and **BOOTREPLY** packets forwarded.

### Example: Configuring DHCP and DHCPv6 Relay Agent Group-Level Selective Traffic Processing

This example shows how to configure named interface group-based support for DHCPv6 relay agent selective processing, which uses DHCP option strings to identify, filter, and process client traffic.

This example describes DHCPv6 relay agent configuration—you can configure the related procedure for DHCP relay agent groups at the **[edit forwarding-options dhcp-relay]**

hierarchy level. DHCPv6 selective processing supports DHCPv6 options 15 and 16. DHCP selective processing supports option 60 (MX Series routers only) and option 77.

- [Requirements on page 268](#)
- [Overview on page 268](#)
- [Configuration on page 269](#)
- [Verification on page 271](#)

---

## Requirements

This example uses the following hardware and software components:

- MX Series 5G Universal Routing Platforms or PTX Series Packet Transport Routers

Before you configure DHCPv6 relay agent selective processing support, be sure you:

- Configure DHCPv6 relay agent.  
[See “Extended DHCP Relay Agent Overview” on page 234 and “DHCPv6 Relay Agent Overview” on page 391.](#)
- Configure the DHCPv6 named interface groups used for the configuration.  
[See “Grouping Interfaces with Common DHCP Configurations” on page 340.](#)
- Configure the DHCPv6 server groups used for the processing actions.  
[See “Grouping Interfaces with Common DHCP Configurations” on page 340.](#)

---

## Overview

In this example, you configure group-level DHCPv6 relay agent named interface support for selective processing of client packets based on DHCPv6 option strings. To configure selective processing, you perform the following procedures:

1. Identify the client traffic—Specify the DHCPv6 option that DHCPv6 relay agent uses to identify the client traffic you want to process. The DHCPv6 option you specify matches the option in the client traffic.
2. Configure the default action—Specify the default processing action, which DHCPv6 relay uses for identified client traffic that does not satisfy any configured match criteria.
3. Create match filters and associate an action with each filter—Specify match criteria that filters the client traffic. The criteria can be an exact match or a partial match with the DHCPv6 option string in the client traffic. Associate a processing action with each match criteria.

## Configuration

To configure group-level DHCPv6 relay agent selective processing based on DHCPv6 option information, perform these tasks:

- [Configuring a DHCPv6 Relay Agent Named Interface Group To Selectively Process Client Traffic Based on DHCPv6 Option Strings on page 269](#)
- [Results on page 270](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the command into the CLI at the **[edit]** hierarchy level. The quick configuration assumes that the named interface group and the DHCP server groups have been previously configured.

```
set forwarding-options dhcp-relay dhcpv6 group groupv6-east-27
set forwarding-options dhcp-relay dhcpv6 relay-option option-number 15
set forwarding-options dhcp-relay dhcpv6 relay-option equals ascii triple-gold
  relay-server-group relayserver-triple-8
set forwarding-options dhcp-relay dhcpv6 relay-option equals ascii triple-silver
  relay-server-group relayserver-triple-23
set forwarding-options dhcp-relay dhcpv6 relay-option starts-with ascii single
  relay-server-group relayserver-1-aa
set forwarding-options dhcp-relay dhcpv6 relay-option default-action drop
```

### *Configuring a DHCPv6 Relay Agent Named Interface Group To Selectively Process Client Traffic Based on DHCPv6 Option Strings*

### Step-by-Step Procedure

This procedure assumes that you have previously created the named interface group and the DHCPv6 server groups. To configure DHCPv6 relay group-level selective processing:

1. Specify that you want to configure DHCPv6 relay agent support.

```
[edit forwarding-options]
user@host# edit dhcp-relay dhcpv6
```

2. Specify that you want to configure group-level DHCPv6 relay agent support.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group groupv6-east-27
```

3. Specify the DHCPv6 option number that DHCPv6 relay agent uses to identify incoming client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]
user@host# set relay-option option-number 15
```

4. Configure the default action, which DHCPv6 relay agent uses when the incoming client traffic does not satisfy any configured match criteria.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]  
user@host# set relay-option default-action relay-server-group relayserver-def-4
```

5. Configure an exact match condition and associated action that DHCPv6 relay uses to process the identified client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]  
user@host# set relay-option equals ascii triple-gold relay-server-group  
relayserver-triple-8
```

6. Configure a second exact match condition and associated action that DHCPv6 relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]  
user@host# set relay-option equals ascii triple-silver relay-server-group  
relayserver-triple-23
```

7. Configure a partial match criteria and associated action that DHCPv6 relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]  
user@host# set relay-option starts-with ascii single relay-server-group  
relayserver-1-aa
```

## Results

From configuration mode, confirm the results of your configuration by issuing the **show** statement at the **[edit forwarding-options dhcp]** hierarchy level. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
dhcpv6 {  
  group test-1 {  
    relay-option {  
      option-number 15;  
      equals {  
        ascii triple-gold {  
          relay-server-group relayserver-triple-8;  
        }  
        ascii triple-silver {  
          relay-server-group relayserver-triple-23;  
        }  
      }  
    }  
    default-action {  
      relay-server-group relayserver-def-4;  
    }  
  }  
}
```

```
starts-with {
  ascii single {
    relay-server-group relayserver-1-aa;
  }
}
interface ge-1/0/0.0 upto ge-1/1/0.0;
}
server-group {
  relayserver-1-aa;
  relayserver-triple-8;
  relayserver-triple-23;
  relayserver-def-4;
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Verification

To verify the status of DHCPv6 relay agent selective traffic processing, perform this task:

- [Verifying the Status of DHCPv6 Relay Agent Selective Traffic Processing on page 271](#)

#### *Verifying the Status of DHCPv6 Relay Agent Selective Traffic Processing*

**Purpose** Verify the DHCPv6 relay agent selective traffic processing status.

**Action** Display statistics for DHCPv6 relay agent.

```
user@host> show dhcpv6 relay statistics
```

```
DHCPv6 Packets dropped:
  Total 0

Messages received:
  DHCPV6_DECLINE 0
  DHCPV6_SOLICIT 10
  DHCPV6_INFORMATION_REQUEST 0
  DHCPV6_RELEASE 0
  DHCPV6_REQUEST 10
  DHCPV6_CONFIRM 0
  DHCPV6_RENEW 0
  DHCPV6_REBIND 0
  DHCPV6_RELAY_REPL 0

Messages sent:
  DHCPV6_ADVERTISE 0
  DHCPV6_REPLY 0
  DHCPV6_RECONFIGURE 0
  DHCPV6_RELAY_FORW 0

Packets forwarded:
  Total 4
  FWD REQUEST 2
  FWD REPLY 2
```

**Meaning** The **Packets forwarded** field in the **show dhcpv6 relay statistics** command output displays the number of client packets that have been forwarded as a result of the selective traffic processing configuration. In this example, the output indicates the total number of packets that DHCPv6 relay agent has forwarded, as well as a breakdown for the number of **FWD REQUEST** and **FWD REPLY** packets forwarded.

## DHCP Message Exchange Between DHCP Clients and DHCP Server in Different VRFs

In some service provider networks, the service network in which the DHCP server resides is isolated from the actual subscriber network. This separation of the service and subscriber networks can sometimes introduce potential security issues, such as route leaking. Starting in Junos OS Release 14.2, you can use the DHCP relay agent to provide additional security when exchanging DHCP messages between different VRFs. The DHCP relay agent can ensure that there is no direct routing between the client virtual routing and forwarding instance (VRF) and the DHCP server VRF, and that only acceptable DHCP packets are relayed across the two VRFs. Subscriber management supports the cross-VRF message exchange for both DHCP and DHCPv6 packets.

To exchange DHCP messages between different VRFs, you must enable both the server side and the client side of the DHCP relay agent to recognize and forward acceptable traffic based on DHCP option information in the packets. The message exchange uses the Agent Circuit ID (DHCP option 82 suboption 1) for DHCPv4 packets and the Relay Agent Interface-ID (DHCPv6 option 18) for DHCPv6 packets to identify traffic to be relayed.

Statistics for DHCP packets using the cross-VRF message exchange are counted in the client VRF.

The following list describe how DHCP relay agent exchanges messages between the DHCP clients and DHCP server in different VRFs:

- Packets from DHCP client to DHCP server—DHCP relay agent receives the DHCP packet from the client in the client VRF, and then inserts the appropriate DHCP option 82 suboption 1 or DHCPv6 option 18 attribute into the packet. The relay agent then forwards the packet to the DHCP server in the server's VRF.
- Packets from DHCP server to DHCP client—DHCP relay agent receives the DHCP reply message from the DHCP server in the server VRF. The relay agent derives the client's interface, including VRF, from the DHCP option 82 suboption 1 or DHCPv6 option 18 attribute in the packet in the DHCP server VRF. The relay agent then forwards the reply message to the DHCP client in the client's VRF.

### Configuring DHCP Message Exchange Between DHCP Server and Clients in Different Virtual Routing Instances

Starting in Junos OS Release 14.2, you can configure DHCP relay agent to provide additional security when exchanging DHCP messages between a DHCP server and DHCP clients that reside in different virtual routing and forwarding instances (VRFs).

You can configure DHCP relay agent to provide additional security when exchanging DHCP messages between a DHCP server and DHCP clients that reside in different virtual routing instances. This type of configuration is for a *stateless* DHCP relay connection between a DHCP server and a DHCP client, when the DHCP server resides in a network that must be isolated from the client network.

A stateless DHCP relay agent does not maintain dynamic state information about the DHCP clients and does not maintain a static route for the traffic to flow between the client and server routing instances.

To enable the DHCP message exchange between the two VRFs, you configure each side of the DHCP relay to recognize and forward acceptable traffic based on the DHCP option information in the packets. The acceptable traffic is identified by either the Agent Circuit ID (DHCP option 82 suboption 1) for DHCPv4 packets or the Relay Agent Interface-ID (DHCPv6 option 18) for DHCPv6 packets.

The following list provides an overview of the tasks required to create the DHCP message exchange between the different VRFs:

- Client-side support—Configure the DHCP relay agent **forward-only** statement to specify the VRF location of the DHCP server, to which the DHCP relay agent forwards the client packets with the appropriate DHCP option information. The **forward-only** statement ensures that DHCP relay agent does not create a new session or perform any other subscriber management operations (such as creating dynamic interfaces or maintaining leases).

You can optionally configure a specific logical system and routing instance for the server VRF. If you do not specify a logical system or routing instance, then DHCP uses the local logical system and routing instance from which the configuration is added.

- Server-side support—Configure the DHCP relay agent **forward-only-replies** statement so the DHCP relay agent forwards the reply packets that have the appropriate DHCP option information. This statement also ensures that DHCP relay agent does not create a new session or perform any other subscriber management operations.

**NOTE:** You do not need to configure the **forward-only-replies** statement if the DHCP client and DHCP server reside in the same logical system/routing instance.

---

- DHCP local server support—Configure the DHCP local server to support option 82 information in DHCP NAK and forcerenew messages. By default, the two message types do not support option 82.
- Additional support—Ensure that the following required support is configured:
  - Proxy ARP support must be enabled on the server-facing interface in the DHCP server VRF so that the DHCP relay agent can receive and respond to the ARP requests for clients and the client-facing interface in the DHCP server VRF.
  - Routes must be available to receive the DHCP packets from the DHCP server in the server VRF for the clients reachable in the client VRF.

The following procedures describe the configuration tasks for creating the DHCP message exchange between the DHCP server and clients in different VRFs.

- [Client-Side Support on page 274](#)
- [Server-Side Support on page 275](#)
- [DHCP Local Server Support on page 276](#)

---

## Client-Side Support

To configure support on the client side of the DHCP relay agent:

1. Enable DHCP relay agent configuration.

```
[edit forwarding-options]  
user@host# edit dhcp-relay
```

2. Specify the DHCP server VRF to which the DHCP relay agent forwards the packets from the DHCP client. DHCP relay agent forwards the acceptable packets that have the appropriate DHCP option information, but does not perform any additional subscriber management operations. You can configure the **forward-only** statement globally or for a named group of interfaces, and for DHCPv4 or DHCPv6. You can specify the current, default, or a specific logical system or routing instance for the server VRF.

The following example configures the **forward-only** statement globally for DHCPv4, and specifies the default logical system and routing instance:

```
[edit forwarding-options dhcp-relay]
user@host# set forward-only logical-system default routing-instance default
```

**NOTE:** For local DHCPv4 clients, the DHCP relay agent adds the Agent Circuit ID option. However, if the Agent Circuit ID option is already present in the packet, you must ensure that the DHCP server supports the option 82 Vendor-Specific Information suboption (suboption 9).

If the **forward-only** statement is configured at the [edit forwarding-options dhcp-relay relay-option] hierarchy level, then that relay-option action takes precedence over the configuration of the **forward-only** statement for the DHCP cross-VRF message exchange.

## Server-Side Support

To configure the cross-VRF message exchange support on the server side of the DHCP relay:

**NOTE:** You do not need to configure the **forward-only-replies** statement if the DHCP client and DHCP server reside in the same logical system/routing instance.

1. Enable DHCP relay agent configuration.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Configure the DHCP relay agent to forward the DHCP packets from the DHCP server VRF to the client. DHCP relay agent only forwards the packets, and does not perform any additional subscriber management operations. You can configure the **forward-only-replies** statement globally for DHCPv4 and DHCPv6.

The following example configures the **forward-only-replies** statement globally for DHCPv4.

```
[edit forwarding-options dhcp-relay]
user@host# set forward-only-replies
```

## DHCP Local Server Support

To configure the DHCP local server to support option 82 information in NAK and forcerenew messages; the cross-VRF message exchange feature uses the option 82 or DHCPv6 option 18 information to determine the client VRF:

1. Enable DHCP local server configuration.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Specify that you want to configure an override option.

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

3. Configure DHCP local server to override the default behavior and support option 82 information in DHCP NAK and forcerenew messages. You can configure the override action globally, for a group of interfaces, or for a specific interface.

```
[edit system services dhcp-local-server overrides]
user@host# set include-option-82 forcerenew nak
```

## DHCP-Initiated Service Change Based on Remote ID

Subscriber management enables you to update a DHCP client's current service through the use of the client's remote ID (Agent Remote ID). The remote ID can be in option 82, suboption 2 for DHCPv4 clients, or option 37 for DHCPv6 clients.

When a DHCP client is initially established, DHCP preserves the client's incoming remote ID in the DHCP client database. When receiving a rebind or renew message for that client, DHCP compares the client's initial remote ID to the remote ID in the DHCP renew or rebind message. If the two remote IDs do not match, DHCP local server tears down the existing binding and sends a NAK message (or logical NAK for DHCPv6), which causes the client to initiate a reconnect sequence. When the client reconnects, the DHCP local server activates the new service, which is encoded within the new Agent Remote ID string.

You can configure the router to support the remote ID service change feature globally or for a specific group, and you can configure the support on DHCP local server and DHCP relay agent.

In a dual-stack environment, the DHCP-initiated service change feature requires that a client's DHCPv4 and DHCPv6 sessions reside over the same VLAN (1:1 mapping) and that the Agent Remote ID strings for the two sessions are identical. The dual-stack support also requires that the same dynamic client profile is applied to both the DHCPv4 and DHCPv6 networks, to ensure remote ID consistency between the two networks. When

DHCP detects a remote ID mismatch in one session of the dual stack, DHCP tears down that session. The incoming remote ID is then compared to the other session of the dual stack, and if there is a mismatch, that other session is torn down gracefully.

During the graceful teardown process, if the other session is currently in the bound state, that session then transitions to the deferred delete state. The deferred delete state allows the session that detected the change to be reestablished immediately with the new service plan, while enabling the router to gracefully tear down the other session by sending NAK messages in response to the subsequent renew and rebind messages.

As part of the DHCP-initiated service change feature, AAA can set a session's client profile. AAA obtains the client profile from the remote-ID, and writes the profile into the session database. A client profile that AAA writes into the database always takes precedence over any local DHCP configuration.

A change in the Agent Remote ID can also initiate a service change during reauthentication. You cannot configure both the **remote-id-mismatch** statement and the **reauthenticate** statement at the global level, **[edit system services dhcp-local-server]**. However, DHCP precedence rules do permit you to configure both statements when they are at different levels. For example, you can configure **reauthenticate** at the global level and **remote-id-mismatch** for DHCPv6 at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level or for a specific group at the **[edit system services dhcp-local-server group name]** hierarchy level, and so on.

## Configuring DHCP-Initiated Service Change Based on Remote ID

This topic describes how to configure support for DHCP-initiated service change on the DHCP local server and the DHCP relay agent.

### Configuring DHCP local server

You can configure support for DHCP-initiated service change for DHCP local server and DHCPv6 local server globally, or for a named group of interfaces.

To configure DHCP local server to support DHCP-initiated service change for a named group:

1. Before starting the configuration for the DHCP-initiated service change feature, ensure that the DHCP or DHCPv6 relay agent is configured to override the default behavior and send a release message to the DHCP server when a remote ID mismatch occurs. This configuration is required because the relay agent cannot directly tear down client bindings; the release packet signals the DHCP server to tear down the original binding.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set overrides send-release-on-delete
```

2. Specify that you want to configure DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

3. Specify the named group that you want to configure.

```
[edit system services dhcp-local-server]
user@host# edit group northwest-321
```

4. Specify that, for the named group, DHCP local server matches the initial and new client remote IDs, and then performs the **disconnect** action when a mismatch occurs.

```
[edit system services dhcp-local-server group northwest-321]
user@host# set remote-id-mismatch disconnect
```

When a mismatch occurs, DHCP local server tears down the existing binding and sends a NAK message to the client, which initiates the client reconnect sequence. The new service, which is encoded in the Agent Remote ID string, is then activated when the client reconnects.

#### Configuring DHCP relay agent

You can configure support for DHCP-initiated service change for DHCP relay agent and DHCPv6 relay agent globally, or for a named group of interfaces.

The following example shows the steps to configure DHCPv6 relay agent to support DHCP-initiated service change on a global basis.

1. Before starting the configuration for the DHCP-initiated service change feature, ensure that the DHCPv6 relay agent is configured to override the default behavior and send a release message to the DHCP server when a remote ID mismatch occurs. This configuration is required because the relay agent cannot directly tear down client bindings; the release packet signals the DHCP server to tear down the original binding.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set dhcp-relay overrides send-release-on-delete
```

2. Specify that you want to configure DHCP relay agent.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

3. Specify that you want to configure DHCPv6 relay agent.

```
[edit forwarding-options dhcp-relay]
user@host# edit dhcpv6
```

4. Specify that DHCPv6 relay agent matches the initial and new client remote IDs, and then performs the **disconnect** action when a mismatch occurs.

```
[edit system services dhcp-local-server group northwest-321]
user@host# set remote-id-mismatch disconnect
```

When a mismatch occurs, DHCPv6 relay agent sends the release message to the DHCPv6 local server and a logical NAK message (a reply packet with a 0 lifetime) to the client. The server then tears down the existing binding, and the client initiates the reconnect sequence. The new service, which is encoded in the Agent Remote ID string, is activated when the client reconnects.

## DHCPv4 and DHCPv6 Forward-Only Action for Relay Traffic with Unknown DHCP Server Address

The DHCP relay agent entry, which can be created on a DHCPv4 or DHCPv6 server, is useful for authentication, authorization, accounting, applying filtering, ensuring quality of service (QoS) on the client, and processing of options specified in the packet. The creation of the relay agent or client entry involves participation of the `jdhcpd` process memory resources, session database resources, authentication procedure, accounting, dynamic profile instantiation, dynamic interface creation, firewall, class-of-service (CoS)-association, and more. Customer networks can contain non-customer controlled bindings for which they might not want these relay agent entry functionalities. When a customer's network has such traffic, creation of relay agent entries—which is related to client entry creation—unnecessarily utilizes resources and can also result in wrong association of profiles, because in the current network scenario, all the traffic received from a specific interface is forwarded, without processing any destination address.

Starting in Junos OS Release 17.4R1, a **forward-only** configuration can be enabled on the broadband network gateway (BNG) device for non-customer traffic along with unknown DHCP server address. The configuration of the **forward-only** statement, along with the new DHCP options—**option-54** for DHCPv4 and **option-2** for DHCPv6, avoids the creation of the DHCP relay agent entry on the BNG and ensures that traffic is forwarded to the specified destination address.

With these configurations, administrators are able to determine to which servers the clients are bound; which of the clients need to have a relay client entry created and dynamic profile and policies applied, and so on; and for whom (non-customer) the **forward-only** configuration is enabled.

The two new configuration statements—**options-54** and **options-2**—are introduced for processing destination addresses.

### Processing of DHCPv4 and DHCPv6 Destination Addresses

Administrators can configure the **forward-only** statement to avoid the creation of non-customer client entries. The `jdhcpd` process compares the server identifier (**option-54** for DHCPv4 and **option-2** for DHCPv6) with or without destination address in the incoming packet along with the configured server address. If the server identifier and configured server address match, the action is to only forward without creating the client entry.

On nonpassive relay, configuration of the **server-match** statement means implicit enabling of the **delay-authentication** statement for the clients for which the **server-match** statement is processed. You can also configure options 60 and 77 (for DHCPv4) or options 15 and 16 (for DHCPv6) optionally together with associated processing. Configuration of these options also includes the specification of the order in which they are processed. If these options are not configured, the default order is 60, 77 for DHCPv4 and 15, 16 for DHCPv6.

**NOTE:** DHCPv6 option-16 data as defined in RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*, comprises a 4-byte enterprise number and the variable length vendor-class data. The enterprise number is a number registered by the vendor with IANA. As such, it is anticipated that configuring an ASCII match in conjunction with option-16 relay-option match might not work because the enterprise number must coincide with the value of a printable ASCII character.

A similar restriction exists for DHCPv4 option-77 statement because the option-77 data might be subdivided to include suboptions and sublengths. Because of this, configuring an ASCII match with option-77 relay-option match might not work.

On nonpassive relay, if a request packet is received in the *rebind* phase and the corresponding relay entry is not present, then you need to first configure the **bind-on-request** statement, following which the relay entry is created and the packet is forwarded. After an acknowledgment is received, the *jdhcpd* process verifies the source address (with or without option 54 for DHCPv4 and option 2 for DHCPv6) within the **server-match** configuration. If the verification results in a stateless entry, then the relay entry is deleted.

The administrator can specify the DHCP unique identifier (DUID) with or without the address of a server. The *jdhcpd* process first processes address statements and then the DUID statements. If the same server address is specified in address statements and the DUID statement, then it is the administrator's responsibility to specify the same action for both address and the DUID statements.

On both passive and nonpassive relays, if the received packet contains a relay forward header and the destination address is multicast or a link-local address, then the packet is forwarded without any further processing.

**NOTE:** For both DHCPv4 and DHCPv6 subscribers, the **relay-option** and **server-match** statements are at the same hierarchy and have the same priority.

---

### Processing Order and Actions

Relay options and server match processing are mutually exclusive. Although they are at the same hierarchy and have the same priority, for implementation purpose, you process relay options followed by server match.

Following are the DHCPv4 relay option processing actions:

- **drop**—Discard when there is a match.
- **forward-only**—Forward without client services, when there is a match.
- **local-server-group**—Name of DHCP local server group when there is a match.
- **relay-server-group**—Name of DHCP relay server group when there is a match.

Following are the DHCPv6 relay option processing actions:

- **drop**—Discard when there is a match.
- **forward-only**—Forward without client services, when there is a match.
- **relay-server-group**—Name of DHCP relay server group when there is a match.

**NOTE:** The DHCPv6 server match for IPv6 address is available in passive relay only.

The default and configurable option orders are processed as shown in [Figure 4 on page 281](#). If you need the option order to be reversed (either DHCPv4 or DHCPv6), then configure **option-order 77,66** statement for DHCPv4 or **option-order 16,15** statement for DHCPv6 at the [edit forwarding-options dhcp-relay relay-option] hierarchy level.

*Figure 4: DHCPv4 and DHCPv6 Option Order*

#### DHCPv4

##### Default order:

option-60 (equals → starts-with) → option-77 (equals → start-with) → option-60 (default-action) → option-77 (default-action) → not-present

##### When option-order is configured as 77,60 in CLI:

option-77 (equals → starts-with) → option-60 (equals → starts-with) → option-77 (default-action) → option-60 (default-action) → not-present

#### DHCPv6

##### Default order:

option-15 (equals → starts-with) → option-16 (equals → start-with) → option-15 (default-action) → option-16 (default-action) → not-present

##### When option-order is configured as 16,15 in CLI:

option-16 (equals → starts-with) → option-15 (equals → starts-with) → option-16 (default-action) → option-15 (default-action) → not-present

g200200

## Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, the selective traffic processing feature lets you manage multivendor networks with the extended DHCP and DHCPv6 relay agent.
15.1	Starting in Junos OS Release 15.1, you can configure the DHCP relay agent to selectively process client traffic.
14.2	Starting in Junos OS Release 14.2, you can use the DHCP relay agent to provide additional security when exchanging DHCP messages between different VRFs.
14.2	Starting in Junos OS Release 14.2, you can configure DHCP relay agent to provide additional security when exchanging DHCP messages between a DHCP server and DHCP clients that reside in different virtual routing and forwarding instances (VRFs).

- [Extracting an Option 82 or Option 37 Substring to Create an Interface Set on page 291](#)

## Using DHCP Relay Agent Option 82 Information

Subscriber management enables you to configure the DHCP relay agent to include additional option 82 information in the DHCP packets that the relay agent receives from clients and forwards to a DHCP server. The DHCP server uses the additional information to determine the IP address to assign to the client. The server might also use the information for other purposes—for example, to determine which services to grant the client, or to provide additional security against threats such as address spoofing. The DHCP server sends its reply back to the DHCP relay agent, and the agent removes the option 82 information from the message and forwards the packet to the client.

To configure support for the DHCP relay agent information option 82, you use the **relay-option-82** statement. You can configure the DHCP relay agent to include the following suboptions in the packet the relay agent sends to the DHCP server:

- Agent Circuit ID (suboption 1)—An ASCII string that identifies the interface on which the client DHCP packet is received.
- Agent Remote ID (suboption 2)—An ASCII string assigned by the DHCP relay agent that securely identifies the client.

You can configure the option 82 support globally or for a named group of interfaces.

To restore the default behavior, in which option 82 information is not inserted into DHCP packets, you use the **delete relay-option-82** statement.

**NOTE:** The DHCPv6 relay agent provides similar Agent Circuit ID and Agent Remote ID support for DHCPv6 clients. For DHCPv6, subscriber management uses DHCPv6 option 18 to include the circuit ID in the packets that the relay agent sends to a DHCPv6 server, and option 37 to include the remote ID in the packets. See “[DHCPv6 Relay Agent Options](#)” on page 392.

The following sections describe the option 82 operations you can configure:

- [Configuring Option 82 Information on page 283](#)
- [Overriding Option 82 Information on page 285](#)
- [Including a Prefix in DHCP Options on page 286](#)
- [Including a Textual Description in DHCP Options on page 288](#)

### Configuring Option 82 Information

You use the **relay-option-82** statement to configure the DHCP relay agent to insert option 82 information in DHCP packets that the relay agent receives from clients and forwards to a DHCP server. When you configure option 82, you can include one of the suboption statements to specify the type of information you want to include in the DHCP packets. If you configure option 82 without including one of the suboption statements, the Agent Circuit ID option is included by default. Use the **circuit-id** statement to include the Agent Circuit ID (suboption 1) in the packets, or the **remote-id** statement to include the Agent Remote ID (suboption 2).

You can optionally configure DHCP relay agent to include a prefix or the interface description as part of the suboption information. If you specify the **circuit-id** or **remote-id** statement without including any of the optional **prefix**, **use-interface-description**, **use-vlan-id**, **include-irb-and-l2**, or **no-vlan-interface-name** statements, the format of the Agent Circuit ID or Agent Remote ID information for Fast Ethernet (fe), Gigabit Ethernet (ge), and integrated routing and bridging (irb) interfaces is one of the following, depending on your network configuration:

- For Fast Ethernet or Gigabit Ethernet interfaces that do not use VLANs, stacked VLANs (S-VLANs), or bridge domains:

```
(fe | ge)-fpc/pic/port.subunit
```

**NOTE:** For remote systems, the *subunit* is required and is used to differentiate an interface.

- For Fast Ethernet or Gigabit Ethernet interfaces that use VLANs:

```
(fe | ge)-fpc/pic/port:vlan-id
```

- For Fast Ethernet or Gigabit Ethernet interfaces that use S-VLANs:

```
(fe | ge)-fpc/pic/port:svlan-id-vlan-id
```

**NOTE:** Integrated routing and bridging (IRB) provides simultaneous support for Layer 2 bridging and Layer 3 IP routing on the same interface. IRB enables you to route local packets to another routed interface or to another bridging domain that has a Layer 3 protocol configured.

The interface to bridge domain relationship might be implicit (the interface is mapped to the bridge domain by the system based on the VLAN tag) or explicit (the interface is mapped to the bridge domain by configuring it in the bridge domain definition). For the explicit case, tagging might not be relevant for the mapping.

In the case of an IRB interface, the format displays the Layer 2 interface instead of the IRB interface along with the bridge domain name. For IRB interfaces (or other pseudo devices) the default format is as follows:

- IRB interfaces that use bridge domains but do not use VLANs or S-VLANs:

```
(fe | ge)-fpc/pic/port.subunit:bridge-domain-name
```

- IRB interfaces that use VLANs:

```
(fe | ge)-fpc/pic/port.subunit:vlan-name
```

To include the IRB interface name with the Layer 2 interface name, configure the **include-irb-and-l2** statement. The format is as follows:

- IRB interfaces that use bridge domains but do not use VLANs or S-VLANs:

```
(fe | ge)-fpc/pic/port:bridge-domain-name+irb.subunit
```

- IRB interfaces that use VLANs:

```
(fe | ge)-fpc/pic/port:vlan-name+irb.subunit
```

To include only the IRB interface name without the Layer 2 interface and bridge domain or VLAN, configure the **no-vlan-interface-name** statement. The format is as follows:

```
irb.subunit
```

To enable insertion of option 82 information:

- Specify that you want to configure option 82 support.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option-82
```

- Configure the DHCP relay agent to insert the Agent Circuit ID suboption, the Agent Remote ID suboption, or both.

- To insert the Agent Circuit ID:

```
[edit forwarding-options dhcp-relay relay-option-82]
user@host# set circuit-id
```

- To insert the Agent Remote ID:

```
[edit forwarding-options dhcp-relay relay-option-82]
user@host# set remote-id
```

- To insert both, configure both set commands.

3. (Optional) Configure a prefix that is used in the option 82 information in the DHCP packets.

See [“Including a Prefix in DHCP Options” on page 286](#).

4. (Optional) Configure the DHCP relay agent to include the interface's textual description instead of the interface identifier in the option 82 information.

See [“Including a Textual Description in DHCP Options” on page 288](#).

### Overriding Option 82 Information

You can configure the DHCP relay agent to add or remove the DHCP relay agent information option (option 82) in DHCP packets.

This feature causes the DHCP relay agent to perform one of the following actions, depending on the configuration:

- If the DHCP relay agent is configured to add option 82 information to DHCP packets, it clears the existing option 82 values from the DHCP packets and inserts the new values before forwarding the packets to the DHCP server.
- If the DHCP relay agent is not configured to add option 82 information to DHCP packets, it clears the existing option 82 values from the packets, but does not add any new values before forwarding the packets to the DHCP server.

To override the default option 82 information in DHCP packets destined for a DHCP server:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that the option 82 information in DHCP packets is overwritten.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set always-write-option-82
```

### Including a Prefix in DHCP Options

---

When you configure the DHCP relay agent to include DHCP options in the packets that the relay agent sends to a DHCP server, you can specify that the relay agent add a prefix to the DHCP option. You can add a prefix to the following DHCP options:

- DHCPv4 option 82 Agent Circuit ID (suboption 1)
- DHCPv4 option 82 Agent Remote ID (suboption 2)
- DHCPv6 option 18 Relay Agent Interface-ID
- DHCPv6 option 37 Relay Agent Remote-ID

The prefix is separated from the DHCP option information by a colon (:), and it can include any combination of the **host-name**, **logical-system-name**, and **routing-instance-name** options. The DHCP relay agent obtains the values for the **host-name**, **logical-system-name**, and **routing-instance-name** as follows:

- If you include the **host-name** option, the DHCP relay agent uses the hostname of the device configured with the **host-name** statement at the **[edit system]** hierarchy level.
- If you include the **logical-system-name** option, the DHCP relay agent uses the logical system name configured with the **logical-system** statement at the **[edit logical-system]** hierarchy level.
- If you include the **routing-instance-name** option, the DHCP relay agent uses the routing instance name configured with the **routing-instance** statement at the **[edit routing-instances]** hierarchy level or at the **[edit logical-system logical-system-name routing-instances]** hierarchy level.

If you include the hostname and either or both of the logical system name and the routing instance name in the prefix, the hostname is followed by a forward slash (/). If you include both the logical system name and the routing instance name in the prefix, these values are separated by a semicolon (;).

The following examples show several possible formats for the DHCP option information when you specify the **prefix** statement for Fast Ethernet (fe) or Gigabit Ethernet (ge) interfaces with S-VLANs.

- If you include only the hostname in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
hostname:(fe | ge)-fpc/pic/port:svlan-id-vlan-id
```

- If you include only the logical system name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
logical-system-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id
```

- If you include only the routing instance name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
routing-instance-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id
```

- If you include both the hostname and the logical system name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
host-name/logical-system-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id
```

- If you include both the logical system name and the routing instance name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
logical-system-name;routing-instance-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id
```

- If you include the hostname, logical system name, and routing instance name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
host-name/logical-system-name;routing-instance-name:(fe |  
ge)-fpc/pic/port:svlan-id-vlan-id
```

For Fast Ethernet or Gigabit Ethernet interfaces that use VLANs but not S-VLANs, only the *vlan-id* value appears in the DHCP option format.

(DHCPv4) To configure a prefix with the option 82 information:

1. Specify that you want to configure option 82 support.

```
[edit forwarding-options dhcp-relay]  
user@host# edit relay-option-82
```

2. Configure DHCP relay agent to insert the Agent Circuit ID, the Agent Remote ID, or both.

- To configure the Agent Circuit ID:

```
[edit forwarding-options dhcp-relay relay-option-82]  
user@host# edit circuit-id
```

- To configure the Agent Remote ID:

```
[edit forwarding-options dhcp-relay relay-option-82]  
user@host# edit remote-id
```

3. Specify that the prefix be included in the option 82 information. In this example, the prefix includes the hostname and logical system name.

- To include the prefix with the Agent Circuit ID:

```
[edit forwarding-options dhcp-relay relay-option-82 circuit-id]  
user@host# set prefix host-name logical-system-name
```

- To include the prefix with the Agent Remote ID:

```
[edit forwarding-options dhcp-relay relay-option-82 remote-id]
```

```
user@host# set prefix host-name logical-system-name
```

(DHCPv6) To use a prefix with the DHCPv6 option 18 or option 37 information:

1. Specify that you want to configure DHCPv6 relay agent support.

```
[edit forwarding-options dhcp-relay]
user@host# edit dhcpv6
```

2. Configure DHCPv6 relay agent to insert option 18 (Relay Agent Interface-ID), option 37 (Relay Agent Remote-ID), or both.

- To configure option 18:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit relay-agent-interface-id
```

- To configure option 37:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit relay-agent-remote-id
```

3. Specify that the prefix is included in the option information. In this example, the prefix includes the hostname and logical system name

- To include the prefix with option 18:

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]
user@host# set prefix host-name logical-system-name
```

- To include the prefix with option 37:

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-remote-id]
user@host# set prefix host-name logical-system-name
```

### Including a Textual Description in DHCP Options

By default, when DHCP relay agent inserts option information in the packets sent to a DHCP server, the options include the interface identifier. However, you can configure the DHCP relay agent to include the textual description that is configured for the interface instead of the interface identifier. You can use the textual description for either the logical interface or the device interface.

You can include the textual interface description in the following DHCP options:

- DHCPv4 option 82 Agent Circuit ID (suboption 1)
- DHCPv4 option 82 Agent Remote ID (suboption 2)
- DHCPv6 option 18 Relay Agent Interface-ID
- DHCPv6 option 37 Relay Agent Remote-ID

The textual description is configured separately, using the **description** statement at the **[edit interfaces *interface-name*]** hierarchy level. If you specify that the textual description is used and no description is configured for the interface, DHCP relay defaults to using the Layer 2 interface name.

In the case of integrated routing and bridging (IRB) interfaces, the textual description of the Layer 2 interface is used instead of the textual description of the IRB interface. If there is no description configured, the Layer 2 logical interface name is used.

**NOTE:** For IRB interfaces, the option 82 field must be able to uniquely identify the incoming interface based on either the Agent Circuit ID or Agent Remote ID. You can modify the information in the textual interface description to match the raw IFD (physical interface without a subunit) name and configure the option 82 field to use the interface description.

You can use the textual description with the following DHCP options:

- DHCPv4 Option 82 Agent Circuit ID (suboption 1)
- DHCPv4 Option 82 Agent Remote ID (suboption 2)
- DHCPv6 Relay Agent Interface-ID (option 18)
- DHCPv6 Relay Agent Remote-ID (option 37)

(DHCPv4) To configure the DHCP relay option 82 suboption to include the textual interface description:

1. Specify that you want to configure option 82 support.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option-82
```

2. Configure DHCP relay agent to insert the Agent Circuit ID, Agent Remote ID, or both.

```
[edit forwarding-options dhcp-relay relay-option-82]
user@host# edit circuit-id
```

3. Specify that the textual description is included in the option 82 information. In this example, the option 82 information includes the description used for the device interface.

```
[edit forwarding-options dhcp-relay relay-option-82 circuit-id]
user@host# set use-interface-description device
```

(DHCPv6) To configure the DHCPv6 option 18 or option 37 to include the textual interface description:

1. Specify that you want to configure DHCPv6 relay agent support.

```
[edit forwarding-options dhcp-relay]
user@host# edit dhcpv6
```

2. Configure DHCPv6 relay agent to insert option 18 (Relay Agent Interface-ID), option 37 (Relay Agent Remote-ID), or both.

- To configure option 18:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit relay-agent-interface-id
```

- To configure option 37:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit relay-agent-remote-id
```

3. Specify that the textual description is included in the option information. In the following example, the option information includes the description used for the device interface.

- To include the textual description in option 18:

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]
user@host# set use-interface-description device
```

- To include the textual description in option 37:

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-remote-id]
user@host# set use-interface-description device
```

**See Also** • *Configuring Interface Description*

## Enable Processing of Untrusted Packets So Option 82 Information Can Be Used

By default, the DHCP relay agent treats client packets with a giaddr of 0 (zero) and option 82 information as if the packets originated at an untrusted source, and drops them without further processing. You can override this behavior and specify that the DHCP relay agent process DHCP client packets that have a giaddr of 0 (zero) and contain option 82 information.

To configure DHCP relay agent to trust option 82 information:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that the DHCP relay agent process DHCP client packets with a giaddr of 0 and that contain option 82 information.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set trust-option-82
```

## Extracting an Option 82 or Option 37 Substring to Create an Interface Set

Starting in Junos OS Release 17.2R1, you can create an interface set based on a specific, delimited substring of the agent remote ID (ARI) string received in DHCP packets. Specify the predefined variable `$junos-pon-id-interface-set-name` in a dynamic profile to extract the substring from DHCPv4 (Option 82, suboption 2) or DHCPv6 (Option 37). This substring is inserted by the optical line terminal (OLT) in a passive optical network (PON) and is unique for that PON. The extracted substring is used as the name of the interface set.

The OLT must format the ARI string with a pipe symbol (|) as the delimiter between substrings. The substring extracted for the interface set name consists of the characters following the last delimiter in the ARI string. You determine the format and contents of the substring, and configure your OLT to insert the information. Typically, the substring may include the name and port of the OLT accessed by the CPE optical network terminal (ONT).

For example, the ARI format might be something like the following:

```
circuit-id|plan-name|ONT-serial-number|OLT-info
```

The following sample ARI strings follow that format:

```
ari-1001|100M|AAAA01234|ot101.xyz101-202
ari-9505|100M|AAAA01234|ot101.xyz101-202
ari-1238|100M|AAAA01234|ot101.xyz101-111
```

The first two ARIs share the same substring after the last delimiter, `ot101.xyz101-202`. The third ARI has a different last substring, `ot101.xyz101-111`. The predefined variable extracts both of these substrings. Two interface sets are created, named `ot101.xyz101-202` and `ot101.xyz101-111`.

The two customer circuits identified by `ot101.xyz101-202` are aggregated into that interface set. The single circuit identified by `ot101.xyz101-111` is associated with the other set. The interface sets can subsequently be used to apply CoS and services to their associated subscriber circuits.

Before you begin:

- Configure your OLTs to provide an agent remote ID string in the required format.
- Configure your DHCPv4 or DHCPv6 relay agents to insert the agent remote ID received from the OLT for forwarding to the DHCP local server.
- Create the dynamic profile.

This procedure shows only the configuration required for specifying the predefined variable.

1. Access the desired dynamic profile.

```
[edit]
user@host# edit dynamic-profiles profile-name
```

2. Specify the predefined variable to create the interface set.

```
[edit dynamic-profiles profile-name]
user@host# set interfaces interface-set $junos-pon-id-interface-set-name
```

3. Complete the dynamic profile configuration.

You can use the `show subscribers extensive` command to display the interface set name and the complete ARI string.

#### `show subscribers extensive` (Passive Optical Network Circuit Interface Set)

```
user@host> show subscribers client-type dhcp extensive
Type: DHCP
...
Interface Set: ot101.xyz101-202
...
Agent Remote ID: ABCD01234|100M|AAAA01234|ot101.xyz101-202
...
```

## Default Services for DHCP Subscribers

---

- [Default Subscriber Service Overview on page 293](#)
- [Configuring a Default Subscriber Service on page 293](#)

### Default Subscriber Service Overview

Subscriber management enables you to specify a default subscriber service for DHCP subscribers. The default service (dynamic profile) is applied to subscribers when the subscriber logs in. By configuring a default service, you can apply a particular service (for example, a basic service) to subscribers who are not explicitly assigned a service.

When a subscriber logs in, the configured default service is always activated, even when remote service provisioning or RADIUS service activation is configured for the subscriber. The default service is deactivated only when the subscriber is successfully provisioned by the PCRF by means of the GX-Plus application. (Remote provisioning is configured by the **provisioning-order** statement at the **[edit access profile]** hierarchy level.)

In all other cases, the default service remains active. For example, if RADIUS authentication is configured but service activation is not, the default subscriber service remains activated. Likewise, if RADIUS authentication is not configured, the default subscriber service remains activated.

Default services can also be deactivated either with a RADIUS CoA deactivate request or with the **request network-access aaa subscriber delete session-id** command.

To create and assign a default subscriber service, you must complete the following operations:

- Create the service—Ensure that the service you want to use has been configured in a dynamic service profile. The actual service is no different than any other service used for subscriber management.
- Specify the default service—Use the Junos OS CLI to specify the service that is used as the default service.
- Specify the interfaces on which the default service is assigned —Use the Junos OS CLI to specify that the default service is used globally, for a group of interfaces, or for a specific interface.

### Configuring a Default Subscriber Service

Subscriber management enables you to specify a default subscriber service for DHCP (and DHCPv6) local server and DHCP relay agent. The default service is the service (dynamic profile) that is applied to subscribers when they log in.

Default services are subsequently deactivated in any of the following circumstances:

- A PCRF responds to AAA for the subscriber.
- A RADIUS CoA deactivation request is issued.

- You deactivate the service manually through the CLI.

To configure a default subscriber service:

1. Ensure that the service you want to use as the default has been configured in a dynamic profile.
2. Specify the default service.

The following example configures the default service for DHCP local server subscribers.

```
[edit system services dhcp-local-server]
user@host# set service-profile retailer1-subscriber
```

3. Attach the default service—you can attach the profile globally, for a group of interfaces, or for a specific interface.

The following example attaches the profile to a named group of interfaces for DHCP local server.

- Specify the group to which the default service is attached.

```
[edit system services dhcp-local-server]
user@host# set group subscriber-svl
```

- Specify the dynamic profile that defines the default service.

```
[edit system services dhcp-local-server group subscriber-svl]
user@host# set dynamic-profile retailer1-subscriber
```

## DHCP Attributes Overview

You can configure features that are specific to the DHCP application that are applied to only certain DHCP clients or to all DHCP clients with DHCP attributes. DHCP uses the attributes to determine the scope of the client operation. For example, you can configure attributes that set the maximum lease time or preferred lifetime of the lease, the domain in which to search for DHCP servers, match criteria for which address range to use from within an address pool, and so on. You might specify that a client that matches certain prerequisite information is dynamically assigned an address from a particular named address range. Based on which named range is used, DHCP specifies additional DHCP attributes.

You can configure DHCP attributes in the following ways:

- On the RADIUS server so that they are conveyed in the corresponding DHCP option when a subscriber is authenticated. Refer to your RADIUS server documentation for more information.
- For specific DHCPv4 or DHCPv6 clients that receive an address from the local address assignment pool with the **dhcp-attributes** statement at the **[edit access address-assignment pool *pool-name*]** hierarchy level.
- As a set of attributes that you can apply to DHCP clients outside of specific address pools. Define the attribute set with the **protocol-attributes** statement at the **[edit access]** hierarchy level. Then apply the set with a different **protocol-attributes** statement to any of the following:
  - For all DHCPv4 clients at the **[edit system services dhcp-local-server overrides]** hierarchy level.
  - For a group of DHCPv4 clients at the **[edit system services dhcp-local-server group *group-name* overrides]** hierarchy level.
  - For all DHCPv6 clients at the **[edit system services dhcp-local-server dhcpv6 overrides]** hierarchy level.
  - For a group of DHCPv6 clients at the **[edit system services dhcp-local-server dhcpv6 group *group-name* overrides]** hierarchy level.

The DHCP local server processes attributes provided by different methods in the following hierarchy:

RADIUS > address pool > global > other

1. When the attribute is configured in RADIUS, the value in the corresponding option received by the DHCP local server is used.
2. When the attribute is configured for an address pool, that value is used for clients assigned addresses from that pool.
3. When the attribute is configured globally with the **protocol-attributes** statement, that value is used for all clients.
4. When none of the other criteria is met but the attribute is configured at the **[edit access]** hierarchy level, that value is used for all clients. If the attribute is configured at the **[edit access profile]** hierarchy level, that value is used for clients using the profile.

### Benefits of Configuring DHCP Attributes

You can match desired attributes to specific clients based on matching criteria. You have the flexibility to assign attributes and values when an address is assigned from a pool, globally for clients not using address pools, or with RADIUS attributes at authentication.

## Attributes That Can Be Applied to DHCP Clients

This topic provides descriptions of DHCPv4 and DHCPv6 options.

Table 34 on page 296 describes the DHCPv4 client attributes that you can configure.

*Table 34: DHCP Attributes*

Attribute	Description	DHCP Option
<a href="#">boot-file</a>	Boot filename advertised to the client, and used by the client to complete configuration.	67
<a href="#">boot-server</a>	Boot server containing the boot file.	66
<a href="#">domain-name</a>	Domain in which clients search for a DHCP server host.	15
<a href="#">grace-period</a>	Grace period offered with the lease.	—
<a href="#">maximum-lease-time</a>	Maximum lease time allowed by the DHCP server.	51
<a href="#">name-server</a>	IP address of DNS server to which clients can send DNS queries.	6
<a href="#">netbios-node-type</a>	NetBIOS node type.	46
<a href="#">option</a>	User-defined options.	—
<a href="#">option-match</a>	Option 82 value is mapped to named address range.	—

Table 34: DHCP Attributes (continued)

Attribute	Description	DHCP Option
<code>router</code>	IP address for routers on the subnetwork.	3
<code>server-identifier</code>	IP address used as the DHCP source address	54
<code>t1-percentage</code>	Percentage of the <b>preferred-lifetime</b> that the client (router) waits before sending renew messages to the DHCPv4 server that granted the original lease to extend the client's lease.	58
<code>t1-renewal-time</code>	Time that the client (router) waits before sending renew messages to extend the client's lease. The renew messages are sent to the DHCPv4 server that granted the original lease.  This attribute is an alternative to <b>t1-percentage</b> .	58
<code>t2-percentage</code>	Percentage of the <b>preferred-lifetime</b> that the client (router) waits before sending rebind messages to any available DHCPv4 server to extend the client's lease.	59
<code>t2-rebinding-time</code>	Time that the client (router) waits before sending rebind messages to extend the client's lease. The rebind messages are sent to any available DHCPv4 server.  This attribute is an alternative to <b>t2-percentage</b> .	59
<code>tftp-server</code>	Trivial File Transfer Protocol (TFTP) server that the client uses to obtain the client configuration file.	150
<code>wins-server</code>	IP address of the Windows NetBIOS name server.	44

Table 35 on page 297 describes the DHCPv6 client attributes that you can configure.

Table 35: DHCPv6 Attributes

Attribute	Description	DHCPv6 Option
<code>dns-server</code>	IPv6 address of DNS server to which clients can send DNS queries.	23
<code>grace-period</code>	Grace period offered with the lease.	—
<code>maximum-lease-time</code>	Maximum lease time allowed by the DHCP server.	—
<code>option</code>	User-defined options.	—
<code>preferred-lifetime</code>	Length of time that a valid address is in the preferred state. When the preferred lifetime expires, the address becomes deprecated.	—

Table 35: DHCPv6 Attributes (continued)

Attribute	Description	DHCPv6 Option
<a href="#">sip-server-address</a>	IPv6 address of SIP outbound proxy server.	22
<a href="#">sip-server-domain-name</a>	Domain name of the SIP outbound proxy server.	21
<a href="#">t1-percentage</a>	Percentage of the <b>preferred-lifetime</b> that the client (router) waits before sending renew messages to the DHCPv6 server that granted the original lease to extend the client's lease.	–
<a href="#">t1-renewal-time</a>	Time that the client (router) waits before sending renew messages to extend the client's lease. The renew messages are sent to the DHCPv6 server that granted the original lease.  This attribute is an alternative to <b>t1-percentage</b> .	–
<a href="#">t2-percentage</a>	Percentage of the <b>preferred-lifetime</b> that the client (router) waits before sending rebind messages to any available DHCPv6 server to extend the client's lease.	–
<a href="#">t2-rebinding-time</a>	Time that the client (router) waits before sending rebind messages to extend the client's lease. The rebind messages are sent to any available DHCPv6 server.  This attribute is an alternative to <b>t2-percentage</b> .	–
<a href="#">valid-lifetime</a>	Length of time that the address remains in the valid state. When the lifetime expires, the address becomes invalid.	–

## Configuring DHCP Attributes for All Clients or a Group of Clients

You can configure DHCP client attributes to determine the scope of the client operation. For example, you can configure attributes that set the maximum lease time or preferred lifetime of the lease, the domain in which to search for DHCP servers, the match criteria that determine the address range to use from within an address pool, and so on.

You can configure DHCP attributes to be applied to clients in the following ways:

- Globally to all clients or only to clients in specific groups.
- By an address-assignment pool; the attributes apply only to clients that receive addresses from a specific address assignment pool. See [“Configuring DHCP Client-Specific Attributes Applied When Clients Obtain an Address”](#) on page 299 for more information about this method.

To assign attributes globally or to a group:

1. Create a DHCP attribute set that you want to apply to clients with the DHCPv4 or DHCPv6 local server.

```
[edit access]
user@host# edit protocol-attributes attribute-set-name
```

2. Specify the attributes to include in the attribute set.

```
[edit access protocol-attributes attribute-set-name]
user@host# set attribute
```

3. Apply the attribute set to the desired DHCP clients.

- To all DHCPv4 clients:

```
[edit system services dhcp-local-server overrides]
user@host# set protocol-attributes attribute-set-name
```

- To a group of DHCPv4 clients:

```
[edit system services dhcp-local-server group group-name overrides]
user@host# set protocol-attributes attribute-set-name
```

- To all DHCPv6 clients:

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set protocol-attributes attribute-set-name
```

- To a group of DHCPv6 clients:

```
[edit system services dhcp-local-server dhcpv6 group group-name overrides]
user@host# set protocol-attributes attribute-set-name
```

For example, the following configuration creates an attribute set named `attr-v4-1` and applies the set to all DHCPv4 clients.

```
[edit]
user@host# set access protocol-attributes attr-v4-1 maximum-lease-time seconds
user@host# set access protocol-attributes attr-v4-1 t1-renewal-time 120000
user@host# set system services dhcp-local-server overrides protocol-attributes attr-v4-1
```

## Configuring DHCP Client-Specific Attributes Applied When Clients Obtain an Address

You use the address-assignment pool feature to include DHCP attributes specific to the client when clients obtain an address. The DHCP client application uses the attributes to determine how addresses are assigned, and to also provide optional characteristics to the client. For example, the DHCP application might specify that a client that matches certain prerequisite information is dynamically assigned an address from a particular named range. Based on which named range is used, DHCP specifies additional DHCP attributes such as the boot file that the client uses, the lease grace period, and the maximum lease time.

You use the **dhcp-attributes** statement to configure DHCP client-specific attributes for address-assignment pools. “Attributes That Can Be Applied to DHCP Clients” on page 296 describes the supported attributes you can configure for IPv4 and IPv6 address-assignment pools (or optionally assign to all clients or clients in a group).

To configure address-assignment pool attributes for DHCP clients:

1. Specify the name and IP family of the address-assignment pool.

```
[edit access]
user@host# edit address-assignment pool pool-name family inet
```

2. Configure optional DHCP client attributes.

```
[edit access address-assignment pool isp_1 family inet]
user@host# set dhcp-attributes attribute1 value1 attribute 2 value2 attribute 3 value3
```

For example, the following configuration specifies values for the boot server, grace period, and maximum lease time for the isp1 pool for DHCPv4:

```
[edit access]
user@host# edit address-assignment pool isp_1 family inet
[edit access address-assignment pool isp_1 family inet]
user@host# set dhcp-attributes boot-server 192.168.200.100 grace-period 3600
maximum-lease-time 18000
```

**NOTE:** The DNS name server addresses that are configurable as DHCP attributes can also be configured globally at the routing instance level and in access profiles. For more information, see “DNS Name Server Address Overview” on page 589.

## Configuring How the Extended DHCP Local Server Determines Which Address-Assignment Pool to Use

You can specify the match order in which the extended DHCP local server uses the client data to determine the address-assignment pool that provides the IP address and configuration for a DHCP client. You use the **pool-match-order** statement to specify the match order. If you do not specify the **pool-match-order**, the router (or switch) uses the default **ip-address-first** matching to select the address pool. After DHCP local server determines the address assignment pool to use, the server performs the matching based on the criteria you specified in the pool configuration.

In the default **ip-address-first** matching, the server selects the address-assignment pool to use by matching the IP address in the client DHCP request with the network address of the address-assignment pool. If the client request contains the gateway IP address (giaddr), the local server matches the giaddr to the address-assignment pool's address. If there is no giaddr in the request, then the DHCP local server matches the IP address of the receiving interface to the address of the address-assignment pool.

In **external-authority** matching, the DHCP local server receives the address assignment from an external authority, such as RADIUS or Diameter. If RADIUS is the external authority, the DHCP local server uses the Framed-IPv6-Pool attribute (RADIUS attribute 100) to select the pool. If Diameter is the external authority, the server uses the Diameter counterpart of the Framed-IPv6-Pool attribute to determine the pool.

For IPv4 address-assignment pools, you can optionally configure the extended DHCP local server to match the DHCP relay agent information option (option 82) in the client DHCP packets to a named range in the address-assignment pool used for the client. Named ranges are subsets within the overall address-assignment pool address range, which you can configure when you create the address-assignment pool.

**NOTE:** To use the DHCP local server option 82 matching feature with an IPv4 address-assignment pool, you must ensure that the **option-82** statement is included in the **dhcp-attributes** statement for the address-assignment pool.

To configure the matching order the extended DHCP local server uses to determine the address-assignment pool used for a client:

1. Access the **pool-match-order** configuration.

```
[edit system services dhcp-local-server]
user@host# edit pool-match-order
```

2. Specify the pool matching methods in the order in which the router (switch) performs the methods. You can specify the methods in any order. All methods are optional—the router (switch) uses the **ip-address-first** method by default.

- Configure the router (switch) to use an external addressing authority.

```
[edit system services dhcp-local-server pool-match-order]
user@host# set external-authority
```

- Configure the router (switch) to use the ip-address-first method.

```
[edit system services dhcp-local-server pool-match-order]
user@host# set ip-address-first
```

- (IPv4 address-assignment pools only) Specify the option 82 matching method.

```
[edit system services dhcp-local-server pool-match-order]
user@host# set option-82
```

## Assign a Specific IP Address to a Client Using DHCP Option 50 and DHCPv6 IA\_NA Option

Subscriber management or DHCP management enables you to specify that DHCP local server assign a particular address to a client. For example, if a client is disconnected, you

might use this capability to assign the same address that the client was using prior to being disconnected. If the requested address is available, DHCP assigns it to the client. If the address is unavailable, the DHCP local server offers another address, based on the address allocation process.

Both DHCP local server and DHCPv6 local server support the specific address request feature. DHCP local server uses DHCP option 50 in DHCP discover messages to request a particular address, while DHCPv6 local server uses the IA\_NA option (Identity Association for Non-Temporary Addresses) in DHCPv6 solicit messages.

**NOTE:** Subscriber management (DHCP management) supports only one address for each of the DHCPv6 IA\_NA or IA\_PD address types. If the DHCPv6 client requests more than one address for a given type, the DHCPv6 local server uses only the first address and ignores the other addresses.

---

## Specifying the Subnet for DHCP Client Address Assignment

Subscriber management enables you to explicitly specify the subnet to which the DHCP local server matches the requested IP address. The server accepts and uses an active client's requested IP address for address assignment only when the requested address and the IP address of the DHCP server interface are in the same subnet. The server accepts and uses a passive client's requested IP address only when the requested address and the IP address of the relay interface are in the same subnet. The DHCPv6 local server supports the same process for DHCPv6 clients and addresses.

To specify the subnet used for client address assignment:

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set requested-ip-network-match 10
```

- For DHCPv6 local server:

```
[edit forwarding-options dhcp-local-server dhcpv6]
user@host# set requested-ip-network-match 30
```

## DHCP Local Server Handling of Client Information Request Messages

DHCP clients that already have externally provided addresses may solicit further configuration information from a DHCP server by sending a DHCP inform or DHCPv6 information-request message that indicates what information is desired. These message types can be collectively referred to as information request messages. By default, DHCP local server and DHCPv6 local server ignore any DHCP information requests that they receive. You can override this default behavior to enable processing of these messages.

If you enable processing of information requests, DHCP local server responds to the client with a DHCP acknowledgment message that includes the requested information—if it is available. DHCPv6 local server responds in the same manner but uses a DHCP reply

message. No subscriber management or DHCP-management is applied as a result of the DHCP information request message.

By default, DHCP relay and DHCP relay proxy automatically forward DHCP information request messages without modification if the messages are received on an interface configured for a DHCP server group. DHCP relay and relay proxy drop information request messages received on any other interfaces. You cannot disable this default DHCP relay and relay proxy behavior.

The information requested by these clients is typically configured with the **dhcp-attributes** statement for an address pool defined by the **address-assignment pool pool-name** statement at the **[edit access]** hierarchy level.

When you enable processing of DHCP information requests, you can optionally specify the name of the pool from which the local server retrieves the requested configuration information for the client. If you do not specify a local pool, then the local server requests that AAA selects and returns only the name of the relevant pool.

**NOTE:** PPP interfaces are not supported on EX Series switches.

When DHCPv6 is configured over PPP interfaces, the PPP RADIUS authentication data can be used to select the pool from which the response information is taken. Additionally other RADIUS attributes can also be inserted into the DHCPv6 reply message. If an overlap exists between RADIUS attributes and local pool attributes, the RADIUS values are used instead of the local configuration data. If no RADIUS information is received from the underlying PPP interface, then the behavior is the same as described previously for non-PPP interfaces.

## Enabling Processing of Client Information Requests

By default, DHCP local server and DHCPv6 local server do not respond to information request (DHCP inform and DHCPv6 information-request) messages from the client. You can enable DHCP local server and DHCPv6 local server to process these messages and respond to them with an acknowledgment (ack or reply message, respectively) and the requested information.

DHCP relay agent automatically forwards the information request messages without modification to the configured server group by means of the interfaces configured for the respective server group. The messages are dropped if they are received on an unconfigured interface. DHCP relay proxy also supports forwarding these messages. You cannot disable forwarding of the information request messages.

Configure one or more local address pools if you want to use a local pool rather than one provided by AAA. See [“Configuring an Address-Assignment Pool Name and Addresses” on page 571](#). For processing information request messages, the address configuration is not necessary. For DHCP local server, you must specify the IPv4 family; for DHCPv6 local server, you must specify the IPv6 family.

See [“Configuring DHCP Client-Specific Attributes Applied When Clients Obtain an Address” on page 299](#) for details about how to configure the information sought by clients that send information request messages.

To enable processing of DHCP client information request messages:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server overrides]
user@host# set process-inform
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set process-inform
```

2. (Optional) Specify a pool name from which DHCP information is returned to the client.

- For DHCP local server:

```
[edit system services dhcp-local-server overrides process-inform]
user@host# set pool pool-name
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6 overrides process-inform]
user@host# set pool pool-name
```

## DNS Address Assignment Precedence

Subscriber management supports four methods for assigning addresses to DHCP clients. When multiple methods are configured, the router uses the following precedence order to determine which address to assign to the client.

1. Address defined on the RADIUS server by Internet Assigned Numbers Authority (IANA) vendor ID 4874 attributes 26-4 (Primary-DNS) and 26-5 (Secondary-DNS).
2. Address defined on the RADIUS server by IANA vendor ID 2636 attributes 26-31 (Primary-DNS) and 26-33 (Secondary-DNS).
3. Address defined on the RADIUS server by IANA vendor ID 311 attributes 26-28 (MS-Primary-DNS-Server) and 26-29 (MS-Secondary-DNS-Server).
4. Address defined in the local address pool on the router.

## Example: Extended DHCP Local Server Configuration with Optional Pool Matching

This example shows an extended DHCP local server configuration that includes optional IPv4 address-assignment pool matching and interface groups. For pool matching, this configuration specifies that the DHCP local server first check the response from an external authentication authority (for example, RADIUS) and use the Framed-IPv6-Pool attribute to determine the address-assignment pool to use for the client address. If no

external authority match is found, the DHCP local server then uses ip-address-first matching together with the option 82 information to match the named address range for client IPv4 address assignment. The option 82 matching must also be included in the address-assignment pool configuration.

```
[edit system services]
dhcp-local-server {
  group group_one {
    interface fe-0/0/2.0;
    interface fe-0/0/2.1;
  }
  group group_two {
    interface fe-0/0/3.0;
    interface fe-0/0/3.1;
  }
  pool-match-order {
    external-authority
    ip-address-first;
    option-82;
  }
}
```

**NOTE:** The interface type in this topic is just an example. The fe- interface type is not supported by EX Series switches.

## DHCP Lease Times for IP Addresses

- [DHCP Lease Timers on page 306](#)
- [DHCP Lease-Time Validation Overview on page 307](#)
- [Configuring a DHCP Lease-Time Threshold on page 308](#)
- [DHCP Asymmetric Leasing Overview on page 309](#)
- [Configuring DHCP Asymmetric Leasing on page 310](#)

## DHCP Lease Timers

Subscriber management supports configurable timers that you can use to manage the DHCPv4 and DHCPv6 address leases provided by address-assignment pools. In addition to the maximum-lease-time timer, which sets the maximum time for which the DHCP local server can grant a lease, you can use DHCP client-specific attributes to configure timers that govern the lifetimes of existing leases that have been obtained from an address-assignment pool. Starting in Junos OS Release 17.2R1, this feature is supported for both DHCPv4 and DHCPv6; in earlier releases, only DHCPv6 is supported.

The following list describes the configurable timers for DHCPv4 and DHCPv6 address-assignment pools:

- **preferred-lifetime**—Length of time that a valid address is in the preferred state and can be used without any restrictions. When the preferred-lifetime expires, the address becomes deprecated. A deprecated address should not be used for new communications, but might continue to be used for existing communications in certain cases.

If the valid-lifetime is also configured, the preferred-lifetime must be less than the valid-lifetime. The preferred-lifetime and the maximum-lease-time are mutually exclusive and cannot both be configured.

- **valid-lifetime**—Length of time that an address remains in the valid state, during which the address can be used for new or existing communications. When the valid-lifetime expires, the address becomes invalid, and can no longer be used.

If the preferred-lifetime is also configured, the valid-lifetime must be greater than the preferred-lifetime. The valid-lifetime and the maximum-lease-time are mutually exclusive and cannot both be configured.

- **t1 percentage**—Percentage of the **preferred-lifetime** that the client waits before contacting the DHCP local server that originally granted the lease to request that the address lease be extended. T1 is also called the renewal time.
- **t1-renewal-time**—Time in seconds that the client waits before contacting the DHCP local server that originally granted the lease to request that the address lease be extended. T1 is also called the renewal time.
- **t2 percentage**—Percentage of the **preferred-lifetime** that the client waits before sending a request to any available DHCP local server to extend the address lease. T2 is also called the rebind time.
- **t2-rebinding-time**—Time in seconds that the client waits before broadcasting a request to all available DHCP local servers to request that the address lease be extended. T2 is also called the rebind time.

---

### Benefits of Configuring DHCP Timers in Address Pools

Using address pools to configure values for these timers gives you fine-grained control over which clients get specific values.

## DHCP Lease-Time Validation Overview

In a subscriber access environment, a DHCP server obtains an address lease from either local configuration or from an external DHCP server, and assigns the lease to the DHCP client address.

Obtaining leases from external sources can present issues when the external source is owned or managed by a third party—the third party might configure the external source to provide address leases that are unsuitable for the subscriber access environment. For example, extremely short lease times can create unnecessary traffic that results in reduced performance in the network.

To avoid potential issues caused by short DHCP lease times, subscriber management provides a lease-time validation feature. Lease-time validation enables you to explicitly configure a threshold for the minimum lease time allowed in your subscriber access environment, and to specify a violation action (such as dropping the lease offer) the router takes when a short lease time is offered by a third party. You can specify the following violation actions:

- **drop**—(DHCPv4 and DHCPv6 relay agent) The third-party lease offer is dropped and the client binding fails.
- **override-lease**—(DHCPv4 and DHCPv6 local server) The third-party lease time is overridden by the specified threshold value.
- **strict**—(DHCPv4 and DHCPv6 local server) The third-party lease is ignored and the client binding fails.
- **no action**—If you do not specify a violation action, DHCP binds the client using the third-party lease but marks the binding as lease-time violating.

A lease-time violation can occur during the initial lease grant or during a rebinding or renewal operation. To reduce excessive and redundant log messages, the router consolidates lease-time violation reporting, as shown in [Table 36 on page 307](#).

**Table 36: Lease-Time Violation Event Logging**

Event	syslog	Extended DHCP Traceoptions
Initial lease-time violation for the specific DHCP server	warning	warning
Number of lease-time violations return to zero for the specific DHCP server	warning	warning
Status of lease-time violations caused by specific DHCP server, reported in the interval configured in <b>ltv-syslog-interval</b> command	warning	—
Violation action of <b>drop</b> occurred, or the DHCP packet was not generated	—	warning

Table 36: Lease-Time Violation Event Logging (continued)

Event	syslog	Extended DHCP Traceoptions
Violation action of <b>override-lease</b> occurred (DHCP local server only)	–	warning
Lease-time violation	–	warning

## Configuring a DHCP Lease-Time Threshold

Starting in Junos OS Release 14.1, subscriber management provides a lease-time validation feature that enables you to specify the minimum DHCP lease time allowed in your subscriber access environment. When you configure lease-time validation, you specify the lease-time threshold and the action the router performs when an offered lease time is less than the threshold (such as dropping the lease).

Lease-time validation ensures that leases that are offered by third-party DHCP servers or address assignment pools always meet the requirements of your network. For example, you want short leases to be rejected because they can result in excessive renewal traffic that can impact network performance.

You can configure lease-time validation on DHCPv4 and DHCPv6 local servers, and DHCPv4 and DHCPv6 relay agents, and for individual interfaces or interface groups. DHCP relay proxy also supports lease-time validation.

The following procedure describes the steps you use to configure lease-time validation. This example describes a configuration for DHCP relay agent. You use similar steps at the appropriate hierarchy levels for DHCP local server, DHCPv6 local server, and DHCPv6 relay agent.

To configure lease time validation for DHCP relay agent:

1. Specify that you want to configure DHCP relay agent support.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Specify that you want to configure the DHCP lease time validation feature.

```
[edit forwarding-options dhcp-relay]
user@host# set lease-time-validation
```

3. Configure the threshold that specifies the minimum DHCP client lease time allowed in your network.

```
[edit forwarding-options dhcp-relay lease-time-validation]
user@host# set lease-time-threshold 3600
```

4. Configure the action the router takes when a lease time violation occurs.

```
[edit forwarding-options dhcp-relay lease-time-validation]
user@host# set violation-action drop
```

**NOTE:** DHCP relay agent and DHCP local server support different violation actions. See the `violation-action` statement for descriptions of the actions.

If a lease violation occurs when you have not configured a violation action, DHCP binds the client using the third-party lease. DHCP then marks the binding as having violated the lease time.

5. (Optional) Configure how often you want the router to consolidate and log syslog warning messages.

```
[edit system processes dhcp-service]
user@host# set ltv-syslog-interval 3600
```

## DHCP Asymmetric Leasing Overview

Starting in Junos OS Release 17.1R1, *asymmetric leasing* provides a way to send a DHCP client a lease that is shorter than the actual lease granted by the DHCP local server. In some networks, you might need to change an existing DHCP address assignment before the granted lease time has expired, or learn as soon as possible that a client is no longer using an address. The shorter lease is called the *asymmetric lease* or the *short lease*. The originally granted lease is called the *long lease* or simply, the lease.

You can configure asymmetric leasing on either the DHCP relay agent or the DHCP local server. In a typical configuration, you configure it on the relay agent. When the DHCP local server receives a discover packet from a DHCP client, it returns an offer packet to the client. The client selects a local server and requests an address assignment. The DHCP local server sends an acknowledgment packet containing the address, lease duration and other information to the client. Rather than forwarding this packet, the relay agent saves the lease information and then generates a new acknowledgment packet with a short lease and forwards that to the client.

When the DHCP client makes a subsequent request for lease renewal, the relay agent does not pass the request to the local server. Instead, the relay agent recreates the short lease from the saved information and returns it to the client in an acknowledgment packet. The relay agent continues to renew the short leases for the client until the long lease renew time expires. By default, the long lease renew time is equal to one-half the duration of the long lease.

When the long lease renew time expires, the asymmetric lease is no longer valid. Subsequent renewal requests from the client are forwarded by the relay agent to the local server. If the local server acknowledges the request, it renews the long lease and the process begins again, with the relay agent generating a short lease for the client instead of sending the long lease. Otherwise, the lease is not renewed.

With asymmetric leasing, there is also a renew time for the short lease. The client sends renewal requests to the relay agent at intervals equal to the short lease renew time. By default, this period is equal to one-half the short lease duration. If the DHCP client does not request renewal of the lease before the short lease time expires, the relay agent notifies the local server that the lease is no longer in use and the address can be reassigned.

### Benefits of Asymmetric DHCP Lease Timing

---

- Allows the early renewal of DHCP client leases without requiring device support for a forced renewal. Because the lease can be administratively rescinded on the DHCP local server or DHCP relay agent, the next short-duration lease refresh cycle can trigger a full renegotiation of the client lease. This capability reduces the number of devices that must be managed to trigger a new address allocation cycle.
- Enables early detection of inactive client leases. The asymmetric lease includes an upstream notification from the DHCP client back to the lease grantor, effectively providing a liveness detection that enables unused addresses to be reclaimed sooner. Because this mechanism is all within DHCP, the service provider does not have to rely on the set of devices involved in address allocation to be configured with other protocols that support some kind of liveness detection, such as bidirectional forwarding detection (BFD).

## Configuring DHCP Asymmetric Leasing

You can configure asymmetric leasing to provide a DHCP or DHCPv6 client with a lease that is shorter than the lease granted by the DHCP local server. The shorter lease duration means that the client must renew the lease more frequently. When it does not renew the lease, the address is freed up sooner than when the client uses the original long lease. You configure asymmetric leasing by overriding the DHCP configuration at the global level, for a named group of interfaces, or for a specific interface within a named group.

**NOTE:** For simplicity, the procedures in this topic show only the global-level configuration. For information about overriding the DHCP configuration at other levels, see [“Overriding the Default DHCP Relay Configuration Settings” on page 246](#) and [“Overriding the Default DHCP Local Server Configuration Settings Overview” on page 243](#).

You can configure asymmetric leasing on either the DHCP relay agent or the DHCP local server. For most networks, the relay agent configuration is more useful.

To configure asymmetric leasing for DHCP relay agent for DHCPv4:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]  
user@host# edit overrides
```

2. Configure the duration of the short (asymmetric) lease.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set asymmetric-lease-time seconds
```

To configure asymmetric leasing for DHCP relay agent for DHCPv6:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

2. Configure the duration of the short (asymmetric) lease for DHCPv4 clients and separately for DHCPv6 clients.

```
[edit forwarding-options dhcp-relay dhcpv6 overrides]
user@host# set asymmetric-lease-time seconds
user@host# set asymmetric-prefix-lease-time seconds
```

To configure asymmetric leasing for DHCP local server for DHCPv4:

1. Specify that you want to configure override options.

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

2. Configure the duration of the short (asymmetric) lease.

```
[edit system services dhcp-local-server overrides]
user@host# set asymmetric-lease-time seconds
```

To configure asymmetric leasing for DHCP local server for DHCPv6:

1. Specify that you want to configure override options.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Configure the duration of the short (asymmetric) lease for DHCPv4 clients and separately for DHCPv6 clients.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set asymmetric-lease-time seconds
user@host# set asymmetric-prefix-lease-time seconds
```

**Release History Table**

Release	Description
17.2R1	Starting in Junos OS Release 17.2R1, this feature is supported for both DHCPv4 and DHCPv6; in earlier releases, only DHCPv6 is supported.
17.1	Starting in Junos OS Release 17.1R1, <i>asymmetric leasing</i> provides a way to send a DHCP client a lease that is shorter than the actual lease granted by the DHCP local server.
14.1	Starting in Junos OS Release 14.1, subscriber management provides a lease-time validation feature that enables you to specify the minimum DHCP lease time allowed in your subscriber access environment.

## DHCP Leasequery and Bulk Leasequery

In a subscriber access network, a DHCP server maintains a significant amount of information related to the IP addresses or DHCPv6 delegated prefixes that the server has leased to DHCP clients. When DHCP clients are connected to the DHCP server by way of a DHCP relay, the DHCP relay also maintains the same lease and route information as the DHCP server, and uses that information when providing subscriber services for the clients.

Starting in Junos OS Release 16.1, subscriber management supports the leasequery feature to enable the DHCP relay to quickly and efficiently obtain the current lease information from a DHCP server. DHCP relay typically uses leasequery to restore the relay's lease information database when the information has been lost; such as after the DHCP relay has been rebooted or replaced. Subscriber management supports two types of leasequery operations—the traditional individual leasequery, which updates lease information related to a specific client, and a more powerful bulk leasequery.

Bulk leasequery enables the DHCP relay agent to retrieve bulk lease information for a group of subscribers from a configured DHCP server in a programmed manner that is more resource-efficient than the individual leasequery method. Bulk leasequery uses a TCP connection between the DHCP relay agent and a configured DHCP server in the same logical system/routing instance. The TCP connection is more reliable and consumes less resources than the UDP connection used for the individual leasequery process. Bulk leasequery also extends the individual leasequery by providing additional query options and functionality, as opposed to the individual leasequery, which queries the individual binding for a known target only.

To configure individual leasequery or bulk leasequery operation, you enable support on both the DHCP relay agent and the DHCP server, and you specify the query options you want the query operation to use. Once the options are configured, you invoke the appropriate CLI **request** command to initiate the bulk or individual leasequery operation.

For a DHCPv6 bulk leasequery, you can optionally configure the DHCPv6 relay agent to automatically initiate the bulk leasequery operation whenever the **jdhcpd** process starts a connection with the session database (SDB) and there are no bound subscribers in the database. For example, the automatic process would ensure that the bulk leasequery always updates the DHCP relay information after a reboot, GRES, or ISSU operation, and if there are no bound subscribers.

## Guidelines for Configuring Support for Leasequery and Bulk Leasequery Operations

When configuring individual or bulk leasequery support, consider the following guidelines:

- The router supports simultaneous configuration of both individual leasequery and bulk leasequery.
- The router supports simultaneous dual-stack configuration for both DHCPv4 and DHCPv6. However, for dual stack environments, you must trigger the DHCPv4 and DHCPv6 individual leasequery or bulk leasequery operations separately.

- DHCP relay agent supports individual leasequery or bulk leasequery over static and dynamic interfaces.
- DHCP local server supports bulk leasequery on static relay-facing interfaces only.
- DHCP local server listens for bulk leasequery requests from the DHCP relay agent on TCP port 547 for DHCPv6, and on TCP port 67 for DHCPv4.
- Bulk leasequery is not supported for DHCP over PPP/PPPoE.
- If the network includes integrated routing and bridging (IRB) interfaces, you must configure DHCP relay agent to include the layer 2 interface name along with IRB name in the circuit ID of option 82. DHCP relay agent uses the layer 2 interface name when using leasequery or bulk leasequery to restore the lease database.

## Configuring and Using DHCP Individual Leasequery

The individual leasequery operation updates a DHCP relay agent's lease database with information related to a single, specified subscriber. You identify DHCPv4 subscribers by IPv4 address, MAC address, or client ID. You identify DHCPv6 subscribers by IPv6 address or client ID.

Before you begin, ensure that the following required support is configured on the DHCP relay agent.

- (DHCPv4 only) DHCP relay agent inserts option 82 suboption 1 (Agent Circuit ID), in the DHCP packets that the relay forwards to DHCP servers. See [“Using DHCP Relay Agent Option 82 Information” on page 282](#).

If the network includes integrated routing and bridging (IRB) interfaces, you must also include the **include-irb-and-l2** statement, as shown in the following example. This statement configures DHCP relay agent to include the layer 2 interface name along with IRB name in the circuit ID of option 82. DHCP relay agent uses the layer 2 interface name when restoring the lease database using leasequery or bulk leasequery.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option-82 circuit-id include-irb-and-l2
```

- (DHCPv4 only) DHCP relay agent always includes the new option 82 information in the DHCP packets that the relay forwards to DHCP servers. See [“Overriding Option 82 Information” on page 285](#).

```
[edit forwarding-options dhcp-relay]
user@host# set overrides always-write-option-82
```

- (DHCPv6 only) DHCP relay agent inserts the DHCPv6 Interface-ID (option 18) in the packets that the relay forwards to DHCPv6 servers. See [“Inserting DHCPv6 Interface-ID Option \(Option 18\) In DHCPv6 Packets” on page 394](#).

If your network includes integrated routing and bridging (IRB) interfaces, you must also include the **include-irb-and-l2** statement, as shown in the following example. This statement configures DHCPv6 relay agent to include the layer 2 interface name along with IRB name in the circuit ID of option 82. DHCP relay agent uses the layer 2 interface name when using leasequery or bulk leasequery to restore the lease database.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-interface-id include-irb-and-l2
```

Use the following steps to configure and use the individual leasequery operation.

1. Configure DHCP relay agent to support leasequery:

Configure the leasequery parameters the DHCP relay agent uses when querying the DHCP local servers. The following steps describe the configuration for DHCPv4. For DHCPv6, use the procedure at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

a. Specify that you want to configure leasequery options for the DHCP relay agent.

```
[edit forwarding-options dhcp-relay]
user@host# edit leasequery
```

b. Specify the number of seconds DHCP relay waits before resending leasequery messages to the configured DHCP servers in the same logical system/routing instance.

```
[edit forwarding-options dhcp-relay leasequery]
user@host# set timeout 8
```

c. Specify the number of times DHCP relay resends leasequery messages. DHCP relay resends the messages when the configured timeout value expires. The messages are resent if the DHCP relay has not received confirmed lease information for a client.

```
[edit forwarding-options dhcp-relay leasequery]
user@host# set attempts 3
```

2. Configure DHCP local server to support leasequery:

Configure the leasequery parameters the DHCP local server uses when responding to leasequery messages from a DHCP relay agent. The following steps describe the configuration for DHCPv4. For DHCPv6, use the procedure at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

a. Enable leasequery support for the DHCP local server.

```
[edit system services dhcp-local-server]
user@host# edit allow-leasequery
```

b. (Optional) Specify that the DHCP local server responds to a leasequery by sending the binding information only to restricted requestors. For DHCPv4, restricted requestors are those whose giaddr matches the giaddr of the client. For DHCPv6, the client ID of the request must match the relay ID of the client. This step provides

additional security by ensuring that the requestor is the originator of the binding request.

```
[edit system services dhcp-local-server allow-leasequery]
user@host# set restricted-requestor
```

3. Initiate the leasequery operation on the DHCP relay agent.

See [“Initiating DHCP Leasequery to Update the DHCP Relay Agent Lease Database” on page 320](#). DHCP relay agent uses the specified options when sending the leasequery messages to all configured DHCP local servers in the same logical system/routing instance.

Use the supported **show** and **clear** commands to manage and display information about the leasequery operation for the DHCP relay agent and the DHCP local server. See [“Verifying and Managing DHCP Leasequery and Bulk Leasequery Configuration” on page 321](#).

## Configuring and Using DHCP Bulk Leasequery

The bulk leasequery operation updates a DHCP relay agent's lease database with information for multiple subscribers, as opposed to the individual leasequery, which queries individual bindings for known targets only. Bulk leasequery also extends the individual leasequery by providing additional query options and functionality.

You use the following steps to configure and use bulk leasequery.

Before you begin, ensure that the following required support is configured on the DHCP relay agent.

- (DHCPv4 only) DHCP relay agent inserts option 82 suboption 1 (Agent Circuit ID), in the DHCP packets that the relay forwards to DHCP servers. See [“Using DHCP Relay Agent Option 82 Information” on page 282](#).

If the network includes integrated routing and bridging (IRB) interfaces, you must also include the **include-irb-and-l2** statement, as shown in the following example. This statement configures DHCPv6 relay agent to include the layer 2 interface name along with IRB name in the circuit ID of option 82. DHCP relay agent uses the layer 2 interface name when using leasequery or bulk leasequery to restore the lease database.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option-82 circuit-id include-irb-and-l2
```

- (DHCPv4 only) DHCP relay agent always includes the new option 82 information in the DHCP packets that the relay forwards to DHCP servers. See [“Overriding Option 82 Information” on page 285](#).

```
[edit forwarding-options dhcp-relay]
user@host# set overrides always-write-option-82
```

- (DHCPv6 only) DHCP relay agent inserts the DHCPv6 Interface-ID (option 18) in packets forwarded to DHCPv6 servers. See [“Inserting DHCPv6 Interface-ID Option \(Option 18\) In DHCPv6 Packets” on page 394.](#)

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-interface-id
```

If your network includes integrated routing and bridging (IRB) interfaces, you must also include the **include-irb-and-l2** statement, as shown in the following example. This statement configures DHCPv6 relay agent to include the layer 2 interface name along with IRB name in the circuit ID of option 82. DHCP relay agent uses the layer 2 interface name when using leasequery or bulk leasequery to restore the lease database.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-interface-id include-irb-and-l2
```

Use the following steps to configure and use the bulk leasequery operation.

1. Configure the number of connections that the router can use for bulk leasequery.

Specify the maximum number of TCP connections the DHCP local server can simultaneously accept for bulk leasequery operations, and the number of simultaneous connections that the DHCP relay agent can request for bulk leasequery. This is a chassis-wide configuration and includes all logical systems/routing instances, and all address families.

```
[edit system processes dhcp-service]
user@host# set accept-max-tcp-connections 6
user@host# set request-max-tcp-connections 7
```

2. Configure DHCP relay agent to support bulk leasequery:

Configure the bulk leasequery parameters the DHCP relay agent uses when querying the DHCP local servers. The following steps describe the configuration for DHCPv4. For DHCPv6, use the procedure at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

- a. Specify that you want to configure bulk leasequery options for the DHCP relay agent.

```
[edit forwarding-options dhcp-relay]
user@host# edit bulk-leasequery
```

- b. Specify the number of seconds DHCP relay waits before retrying the TCP connection to send bulk leasequery messages to the configured DHCP servers in the same logical system/routing instance.

```
[edit forwarding-options dhcp-relay bulk-leasequery]
user@host# set timeout 5
```

- c. Specify the number of times DHCP relay attempts the TCP connection with the server to send bulk leasequery messages. DHCP relay resends the messages when the configured timeout value expires. The TCP connection is reestablished only to DHCP servers to which the connection failed or was abruptly closed.

```
[edit forwarding-options dhcp-relay bulk-leasequery]
user@host# set attempts 6
```

- d. (Optional, DHCPv6 only) Specify the optional automatic trigger. The automatic trigger configures DHCPv6 relay agent to automatically initiate bulk leasequery whenever the jdchp daemon starts (for example, after a reboot, a graceful Routing Engine switchover, or unified ISSU) and there are no bound subscribers in the session database. When the automatic trigger support is configured, you can still use the CLI command to manually trigger bulk leasequery.

```
[edit forwarding-options dhcp-relay bulk-leasequery]
user@host# set trigger automatic
```

3. Configure DHCP local server to support bulk leasequery:

Configure the parameters the DHCP local server uses when responding to bulk leasequery messages from a DHCP relay. The following steps describe the configuration for DHCPv4. For DHCPv6, use the procedure at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

- a. Enable bulk leasequery support for the DHCP local server.

```
[edit system services dhcp-local-server]
user@host# edit allow-bulk-leasequery
```

- b. (Optional) Specify the maximum number of concurrent TCP connections allowed in the DHCP local server's logical system/routing instance:

```
[edit system services dhcp-local-server allow-bulk-leasequery]
user@host# set max-connections 5
```

- c. (Optional) Specify the maximum number of empty replies that the DHCP local server sends to a specific requestor. When the maximum number of replies is reached, the DHCP server closes the connection.

An empty reply is a response that contains no bindings or has an option status code error. Empty replies are often a response to an unauthorized requestor that has sent an invalid or incorrect query. By limiting the number of empty replies that the DHCP local server sends, you prevent the connection from being consumed by unauthorized or malicious requesters.

```
[edit system services dhcp-local-server allow-bulk-leasequery]
user@host# set max-empty-replies 4
```

- d. (Optional) Specify that the DHCP local server sends the binding information to restricted requestors only. This step ensures that the requestor is the originator of the binding request,

For DHCPv4 leasequery and bulk leasequery requests, the giaddr of the requestor must match the giaddr of the client. For DHCPv6 bulk leasequery requests, the requestor's client ID in the bulk leasequery message must match the relay ID that was sent during binding creation.

```
[edit system services dhcp-local-server allow-bulk-leasequery]
user@host# set restricted-requestor
```

- e. (Optional) Specify the number of seconds that a connection on the TCP socket is idle before the DHCP local server closes the connection.

```
[edit system services dhcp-local-server allow-bulk-leasequery]
user@host# set timeout 90
```

4. Initiate the bulk leasequery operation on the DHCP relay agent.

DHCP relay agent uses the specified options when sending the bulk leasequery messages to all configured DHCP local servers in the same logical system/routing instance.

- Automatically initiating bulk leasequery—When the automatic trigger feature is configured, DHCP relay agent initiates the bulk leasequery whenever the jdhcpd process starts and there are no bound subscribers in the session database.
- Manually initiating bulk leasequery—Use the appropriate CLI command to manually initiate bulk leasequery. See [“Initiating DHCP Leasequery to Update the DHCP Relay Agent Lease Database” on page 320](#).

Use the supported **show** and **clear** commands to manage and display information about the bulk leasequery operation for the DHCP relay agent and the DHCP local server. See [“Verifying and Managing DHCP Leasequery and Bulk Leasequery Configuration” on page 321](#).

## Initiating DHCP Leasequery to Update the DHCP Relay Agent Lease Database

You can manually request that DHCP relay agent initiate an individual leasequery or bulk leasequery operation, which requests current lease information from DHCP local servers.

A leasequery updates the DHCP relay agent's lease database with information for an individual client—for DHCPv4, you can specify clients by IP address, MAC address or client ID. For DHCPv6, you can identify clients by IPv6 prefix or client ID.

A bulk leasequery updates the relay agent's lease database for a group of clients—for DHCPv4, you can specify clients by IPv4 address, MAC address or client ID. For DHCPv6, you can identify clients by IPv6 prefix, client ID, Relay-ID option, Relay Agent Remote-ID option, or IPv6 link address.

When you initiate a leasequery or bulk leasequery, you can optionally specify a particular DHCP server (by address), server group, routing instance, or logical system to be queried.

To initiate a DHCPv4 individual leasequery to update binding information:

- For a DHCPv4 client, based on the client's IP address:

```
user@host> request dhcp relay leasequery 192.168.10.34
```

- For a DHCPv4 client, based on the client's MAC address:

```
user@host> request dhcp relay leasequery 00:00:5E:00:53:cd
```

- For a DHCPv4 client, based on the client identifier option (option 61):

```
user@host> request dhcp relay leasequery 4/1224
```

To initiate a DHCPv6 individual leasequery to update binding information:

- For a DHCPv6 client, based on the client's IPv6 address:

```
user@host> request dhcpv6 relay leasequery 2001:db8:1001::1
```

- For a DHCPv6 client, based on the client ID option (option 1):

```
user@host> request dhcpv6 relay leasequery 4/1224
```

To initiate a DHCPv4 bulk leasequery to update binding information:

- For a DHCPv4 client, based on the client identifier option (option 61):

```
user@host> request dhcp relay bulk-leasequery 4/1224
```

- For a DHCPv4 client, based on the client's MAC address:

```
user@host> request dhcp relay bulk-leasequery 00:00:5E:00:53:cd
```

To initiate a DHCPv6 bulk leasequery to update binding information:

- For a DHCPv6 client, based on the client ID option (option 1):

```
user@host> request dhcpv6 relay bulk-leasequery 4/1223
```

- For DHCPv6 clients, based on IPv6 prefix:

```
user@host> request dhcpv6 relay bulk-leasequery 2001:db8:1001::1
```

- For DHCPv6 clients associated with the DHCPv6 relay identified in the specified Relay-ID option:

```
user@host> request dhcpv6 relay bulk-leasequery relay-id 4/2121
```

- For DHCPv6 clients associated with the specified IPv6 link address:

```
user@host> request dhcpv6 relay bulk-leasequery link-address 2001:db8:1001::1
```

- For DHCPv6 clients associated with the specified Relay Agent Remote-ID option:

```
user@host> request dhcpv6 relay bulk-leasequery remote-id host:ge-1/0/0:100
```

**NOTE:** If you use the `bulk-leasequery` command without specifying a remote ID, by default the DHCPv6 relay queries its one relay ID.

## Verifying and Managing DHCP Leasequery and Bulk Leasequery Configuration

**Purpose** View or clear information about DHCP leasequery and bulk leasequery operations.

Use the supported **show** and **clear** commands to manage and display information about the leasequery and bulk leasequery operations; for the DHCP relay agent and the DHCP local server.

- Action**
- To display leasequery and bulk leasequery information for DHCPv4 or DHCPv6 relay agent:

```
user@host> show dhcp relay statistics (leasequery | bulk-leasequery-connections)
user@host> show dhcpv6 relay statistics (leasequery | bulk-leasequery-connections)
```

- To clear leasequery and bulk leasequery information for DHCPv4 or DHCPv6 relay agent:

```
user@host> clear dhcp relay statistics (leasequery | bulk-leasequery-connections)
user@host> clear dhcpv6 relay statistics (leasequery | bulk-leasequery-connections)
```

- To display leasequery and bulk leasequery information for DHCPv4 or DHCPv6 local server:

```
user@host> show dhcp server statistics bulk-leasequery-connections
user@host> show dhcpv6 server statistics bulk-leasequery-connections
```

- To clear leasequery and bulk leasequery information for DHCPv4 or DHCPv6 local server:

```
user@host> clear dhcp server statistics bulk-leasequery-connections
user@host> clear dhcpv6 server statistics bulk-leasequery-connections
```

#### Release History Table

Release	Description
16.1	Starting in Junos OS Release 16.1, subscriber management supports the leasequery feature to enable the DHCP relay to quickly and efficiently obtain the current lease information from a DHCP server.

## DHCP Client Authentication With An External AAA Authentication Service

- [Using External AAA Authentication Services with DHCP on page 322](#)
- [Creating Unique Usernames for DHCP Clients on page 323](#)
- [Configuring Passwords for Usernames on page 326](#)

### Using External AAA Authentication Services with DHCP

The extended DHCP local server, including DHCPv6 local server, and the extended DHCP relay agent, including DHCPv6 relay agent, support the use of external AAA authentication services, such as RADIUS, to authenticate DHCP clients. When the extended DHCP local server or relay agent receives a discover PDU from a client, the extended DHCP application contacts the AAA server to authenticate the DHCP client. The extended DHCP application can obtain client addresses and DHCP configuration options from the external AAA authentication server.

**NOTE:** This section uses the term *extended DHCP application* to refer to both the extended DHCP local server and the extended DHCP relay agent.

The external authentication feature also supports AAA directed logout. If the external AAA service supports a user logout directive, the extended DHCP application honors the logout and responds as though it were requested by a CLI management command. All of the client state information and allocated resources are deleted at logout. The extended DHCP application supports directed logout using the list of configured authentication

servers you specify with the **authentication-server** statement at the **[edit access profile profile-name]** hierarchy level.

You can configure either global authentication support or group-specific support.

You must configure the **username-include** statement to enable the use of authentication. The **password** statement is not required and does not cause DHCP to use authentication if the **username-include** statement is not included.

To configure DHCP local server and DHCP relay agent authentication support:

1. Specify that you want to configure authentication options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit authentication
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit authentication
```

2. (Optional) Configure a password that authenticates the username to the external authentication service.

See [“Configuring Passwords for Usernames” on page 326](#).

3. (Optional) Configure optional features to create a unique username.

See [“Creating Unique Usernames for DHCP Clients” on page 323](#).

## Creating Unique Usernames for DHCP Clients

You can configure the extended DHCP application to include additional information in the username that is passed to the external AAA authentication service when the DHCP client logs in. This additional information enables you to construct usernames that uniquely identify subscribers (DHCP clients).

**NOTE:** If you do not include a username in the authentication configuration, the router (or switch) does not perform authentication; however, the IP address is provided by the local pool if it is configured.

When you use the DHCPv6 local server, you must configure authentication and the client username; otherwise client login fails.

The following list describes the optional information that you can include as part of the username:

- **circuit-type**—The circuit type used by the DHCP client, for example **enet**.
- **client-id**—The client identifier option (option 1). (DHCPv6 local server DHCPv6 relay agent only)
- **delimiter**—The delimiter character that separates components that make up the concatenated username. The default delimiter is a period (.). The semicolon (;) is not supported as a delimiter character.
- **domain-name**—The client domain name as a string. The router adds the @ delimiter to the username.
- **interface-description**—The description of the device (physical) interface or the logical interface.
- **interface-name**—The interface name, including the interface device and associated VLAN IDs.
- **logical-system-name**—The name of the logical system, if the receiving interface is in a logical system.
- **mac-address**—The client MAC address, in a string of the format **xxxx.xxxx.xxxx**.

For DHCPv6 clients, because the DHCPv6 packet format has no specific field for the client MAC address, the MAC address is derived from among several sources with the following priority:

- Client DUID Type 1 or Type 3.
- Option 79 (client link-layer address), if present.
- The packet source address if the client is directly connected.
- The link local address.
- **option-60**—The portion of the option 60 payload that follows the length field. (Not supported for DHCPv6 local server)
- **option-82 <circuit-id> <remote-id>**—The specified contents of the option 82 payload. (Not supported for DHCPv6 local server)
  - **circuit-id**—The payload of the Agent Circuit ID suboption.
  - **remote-id**—The payload of the Agent Remote ID suboption.

- Both **circuit-id** and **remote-id**—The payloads of both suboptions, in the format: **circuit-id[delimiter]remote-id**.
- Neither **circuit-id** or **remote-id**—The raw payload of the option 82 from the PDU is concatenated to the username.

**NOTE:** For DHCP relay agent, the option 82 value used in creating the username is based on the option 82 value that is encoded in the outgoing (relayed) PDU.

- **relay-agent-interface-id**—The Interface-ID option (option 18). (DHCPv6 local server or DHCPv6 relay agent only)
- **relay-agent-remote-id**—The DHCPv6 Relay Agent Remote-ID option (option 37). (DHCPv6 local server or DHCPv6 relay agent only)
- **relay-agent-subscriber-id**—(On routers only) The DHCPv6 Relay Agent Subscriber-ID option (option 38). (DHCPv6 local server or DHCPv6 relay agent only)
- **routing-instance-name**—The name of the routing instance, if the receiving interface is in a routing instance.
- **user-prefix**—A string indicating the user prefix.
- **vlan-tags**—The subscriber VLAN tags. Includes the outer VLAN tag and, if present, the inner VLAN tag. You can use this option instead of the **interface-name** option when the outer VLAN tag is unique across the system and you do not need the underlying physical interface name to be part of the format.

The router (switch) creates the unique username by including the specified additional information in the following order, with the fields separated by a delimiter.

For DHCP local server and DHCP relay agent:

```
user-prefix[delimiter]mac-address[delimiter]logical-system-name[delimiter]
routing-instance-name[delimiter]circuit-type[delimiter]interface-name[delimiter]option-82[delimiter]
option-60@domain-name
```

For DHCPv6 local server:

```
user-prefix[delimiter]mac-address[delimiter]logical-system-name[delimiter]routing-instance-name[delimiter]
circuit-type[delimiter]interface-name[delimiter]relay-agent-remote-id[delimiter]
relay-agent-subscriber-id[delimiter]relay-agent-interface-id[delimiter]client-id@domain-name
```

To configure a unique username:

1. Specify that you want to configure authentication.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit authentication
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit authentication
```

**NOTE:** You can also configure authentication and usernames for groups at additional hierarchy levels. See [authentication \(DHCP Local Server\)](#) and [authentication \(DHCP Relay Agent\)](#).

2. Specify that you want to include optional information in the username. (DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent all support the **username-include** statement.)

```
[edit system services dhcp-local-server authentication]
user@host# set username-include
```

3. (Optional) Specify the optional information you want to include in the username. DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent all support the **username-include** statement.

The following sample configuration produces this unique username:

**wallybrown.00:00:5e:00:53:ff.enet@example.com**

```
[edit system services dhcp-local-server authentication username-include]
user@host# set username-include circuit-type
user@host# set username-include domain-name example.com
user@host# set username-include mac-address
user@host# set username-include user-prefix wallybrown
```

## Configuring Passwords for Usernames

You can configure an optional password that the extended DHCP application presents to the external AAA authentication service to authenticate the specified username.

To configure a password that authenticates the username:

1. Specify that you want to configure authentication options.
  - For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit authentication
```

2. Configure the password. (DHCP local server, DHCPv6 local server, and DHCP relay agent all support the **password** statement.)

```
[edit system services dhcp-local-server authentication]
user@host# set password $ABC123
```

## Receiving DHCP Options From a RADIUS Server

- [Centrally Configured Opaque DHCP Options on page 328](#)
- [Exchange of DHCPv4 and DHCPv6 Parameters with the RADIUS Server Overview on page 332](#)
- [Dedicated Session Database and Vendor-Specific Attributes for DHCPv4 and DHCPv6 Subscribers on page 335](#)
- [Monitoring DHCP Options Configured on RADIUS Servers on page 337](#)

## Centrally Configured Opaque DHCP Options

Subscriber management (on the routers) or DHCP management (on the switches) enables you to centrally configure DHCP options on a RADIUS server and then distribute the options on a per-subscriber or per DHCP-client basis. This method results in RADIUS-sourced DHCP options—the DHCP options originate at the RADIUS server and are sent to the subscriber (or DHCP client). This differs from the traditional client-sourced method (also called DHCP-sourced) of configuring DHCP options, in which the options originate at the client and are sent to the RADIUS server. The subscriber management (DHCP management) RADIUS-sourced DHCP options are also considered to be *opaque*, because DHCP local server performs minimal processing and error checking for the DHCP options string before passing the options to the subscriber (DHCP client).

Subscriber management (or DHCP management) uses Juniper Networks VSA 26-55 (DHCP-Options) to distribute the RADIUS-sourced DHCP options. The RADIUS server includes VSA 26-55 in the Access-Accept message that the server returns during subscriber authentication or DHCP client authentication. The RADIUS server sends the Access-Accept message to the RADIUS client, and then on to DHCP local server for return to the DHCP subscriber. The RADIUS server can include multiple instances of VSA 26-55 in a single Access-Accept message. The RADIUS client concatenates the multiple instances and uses the result as a single instance.

There is no CLI configuration required to enable subscriber management (DHCP management) to use the centrally configured DHCP options—the procedure is triggered by the presence of VSA 26-55 in the RADIUS Access-Accept message.

When building the offer packet for the DHCP client, DHCP local server uses the following sequence:

1. Processes any RADIUS-configured parameters that are passed as separate RADIUS attributes; for example, RADIUS attribute 27 (Session Timeout).
2. Processes any client-sourced parameters; for example, RADIUS attributes 53 (DHCP Message Type) and 54 (Server Identifier).
3. Appends (without performing any processing) the opaque DHCP options string contained in the VSA 26-55 received from the RADIUS server.

In addition to supporting central configuration of DHCP options directly on the RADIUS server (RADIUS-sourced options), subscriber management (DHCP management) also supports the traditional client-sourced options configuration, in which the router's (switch's) DHCP component sends the options to the RADIUS server. The client-sourced DHCP options method is supported for both DHCP local server and DHCP relay agent; however, the RADIUS-sourced central configuration method is supported on DHCP local server only. Both the RADIUS-sourced and client-sourced methods support DHCPv4 and DHCPv6 subscribers (clients).

**NOTE:** You can use the RADIUS-sourced and client-sourced methods simultaneously on DHCP local server. However, you must ensure that the central configuration method does not include options that override client-sourced DHCP options, because this can create unpredictable results.

- [Multiple VSA 26-55 Instances Configuration on page 331](#)
- [DHCP Options That Cannot Be Centrally Configured on page 331](#)

### Data Flow for RADIUS-Sourced DHCP Options

Figure 5 on page 330 shows the procedure subscriber management (DHCP management) uses when configuring DHCP options for subscribers (DHCP clients).

Figure 5: DHCP Options Data Flow

The following general sequence describes the data flow when subscriber management (DHCP management) uses RADIUS-sourced DHCP options and VSA 26-55 to configure a DHCP subscriber (client):

1. The subscriber (DHCP client) sends a DHCP discover message (or DHCPv6 solicit message) to the DHCP local server. The message includes client-sourced DHCP options.
2. The DHCP local server initiates authentication with the Junos OS RADIUS client.
3. The RADIUS client sends an Access-Request message on behalf of the subscriber (DHCP client) to the external RADIUS server. The message includes the subscriber's (DHCP client's) client-sourced DHCP options.
4. The external RADIUS server responds by sending an Access-Accept message to the RADIUS client. The Access-Accept message includes the RADIUS-sourced opaque DHCP options in VSA 26-55.
5. The RADIUS client sends the DHCP options string to DHCP local server. If there are multiple VSA 26-55 instances, the RADIUS client first assembles them into a single options string.
6. DHCP local server processes all options into the DHCP offer (or DHCPv6 reply) message, except for the RADIUS-sourced VSA 26-55 DHCP options. After processing

all other options, DHCP local server then appends the unmodified VSA 26-55 DHCP options to the message and sends the message to the subscriber (DHCP client).

7. The subscriber (DHCP client) is configured with the DHCP options.
8. The following operations occur after the subscriber (DHCP client) receives the DHCP options:
  - Accounting—The RADIUS client sends Acct-Start and Interim-Accounting requests to the RADIUS server, including the RADIUS-sourced DHCP options in VSA 26-55. By default, the DHCP options are included in accounting requests.
  - Renewal—When the subscriber (DHCP client) renews, the cached DHCP options value is returned in the DHCP renew (or DHCPv6 ACK) message. The originally assigned DHCP options cannot be modified during a renew cycle.
  - Logout—When the subscriber (DHCP client) logs out, the RADIUS client sends an Acct-Stop message to the RADIUS server, including the RADIUS-sourced VSA 26-55.

### Multiple VSA 26-55 Instances Configuration

VSA 26-55 supports a maximum size of 247 bytes. If your RADIUS-sourced DHCP options field is greater than 247 bytes, you must break the field up and manually configure multiple instances of VSA 26-55 for the RADIUS server to return. When using multiple instances for an options field, you must place the instances in the packet in the order in which the fragments are to be reassembled by the RADIUS client. The fragments can be of any size of 247 bytes or less.

**BEST PRACTICE:** For ease of configuration and management of your DHCP options, you might want to have one DHCP option per VSA 26-55 instance, regardless of the size of the option field.

When the RADIUS client returns a reassembled opaque options field in an accounting request to the RADIUS server, the client uses 247-byte fragments. If you had originally created instances of fewer than 247 bytes, the returned fragments might not be the same as you originally configured on the RADIUS server.

**NOTE:** If you are configuring Steel-Belted Radius (SBR) to support multiple VSA 26-55 instances, ensure that you specify VSA 26-55 with the RO flags in the Subscriber Management RADIUS dictionary file. The R value indicates a multivalued reply attribute and the O value indicates an ordered attribute.

### DHCP Options That Cannot Be Centrally Configured

Table 37 on page 332 shows the DHCP options that you must not centrally configure on the RADIUS server.

*Table 37: Unsupported Opaque DHCP Options*

DHCP Option	Option Name	Comments
Option 0	Pad Option	Not supported.
Option 51	IP Address Lease Time	Value is provided by RADIUS attribute 27 (Session-Timeout).
Option 52	Option Overload	Not supported.
Option 53	DHCP Message Type	Value is provided by DHCP local server.
Option 54	Server Identifier	Value is provided by DHCP local server.
Option 55	Parameter Request List	Value is provided by DHCP local server.
Option 255	End	Value is provided by DHCP local server.
–	DHCP magic cookie	Not supported.

## Exchange of DHCPv4 and DHCPv6 Parameters with the RADIUS Server Overview

The RADIUS server, which is configured independently of DHCPv4 and DHCPv6, authenticates clients and supplies the IPv4 or IPv6 prefix and client configuration parameters. To establish the client sessions on the network, the DHCPv4 and DHCPv6 parameters are sent from the client device through the DHCP (either DHCPv4 or DHCPv6) server to the RADIUS server and vice versa. Starting in Junos OS Release 17.4R1, the exchange of parameters is enhanced with the introduction of several new vendor-specific attributes (VSAs) and changes to the existing DHCP-Options VSA (26-55).

An immediate interim accounting report is sent to the RADIUS server when configurable events occur, such as a change in family state. When these events occur, the RADIUS server has no direct way to determine the reason for the report. You can use the Acct-Request-Reason VSA (26-210) to send the reason in the start accounting report as well as in the immediate interim accounting report.

The broadband network gateway (BNG) sends an interim accounting report to the RADIUS server whenever the second family (either IPv4 or IPv6) of a dual-stack session (DHCPv4, DHCPv6, or PPPoE) is activated or the first family (either IPv4 or IPv6) of a dual-stack session (DHCPv4, DHCPv6, or PPPoE) is deactivated. For the immediate interim accounting report to be sent, configure the **family-state-change-immediate-update** statement on the BNG at the **[edit access profile *profile-name* accounting]** hierarchy level.

The following VSAs are used for exchanging the client parameters with the RADIUS server:

- DHCPv6-Options VSA (26-207):

- The DHCPv6-Options VSA (26-207) is used to exchange DHCPv6 options with the RADIUS server. In releases earlier than Junos OS Release 17.4R1, the DHCPv6 options are included with DHCPv4 options in the DHCP-Options VSA (26-55).

The option values sent from the DHCPv6 client to the DHCPv6 server are saved in the session database separately from the values sent from the DHCPv6 server to the DHCPv6 client.

- If the DHCPv6 options are too large to fit in one VSA, then they are split into multiple, sequential VSAs in the RADIUS packet. In this case, the options are split at the VSA size limit rather than at the type-length-value (TLV) boundary.
- If multiple instances of the VSA are included in the RADIUS Access-Accept message, then they are concatenated into a single block and stored in the session database without checking the TLV for validity.
- DHCP-Options VSA (26-55):
  - The DHCP-Options VSA (26-55) is used to exchange DHCPv4 options with the RADIUS server.
  - With the introduction of VSA 26-207, VSA 26-55 includes only DHCPv4 options.
  - If the DHCPv4 options are too large to fit in one VSA, then they are split into multiple, sequential VSAs in the RADIUS packet. In this case, the options are split at the VSA size limit rather than at the TLV boundary.
  - If multiple instances of the VSA are included in the RADIUS Access-Accept message, then they are concatenated into a single block and stored in the session database without checking the TLV for validity.
- DHCP-Header VSA (26-208):
  - The DHCP-Header VSA (26-208) conveys the DHCPv4 packet header to the RADIUS server. The header information is used for instantiating dynamic subscriber interfaces.
  - The VSA is allowed only in RADIUS Access-Request messages and is stored in the session database.
- DHCPv6-Header VSA (26-209):
  - The DHCPv6-Header VSA (26-209) conveys the DHCPv6 packet header to the RADIUS server. The header information is used for instantiating dynamic subscriber interfaces.
  - The VSA is allowed only in RADIUS Access-Request messages and is stored in the session database.
- Acct-Request-Reason VSA (26-210):
  - The Acct-Request-Reason VSA (26-210) conveys the reason for sending an accounting request. The VSA is included only in RADIUS Acct-Start and Interim-Update messages. The VSA is present only for subscriber accounting reports; it is not present for service session or Extensible Subscriber Services Manager (ESSM) reports.

- The typical value for the VSA in Acct-Start messages is IP active (0x0004) or IPv6 active (0x0010), indicating that the IPv4 or IPv6 address family has been activated. For Layer 2 wholesale VLAN networks, the value is Session active (0x0040), because there is no IPv4 or IPv6 family. The value for MLPPP is also Session active, because accounting messages are sent for the link session rather than the bundle session. ESSM sessions are child sessions of a parent subscriber session and are treated as ESSM service sessions. The VSA is sent only for the parent subscriber session.

### Differentiating Subscriber Classes with DHCPv6 Option 17 and VSA 26-207

Starting in Junos OS Release 18.3R1, you can use the DHCPv6-Options VSA (26-207) to differentiate between different classes of subscribers during DHCPv6 relay authentication. For example, you may want to assign different IPv6 prefixes to different subscriber classes.

You must configure your RADIUS server to include the following information in the VSA:

- Juniper Networks enterprise number, 2636
- Suboption 5, JDHCPD\_VS\_OPT\_CODE\_KT\_SUBSCRIBER\_CLASS

**NOTE:** To configure this information, refer to the documentation for your RADIUS server. You must encode the information in the DHCPv6 options format in RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*.

You set a different value for suboption 5 for each class you want to differentiate. You develop your own scheme to determine the mapping between value and class.

VSA 26-207 conveys the subscriber class information in the Access-Accept message returned by the RADIUS server during DHCPv6 subscriber authentication. The contents of the VSA are passed from the AAA process to the DHCP process in the session database attribute, SDB\_SERVER\_DHCPV6\_OPTIONS. The DHCPv6 relay agent extracts the information from the SDB attribute and places it in DHCPv6 option 17. The relay agent subsequently passes option 17 to the DHCPv6 local server in the Relay-Forward header. The local server can then return the relay agent configuration and service information specific to the relevant subscriber classes.

In releases earlier than Junos OS 18.3R1, only the DHCP local server supports VSA 26-207. Only suboption 1(JDHCPD\_VS\_OPT\_CODE\_HOST\_NAME) and suboption 4 (JDHCPD\_VS\_OPT\_CODE\_LOCATION\_NAME) are supported. The DHCP relay agent also discards the SDB\_SERVER\_DHCPV6\_OPTIONS attribute if it is received.

Suboptions received from RADIUS have a higher precedence than the information configured locally. For example, if the host name and the location are configured with the **host-name** statement at the **[edit forwarding-options dhcp-relay dhcpv6 relay-option-vendor-specific]** hierarchy level and they are received in suboptions 1 and 4 from RADIUS, the RADIUS values are used.

### Excluding the VSAs from RADIUS Messages

You can exclude any of these VSAs from being sent by using the **exclude** statement as shown in the following example:

```
[edit access profile profile-name radius attributes]
user@host# set exclude acct-request-reason [accounting-start | accounting-stop]
user@host# set exclude dhcp-header [access-request]
user@host# set exclude dhcpv6-header [access-request]
user@host# set exclude dhcpv6-options [access-request | accounting-start |
accounting-stop]
```

### Dedicated Session Database and Vendor-Specific Attributes for DHCPv4 and DHCPv6 Subscribers

The Dynamic Host Configuration Protocol (DHCP) server can serve as a DHCP local server, a DHCP client, or a DHCP relay agent, for both DHCPv4 and DHCPv6 subscribers.

Currently, some of the client parameters—for example, the DHCPv4 and DHCPv6 packet header—cannot be passed to and from the RADIUS server. From Junos OS Release 17.4 onward, enhancements are made to facilitate better communication between the DHCP servers (both DHCPv4 and DHCPv6) and the RADIUS server. The client parameters are saved in a session database and sent to the RADIUS server; and the RADIUS server, in turn, authenticates the client and also responds with the options to be sent back to that client.

- [Client Options on page 335](#)
- [Exchange of DHCPv4 Client, DHCPv4 Server, and RADIUS-Sourced Options on page 336](#)
- [Exchange of DHCPv6 Client, DHCPv6 Server, and RADIUS-Sourced Options on page 336](#)

#### Client Options

The client options can be configured in multiple locations such as DHCPv4 or DHCPv6 servers, or in the RADIUS server. If the client configuration is available in multiple locations, a conflict can arise regarding the source of the configuration details. In case of such conflicts, the following order of preference is considered:

- Options received from the RADIUS server through vendor-specific attributes (VSAs)
- Options received from the RADIUS server through the respective session databases
- Options from the DHCP local configuration, which are present on the DHCP server

As an example of the aforementioned preference, consider the case of DHCPv4 lease time. If the **AUTHD\_ATTR\_SESSION\_TIMEOUT** option, which is a VSA stored in the RADIUS server, is returned from the RADIUS server, preference is given to it. If this option is not returned, preference is given to option 51 in respective session database for DHCPv4. If that option is also not returned, the option is sourced from DHCP local configuration.

Similarly, for DHCPv6 lease time, the first preference is given to the **AUTHD\_ATTR\_SESSION\_TIMEOUT** VSA from the RADIUS server. If **AUTHD\_ATTR\_SESSION\_TIMEOUT** is not present, the RADIUS-sourced option **valid-lifetime**

or **preferred-lifetime** takes the precedence. If that is also not available, then the option is sourced from the DHCPv6 local configuration.

### Exchange of DHCPv4 Client, DHCPv4 Server, and RADIUS-Sourced Options

The following steps illustrate the process of exchange of configuration options between a DHCPv4 client, a DHCPv4 server, and the RADIUS server:

- A *discover* message from a DHCPv4 client is received by the DHCPv4 server.
- The DHCP option is saved to the respective session database.

In Junos OS releases before 17.4R1, the same attribute is used to store both DHCPv4 and DHCPv6 options. However, with the support for single-session DHCP dual-stack, there are separate session database attributes for DHCPv4 and DHCPv6.

- The DHCP header information is saved in the session database.

A new session database attribute is added to store the header information, and this information is sent to the RADIUS server for authentication.

- An *access request* message is sent from the DHCPv4 server to the RADIUS server, and when an *access accept* message is received from the RADIUS server, the DHCPv4 options are saved to the respective session database attributes and sent to the client.
- DHCPv4 server-specific options are added to the packet.

**NOTE:** The DHCPv4 server can source both solicited and unsolicited options from the local configuration. Thus, it is important to prevent duplication while the options are added.

- DHCPv4 lease information is extracted from the RADIUS-sourced DHCP option 51.

The respective session database attribute is used to check whether option 51 (lease time) is sourced by RADIUS. If it is, then the attribute value is extracted and saved in the client data structure. If it is not sourced by RADIUS, the attribute value is taken from the local pool configuration or the DHCPv4 attribute configuration, which is an existing functionality. A similar check is performed for option 58 (renewal time (T1)) and option 59 (rebinding time (T2)).

- An *offer message* is sent from the DHCPv4 server to DHCPv4 client.

### Exchange of DHCPv6 Client, DHCPv6 Server, and RADIUS-Sourced Options

The following steps illustrate the process of exchange of configuration options between a DHCPv6 client, a DHCPv6 server, and the RADIUS server:

- A *solicit* message from a DHCP client is received by the DHCPv6 server.
- DHCPv6 options are saved in the session database of the DHCPv6 server.

In Junos OS releases before 17.4R1, DHCPv6 options are saved in the respective session database attribute. Because of the current single-session DHCP dual-stack support, there is need to have separate session database attributes for saving DHCPv4 and

DHCPv6 options. If the client is part of a single-session dual-stack configuration, the respective DHCPv6 options session database attribute is used. The DHCPv6 options are directly copied to the session database without any changes and then sent to the RADIUS server.

**NOTE:** DHCPv6 auth-option (option 11) is also part of these options.

- A DHCPv6 message header is saved to the session database.

A new session database attribute is added to copy the DHCPv6 message header.

- An *access request* message is sent from the DHCPv6 server, which in turn receives an *access accept* message from the RADIUS server. This message contains RADIUS-sourced DHCPv6 options that are stored in a new session database attribute.
- DHCPv6 lease information is extracted from the RADIUS-sourced DHCPv6 option.

In case of DHCPv6, the lease time is embedded within the options **OPTION\_IA\_NA** and **OPTION\_IA\_PD**. Client lease time starts with these values from the RADIUS Server. If the **IA\_ADDRESS**, **IA\_PREFIX**, **IA\_NA**, or **IA\_PD** option is not sourced from RADIUS, then these options are taken from the local pool and delegated pool configuration.

- DHCPv6 server-specific options are added to the packet.

**NOTE:** A DHCPv6 server can source both solicited and unsolicited options from the local configuration. Thus, it is important to prevent duplication while the options are added.

- An *advertise* message is sent from the DHCPv6 server to the DHCPv6 client.

## Monitoring DHCP Options Configured on RADIUS Servers

**Purpose** View information for DHCP options that are centrally configured on a RADIUS server and that are distributed using Juniper Networks VSA 26-55 (DHCP-Options).

**Action** To display information for opaque DHCP options:

```
user@host> show subscribers detail
Type: DHCP
IP Address: 192.168.9.7
IP Netmask: 255.255.0.0
Logical System: default
Routing Instance: default
Interface: demux0.1073744127
Interface type: Dynamic
Dynamic Profile Name: dhcp-prof-23
MAC Address: 00:00:5E:00:53:98
State: Active
Radius Accounting ID: jnpr :2304
Session Timeout (seconds): 3600
Idle Timeout (seconds): 600
```

```
Login Time: 2011-08-25 14:43:52 PDT
DHCP Options: len 52
35 01 01 39 02 02 40 3d 07 01 00 10 94 00 00 08 33 04 00 00
00 3c 0c 15 63 6c 69 65 6e 74 5f 50 6f 72 74 20 2f 2f 36 2f
33 2d 37 2d 30 37 05 01 06 0f 21 2c
```

**Meaning**

```

DHCP Options: len 52
35 01 01 39 02 02 40 3d 07 01 00 10 94 00 00 08 33 04 00 00
00 3c 0c 15 63 6c 69 65 6e 74 5f 50 6f 72 74 20 2f 2f 36 2f
33 2d 37 2d 30 37 05 01 06 0f 21 2c

```

The DHCP options output provides the following information:

- The **len** field is the total number of hex values in the message.
- The hex values specify the type, length, and value (TLV) of DHCP options, and are converted to decimal to identify the DHCP options, as defined in RFC 2132.

The number of hex values that make up a particular DHCP option varies, depending on the length of the option. For example, the first DHCP option specified in the output includes three sets of hex values (**35 01 01**). The first hex value (**35**) identifies the option type, the second value (**01**) indicates the length of the value entry, which in this case is one set of hex values. The third hex value (**01**) specifies the value for the DHCP option.

In the second DHCP option specification (**39 02 02 40**), the hex value **39** is the type, and the length of **02** specifies that two sets of hex entries make up the value for the option. Therefore, this option specification uses four sets of hex entries; one for the type (**39**), one to specify the length (**02**), and two for the option value (**02 40**).

The third DHCP option is specified by the hex values **3d 07 01 00 10 94 00 00 08**. The hex value **3d** is the type, followed by the length (**07**), which specifies that the next seven sets of hex entries make up the value for the option. Therefore, this option specification uses a total of nine sets of hex entries; one for the type (**3d**), one to specify the length (**07**), and seven for the value of the DHCP option (**01 00 10 94 00 00 08**).

[Table 38 on page 339](#) describes the first two options in more detail.

**Table 38: DHCP Options Description**

Option	Type	Length	Value
35 01 01	35 = decimal 53 (Code 53 in RFC 2132 is the DHCP Message Type option)	01 = the length of the option is one set of hex values (the next set in the list)	01 = value of the message type that is described in RFC 2132. The code 01 specifies a message type of DHCPDISCOVER.
39 02 02 40	39 = decimal 57 (Code 57 is the Maximum DHCP Message Size option)	02 = the length of the option is two sets of hex values (the next two sets in the list)	0240 = converted to a length of 576 octets

## Release History Table

Release	Description
18.3R1	Starting in Junos OS Release 18.3R1, you can use the DHCPv6-Options VSA (26-207) to differentiate between different classes of subscribers during DHCPv6 relay authentication.
17.4R1	Starting in Junos OS Release 17.4R1, the exchange of parameters is enhanced with the introduction of several new vendor-specific attributes (VSAs) and changes to the existing DHCP-Options VSA (26-55).

- [Configuring Group-Specific DHCP Relay Options on page 343](#)
- [Configuring Active Server Groups to Apply a Common DHCP Relay Agent Configuration to Named Server Groups on page 344](#)

### Grouping Interfaces with Common DHCP Configurations

You use the group feature to group a set of interfaces and then apply a common DHCP configuration to the named interface group. The extended DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent all support interface groups.

The following steps create a DHCP local server group; the steps are similar for the DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent.

To configure a DHCP local server interface group:

1. Specify that you want to configure DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Create the group and assign a name.

```
[edit system services dhcp-local-server]
user@host# edit group boston
```

- Specify the names of one or more interfaces on which the extended DHCP application is enabled. You can repeat the `interface interface-name` statement to specify multiple interfaces within the group, but you cannot use the same interface in more than one group.

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.1
user@host# set interface fe-1/0/1.2
```

- (Optional) You can use the `upto` option to specify a range of interfaces for a group.

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.3 upto fe-1/0/1.9
```

- (Optional) You can use the `exclude` option to exclude a specific interface or a specified range of interfaces from the group. For example:

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.1 upto fe-1/0/1.102
user@host# set interface fe-1/0/1.6 exclude
user@host# set interface fe-1/0/1.70 upto fe-1/0/1.80 exclude
```

## Guidelines for Configuring Interface Ranges for Groups of DHCP Interfaces

This topic describes guidelines to consider when configuring interface ranges for named interface groups for DHCP local server and DHCP relay. The guidelines refer to the following configuration statement:

```
user@host# set interface interface-name upto upto-interface-name
```

- The start subunit, `interface interface-name`, serves as the key for the stanza. The remaining configuration settings are considered attributes.
- If the subunit is not included, an implicit `.0` subunit is enforced. The implicit subunit is applied to all interfaces when autoconfiguration is enabled. For example, `interface ge-2/2/2` is treated as `interface ge-2/2/2.0`.
- Ranged entries contain the `upto` option, and the configuration applies to all interfaces within the specified range. The start of a ranged entry must be less than the end of the range. Discrete entries apply to a single interface, except in the case of autoconfiguration, in which a `0` (zero) subunit acts as a wildcard.
- Interface stanzas defined within the same router or switch context are dependent and can constrain each other—both DHCP local server and DHCP relay are considered. Interface stanzas defined across different router (switch) contexts are independent and do not constrain one another.
- Each interface stanza, whether discrete or ranged, has a unique start subunit across a given router context. For example, the following configuration is not allowed within the same group because `ge-1/0/0.10` is the start subunit for both.

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.10
```

- Two groups cannot share interface space. For example, the following configuration is not allowed because the three stanzas share the same space and interfere with one another—interface **ge-1/0/0.26** is common to all three.

```
dhcp-relay group diamond interface ge-1/0/0.10 upto ge-1/0/0.30
dhcp-local-server group ruby interface ge-1/0/0.26
dhcp-relay group sapphire interface ge-1/0/0.25 upto ge-1/0/0.35
```

- Two ranges cannot overlap, either within a group or across groups. Overlapping occurs when two interface ranges share common subunit space but neither range is a proper subset of the other. The following ranges overlap:

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.20 upto ge-1/0/0.40
```

- A range can contain multiple nested ranges. A nested range is a proper subset of another range. When ranges are nested, the smallest matching range applies.

In the following example, the three ranges nest properly:

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.12 upto ge-1/0/0.15 exclude
interface ge-1/0/0.25 upto ge-1/0/0.29 exclude
```

- Discrete interfaces take precedence over ranges. In the following example, interface **ge-1/0/0.20** takes precedence and enforces an interface client limit of 5.

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.15 upto ge-1/0/0.25 exclude
interface ge-1/0/0.20 overrides interface-client-limit 5
```

## Configuring Group-Specific DHCP Local Server Options

You can include the following statements at the **[edit system services dhcp-local-server group group-name]** hierarchy level to set group-specific DHCP local server configuration options. Statements configured at the **[edit system services dhcp-local-server group group-name]** hierarchy level apply only to the named group of interfaces, and override any global DHCP local server settings configured with the same statements at the **[edit system services dhcp-local-server]** hierarchy level.

DHCPv6 local server supports the same set of statements with the exception of the **dynamic-profile** statement.

- authentication**—Configure the parameters the router sends to the external AAA server.
- dynamic-profile**—Specify the dynamic profile that is attached to a group of interfaces.
- interface**—Specify one or more interfaces, or a range of interfaces, that are within the specified group.

- **liveness-detection**—Configure bidirectional failure detection timers and authentication criteria for static routes, or Layer 2 liveness detection using ARP and Neighbor Discovery packets. For more information, see *DHCP Liveness Detection Overview*.
- **overrides**—Override the default configuration settings for the extended DHCP local server. For information, see “[Overriding the Default DHCP Local Server Configuration Settings Overview](#)” on page 243.

## Configuring Group-Specific DHCP Relay Options

You can include the following statements at the **[edit forwarding-options dhcp-relay group group-name]** hierarchy level to set group-specific DHCP relay agent configuration options. Group-specific statements apply only to the named group of interfaces, and override any global DHCP relay agent settings for the same statement.

Include the statements at the **[edit forwarding-options dhcp-relay dhcpv6 group group-name]** hierarchy level to configure group-specific options for DHCPv6 relay agent.

- **active-server-group**—Configure an active server group to apply a common DHCP relay agent configuration for a named group of DHCP server addresses. For information, see “[Configuring Active Server Groups to Apply a Common DHCP Relay Agent Configuration to Named Server Groups](#)” on page 344.
- **authentication**—Configure the parameters the router (or switch) sends to the external AAA server.
- **dynamic-profile**—Specify the dynamic profile that is attached to a group of interfaces.
- **interface**—Specify one or more interfaces, or a range of interfaces, that are within the specified group.
- **liveness-detection**—Configure bidirectional failure detection timers and authentication criteria for static routes, or Layer 2 liveness detection using ARP and Neighbor Discovery packets. For more information, see *DHCP Liveness Detection Overview*.
- **overrides**—Override the default configuration settings for the extended DHCP relay agent. For information, see “[Overriding the Default DHCP Relay Configuration Settings](#)” on page 246.
- **relay-agent-interface-id**—(DHCPv6 only) Insert the DHCPv6 Relay Agent Interface-ID option (option 18) in DHCPv6 packets destined for the DHCPv6 server.
- **relay-agent-remote-id**—(DHCPv6 only) Insert the DHCPv6 Relay Agent Remote-ID option (option 37) in DHCPv6 packets destined for the DHCPv6 server.
- **relay-option**—Configure selective processing, which uses DHCP options in client packets to identify and filter client traffic, and to specify the action DHCP relay agent takes with the traffic. For more information, see “[Using DHCP Option Information to Selectively Process DHCP Client Traffic](#)” on page 262.

- **relay-option-82**—(DHCPv4 only) Enable or disable the insertion of option 82 information in packets destined for a DHCP server. For information, see [“Using DHCP Relay Agent Option 82 Information” on page 282](#).
- **service-profile**—Specify the default subscriber service, (or default profile) which is activated when the subscriber (or DHCP client) logs in and no other service is activated by a RADIUS server or a provisioning server. For more information, see [“Default Subscriber Service Overview” on page 293](#).

## Configuring Active Server Groups to Apply a Common DHCP Relay Agent Configuration to Named Server Groups

You can apply a common DHCP or DHCPv6 relay configuration to a set of DHCP server IP addresses configured as a server group, by specifying that group with the **active-server-group** statement globally or at the group level (configured with the **group** statement). When you apply the active server group at the group level, it overrides a global active server group configuration. An active server group is sometimes referred to as a trusted group of servers.

For example, you might want to direct certain DHCP clients to a different DHCP server than other clients, and you have different relay configurations for the clients. You can configure an interface group for each set of clients, specifying the DHCP relay interfaces for the group and any other relay configuration. In each of these groups, you specify an active server group to which each client groups traffic is forwarded.

To configure a group of DHCP server addresses and apply them as an active server group:

1. Specify the name of the server group.

- For DHCPv4 servers:

```
[edit forwarding-options dhcp-relay]
user@host# set server-group server-group-name
```

- For DHCPv6 servers:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set server-group server-group-name
```

2. Add the IP addresses of the DHCP servers belonging to the group.

```
[edit forwarding-options dhcp-relay server-group server-group-name]
user@host# set ip-address1
user@host# set ip-address2
```

**NOTE:** Starting in Junos OS Release 18.4R1, up to 32 server IP addresses are supported per DHCPv4 server group. In earlier releases, a maximum of 5 server IP addresses are supported for DHCPv4 servers. Configuring more than the maximum number of server addresses results in a commit check failure.

3. Apply the server group as an active server group.

- For all DHCP clients, unless overridden:

```
[edit forwarding-options dhcp-relay]
user@host# set active-server-group server-group-name
```

- For a group of DHCP relay interfaces, overriding the global active server group:

```
[edit forwarding-options dhcp-relay group interface-group-name]
user@host# set active-server-group server-group-name
```

- For all DHCPv6 clients, unless overridden for a group:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set active-server-group server-group-name
```

- For a group of DHCPv6 relay interfaces, overriding the global active server group:

```
[edit forwarding-options dhcp-relay dhcpv6 group interface-group-name]
user@host# set active-server-group server-group-name
```

Consider the following example. Three groups of DHCP server addresses are configured, Default, Campus-A, and Campus-B. The Default group is applied as the global active server group for the overall DHCP relay configuration.

The Campus-A server group is assigned as the active server group for interface group Campus-A-v10-DHCP-RELAY. DHCP traffic received on the interfaces in Campus-A-v10-DHCP-RELAY is forwarded to DHCP servers 198.51.100.100 and 198.51.100.101.

The Campus-B server group is assigned as the active server group for interface group Campus-B-v200-DHCP-RELAY. DHCP traffic received on the interfaces in Campus-B-v200-DHCP-RELAY is forwarded to DHCP servers 198.51.100.55 and 198.51.100.56.

All other DHCP traffic is forwarded to DHCP server 203.0.113.1.

```
[edit forwarding-options dhcp-relay]
#
# Server groups
user@host# set server-group Default 203.0.113.1
user@host# set server-group Campus-A 198.51.100.100
user@host# set server-group Campus-A 198.51.100.101
user@host# set server-group Campus-B 198.51.100.55
user@host# set server-group Campus-B 198.51.100.56
#
# Default server group applied globally.
user@host# set active-server-group Default
#
# Interface groups with application of active server groups
user@host# set group Campus-A-v10-DHCP-RELAY interface ge-1/1/0.1
user@host# set group Campus-A-v10-DHCP-RELAY interface ge-1/1/0.2
```

```

user@host# set group Campus-A-v10-DHCP-RELAY interface ge-1/1/0.3
user@host# set group Campus-A-v10-DHCP-RELAY active-server-group Campus-A
user@host# set group Campus-B-v200-DHCP-RELAY interface ge-2/2/0.4
user@host# set group Campus-B-v200-DHCP-RELAY interface ge-2/2/0.5
user@host# set group Campus-B-v200-DHCP-RELAY interface ge-2/1/0.6
user@host# set group Campus-B-v200-DHCP-RELAY active-server-group Campus-B

```

In some configurations, servers in an active server group maintain redundant information about the DHCP clients. If the binding server later becomes inaccessible, the client is unable to renew the lease from that server. When the client attempts to rebind to a server, other servers in the group with the client information can reply with an ACK message. By default, instead of forwarding the ACK to the DHCP client, the relay agent drops any such ACKs that it receives from any server other than the binding server because the new server address does not match the expected server address in the DHCP client entry. Consequently the lease cannot be extended by any of the redundant servers.

Starting in Junos OS Release 16.2R1, you can enable a DHCPv4 relay agent to forward DHCP request (renew or rebind) ACKs from any server in the active server group (thus, any trusted server). The relay agent updates the client entry with the new server address. Because the servers in the group are expected to mirror the client information exactly, the lease option is expected to be the same as for the original server and the relay agent does not need to verify the lease option.

Starting in Junos OS Release 18.4R1, this capability is extended to allow a DHCP relay agent to forward DHCP information request (DHCPINFORM) ACK messages from any server in the active server group.

To enable ACK forwarding from any server in the active server group:

- Enable forwarding for the active server group.

```

[edit forwarding-options dhcp-relay active-server-group]
user@host# set allow-server-change

```

## Number of DHCP Clients Per Interface

- [Specifying the Maximum Number of DHCP Clients Per Interface on page 347](#)
- [Allowing Only One DHCP Client Per Interface on page 348](#)

### Specifying the Maximum Number of DHCP Clients Per Interface

By default, there is no limit to the number of DHCP local server or DHCP relay clients allowed on an interface. However, you can override the default setting and specify the maximum number of clients allowed per interface, in the range 1 through 500,000. When the number of clients on the interface reaches the specified limit, no additional DHCP Discover PDUs or DHCPv6 Solicit PDUs are accepted. When the number of clients subsequently drops below the limit, new clients are again accepted.

**NOTE:** The maximum number of DHCP (and DHCPv6) local server clients or DHCP (and DHCPv6) relay clients can also be specified by Juniper Networks VSA 26-143 during client login. The VSA-specified value always takes precedence if the interface-client-limit statement specifies a different number.

If the VSA-specified value differs with each client login, DHCP uses the largest limit set by the VSA until there are no clients on the interface.

To configure the maximum number of DHCP clients allowed per interface:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

2. Configure the maximum number of clients allowed per interface. (DHCP local server, DHCPv6 local server, DHCP relay agent and DHCPv6 relay agent all support the **interface-client-limit** statement.)

```
[edit system services dhcp-local-server overrides]
user@host# set interface-client-limit number
```

**NOTE:** For DHCP local server and DHCP relay agent, you can use either the `interface-client-limit` statement or the `client-discover-match incoming-interface` statement to set a limit of one client per interface. The `interface-client-limit` statement with a value of 1 retains the existing client and rejects any new client connections. The `client-discover-match incoming-interface` statement deletes the existing client and allows a new client to connect.

## Allowing Only One DHCP Client Per Interface

Subscriber management provides two methods that you can use to configure DHCP local server and DHCP relay agent to allow only one DHCP client per interface. The two methods differ on which client is allowed on the interface—the new client or the existing client. The two methods are supported by both DHCP local server and DHCP relay agent, and can be configured globally, for a group of interfaces, or for a specific interface.

- Accept new client—Delete the existing client binding and allow the new client to connect. To configure this action, use the ... **overrides client-discover-match incoming-interface** statement.
- Keep existing client—Retain the existing client binding on the interface and reject any requests from new DHCP clients. To configure this action, use the ... **overrides interface-client-limit 1** statement to specify a maximum of one client.

To configure the router to delete the existing client binding on the interface and allow the new client to connect:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Configure the router to view all client connections on the interface as coming from the same client, which allows a new client to replace the existing client. This example shows the DHCP local server configuration. The DHCP relay agent configuration is similar.

```
[edit system services dhcp-local-server overrides]
user@host# set client-discover-match incoming-interface
```

To configure the router to keep the existing client binding on the interface and refuse connections from new clients:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Set the maximum number of clients allowed per interface to one. This example shows the DHCP local server configuration. The DHCP relay agent configuration is similar.

```
[edit system services dhcp-local-server overrides]
user@host# set interface-client-limit 1
```

## Maintaining DHCP Subscribers During Interface Delete Events

- [Maintaining Subscribers During Interface Delete Events on page 349](#)
- [Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events on page 350](#)
- [Configuring an ACX Series DHCP Local Server to Preserve Subscriber Binding Information on page 351](#)
- [Verifying and Managing DHCP Subscriber Binding During Interface Delete Events on page 352](#)

### Maintaining Subscribers During Interface Delete Events

You can configure the router to maintain DHCP subscribers (maintain the subscriber bindings) when an event occurs that normally results in the router deleting the subscriber. For example, by default, the router logs out DHCP subscribers when an interface delete event occurs, such as a line card reboot or failure. However, if you configure the router to maintain subscribers, the router identifies each subscriber that was on the deleted interface, and resumes normal packet processing for the subscriber when the interface

is restored. This procedure does not maintain subscribers that are deleted during router reboots or failures.

**NOTE:** Subscribers are logged off as usual when their lease expires, even if the router is configured to maintain subscribers and the subscriber is on a deleted interface that has not yet been restored.

You configure the router to maintain subscribers on a global basis—the configuration applies to DHCP local server, DHCPv6 local server, and DHCP relay clients in all logical routers and routing instances. When you enable the maintain subscribers feature, the router applies the feature to existing subscribers as well as subscribers who later connect.

If the maintain subscribers feature is enabled on the router, you can explicitly delete a subscriber binding and log out the subscriber by either specifying a lease expiration timeout or using one of the following commands, as appropriate:

- `clear dhcp server binding`
- `clear dhcpv6 server binding`
- `clear dhcp relay binding`

### Benefits of Maintaining Subscriber Bindings

---

Reduces the time to restore the subscriber session and minimizes loss of subscriber service.

## Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events

You can specify a configuration in which the router does not log out a subscriber when the subscriber's interface is deleted.

**NOTE:** This procedure does not maintain subscribers during router reboots or failures.

To configure the router to maintain DHCP subscribers when the subscriber interface is deleted:

1. Specify that you want to configure subscriber management.

```
[edit system services]  
user@host# edit subscriber-management
```

2. Configure the router to support the maintain-subscriber feature.

```
[edit system services subscriber-management]  
user@host# edit maintain-subscriber
```

3. Configure the router to enable the maintain-subscriber feature when an interface-delete event occurs.

```
[edit system services subscriber-management maintain-subscriber]
user@host# set interface-delete
```

## Configuring an ACX Series DHCP Local Server to Preserve Subscriber Binding Information

When an ACX series router functioning as a DHCP local server reboots, by default, all the subscriber binding information is lost. You can configure the local server to preserve the subscriber binding information to a file in **/var/preserve**. When the router reboots, the DHCP local server reads the file and restores the subscriber binding information and resumes normal packet processing for the subscriber. By default, a new file is generated every 24 hours from the commit time, but you can specify a backup interval of 1 through 48 hours. The configuration is a global setting for each routing instance.

To configure an ACX Series DHCP local server to store subscriber binding information:

- Enable persistent storage.

```
[edit system services dhcp-local-server]
user@host# set persistent-storage automatic
```

To configure a file to store subscriber binding information:

1. Specify a filename for storing subscriber binding information. By default, the file is named `jdhcpd_client_data`.

**NOTE:** A commit error occurs if you try to configure the file with a name that is already present in the **/var/preserve** directory.

```
[edit system processes dhcp-service]
user@host# set persistent-storage file-name
```

2. Specify a frequency to back up the file.

```
[edit system processes dhcp-service]
user@host# set persistent-storage backup-interval hours
```

The following example saves the binding information to **/var/preserve/acx-local-server1-client-data** every 8 hours:

```
[edit system processes dhcp-service]
user@host# set persistent-storage acx-local-server1-client-data backup-interval 8
```

## Verifying and Managing DHCP Subscriber Binding During Interface Delete Events

**Purpose** Display information related to the DHCP maintain-subscribers feature and explicitly log out maintained clients.

**Action**

- To display DHCP local server binding information for the DHCP maintain subscribers feature:

```
user@host>show dhcp server binding detail
```

- To display DHCPv6 local server binding information for the DHCP maintain subscribers feature:

```
user@host>show dhcpv6 server binding detail
```

- To display DHCP relay binding information for the DHCP maintain subscribers feature:

```
user@host>show dhcp relay binding detail
```

- To explicitly log out a DHCP local server subscriber when the maintain subscriber feature is enabled:

```
user@host>clear dhcp server binding binding-type
```

- To explicitly log out a DHCPv6 local server subscriber when the maintain subscriber feature is enabled:

```
user@host>clear dhcpv6 server binding binding-type
```

- To explicitly log out a DHCP relay subscriber when the maintain subscriber feature is enabled:

```
user@host>clear dhcp relay binding binding-type
```

## Understanding Dynamic Reconfiguration of Extended DHCP Local Server Clients

Dynamic reconfiguration of clients enables the extended DHCP local server to initiate a client update without waiting for the client to initiate a request.

### Default Client/Server Interaction

Typically the DHCP client initiates all of the basic DHCP client/server interactions. The DHCP server sends information to a client only in response to a request from that client. This behavior does not enable a client to be quickly updated with its network address and configuration in the event of server changes:

**NOTE:** Technically, the DHCP client/server interactions are the same on routers and switches. However, the primary usage of this technology on the routers is for subscriber management. The switches are not used for subscriber management. Therefore, this topic provides two sample scenarios. The actions are the same, but the implementation details are different.

- On routers—Suppose a service provider restructures its addressing scheme or changes the server IP addresses that it provided to clients. Without dynamic reconfiguration, the service provider typically clears the DHCP server binding table, but cannot inform the DHCP clients that their bindings have been cleared. Consequently, the DHCP client operates as though its IP address is still valid, but it is now unable to communicate over the access network, resulting in an outage. The DHCP local server needs to wait for the client to send a message to renew its lease or rebind to the server. In response, the server sends a NAK message to the client to force it to begin the DHCP connection process again. Alternatively, the provider can wait for customers to make a service call about the network failures and then instruct them to power cycle their customer

premises equipment to reinitiate the connection. Neither of these actions is timely or convenient for customers.

- On switches—Suppose you restructure the addressing scheme or change the server IP addresses that the DHCP server provides to clients. Without dynamic reconfiguration, the network typically clears the DHCP server binding table, but cannot inform the DHCP clients that their bindings have been cleared. Consequently, the DHCP client operates as though its IP address is still valid, but it is now unable to communicate over the access network, resulting in an outage. The DHCP local server needs to wait for the client to send a message to renew its lease or rebind to the server. In response, the server sends a NAK message to the client to force it to begin the DHCP connection process again. Alternatively, you can wait for users to notify you of the network failures and then instruct them to power cycle their equipment to reinitiate the connection. Neither of these actions is timely or convenient for users.

---

### Dynamic Client/Server Interaction for DHCPv4

Dynamic reconfiguration for DHCPv4 is available through a partial implementation of RFC 3203, *DHCP Reconfigure Extension* for DHCPv4. It enables the DHCPv4 local server to send a message to the client to force reconfiguration.

The server sends a `forcerenew` message to a DHCPv4 client, initiating a message exchange. In response, DHCPv4 clients that support the `forcerenew` message then send a lease renewal message to the server. The server rejects the lease renewal request and sends a NAK to the client, causing the client to reinitiate the DHCP connection. A successful reconnection results in the reconfiguration of the DHCP client. Only the exchange of `forcerenew`, `renew`, and NAK messages is supported from RFC 3202. DHCP relay and DHCP relay proxy do not participate in the client reconfiguration or react to `forcerenew` messages other than to forward them to the client.

When the local server state machine starts the reconfiguration process on a bound client, the client transitions to the reconfiguring state and the local server sends a `forcerenew` message to the client. Because the client was in the bound state before entering the reconfiguring state, all subscriber services or DHCP-managed services, such as forwarding and statistics, continue to work. Client statistics are not maintained in the interval between a successful reconfiguration and the subsequent client binding. When the server responds to the client renewal request with a NAK, the client entry is removed from the binding table and final statistics are reported. New statistics are collected when the client sends a discover message to establish a new session.

---

### Dynamic Client/Server Interaction for DHCPv6

Dynamic reconfiguration for DHCPv6 is available through a partial implementation of RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. It enables the DHCPv6 local server to send a message to the client to force reconfiguration.

DHCPv6 servers send reconfigure messages to DHCPv6 clients, initiating a message exchange. In response, DHCPv6 clients that support the reconfigure message transition to the renewing state and send a renew message to the server. The server returns a reply message with a lifetime of zero (0). The client transitions to the init state and sends a solicit message. The server sends an advertise message to indicate that it is available

for service. The client sends a request for configuration parameters, which the server then includes in its reply. DHCP relay and DHCP relay proxy do not participate in the client reconfiguration or react to reconfigure messages other than to forward them to the client.

When a DHCPv6 server is triggered to initiate reconfiguration on a bound DHCPv6 client, the client transitions to the reconfigure state. All subscriber services, such as forwarding and statistics, continue to work. The server then sends the reconfigure message to the client. If the DHCPv6 client is already in the reconfigure state, the DHCPv6 server ignores the reconfiguration trigger. For clients in any state other than bound or reconfigure, the server clears the binding state of the client, as if the **clear dhcpv6 server binding** command had been issued.

### Manually Forcing the Local Server to Initiate the Reconfiguration Process

You can force the local server to initiate the reconfiguration process for clients by issuing the **request dhcp server reconfigure** command for DHCPv4 clients, and the **request dhcpv6 server reconfigure** command for DHCPv6 clients. Command options determine whether reconfiguration is then attempted for all clients or specified clients.

### Action Taken for Events That Occur During a Reconfiguration

Events that take place while a reconfiguration is in process take precedence over the reconfiguration. [Table 39 on page 355](#) lists the actions taken in response to several different events.

*Table 39: Action Taken for Events That Occur During a Reconfiguration*

Event	Action
Server receives a discover (DHCPv4) or solicit (DHCPv6) message from the client.	Server drops packet and deletes client.
Server receives a request, renew, rebind, or init-reboot message from the client.	DHCPv4—Server sends NAK message and deletes client.  DHCPv6—Server drops packet and deletes client. Server replies to renew message with lease time of zero (0).
Server receives a release or decline message from the client.	Server deletes client.
The client lease times out.	Server deletes client.
The <b>clear dhcp server binding</b> command is issued.	Server deletes client.
The <b>request dhcp server reconfigure</b> (DHCPv4) or <b>request dhcpv6 server reconfigure</b> (DHCPv6) command is issued.	Command is ignored.
GRES or DHCP restart occurs.	Reconfiguration process is halted.

## Configuring Dynamic Client Reconfiguration of Extended Local Server Clients Overview

The DHCP local server can initiate reconfiguration of its clients to avoid extended outages because of server configuration changes. You can enable dynamic reconfiguration for all DHCP clients or only the DHCP clients serviced by a specified group of interfaces, and you can modify the behavior accordingly.

Starting in Junos OS Release 14.1, you can modify the behavior of the process in which the DHCP local server initiates reconfiguration of its clients by including the appropriate configuration statements. You can provide the statements at the **[edit system services dhcp-local-server reconfigure]** hierarchy level for all DHCPv4 clients, and at the **[edit system services dhcp-local-server dhcpv6 reconfigure]** hierarchy level for all DHCPv6 clients. To override this global configuration for only the DHCP clients serviced by a specified group of interfaces, you can include the statements with different values at the **[edit system services dhcp-local-server group group-name reconfigure]** hierarchy level for DHCPv4 clients, and at the **[edit system services dhcp-local-server dhcpv6 group group-name reconfigure]** hierarchy level for DHCPv6 clients.

To configure dynamic reconfiguration of DHCP clients:

1. Enable dynamic reconfiguration with default values for all clients.

For DHCPv4:

```
[edit system services dhcp-local-server]
user@host# set reconfigure
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set reconfigure
```

2. (Optional) Enable dynamic reconfiguration for only the clients serviced by a group of interfaces.

For DHCPv4:

```
[edit system services dhcp-local-server group-name]
user@host# set reconfigure
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 group group-name]
user@host# set reconfigure
```

3. (Optional) Configure how the server attempts reconfiguration.

See [“Configuring Dynamic Reconfiguration Attempts for DHCP Clients”](#) on page 357.

4. (Optional) Configure the response to a failed reconfiguration.

See [“Configuring Deletion of the Client When Dynamic Reconfiguration Fails”](#) on page 358.

5. (Optional) Configure the behavior in response to a RADIUS-initiated disconnect.

See [“Configuring Reconfiguration of the Client on Receipt of RADIUS-Initiated Disconnect”](#) on page 358.

6. (Optional) Configure a token for rudimentary server authentication.

See [“Configuring a Token for DHCP Local Server Authentication”](#) on page 359.

7. (Optional) Prevent DHCPv6 clients from binding if they do not support reconfigure messages.

See [“Preventing Binding of Clients That Do Not Support Reconfigure Messages”](#) on page 387.

## Configuring Dynamic Reconfiguration Attempts for DHCP Clients

You can configure how many attempts the local server makes to initiate reconfiguration of the DHCP client by sending `forcerenew` or `reconfigure` messages. You can also specify how long the server waits between attempts. By default, eight attempts are made and the initial interval is two seconds.

Each successive attempt doubles the interval between attempts. For example, if the first value is 2, the first retry is attempted 2 seconds after the first attempt fails. The second retry is attempted 4 seconds after the first retry fails. The third retry is attempted 8 seconds after the second retry fails, and so on. A group configuration takes precedence over a DHCP local server configuration.

(Optional) To configure DHCP local server reconfiguration behavior for all DHCP clients:

1. Specify the number of reconfiguration attempts.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set attempts 5
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set attempts 5
```

2. Specify the interval between reconfiguration attempts.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set timeout 8
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set timeout 8
```

To override the global configuration for a particular group of clients, include the statements at the `[edit system services dhcp-local-server group group-name reconfigure]` hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure]` hierarchy level.

## Configuring Deletion of the Client When Dynamic Reconfiguration Fails

You can configure the local server to delete the client when the maximum number of reconfiguration attempts has been made without success. By default, the client's original configuration is restored.

(Optional) To configure the DHCP local server to delete the client when reconfiguration is not successful, for all clients:

- Specify the client deletion.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set clear-on-abort
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set clear-on-abort
```

To override the global configuration for a particular group of clients, include the statement at the `[edit system services dhcp-local-server group group-name reconfigure]` hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure]` hierarchy level.

## Configuring Reconfiguration of the Client on Receipt of RADIUS-Initiated Disconnect

You can configure the local server to reconfigure the client when the client receives a RADIUS-initiated disconnect. By default, the client is deleted when a RADIUS-initiated disconnect is received.

(Optional) To configure the DHCP local server to reconfigure the client instead of deleting the client when a RADIUS-initiated disconnect is received, for all clients:

- Specify the RADIUS-initiated disconnect trigger.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure trigger]
user@host# set radius-disconnect
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure trigger]
user@host# set radius-disconnect
```

To override the global configuration for a particular group of clients, include the statement at the `[edit system services dhcp-local-server group group-name reconfigure trigger]` hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure trigger]` hierarchy level.

## Configuring a Token for DHCP Local Server Authentication

You can configure an authentication token to provide rudimentary protection against inadvertently instantiated DHCP servers. You can configure the local server to include a constant, unencoded token in the DHCP forcerenew message as part of the authentication option it sends to clients. If the service provider has previously configured the DHCP client with a token, then the client can compare that token against the newly received token. If the tokens do not match, the DHCP client discards the forcerenew message. This functionality corresponds to RFC 3118, *Authentication for DHCP Messages*, section 4.

(Optional) To configure the DHCP local server to include a token in the forcerenew message sent to the client, for all clients:

- Specify the token.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set token token-value
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set token token-value
```

(Optional) For only a particular group of clients:

- Specify the token.

For DHCPv4:

```
[edit system services dhcp-local-server group group-name reconfigure]
user@host# set token token-value
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 group group-name reconfigure]
user@host# set token token-value
```

**Release History Table**

Release	Description
14.1	Starting in Junos OS Release 14.1, you can modify the behavior of the process in which the DHCP local server initiates reconfiguration of its clients by including the appropriate configuration statements.

### DHCP Auto Logout Overview

This topic provides an introduction to the DHCP auto logout feature and includes the following sections:

- [Auto Logout Overview on page 360](#)
- [How DHCP Identifies and Releases Clients on page 361](#)
- [Option 60 and Option 82 Requirements on page 362](#)

#### Auto Logout Overview

Auto logout is supported for DHCP local server and DHCP relay agent. It improves the efficiency of DHCP IP address assignment by allowing IP addresses to be immediately released and returned to the address pool when DHCP clients are no longer using the addresses. DHCP can then assign the addresses to other clients. Without auto logout, an IP address is blocked for the entire lease period, and DHCP must wait until the address lease time expires before reusing the address.

Auto logout is particularly useful when DHCP uses long lease times for IP address assignments and to help avoid allocating duplicate IP addresses for a single client.

For example, you might have an environment that includes set-top boxes (STB) that are often upgraded or replaced. Each time a STB is changed, the new STB repeats the DHCP discover process to obtain client configuration information and an IP address. DHCP views the new STB as a completely new client and assigns a new IP address—the previous IP address assigned to the client (the old STB) remains blocked and unavailable until the lease expires. If auto logout is configured in this situation, DHCP recognizes that the

new STB is actually the same client and then immediately releases the original IP address. DHCP relay agent acts as a proxy client for auto logout and sends a DHCP release message to the DHCP server.

### How DHCP Identifies and Releases Clients

The auto logout feature requires that DHCP explicitly identify clients. By default, DHCP local server and DHCP relay agent identify clients based on MAC address or Client Identifier, and subnet. However, in some cases this type of identification might not be sufficient. For example, in the previous STB example, each STB has a different MAC address, so DHCP incorrectly assumes that an upgraded or replacement STB is a new client.

In order to explicitly identify clients, auto logout uses a secondary identification method when the primary identification method is unsuccessful— the primary method is considered unsuccessful if the MAC address or Client Identifier does not match that of an existing client. Subscriber management supports two secondary identification methods that you can configure.

- Incoming interface method— DHCP views a new client connection on the interface as if it comes from the same client. DHCP deletes the existing client binding before creating a binding for the newly connected device. This method allows only one client device to connect on the interface.

**NOTE:** The incoming interface method differs from the `overrides interface-client-limit 1` statement, which retains the existing binding and rejects the newly connected client.

- Option 60 and option 82 method— DHCP considers two clients as different if they have the same option 60 and option 82 information, but different subnets.

DHCP local server and DHCP relay agent perform the following operations when auto logout is enabled and the secondary identification method identifies a duplicate client (that is, the Discover packet is from an existing client).

- DHCP local server immediately releases the existing address.
- DHCP relay agent immediately releases the existing client and then sends a DHCP release packet to the DHCP server. Sending the release packet ensures that DHCP relay and the DHCP server are synchronized.

If the DHCP relay receives a Discover message from an existing client, the DHCP relay forwards the Discover message to the DHCP server. The DHCP relay preserves the binding if the client's existing IP address is returned by the DHCP server. This behavior is not applicable if the proxy-mode override or client-discover-match functionality are enabled.

**NOTE:** If the DHCP relay agent is in snoop mode, DHCP relay releases the client but does not send a release packet to the DHCP server if the discover packet is for a passive client (a client added as a result of snooped packets) or if the discover packet is a snooped packet.

### Option 60 and Option 82 Requirements

DHCP local server requires that the received discover packet include both DHCP option 60 and option 82. If either option is missing, DHCP local server cannot perform the secondary identification method and auto logout is not used.

DHCP relay agent requires that the received discover packet contain DHCP option 60. DHCP relay determines the option 82 value based on the guidelines provided in “[DHCP Relay Agent Option 82 Value for Auto Logout](#)” on page 363.

### Automatically Logging Out DHCP Clients

You can configure the extended DHCP local server and extended DHCP relay to automatically log out DHCP clients. Auto logout immediately releases an existing client when DHCP receives a discover packet from a client whose identity matches an existing client. DHCP then releases the existing client IP address without waiting for the normal lease expiration.

**NOTE:** When the existing client is released, the new client undergoes the normal authentication process. The new client might not receive the same IP address as the original client.

To configure DHCP client auto logout:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Enable auto logout and specify the secondary identification method you want to use when the primary identification method is unsuccessful.

- For example, to configure DHCP local server to use the incoming interface method:

```
[edit system services dhcp-local-server overrides]
user@host# set client-discover-match incoming-interface
```

- For example, to configure DHCP relay agent to use the option 60 and option 82 method:

```
[edit forwarding-options dhcp-relay overrides]
user@host# set client-discover-match option60-and-option82
```

**NOTE:** If you change the auto logout configuration, existing clients continue to use the auto logout setting that was configured when they logged in. New clients use the new setting.

## How DHCP Relay Agent Uses Option 82 for Auto Logout

Table 40 on page 363 indicates how the DHCP relay agent determines the option 82 value used for the client auto logout feature. Depending on the configuration settings, DHCP relay agent takes the action indicated in the right column.

*Table 40: DHCP Relay Agent Option 82 Value for Auto Logout*

DHCP Relay Agent Configuration Settings				giaddr in non-snooped packet	Action Taken
DHCP Relay Configured with Option 82	Discover Packet Contains Option 82	Override "trust-option-82"	Override "always-write-option-82"		
No	No	—	—	—	No secondary search performed
No	Yes	Yes	—	—	Use option 82 from packet
No	Yes	No	—	Zero	Drop packet
No	Yes	No	—	Non-zero	Use option 82 from packet
Yes	No	—	—	—	Use configured option 82
Yes	Yes	No	—	Zero	Drop packet
Yes	Yes	No	No	Non-zero	Use option 82 from packet
Yes	Yes	No	Yes	Non-zero	Overwrite the configured option 82

Table 40: DHCP Relay Agent Option 82 Value for Auto Logout (continued)

DHCP Relay Agent Configuration Settings				giaddr in non-snooped packet	Action Taken
DHCP Relay Configured with Option 82	Discover Packet Contains Option 82	Override "trust-option-82"	Override "always-write-option-82"		
Yes	Yes	Yes	No	—	Use option 82 from packet
Yes	Yes	Yes	Yes	—	Overwrite the configured option 82

## DHCPv6 Match Criteria for Identifying DHCPv6 Subscribers

By default, the DHCPv6 local server and the DHCPv6 relay agent identify clients on the basis of the client identifier. The DHCPv6 local server and the DHCPv6 relay agent can also identify a DHCPv6 client by the incoming interface. You use the **incoming-interface** option with the **client-negotiation-match** statement so that only one client device connects on the interface. If the client device changes, the router deletes the existing client binding and creates a binding for the newly connected device.

For example, consider an environment that includes a set-top box (STB) or any other such customer premises equipment (CPE) device configured to get configuration information from the DHCPv6 server. In the network configuration, one CPE device is supported over an interface. The DHCPv6 server is configured to provide the CPE devices with long lease timers. If the CPE device is disconnected for repair or upgraded, the new CPE device goes through the DHCPv6 Solicit process to receive the configuration information from the DHCPv6 server. Because the client identifier is different from that of the previous device, the DHCPv6 local server or the DHCPv6 relay agent treats the DHCPv6 Solicit message as a new client and adds the new binding. Because the old device might not gracefully log out, the old IP address is not released until the lease expires.

If the **client-negotiation-match incoming-interface** statement is configured, on receiving a DHCPv6 Solicit message, the DHCPv6 clients are searched on the basis of their client identifiers and the incoming interface option. If an existing DHCPv6 client binding is found based on the match criteria, the binding is removed and the new client is processed. If the old CPE device is disconnected and a DHCPv6 Solicit message is received for the new CPE device, the feature uses the incoming interface to identify the client and remove the binding of the old CPE device, which allows for the release of the old IP address. The binding of the new CPE device replaces the old binding.

## Automatically Logging Out DHCPv6 Clients

You can configure the extended DHCPv6 local server and extended DHCPv6 relay agent to automatically log out DHCPv6 clients based on DHCPv6 subscriber-match criteria. The automatic logout feature immediately releases an existing client when DHCPv6 receives a Solicit packet from a client whose incoming interface matches that of an

existing client. DHCPv6 then releases the existing client IP address without waiting for the normal lease expiration.

**NOTE:** When the existing client is released, the new client undergoes the normal authentication process. The new client might not receive the same IP address as the original client.

To configure automatic logout of DHCPv6 clients:

1. Specify that you want to configure override options to override the default configuration settings.

- For the DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

- For the DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

2. Enable automatic logout and specify the incoming interface as the secondary identification method you want to use.

- For the DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set client-negotiation-match incoming-interface
```

- For the DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 overrides]
user@host# set client-negotiation-match incoming-interface
```

**NOTE:** If you change the automatic logout configuration, existing clients continue to use the automatic logout setting that was configured when they logged in. New clients use the new setting.

## DHCP Short Cycle Protection

---

- [DHCP Short Cycle Protection Against Frequent Brief or Failed Client Sessions on page 366](#)
- [Configuring DHCP Short-Cycle Protection on page 369](#)
- [Verifying and Managing DHCP Short-Cycle Protection on page 371](#)

### DHCP Short Cycle Protection Against Frequent Brief or Failed Client Sessions

In highly scaled networks, a significant number of DHCP client negotiations fail before the session is established, resulting in high loading on the router and external authentication servers. Some CPE devices automatically retry negotiation on failure, some with very short retry intervals. A malicious client might mount an authentication attack by sending repeated, frequent login requests. These events can result in a significant load on the router and the external authentication server.

Starting in Junos OS Release 18.2R1, *DHCP short cycle protection*, also called *DHCP client lockout*, enables the router to reduce these loads by identifying and temporarily locking out clients that continually fail negotiation and have short negotiation cycles as well as clients that frequently complete connections but log out soon after logging in.

Identified clients are prevented from access by temporarily locking them out for an exponentially increasing *lockout period*. The router drops DHCP discover or solicit messages from these clients while they are locked-out. The router tracks clients by the client identifier for DHCPv4 clients or DHCP unique identifier (DUID) for DHCPv6 clients. Both types of client identifiers can be referred to as client keys. The client key enables the DHCP server to associate a client with its lease and configuration parameters. Using the client key for DHCP short-cycle protection tracking enables the router to prevent one client from negotiating a session while allowing other clients using the same logical interface to successfully negotiate sessions.

The initial lockout period for a client has a short duration. The goal here is to not negatively affect legitimate clients, for example, those that fail just once or that log in periodically to check their email and then log out again. By targeting clients that continually fail negotiation or log in and out frequently at short intervals, short-cycle protection reduces both the connection processing load on the router and the authentication load on external authentication servers. It has the effect of improving throughput by deferring client sessions that do not make progress in favor of sessions that complete.

#### Conditions That Can Cause Failed or Short-Lived DHCP Client Sessions

---

Conditions that can cause a failed or short-lived client session include:

- Authentication denials from external AAA servers, such as RADIUS or Diameter, due to the absence of a corresponding entry in the RADIUS database or due to improper login attempts.
- Router or external authentication server unreachability due to network failure or misconfiguration.
- Insufficient memory resources to create a dynamic subscriber interface.

- Protocol negotiation failures with the CPE.
- Client logout shortly after a successful login; this action creates a fully negotiated and configured client session before the session is torn down.

### How DHCP Short-Cycle Protection Works

DHCP short-cycle protection is disabled on the router by default. When you enable it by including the **short-cycle-protection** statement at a global, group, or interface level, the router does the following for DHCP sessions on static and dynamic logical interfaces:

1. Detects short-lived client sessions, also referred to as *short-cycle events*, and locks out the client based on the following events:

- E0: Time when `jdhcpd` declares the client session to be active.
- E1: Time when `jdhcpd` declares the client session should be torn down.
- E2: Time when `jdhcpd` deletes the client session entry from the database.

A short-cycle event occurs when the interval between E0 and E1 is less than or equal to 60 seconds. When the interval is greater than 60 seconds, the logout is considered normal. If the router declares the session to be short-lived, it adds the client to the lockout database at time E2.

2. Temporarily locks out the specified DHCP client by preventing connection to the router.

During lockout, the router drops negotiation packets (DHCP discover and solicit messages) from the client until the lockout period expires. When the lockout period expires, the client can resume normal negotiation of the connection.

You can set a range for the lockout period by specifying a minimum and maximum length with the **short-cycle-protection** statement. You must specify both a minimum and a maximum value.

3. Tracks the time between a client's repeated short-cycle events to determine whether to increase the lockout time for a subsequent short-cycle event. The interval between events is compared to the *grace time threshold*. By default, the grace time threshold is 900 seconds, but it is automatically set to the maximum lockout time if that value is greater than 900 seconds.

If no subsequent negotiation is attempted within the grace time, the client entry is removed from the lockout database.

If a subsequent negotiation is attempted before the grace threshold is reached, it is treated as another short-cycle event and the lockout penalty is increased. The penalty is increased exponentially each time the negotiation is attempted within the grace time.

The initial lockout period is based on the configured minimum value. Additional penalties are calculated as follows, where  $n$  is the number of consecutive short-cycle events that occur within the grace time:

$$\text{Lockout time} = (\text{Lockout minimum time}) \times [2^{(n-1)}]$$

For example, with a minimum duration of 1 second and a maximum duration of 300 seconds, the initial lockout period is 1 second; subsequent penalties increase to 2 seconds, then 4 seconds, 8 seconds, 16 seconds, 32 seconds, 64 seconds, 128 seconds, 256 seconds and finally 300 seconds. The final lockout period is 300 seconds instead of 512 seconds because no penalty can exceed the maximum value of the lockout range.

If the lockout time reaches the maximum, then it stays at that value for each subsequent lockout period until the time between short-cycle events is greater than the grace threshold.

---

### Termination of the Lockout Condition

When a DHCP client is locked out, the lockout condition persists until all lockout timers have expired, *except* when any of the following occurs:

- You administratively clear the lockout condition by issuing one of the following operational commands:
  - **clear dhcp relay lockout-entries**
  - **clear dhcp server lockout-entries**
  - **clear dhcpv6 relay lockout-entries**
  - **clear dhcpv6 server lockout-entries**
- You reset the FPC on which the client session undergoing lockout is configured.
- You reset the Routing Engine.

When any of these events occurs, `jdhcpd` terminates lockout and clears the lockout history for all affected client sessions. The released clients are allowed to negotiate again. Because there is no retained history, the lockout period starts with the minimum value if a subsequent short-cycle event occurs for one of these clients.

When a dynamic VLAN or demux VLAN logical interface is removed from an underlying physical interface that is configured with **remove-when-no-subscribers**, the lockout of affected clients persists until all the timers have expired. If the logical interface is recreated before all timers expire, then the lockout state is applied to the re-created logical interfaces.

---

### Benefits of Using DHCP Short Cycle Protection

- Reduces excessive control plane loading on the router and authentication, authorization, and provisioning loading on the external authority server.
- Reduces the resources required to process DHCP control packets and to negotiate and terminate short-lived connections.
- Temporarily defers subsequent attempts for clients with failed or short-lived client sessions in favor of sessions can complete successfully and last for more than a short duration.

- Reduces the resources required to authenticate and terminate these connections on external authentication servers, such as RADIUS and Diameter.
- Enables lockout of a single failed or short-lived DHCP session without disrupting other DHCP sessions on the same interface.

Because DHCP short-cycle protection identifies each client session by its unique client ID, the router can lock out only the offending DHCP client while enabling other DHCP clients on the same interface to successfully negotiate the connection.

## Configuring DHCP Short-Cycle Protection

In highly scaled networks, a significant number of DHCP client negotiations fail before the session is established, resulting in high loading on the router and external authentication servers. You can enable DHCP short cycle protection on the router to identify DHCP clients that either login frequently and briefly or continually fail to connect, then lock the clients out from access and drop subsequent requests from these clients until a lockout timer expires. For clients that repeatedly log in frequently and briefly, the initial lockout time is short enough to have no noticeable impact. As these brief logins continue, the lockout period is exponentially increased. By targeting clients that continually fail negotiation or log in and out frequently at short intervals, short-cycle protection reduces the connection processing load on the router and the authentication, authorization, and provisioning load on external authentication servers.

You can configure the range for the lockout period for DHCPv4 relay, DHCPv6 relay, DHCPv4 local server, and DHCPv6 local server. You can configure the period globally for all relay agent or local server interfaces, for a group of interfaces, or for specific interfaces within a group. For DHCPv4 relay and local server, you can also configure the lockout for a dual-stack group.

When you enable short-cycle protection, you must specify both the minimum and the maximum duration of the lockout period.

To configure the lockout range for DHCPv4 relay agent:

- Specify the minimum and maximum lockout times.
  - For all DHCPv4 relay agents:

```
[edit forwarding-options dhcp-relay]
user@host# set short-cycle-protection <lockout-max-time seconds>
<lockout-min-time seconds>
```

- For a specific group of DHCPv4 relay interfaces:

```
[edit forwarding-options dhcp-relay]
user@host# set group group-name short-cycle-protection <lockout-max-time
seconds> <lockout-min-time seconds>
```

- For a specific interface within a specified group of DHCPv4 relay interfaces:

```
[edit forwarding-options dhcp-relay]
```

```
user@host# set group group-name interface interface-name short-cycle-protection
<lockout-max-time seconds> <lockout-min-time seconds>
```

- For a DHCPv4 relay dual-stack group:

```
[edit forwarding-options dhcp-relay]
user@host# set dual-stack-group dual-stack-group-name short-cycle-protection
<lockout-max-time seconds> <lockout-min-time seconds>
```

To configure the lockout range for DHCPv6 relay agent:

- Specify the minimum and maximum lockout times.
  - For all DHCPv6 relay agents:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set short-cycle-protection <lockout-max-time seconds>
<lockout-min-time seconds>
```

- For a specific group of DHCPv6 relay interfaces:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set group group-name short-cycle-protection <lockout-max-time
seconds> <lockout-min-time seconds>
```

- For a specific interface within a specified group of DHCPv6 relay interfaces:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set group group-name interface interface-name short-cycle-protection
<lockout-max-time seconds> <lockout-min-time seconds>
```

To configure the lockout range for DHCPv4 local server:

- Specify the minimum and maximum lockout times.
  - For all DHCPv4 local servers:

```
[edit system services dhcp-local-server]
user@host# set short-cycle-protection <lockout-max-time seconds>
<lockout-min-time seconds>
```

- For a specific group of DHCPv4 local server interfaces:

```
[edit system services dhcp-local-server]
user@host# set group group-name short-cycle-protection <lockout-max-time
seconds> <lockout-min-time seconds>
```

- For a specific interface within a specified group of DHCPv4 local server interfaces:

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name short-cycle-protection
<lockout-max-time seconds> <lockout-min-time seconds>
```

- For a DHCPv4 local server dual-stack group:

```
[edit system services dhcp-local-server]
user@host# set dual-stack-group dual-stack-group-name short-cycle-protection
<lockout-max-time seconds> <lockout-min-time seconds>
```

To configure the lockout range for DHCPv6 local server:

- Specify the minimum and maximum lockout times.
- For all DHCPv6 local servers:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set short-cycle-protection <lockout-max-time seconds>
<lockout-min-time seconds>
```

- For a specific group of DHCPv6 local server interfaces:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set group group-name short-cycle-protection <lockout-max-time
seconds> <lockout-min-time seconds>
```

- For a specific interface within a specified group of DHCPv6 local server interfaces:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set group group-name interface interface-name short-cycle-protection
<lockout-max-time seconds> <lockout-min-time seconds>
```

## Verifying and Managing DHCP Short-Cycle Protection

**Purpose** View or clear information about DHCP short-cycle protection operations.

Use the supported **show** and **clear** commands to manage and display information about the short-cycle protection operations for the DHCP relay agent and the DHCP local server. You can display information about all locked-out entries or about only individual entries identified by their database index number.

**Action** • To display short-cycle protection information for DHCPv4 or DHCPv6 relay agent:

```
user@host> show dhcp relay lockout-entries (all | index index)
user@host> show dhcpv6 relay lockout-entries (all | index index)
```

- To clear short-cycle protection information for DHCPv4 or DHCPv6 relay agent:

```
user@host> clear dhcp relay lockout-entries (all | index index)
user@host> clear dhcpv6 relay lockout-entries (all | index index)
```

- To display short-cycle protection information for DHCPv4 or DHCPv6 local server:

```
user@host> show dhcp server lockout-entries (all | index index)
user@host> show dhcpv6 server lockout-entries (all | index index)
```

- To clear short-cycle protection information for DHCPv4 or DHCPv6 local server:

```

user@host> clear dhcp server lockout-entries (all | index index)
user@host> clear dhcpv6 server lockout-entries (all | index index)

```

**Meaning** When you include the **all** option with these **show** commands, information is provided for each client entry in the lockout database, such as the index number that corresponds to the entry in the database, the client identification key, the state of the lockout, how many seconds until the current state is over, how long the current state has been in effect, and how many consecutive times the client has been locked out.

When you want to remove information from the lockout database for a particular client, you must first issue the corresponding **show** command with the **all** option to determine the index for the client entry. Then you can specify that index with the **clear** command.

In the following example, you display all locked-out client entries for DHCPv4 relay agent to find the index number for a particular client, then you clear only that entry and verify that it is deleted:

```
user@host> show dhcp relay lockout-entries all
```

Index	Key	State	Expires(s)	Elapsed(s)	Count
1	00:00:5E:00:53:00	LT	30	5200	2
2	00:00:5E:00:53:11	GT	120	780	2
3	00:00:5E:00:53:22	LT	180	2300	1

```
user@host> clear dhcp relay lockout-entries index 2
```

```
user@host> show dhcp relay lockout-entries all
```

Index	Key	State	Expires(s)	Elapsed(s)	Count
1	00:00:5E:00:53:00	LT	30	5200	2
3	00:00:5E:00:53:22	LT	180	2300	1

In the following example, you display all locked-out client entries for DHCPv6 local server, then you clear all entries and verify that they are deleted:

```
user@host> show dhcp relay lockout-entries all
```

Index	Key	State	Expires(s)	Elapsed(s)	Count
1	00:00:5E:00:53:00	LT	30	5200	2
2	00:00:5E:00:53:11	GT	120	780	2
3	00:00:5E:00:53:22	LT	180	2300	1

```
user@host> clear dhcp relay lockout-entries all
```

```
user@host> show dhcp relay lockout-entries all
```

## Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, <i>DHCP short cycle protection</i> , also called <i>DHCP client lockout</i> , enables the router to reduce these loads by identifying and temporarily locking out clients that continually fail negotiation and have short negotiation cycles as well as clients that frequently complete connections but log out soon after logging in.

### Requesting DHCP Local Server to Initiate Reconfiguration of Client Bindings

You can request that the DHCP local server initiate reconfiguration of all of clients or only specified clients.

To request reconfiguration of all clients:

- Specify the **all** option.

```
user@host> request dhcp server reconfigure all
```

You can use any of the following methods to request reconfiguration of specific clients:

- Specify the IP address of the DHCPv4 client.

```
user@host> request dhcp server reconfigure 192.168.27.3
```

- Specify the MAC address of a DHCPv4 client.

```
user@host> request dhcp server reconfigure 00:00:5E:00:53:67
```

- Specify an interface; reconfiguration is attempted for all clients on this interface.

```
user@host> request dhcp server reconfigure interface fe-0/0/0.100
```

- Specify a logical system; reconfiguration is attempted for all clients or the specified clients in this logical system.

```
user@host> request dhcp server reconfigure all logical-system ls-bldg5
```

- Specify a routing instance; reconfiguration is attempted for all clients or the specified clients in this routing instance.

```
user@host> request dhcp server reconfigure all routing-instance ri-boston
```

## Viewing and Clearing DHCP Bindings

This topic provides the procedure you use to display current DHCP bindings, clear selected bindings, and verify that the specified bindings are successfully cleared.

Subscriber management enables you to clear DHCP bindings at several different levels for DHCP local server and DHCP relay agent. For example, you can clear the DHCP bindings on all interfaces, a group of interfaces, or a specific interface. You can also clear DHCP bindings based on IP address, MAC address, session-ID, DHCPv6 prefix, DHCPv6 Client ID, FPC, PIC, port, VLAN, or stacked VLAN (S-VLAN).

This topic includes examples to show several variations of the clear DHCP binding feature. The examples use DHCP local server commands; however, the procedure and commands are similar for DHCP relay agent, DHCPv6 local server, and DHCPv6 relay agent.

To clear bindings and verify the results for a specific IP address:

- Display current bindings. Issue the appropriate variation of the **show dhcp server binding** command.

```
user@host> show dhcp server binding
2 clients, (2 bound, 0 selecting, 0 renewing, 0 rebinding)
```

IP address	Hardware address	Type	Lease expires at
192.168.32.1	00:00:5E:00:53:01	active	2011-10-17 11:38:47 PST
192.168.32.3	00:00:5E:00:53:02	active	2011-00-17 11:38:41 PST

- Clear the binding you want to remove.

```
user@host> clear dhcp server binding 192.168.32.1
```

- Verify that the binding has been cleared.

```
user@host> show dhcp server binding
1 clients, (1 bound, 0 selecting, 0 renewing, 0 rebinding)
```

IP address	Hardware address	Type	Lease expires at
192.168.32.3	00:00:5E:00:53:01	active	2011-00-17 11:38:41 PST

The following examples show variations of the clear DHCP binding feature. The examples use the DHCP local server version of the commands.

**NOTE:** IP demux interfaces are not supported by the show and clear DHCP bindings commands for DHCP local server and DHCP relay agent.

To clear all bindings:

```
user@host> clear dhcp server binding all
```

To clear bindings on a specific interface:

```
user@host> clear dhcp server binding interface fe-0/0/2
```

To clear all bindings over an interface. This example uses the wildcard option.

```
user@host> clear dhcp server binding ge-1/0/0. *
```

To clear bindings on top of a specific VLAN. This example clears all bindings on top of VLAN 100.

```
user@host> clear dhcp server binding ge-1/0/0:100
```

To clear bindings for a specific S-VLAN. This example clears bindings on S-VLAN 100-200.

```
user@host> clear dhcp server binding ge-1/0/0:100-200
```

To clear all bindings on top of all demux VLANs:

```
user@host> clear dhcp server binding demux0
```

To clear all bindings on top of an underlying interface. This example clears the bindings on all demux VLANs on top of interface ae0:

```
user@host> clear dhcp server binding ae0
```

To clear PPP bindings. This example uses the wildcard feature and clears the PPP bindings over interface pp0.100 and pp0.200.

```
user@host> clear dhcp server binding pp0.*
```

To clear all bindings on an FPC. This example uses the wildcard feature and clears all DHCP bindings on FPC 1.

```
user@host> clear dhcp server binding ge-1/*
```

To clear all bindings on a PIC. This example uses the wildcard feature and clears all DHCP bindings on FPC 1, PIC 0.

```
user@host> clear dhcp server binding ge-1/0/*
```

To clear all bindings on a port. This example uses the wildcard feature and clears all DHCP bindings on FPC 1, PIC 0, port 0.

```
user@host> clear dhcp server binding ge-1/0/0.*
```

## Monitoring DHCP Relay Server Responsiveness

You can configure DHCP relay agent and DHCPv6 relay agent to enable the router to monitor DHCP server responsiveness. To monitor DHCP server responsiveness, you specify the length of time during which the router tracks how DHCP servers respond to relayed packets. If a configured DHCP server within the routing instance fails to respond to all relayed packets during the specified time period, the router generates the `DH_SVC_EXTERN_SERVER_STATE_CHG` system log message. When the DHCP server begins responding successfully, the router generates the log message again to indicate that responsiveness is restored. You can also use **show dhcp relay statistics** and **show dhcpv6 relay statistics** commands to display DHCP server responsiveness statistics.

The following procedure describes how to configure DHCP relay agent to enable the router to monitor DHCP server responsiveness. To configure DHCPv6 server responsiveness, include the **server-response-time** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level.

To monitor DHCP server responsiveness:

1. Specify that you want to configure DHCP relay agent.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

- 2.

```
[edit forwarding-options dhcp-relay]
user@host# set server-response-time 86,400
```

## Verifying and Managing DHCP Local Server Configuration

**Purpose** View or clear information about client address bindings and statistics for the extended DHCP local server.

**NOTE:** If you delete the DHCP server configuration, DHCP server bindings might still remain. To ensure that DHCP bindings are removed, issue the **clear dhcp server binding** command before you delete the DHCP server configuration.

**Action** • To display the address bindings in the client table on the extended DHCP local server:

```
user@host> show dhcp server binding routing-instance customer routing instance
```

- To display extended DHCP local server statistics:

```
user@host> show dhcp server statistics routing-instance customer routing instance
```

- To clear the binding state of a DHCP client from the client table on the extended DHCP local server:

```
user@host> clear dhcp server binding routing-instance customer routing instance
```

- To clear all extended DHCP local server statistics:

```
user@host> clear dhcp server statistics routing-instance customer routing instance
```

## Verifying and Managing DHCP Relay Configuration

**Purpose** View or clear address bindings or statistics for extended DHCP relay agent clients:

**Action** • To display the address bindings for extended DHCP relay agent clients:

```
user@host> show dhcp relay binding routing-instance customer routing instance
```

- To display extended DHCP relay agent statistics:

```
user@host> show dhcp relay statistics routing-instance customer routing instance
```

- To clear the binding state of DHCP relay agent clients:

```
user@host> clear dhcp relay binding routing-instance customer routing instance
```

- To clear all extended DHCP relay agent statistics:

```
user@host> clear dhcp relay statistics routing-instance customer routing instance
```

## Tracing Extended DHCP Operations

Both the extended DHCP local server and the extended DHCP relay agent support tracing operations. DHCP tracing operations track extended DHCP operations and record them in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

You can configure DHCP trace operations at the global level and at the interface level. Global DHCP tracing logs all DHCP-related events, whereas interface-level tracing logs only interface-specific DHCP events. If you configure interface-level trace operations, you can specify tracing for a range of interfaces or an individual interface. However, only a single interface-level log file is supported. That is, you cannot specify different interface-level log files for different interfaces or groups of interfaces.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

- Important events for both global and per-interface tracing are logged in a file located in the `/var/log` directory. By default, the router uses the filename, `jdhcpd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
- When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the [System Log Explorer](#).)

- By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure global DHCP tracing operations.

- Specify tracing operations for DHCP local server and DHCP relay:

```
[edit system processes dhcp-service]
user@host# edit traceoptions
```

The tracing configuration is applied globally to all DHCP applications in every LS:RI. Configuration of event tracing on a per-LS:RI basis is not supported. DHCP tracing is configurable only in the default LS:RI. However, DHCP applications (local server or relay) do not have to be configured in the default LS:RI.

**NOTE:** We recommend that you use configure tracing statements at the `[edit system processes dhcp-service]` hierarchy level.

Because you can configure DHCP tracing at three different hierarchy levels (one new and recommended, two old and deprecated), the following rules apply to manage the interaction:

- When you configure a filename or any other options for the trace log file, the configuration at the `[edit system processes dhcp-service]` hierarchy level has the highest precedence, followed by the configuration at the `[edit system services dhcp-local-server]` hierarchy level, and finally with the lowest precedence, the configuration at the `[edit forwarding-options dhcp-relay]` hierarchy level.
- The flag configurations for multiple hierarchy levels are merged and applied to all trace log events.
- The deprecated statements do not support filtering the generation of DHCP trace log events by severity level. If you use these statements, trace logging operates with an implicit severity of **all**, regardless of the severity level configured at the `[edit system processes dhcp-service]` hierarchy level.

For information about configuring per-interface tracing options, see [“Tracing Extended DHCP Operations for Specific Interfaces” on page 382](#).

The extended DHCP traceoptions operations are described in the following sections:

- [Configuring the Extended DHCP Log Filename on page 379](#)
- [Configuring the Number and Size of Extended DHCP Log Files on page 379](#)
- [Configuring Access to the Extended DHCP Log File on page 380](#)
- [Configuring a Regular Expression for Extended DHCP Messages to Be Logged on page 381](#)
- [Configuring the Extended DHCP Tracing Flags on page 381](#)
- [Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged on page 381](#)
- [Tracing Extended DHCP Operations for Specific Interfaces on page 382](#)

### Configuring the Extended DHCP Log Filename

By default, the name of the file that records trace output is **jdhcpd**. You can specify a different name by including the **file** option. DHCP local server and DHCP relay agent both support the **file** option for the **traceoptions** statement and the **interface-traceoptions** statement.

To change the filename:

- Specify a filename for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename
```

- Specify a filename for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename
```

### Configuring the Number and Size of Extended DHCP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats

until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

DHCP local server and DHCP relay agent both support the **files** and **size** options for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename files number size maximum-file-size
```

- Specify the name, number, and size of the file used for the trace output for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename files number size maximum-file-size
```

---

### Configuring Access to the Extended DHCP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

DHCP local server and DHCP relay agent both support the **world-readable** option and the **no-world-readable** option for the **traceoptions** statement and the **interface-traceoptions** statement. To specify that all users can read the log file:

- Configure the log file to be world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename world-readable
```

- Configure the log file to be world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename world-readable
```

To explicitly set the default behavior, in which the log file can only be read by the user who configured tracing:

- Configure the log file to be no-world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename no-world-readable
```

- Configure the log file to be no-world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename no-world-readable
```

### Configuring a Regular Expression for Extended DHCP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events. You can refine the output by including regular expressions to be matched.

DHCP local server and DHCP relay agent both support the **match** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure regular expressions to be matched:

- Specify the regular expression for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename match regular-expression
```

- Specify the regular expression for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename match regular-expression
```

### Configuring the Extended DHCP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

DHCP local server and DHCP relay agent both support the **flag** option for the **traceoptions** statement and the **interface-traceoptions** statement. A smaller set of flags is supported for interface-level tracing than for global tracing. To configure the flags for the events to be logged:

- Specify the flags for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set flag flag
```

- Specify the flags for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set flag flag
```

### Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. A low severity level is less restrictive—filters out fewer messages—than a higher level. When you configure a severity level, all messages at that level and all higher (more restrictive) levels are logged.

The following list presents severity levels in order from lowest (least restrictive) to highest (most restrictive). This order also represents the significance of the messages; for example, **error** messages are of greater concern than **info** messages.

- **verbose**
- **info**
- **notice**
- **warning**
- **error**

The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all**. You can also specify **verbose** with the same result, because **verbose** is the lowest (least restrictive) severity level; it has nothing to do with the terseness or verbosity of the messages. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

DHCP local server and DHCP relay agent both support the **level** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the flags for the events to be logged:

- Specify the severity level for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set level severity
```

- Specify the severity level for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set level severity
```

---

### Tracing Extended DHCP Operations for Specific Interfaces

In addition to the global DHCP tracing operations, subscriber management enables you to trace extended DHCP operations for a specific interface or for a range of interfaces.

Configuring per-interface tracing is a two-step procedure. In the first step, you specify the tracing options that you want to use, such as file information and flags. In the second step, you enable the tracing operation on the specific interfaces.

To configure per-interface tracing operations:

1. Specify the tracing options you want to use.

**NOTE:** Per-interface tracing uses the same default tracing behavior as the global extended DHCP tracing operation. The default behavior is described in [“Tracing Extended DHCP Operations” on page 377](#).

a. Specify that you want to configure per-interface tracing options.

- For DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent:

```
[edit system processes dhcp-service]
user@host# edit interface-traceoptions
```

b. (Optional) Specify the tracing file options.

- Configure the name for the file used for the trace output.

See [“Configuring the Extended DHCP Log Filename” on page 379](#).

- Configure the number and size of the log files.

See [“Configuring the Number and Size of Extended DHCP Log Files” on page 379](#).

- Configure access to the log file.

See [“Configuring Access to the Extended DHCP Log File” on page 380](#).

- Configure a regular expression to filter logging events.

See [“Configuring a Regular Expression for Extended DHCP Messages to Be Logged” on page 381](#).

c. (Optional) Specify tracing flag options.

See [“Configuring the Extended DHCP Tracing Flags” on page 381](#).

d. (Optional) Configure a severity level for messages to specify which event messages are logged.

See [“Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged” on page 381](#).

2. Enable tracing on an interface or interface range.

The following examples show a DHCP local server configuration. You can also use the **trace** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level and at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

- Enable tracing on a specific interface.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name trace
```

- Enable tracing on a range of interfaces.

```
[edit system services dhcp-local-server]
```

```
user@host# set group group-name interface interface-name upto interface  
interface-name trace
```

- [Example: Extended DHCPv6 Local Server Configuration on page 390](#)

## DHCPv6 Local Server Overview

The DHCPv6 local server is compatible with the DHCP local server and the DHCP relay agent, and can be enabled on the same interface as either the extended DHCP local server or DHCP relay agent.

The DHCPv6 local server provides many of the same features as the DHCP local server, including:

- Configuration for a specific interface or for a group of interfaces
- Site-specific usernames and passwords
- Numbered Ethernet interfaces
- Statically configured CoS and filters
- AAA directed login
- Use of the IA\_NA option to assign a specific address to a client

When a DHCPv6 client logs in, the DHCPv6 local server can optionally use the AAA service framework to interact with the RADIUS server. The RADIUS server, which is configured independently of DHCP, authenticates the client and supplies the IPv6 prefix and client configuration parameters.

The client username, which uniquely identifies a subscriber or a DHCP client, must be present in the configuration in order for DHCPv6 local server to use RADIUS authentication.

You can configure DHCPv6 local server to communicate the following attributes to the AAA service framework and RADIUS at login time:

- Client username
- Client password

Based on the attributes that the DHCPv6 local server provides, RADIUS returns the information listed in [Table 41 on page 386](#) to configure the client:

*Table 41: RADIUS Attributes and VSAs for DHCPv6 Local Server*

Attribute Number	Attribute Name	Description
27	Session-Timeout	Lease time, in seconds. If not supplied, the lease does not expire
123	Delegated-IPv6-Prefix	Prefix that is delegated to the client
26-143	Max-Clients-Per-Interface	Maximum number of clients allowed per interface

To configure the extended DHCPv6 local server on the router (or switch), you include the **dhcpv6** statement at the **[edit system services dhcp-local-server]** hierarchy level.

You can also include the **dhcpv6** statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* system services dhcp-local-server]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* system services dhcp-local-server]
- [edit routing-instances *routing-instance-name* system services dhcp-local-server]

## Enabling DHCPv6 Rapid Commit Support

You can configure the DHCPv6 local server to support the DHCPv6 Rapid Commit option (DHCPv6 option 14). When rapid commit is enabled, the server recognizes the Rapid Commit option in Solicit messages sent from the DHCPv6 client. (DHCPv6 clients are configured separately to include the DHCPv6 Rapid Commit option in the Solicit messages.) The server and client then use a two-message exchange (Solicit and Reply) to configure clients, rather than the default four-message exchange (Solicit, Advertise, Request, and Reply). The two-message exchange provides faster client configuration, and is beneficial in environments in which networks are under a heavy load.

You can configure the DHCPv6 local server to support the Rapid Commit option globally, for a specific group, or for a specific interface. By default, rapid commit support is disabled on the DHCPv6 local server.

To configure the DHCPv6 local server to support the DHCPv6 Rapid Commit option:

1. Specify that you want to configure the **overrides** options:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Enable rapid commit support:

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set rapid-commit
```

**See Also** • [Overriding the Default DHCP Local Server Configuration Settings Overview on page 243](#)

## Preventing Binding of Clients That Do Not Support Reconfigure Messages

The DHCPv6 client and server negotiate the use of reconfigure messages. When the client can accept reconfigure messages from the server, then the client includes the Reconfigure Accept option in both solicit and request messages sent to the server.

By default, the DHCPv6 server accepts solicit messages from clients regardless of whether they support reconfiguration. You can specify that the server require clients to accept reconfigure messages. In this case, the DHCPv6 server includes the Reconfigure Accept option in both advertise and reply messages when reconfiguration is configured for the client interface. Solicit messages from nonsupporting clients are discarded and the clients are not allowed to bind.

To configure the DHCPv6 local server to bind only clients that support client-initiated reconfiguration:

- Specify strict reconfiguration.

For all DHCPv6 clients:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]  
user@host# set strict
```

For only a particular group of DHCPv6 clients:

```
[edit system services dhcp-local-server dhcpv6 group group-name reconfigure]  
user@host# set strict
```

The **show dhcpv6 server statistics** command displays a count of solicit messages that the server has discarded.

- See Also**
- [Configuring Dynamic Client Reconfiguration of Extended Local Server Clients Overview on page 356](#)
  - [Understanding Dynamic Reconfiguration of Extended DHCP Local Server Clients on page 353](#)

## Configuring the DUID Type Supported by DHCPv6 Servers

Every DHCPv6 client and server has a DHCP unique identifier (DUID). Each DUID is globally unique across all DHCPv6 clients and servers in an administrative domain. Messages between clients and servers can carry the client DUID in the Client-Identifier option and the server DUID in the Server-Identifier option. Clients and servers may require that some message types that include different messages may be accepted or discarded based on whether they include one or both of these DUIDs. A server or client may discard some message types when the DUID option value does not match the server's DUID or the client's DUID, respectively.

The DUIDs facilitate communication between client/server pairs by providing a means for each to determine whether it is the intended recipient of a message and also identifying where to forward a response. For example, a server uses the server DUID received in a message from a client to determine whether the message is intended for it. Then it can compare the client DUID it has received against its database. When it finds a match, the server sends the associated configuration information to the client. The server also uses the client DUID to select clients for an Identity Association.

The server DUID conveyed to the client enables the client to distinguish between servers. To target a single server, it may include that DUID when it sends multicast messages; only the server identified by the DUID responds.

*RFC, 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6)* defines three types of DUIDs, but we support only the DUID-EN and DUID-LL types:

- DUID-EN—(Supported) A device vendor assigns a DUID of this type when the device is manufactured. The value consists of the vendor's IANA enterprise number followed by a unique number. This is the default type.
- DUID-LL—(Supported) This type of DUID includes a hardware type code recognized by IANA, followed by the link-layer address of any network interface permanently connected to the device. DUID-LL is supported only for DHCPv6 servers.
- DUID-LLT—(Not supported). This type is similar to the DUID-LL type, but additionally includes the time that the DUID is generated relative to a specific date and time.

The DUID type is specified per routing instance.

To configure the router to use the DUID-LL type:

- Specify the type.

```
[edit system services dhcp-local-server dhcpv6]
user@host# set server-duid-type duid-ll
```

Remove this configuration to return to supporting the DUID-EN type.

### Example: Extended DHCPv6 Local Server Configuration

This example shows a sample extended DHCPv6 local server configuration. The second part of the example shows a sample RADIUS authentication configuration—authentication must be configured for DHCPv6 local server operations.

```
[edit system services]
dhcp-local-server {
  dhcpv6 {
    authentication {
      password $ABC123;
      username-include {
        user-prefix wallybrown;
        domain-name example.com;
      }
    }
    group group_two {
      authentication {
        password $ABC123$ABC123;
        username-include {
          user-prefix south5;
          domain-name example.com;
        }
      }
    }
    interface ge-1/0/3.0;
  }
}
```

The following is a sample RADIUS authentication configuration.

```
[edit access]
radius-server {
  192.168.1.250 {
    port 1812;
    secret $ABC123;
  }
}
profile isp-bos-metro-fiber-basic {
  accounting-order radius;
  authentication-order radius;
  radius {
    authentication-server 192.168.1.250;
    accounting-server 192.168.1.250;
  }
  accounting {
    order radius;
    accounting-stop-on-failure;
    accounting-stop-on-access-deny;
    update-interval 10;
    statistics time;
  }
}
```

- [Inserting DHCPv6 Remote-ID Option \(Option 37\) In DHCPv6 Packets on page 395](#)

### DHCPv6 Relay Agent Overview

The DHCPv6 relay agent enhances the DHCP relay agent by providing support in an IPv6 network. The DHCPv6 relay agent passes messages between the DHCPv6 client and the DHCPv6 server, similar to the way DHCP relay agent supports an IPv4 network. DHCPv6 relay agents eliminate the necessity of having a DHCPv6 server on each physical network.

When a DHCPv6 client logs in, the DHCPv6 relay agent uses the AAA service framework to interact with the RADIUS server to provide authentication and accounting. The RADIUS server, which is configured independently of DHCP, authenticates the client and supplies the IPv6 prefix and client configuration parameters, such as session timeout and the maximum number of clients allowed per interface.

**NOTE:** The PTX Series Packet Transport Routers do not support authentication for DHCPv6 relay agents.

**NOTE:**  
The following DHCPv6 functionalities are not supported on ACX Series routers:

- Subscriber authentication for DHCPv6 relay agents
- DHCP snooping
- DHCPv6 client
- Liveness detection
- Dynamic profiles
- Option 37 support for remote ID insertion
- Bidirectional Forwarding Detection (BFD) for DHCPv6 relay
- DHCPv6 relay persistence on router reboot, crash, or power failure

The DHCPv6 relay agent is compatible with the DHCP local server and the DHCP relay agent, and can be enabled on the same interface as either the DHCP local server or DHCP relay agent.

To configure the DHCPv6 relay agent on the router (or switch), you include the **dhcpv6** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level.

You can also include the **dhcpv6** statement at the following hierarchy levels:

- **[edit logical-systems *logical-system-name* forwarding-options dhcp-relay]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options dhcp-relay]**
- **[edit routing-instances *routing-instance-name* forwarding-options dhcp-relay]**

See “[DHCPv6 Monitoring and Management](#)” on page 398 for commands specific to viewing and clearing DHCPv6 bindings and statistics.

## DHCPv6 Relay Agent Options

You can configure DHCPv6 relay agent to include additional information in the client-originated DHCP packets that the relay agent forwards to a DHCPv6 server. This support is equivalent to the option 82 support provided by the DHCPv4 relay agent. The DHCPv6 server uses the additional information in the packets to determine the IPv6 address to assign to the client. The server might also use the information for other purposes; for example, to determine which services to grant the client, or to provide additional security against threats such as address spoofing. The DHCPv6 server sends its reply back to the DHCPv6 relay agent, and the agent removes the option information from the message, and then forwards the packet to the client.

You can configure the DHCPv6 relay agent to include the following options in the packet the relay agent sends to the DHCPv6 server:

- Relay Agent Interface-ID (option 18)—An ASCII string that identifies the interface on which the client DHCPv6 packet is received. This is the equivalent of the DHCPv4 relay agent option 82 Agent Circuit ID suboption (suboption 1).
- Relay Agent Remote-ID (option 37)—An ASCII string assigned by the DHCPv6 relay agent that securely identifies the client. This is the equivalent of the DHCPv4 relay agent option 82 Agent Remote ID suboption (suboption 2).

## Configuring DHCPv6 Relay Agent Options

You can configure DHCPv6 relay agent to insert optional information in the DHCPv6 packets that the relay receives from clients and forwards to a DHCPv6 server. To configure the optional information, you specify the type of information you want to include in the packets. You use the **relay-agent-interface-id** statement to include Relay Agent Interface-ID (option 18) in the packets, or the **relay-agent-remote-id** statement to include Relay Agent Remote-ID (option 37).

When you enable the DHCPv6 options support, you can optionally configure DHCPv6 relay agent to include a prefix or the interface description as part of the option information.

For dual-stack environments, you can also specify that the DHCPv6 relay agent use the DHCPv4 option 82 information to populate DHCPv6 option 18 or option 37.

To enable insertion of DHCPv6 options:

1. Specify that you want to configure DHCPv6 relay agent support.

```
[edit forwarding-options dhcp-relay]
user@host# edit dhcpv6
```

2. Configure DHCPv6 relay agent to insert the Relay Agent Interface-ID option, the Relay Agent Remote-ID option, or both.

- To insert Relay Agent Interface-ID (option 18):

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-interface-id
```

- To insert Relay Agent Remote-ID (option 37):

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-remote-id
```

3. (Optional) Specify additional information that you want to include in option 18 or option 37. The **relay-agent-interface-id** and **relay-agent-remote-id** statements both support inclusion of a prefix, interface description, or the DHCPv4 option 82 information. For example:

- To prepend prefix information—This example prepends a prefix that consists of the hostname and logical system name to option 18. You use the **relay-agent-remote-id** statement to add the prefix to option 37.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-interface-id prefix host-name logical-system-name
```

- To include the textual interface description—This example uses the description for the device interface instead of the interface identifier in option 18. You use the **relay-agent-remote-id** statement to add the interface description to option 37.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-interface-id use-interface-description device
```

- To use the DHCPv4 option-82 value—This example uses the DHCPv4 option-82 (suboption 2) value for the DHCPv6 option 37 value. You use the **relay-agent-interface-id** statement to use DHCPv4 option 82 (suboption 1) in DHCPv6 option 18.

This example also includes the optional **strict** keyword to specify that the router drops Solicit packets if the packets do not include an option 82 value. If you do not include the **strict** keyword, the router sends the RELAY-FORW message without adding option 37. The **strict** keyword is not supported for the **relay-agent-interface-id** statement.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set relay-agent-remote-id use-option-82 strict
```

- See Also**
- [Including a Prefix in DHCP Options on page 286](#)
  - [Including a Textual Description in DHCP Options on page 288](#)

## Inserting DHCPv6 Interface-ID Option (Option 18) In DHCPv6 Packets

You can configure DHCPv6 relay agent to insert the DHCPv6 Interface-ID (option 18) in the packets that the relay sends to a DHCPv6 server. You can configure the option 18 support at either the DHCPv6 global or group level.

When you configure option 18 support, you can optionally include the following additional information:

- **Prefix**—Specify the **prefix** option to add a prefix to the interface identifier. The prefix can be any combination of hostname, logical system name, and routing instance name.
- **Interface description**—Specify the **use-interface-description** option to include the textual interface description instead of the interface identifier. You can include either the device interface description or the logical interface description.
- **Option 82 Agent Circuit ID suboption (suboption 1)**—Specify the **use-option-82** option to include the DHCPv4 Option 82 Agent Circuit ID suboption (suboption 1). This configuration is useful in a dual-stack environment, which has both DHCPv4 and DHCPv6 subscribers that reside over the same underlying logical interface. The router checks for the option 82 suboption 1 value and inserts it into the outgoing packets. If no DHCPv4 binding exists or if the binding does not have an option 82 suboption 1 value, the router sends the packets without adding an option 18.

**NOTE:** If you specify one of the optional configurations, and the specified information does not exist (for example, there is no interface description), DHCPv6 relay ignores the optional configuration and inserts the default interface identifier in the packets.

To insert the DHCPv6 Interface-ID option (option 18) in DHCPv6 packets:

1. Configure the DHCPv6 relay to include option 18.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit relay-agent-interface-id
```

2. (Optional) Specify the prefix to include in option 18.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]
user@host# set prefix prefix
```

3. (Optional) Specify that option 18 include the textual description of the interface. You can specify either the **logical** interface description or the **device** interface description.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]
user@host# set use-interface-description (logical | device)
```

4. (Optional) Specify that option 18 use the DHCPv4 Option 82 Agent Circuit ID suboption (suboption 1) value.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]
user@host# set use-option-82
```

- See Also**
- [Including a Prefix in DHCP Options on page 286](#)
  - [Including a Textual Description in DHCP Options on page 288](#)

## Inserting DHCPv6 Remote-ID Option (Option 37) In DHCPv6 Packets

Starting in Junos OS Release 14.1, you can configure DHCPv6 relay agent to insert DHCPv6 Remote-ID (option 37) in the packets that the relay sends to a DHCPv6 server. You can configure option 37 support at either the DHCPv6 global or group level.

When you configure option 37 support, you can optionally include the following information:

- **Prefix**—Specify the **prefix** option to add a prefix to the interface identifier. The prefix can be any combination of hostname, logical system name, and routing instance name.
- **Interface description**—Specify the **use-interface-description** option to include the textual interface description instead of the interface identifier. You can include either the device interface description or the logical interface description.
- **Option 82 Agent Remote-ID suboption (suboption 2)**—Specify the **use-option-82** option to use the value of the DHCPv4 option 82 Remote-ID suboption (suboption 2). This configuration is useful in a dual-stack environment, which has both DHCPv4 and DHCPv6 subscribers that reside over the same underlying logical interface. The router checks for the option 82 suboption 2 value and inserts it into the outgoing packets.

**NOTE:** If you specify one of the optional configurations, and the specified information does not exist (for example, there is no interface description), DHCPv6 relay ignores the optional configuration and inserts the default interface identifier in the packets.

To insert the DHCPv6 Remote-ID option (option 37) in DHCPv6 packets:

1. Configure the DHCPv6 relay to include option 37.

```
[edit forwarding-options dhcp-relay dhcpv6]
```

```
user@host# edit relay-agent-remote-id
```

- (Optional) Specify the prefix to include with the option 37 information.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-remote-id]
user@host# set prefix prefix
```

- (Optional) Specify that option 37 include the textual description of the interface. You can specify either the **logical** interface description or the **device** interface description.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-remote-id]
user@host# set use-interface-description (logical | device)
```

- (Optional) Specify that option 37 use the DHCPv4 option 82 Remote-ID suboption (suboption 2) value.

If no DHCPv4 binding exists, or if the binding does not include an option 82 suboption 2 value, by default the router sends the packets without adding option 37. However, you can use the optional **strict** keyword to specify that the router drop packets that do not have a suboption 2 value.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-remote-id]
user@host# set use-option-82 strict
```

#### Release History Table

Release	Description
14.1	Starting in Junos OS Release 14.1, you can configure DHCPv6 relay agent to insert DHCPv6 Remote-ID (option 37) in the packets that the relay sends to a DHCPv6 server.

**Related Documentation**

- [DHCPv6 Local Server on page 385](#)
- [DHCP Overview on page 227](#)

## DHCPv6 Client MAC Address Validation to Prevent Session Hijacking

Starting in Junos OS Release 18.2R1, a nonconfigurable mechanism exists for DHCPv6 local servers and relay agents to drop packets from a client with an unknown MAC address to prevent a malicious client from hijacking a session. When a DHCPv6 local server or relay agent receives a solicit message from a client to establish a session, it extracts the client MAC address (link-layer address) from the message and adds it to a local table that maps MAC addresses to client IPv6 addresses or prefixes. The server or relay agent uses this table to compare MAC addresses received in subsequent messages from the

client to validate whether the client is known; if not, it is assumed to be malicious and the control packet is dropped. Because the packet has failed MAC validation, the Client MAC validation counter is incremented.

**NOTE:** The assumption here is that the client sending the initial solicit message is benign. In this case, client MAC address validation protects against a malicious client trying to hijack a client session that is already established or in the process of being established. The client MAC address validation does not protect against a malicious client that sends the initial solicit message.

When no relay agent is present; the local server shares a link or access node with the client. In this case, the local server extracts the client MAC address directly from the Layer 2 header of the DHCPv6 control packet and validates the address against the table.

When a relay agent is present, validation is performed by the relay agent. *RFC 6939, Client Link-Layer Address Option in DHCPv6*, enables DHCPv6 relay agents that are connected to the same link as a DHCPv6 client to extract the client MAC address from the Ethernet (Layer 2) header in the received DHCPv6 control packet. The packet includes the client link-layer address as the source MAC address in its Ethernet header. The relay agent validates the MAC address against the value for this client that is stored in its local table. If the address does not match it drops the packet.

If the address is validated by the relay agent and the packet is not dropped, then the relay agent also includes that MAC address in option 79 (Client Link-Layer Address) in the header of the DHCPv6 relay-forward message that the relay agent sends to the local server. When the DHCPv6 local server receives a relay-forward message from a relay agent, the server automatically examines the message for the presence of option 79. When the option is present, the local server extracts the MAC address and validates it against the value stored in the table for this client. If option 79 is not present, the local server cannot perform the validation.

However, because the relay agent has already validated the address, the local server should not discover any address mismatches.

The following scenarios describe possible relay agent configurations and their implications for server validation:

- A single Lightweight DHCPv6 Relay Agent (LDRA; Layer 2) is connected between the client and the server. If the LDRA did not add option 79 to the header, then the local server extracts the client MAC address directly from the Layer 2 header of the DHCPv6 control packet and validates the address against the table.
- One or more Layer 3 DHCPv6 relay agents are connected between the client and the server. In this case, the server checks for option 79 in the header of the innermost relay-forward message sent by the relay agent. The innermost header is viewed because it is the header modified by the first relay agent reached by the client. Other headers are added by subsequent relay agents in the path. These agents do not add option 79 and they cannot extract the MAC address from the first relay agent's Layer 2 header,

because that agent changes the address to its own address, as does each subsequent relay agent.

- A combination of a client-facing Layer 2 (LDRA) relay agent followed by one or more Layer 3 DHCPv6 relay agents is connected between the client and the server. The server checks for option 79 in the innermost header of the relay-forward message sent by the relay agent. If the LDRA did not add option 79 to the header, it is probably not capable of changing the MAC address in the header to its own. Consequently, the server next checks the second innermost header for the option, because the first Layer 3 relay agent may have extracted the MAC address and added option 79 to convey the address.

No configuration is required to enable validation of client MAC addresses. You can view how many control packets have been dropped because of a validation failure by issuing the **show dhcpv6 server statistics** command.

## Benefits

- Client MAC address validation enables you to prevent a DHCPv6 client with an unknown MAC address from hijacking a session established by a known client. Usage of DHCPv6 client MAC addresses is likely to increase as it is convenient for correlating DHCPv4 and DHCPv6 clients in a dual-stack environment.

### Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, a nonconfigurable mechanism exists for DHCPv6 local servers and relay agents to drop packets from a client with an unknown MAC address to prevent a malicious client from hijacking a session.

- [Requesting DHCPv6 Local Server to Initiate Reconfiguration of Client Bindings on page 398](#)
- [Verifying and Managing DHCPv6 Local Server Configuration on page 399](#)
- [Verifying and Managing DHCPv6 Relay Configuration on page 400](#)

### Requesting DHCPv6 Local Server to Initiate Reconfiguration of Client Bindings

You can request that the DHCPv6 local server initiate reconfiguration of all clients or only specified clients.

To request reconfiguration of all clients:

- Specify the **all** option.

```
user@host> request dhcpv6 server reconfigure all
```

You can use any of the following methods to request reconfiguration of specific clients:

- Specify the IP address of the DHCPv6 client.

```
user@host> request dhcpv6 server reconfigure 2001:db8:1111:2222::
```

- Specify the client ID of a DHCPv6 client.

```
user@host> request dhcpv6 server reconfigure
LL_TIME0x1-0x2e159c0-00:10:94:00:00:02
```

- Specify the session ID of a DHCPv6 client.

```
user@host> request dhcpv6 server reconfigure 5
```

- Specify an interface; reconfiguration is attempted for all clients on this interface.

```
user@host> request dhcpv6 server reconfigure interface fe-0/0/0.100
```

- Specify a logical system; reconfiguration is attempted for all clients or the specified clients in this logical system.

```
user@host> request dhcpv6 server reconfigure all logical-system ls-bldg5
```

- Specify a routing instance; reconfiguration is attempted for all clients or the specified clients in this routing instance.

```
user@host> request dhcpv6 server reconfigure all routing-instance ri-boston
```

**See Also** • [Dynamic Reconfiguration of Clients From a DHCP Local Server on page 353](#)

## Verifying and Managing DHCPv6 Local Server Configuration

**Purpose** View or clear information about client address bindings and statistics for the DHCPv6 local server.

**Action** • To display the address bindings in the client table on the DHCPv6 local server:

```
user@host> show dhcpv6 server binding
```

- To display DHCPv6 local server statistics:

```
user@host> show dhcpv6 server statistics
```

- To clear all DHCPv6 local server statistics:

```
user@host> clear dhcpv6 server binding
```

- To clear all DHCPv6 local server statistics:

```
user@host> clear dhcpv6 server statistics
```

## Verifying and Managing DHCPv6 Relay Configuration

**Purpose** View or clear address bindings or statistics for extended DHCPv6 relay agent clients:

**Action**

- To display the address bindings for extended DHCPv6 relay agent clients:

```
user@host> show dhcpv6 relay binding
```

- To display extended DHCPv6 relay agent statistics:

```
user@host> show dhcpv6 relay statistics
```

- To clear the binding state of DHCPv6 relay agent clients:

```
user@host> clear dhcpv6 relay binding
```

- To clear all extended DHCPv6 relay agent statistics:

```
user@host> clear dhcpv6 relay statistics
```

## Introduction to IPv6 Addresses

---

IPv6 uses a 128-bit addressing model compared with the 32-bit addresses used for IPv4. In addition to being larger, IPv6 addresses differ from IPv4 addresses in several ways:

- Notation
- Prefixes
- Address types

These differences give IPv6 addressing greater simplicity and scalability than IPv4 addressing gives.

- [IPv6 Notation on page 404](#)
- [IPv6 Prefixes on page 404](#)
- [IPv6 Address Types on page 404](#)

## IPv6 Notation

IPv6 addresses are 128 bits long (expressed as 32 hexadecimal numbers) and consist of eight colon-delimited sections. Each section contains 2 bytes, and each byte is expressed as a hexadecimal number from 0 through FF.

An IPv6 address looks like this:

2001:0db8:0000:0000:0000:0800:200c:7334

By omitting the leading zeroes from each section or substituting contiguous sections that contain zeroes with a double colon, you can write the example address as:

2001:db8:0:0:0:800:200c:7334 or 2001:db8::800:200c:7334

You can use the double-colon delimiter only once within a single IPv6 address. For example, you cannot express the IPv6 address 2001:db8:0000:0000:ea34:0000:71ff:fe01 as 2001:db8::ea34::71ff:fe01.

## IPv6 Prefixes

An IPv6 address prefix represents a block of address space or a network. The prefix is a combination of an IPv6 prefix (address) and a prefix length. It takes the form *ipv6-prefix/prefix-length*.

IPv6 addresses can be broken into prefixes of varying length. The prefix length is a decimal value that specifies the number of the leftmost bits in the address that make up the prefix. The prefix length follows a forward slash and, in most cases, identifies the portion of the address owned by an organization. All remaining bits (up to the right-most bit) represent individual nodes or interfaces.

For example, 2001:db8:0000:0000:250:af:34ff:fe26/64 has a prefix length of 64.

The first 64 bits of this address (2001:db8:0000:0000) are the prefix. The rest (250:af:34ff:fe26) identify the interface.

## IPv6 Address Types

There are three major categories of IPv6 addresses:

- Unicast—For a single interface.
- Multicast—For a set of interfaces on the same physical medium. A packet is sent to all interfaces associated with the address.
- Anycast—For a set of interfaces on different physical media. A packet is sent to only one of the interfaces associated with this address, not to all the interfaces.

---

## Unicast Addresses

A unicast address identifies a single interface. When a network device sends a packet to a unicast address, the packet goes only to the specific interface identified by that address. Unicast addresses support a global address scope and two types of local address scopes.

A unicast address consists of  $n$  bits for the prefix, and  $128 - n$  bits for the interface ID.

In the IPv6 implementation for a subscriber access network, the following types of unicast addresses can be used:

- Global unicast address—A unique IPv6 address assigned to a host interface. These addresses have a global scope and essentially the same purposes as IPv4 public addresses. Global unicast addresses are routable on the Internet.
- Link-local IPv6 address—An IPv6 address that allows communication between neighboring hosts that reside on the same link. Link-local addresses have a local scope, and cannot be used outside the link. They always have the prefix FE80::/10.
- Loopback IPv6 address—An IPv6 address used on a loopback interfaces. The IPv6 loopback address is 0:0:0:0:0:0:0:1, which can be notated as ::1/128.
- Unspecified address—An IPv6 unspecified address is 0:0:0:0:0:0:0:0, which can be notated as ::/128.

---

## Multicast Addresses

A multicast address identifies a set of interfaces that typically belong to different nodes. When a network device sends a packet to a multicast address, the device broadcasts the packet to all interfaces identified by that address. IPv6 does not support broadcast addresses, but instead uses multicast addresses in this role.

Multicast addresses support 16 different types of address scope, including node, link, site, organization, and global scope. A 4-bit field in the prefix identifies the address scope.

The following types of multicast addresses can be used in an IPv6 subscriber access network:

- Solicited-node multicast address—Neighbor Solicitation (NS) messages are sent to this address.
- All-nodes multicast address—Router Advertisement (RA) messages are sent to this address.
- All-routers multicast address—Router Solicitation (RS) messages are sent to this address.

Multicast addresses use the prefix FF00::/8.

---

## Anycast Addresses

An anycast address identifies a set of interfaces that typically belong to different nodes. Anycast addresses are similar to multicast addresses, except that packets are sent only to one interface, not to all interfaces. The routing protocol used in the network usually

determines which interface is physically closest within the set of anycast addresses and routes the packet along the shortest path to its destination.

There is no difference between anycast addresses and unicast addresses except for the subnet-router address. For an anycast subnet-router address, the low-order bits, typically 64 or more, are zero. Anycast addresses are taken from the unicast address space.

For more information about anycast addresses, see RFC 2526, *Reserved IPv6 Subnet Anycast Addresses*.

## Migration to IPv6 Using IPv4 and IPv6 Dual Stack

As a service provider, you can use the Junos OS IPv4/IPv6 dual-stack feature to begin your migration from IPv4 to IPv6 by implementing IPv6 alongside IPv4 in your existing subscriber networks. The feature allows you to implement IPv6 so that you can provide the same subscriber services over IPv6—video, voice, high-quality data—that you currently provide in your IPv4 networks. You can then perform incremental upgrades to IPv6 and avoid service disruptions while migrating from IPv4 to IPv6.

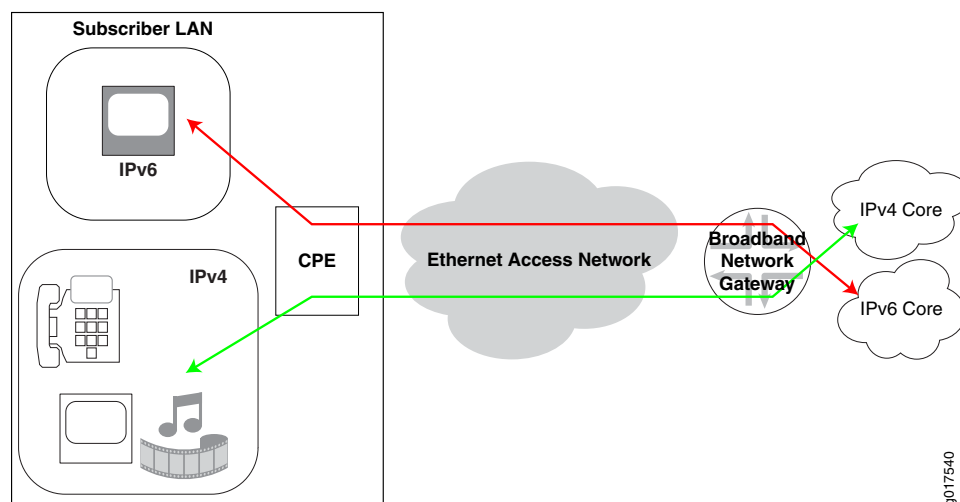

- [Basic Architecture of a Subscriber Access Dual-Stack Network on page 406](#)

- [IPv6 Addressing Requirements for a Subscriber Access Network on page 409](#)

### Basic Architecture of a Subscriber Access Dual-Stack Network

This Juniper Networks dual-stack architecture is designed for either DHCP-based or PPP/PPPoE-based subscriber access networks. In addition, this design allows you to layer DHCPv6 over PPPoE-based networks.

[Figure 6 on page 407](#) shows the components of a basic subscriber access network in which the subscriber LAN is running both IPv4 and IPv6 and is connected to the IPv4 and IPv6 core using a broadband network gateway (BNG) configured for dual stack. Using IPv4/IPv6 dual stack, the BNG can provide both IPv4 and IPv6 services over the access network to the subscriber LAN. A single interface can operate simultaneously in IPv4 and IPv6 modes.

Figure 6: IPv4 and IPv6 Dual-Stack Architecture in a Subscriber Access Network

g017540

## Terms Used in IPv6 Subscriber Management Documentation

Table 42 on page 407 defines terms used in the IPv6 subscriber management documentation.

Table 42: IPv6 Subscriber Management Terms

Term	Definition
BNG	Broadband network gateway. An IP edge router in which bandwidth and QoS policies may be applied. The BNG may encompass any or all of the functionality of B-RAS.
CPE	Customer premises equipment on the subscriber network that connects the subscriber network to the BNG.
Delegated addressing	Method of address assignment in which a host uses IPv6 prefixes to delegate IPv6 global addresses. In a dual-stack network, the CPE uses IPv6 prefixes that it receives to delegate global IPv6 addresses to individual subscriber equipment.
Delegating router	Role of the BNG when it delegates IPv6 prefixes to the requesting router (the CPE).
DHCPv6 IA	Identity association. A collection of addresses assigned to a client.  Each IA contains one type of address. For example, IA_NA carries assigned addresses that are nontemporary addresses; IA_PD carries a prefix.
DHCPv6 IA_PD	IA for prefix delegation. An IA that carries a prefix that is assigned to the requesting router. Instead of assigning a single address, IA_PD assigns a prefix or a complete subnet.  Referred to as DHCPv6 prefix delegation.
DHCPv6 IA_NA	IA for nontemporary addresses. An IA that carries assigned addresses that are not temporary addresses.  DHCPv6 IA_NA is used to assign global IPv6 addresses.

Table 42: IPv6 Subscriber Management Terms (continued)

Term	Definition
Global IPv6 address	Unique IPv6 address that identifies a single interface and allows the interface to access the IPv6 internet.
IPv6 address prefix/prefix length	<p>Combination of an IPv6 prefix (address) and a prefix length.</p> <p>The prefix takes the form <i>ipv6-prefix/prefix-length</i> and represents a block of address space (or a network).</p> <p>The <i>/prefix-length</i> indicates the number of contiguous, higher-order bits of the address that make up the network portion of the address.</p> <p>For example, 2001:DB8::/32 is an IPv6 prefix.</p>
IPCP	IPv4 Control Protocol. A PPP protocol that establishes the IPv4 link between the BNG and the CPE if you are using PPPoE in your access network.
IPv6CP	IPv6 Control Protocol. A PPP protocol that establishes the IPv6 link between the BNG and the CPE if you are using PPPoE in your access network.
Link-local address	<p>Locally derived address that is designed to be used for addressing on a single link for purposes such as automatic address configuration, Neighbor Discovery, or when no routers are present. It is indicated by the prefix FE80::/10.</p> <p>In your dual-stack network, you can use a link-local address on the interface that connects the CPE and the BNG.</p>
NDRA	Neighbor Discovery Router Advertisement. An IPv6 protocol that is used in the dual-stack network to allow automatic addressing on the CPE WAN link.
Neighbor discovery	Protocol in the IPv6 protocol suite that allows nodes on the same link to advertise their existence to their neighbors, and to learn about the existence of their neighbors.
Prefix list	Table that contains IPv6 prefixes.
Requesting router	Role of the CPE when it requests IPv6 prefixes from the delegating router (the BNG).
Router Advertisement (RA)	<p>Message that the BNG periodically sends to hosts or sends in response to Router Solicitation (RS) requests from another host. The message includes IPv6 prefixes and other autoconfiguration information.</p> <p>In a dual-stack network, the router sends RAs to CPE devices on its access network.</p>
Router Solicitation (RS)	Message that hosts send to discover the presence of on-link routers. In a dual-stack network, CPE devices send RS messages to the BNG.
Unnumbered address	Address that can be used on the router's PPPoE loopback interface that connects to the CPE.

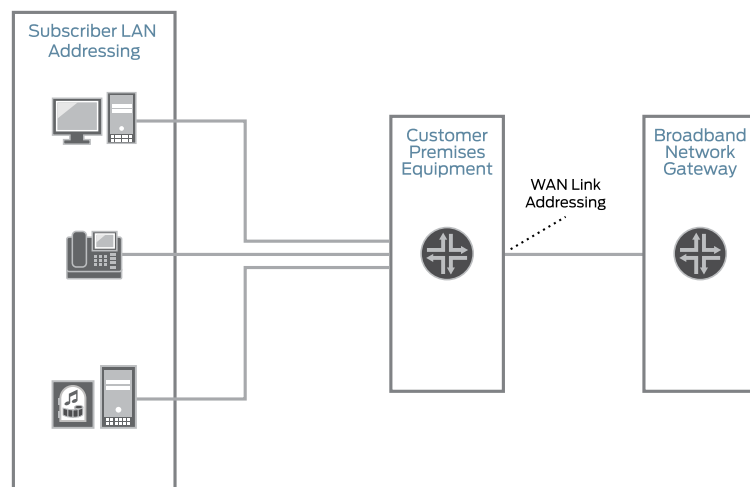

## IPv6 Addressing Requirements for a Subscriber Access Network

You need to implement two types of addressing for IPv6 in a subscriber access network:

- WAN link addressing—For the WAN interface on the CPE (CPE upstream interface).
- Subscriber LAN addressing—For devices connected to the CPE on the subscriber LAN (CPE downstream interfaces).

Figure 7 on page 409 shows where WAN link addressing and subscriber addressing are assigned in a dual-stack network.

*Figure 7: IPv6 Address Requirements in a Subscriber Access Network*

8017542

You can use the following methods for assigning IPv6 addresses:

- For WAN link addressing, you can use Neighbor Discovery Router Advertisement (NDRA) or DHCPv6 Identity association for nontemporary addresses (IA\_NA) to provision a global IPv6 address.
- For subscriber LAN addressing, you can use DHCPv6 prefix delegation to provision global IPv6 addresses to subscribers on the LAN.

### Alternatives to Using a Global IPv6 Address on the CPE WAN Link

If the CPE is supplied by or recommended by the service provider, you do not need to provision a unique global IPv6 address on the CPE. In this case, the broadband network gateway (BNG) can use the loopback interface to manage the CPE. You can use one of the following methods to provision an address on the loopback interface:

- Link-local IPv6 address—Can be used on PPPoE access networks. The link-local address is provisioned by appending the interface identifier negotiated by IPv6CP with the IPv6 link-local prefix (FE80::/10).
- Address derived from DHCPv6 prefix delegation—Can be used on PPPoE access networks or on DHCP access networks. If you use DHCPv6 prefix delegation for

subscriber addressing, the CPE can use the prefix it receives from the BNG to assign an IPv6 address on the loopback interface between the CPE and the BNG. This address can be used to manage the CPE, and the CPE uses it as a source address when it communicates with the BNG.

### Using NDRA to Provide IPv6 WAN Link Addressing Overview

In a dual-stack network, NDRA (Neighbor Discovery Router Advertisement) provides a lightweight address assignment method for autoconfiguration of the global IPv6 address on the CPE WAN link. The CPE device can construct its own IPv6 global address by combining the interface ID that is negotiated by IPv6CP and the prefix obtained through NDRA.

Before NDRA can provide IPv6 address information to the CPE, you need to first obtain a link-local address for the CPE WAN link. NDRA provides address assignment in two phases:

1. Link-local address assignment for local connectivity to the BNG
2. Global address assignment for global connectivity

The process is as follows:

1. During IPv6CP negotiation to establish the PPPoE link between the BNG and the CPE, an interface identifier is negotiated for the CPE.
2. The CPE creates a link-local address by appending the interface identifier with the IPv6 link-local prefix (FE80::/10).

**NOTE:** When the interface ID is 0, such as for Windows 7 clients, PPP uses the subscriber's session ID in place of the interface ID.

The CPE now has IPv6 connectivity to the BNG, and it can use NDRA to obtain its global IPv6 address.

3. The CPE sends a router solicitation message to the BNG.
4. The BNG responds with a router advertisement message that includes an IPv6 prefix with a length of /64.  
  
This prefix can come directly from a local NDRA address pool configured on the BNG. If you are using AAA, a RADIUS server can specify the prefix in the *Framed-Ipv6-Prefix* attribute, or it can specify an NDRA pool on the BNG from which the prefix is assigned in the *Framed-Ipv6-Pool* attribute.
5. When the CPE receives the 64-bit prefix, it appends its interface ID to the supplied prefix to form a globally routable 128-bit address.
6. The CPE verifies that the global address is unique by sending a neighbor solicitation message destined to the new address. If there is a reply, the address is a duplicate. The process stops and requires operator intervention.

## IPv6 Neighbor Discovery Protocol Overview

Neighbor Discovery is a protocol in the IPv6 protocol suite that allows nodes on the same link to advertise their existence to their neighbors and to learn about the existence of their neighbors. Neighbor Discovery is built on top of Internet Control Message Protocol version 6 (ICMPv6). It replaces the following IPv4 protocols: Router Discovery (RDISC), Address Resolution Protocol (ARP), and ICMPv4 redirect.

Neighbor Discovery uses router advertisement messages to detect neighbors, advertise IPv6 prefixes, assist in address provisioning, and share link parameters such as MTU, hop limit, advertisement intervals, and lifetime.

## Neighbor Discovery Messages

---

Neighbor Discovery uses the following message types:

- Router advertisement (RA)—Messages sent to announce the presence of the router, advertise prefixes, assist in address configuration, and share other link information such as MTU size and hop limit. The IPv6 nodes on the link can use this information to configure themselves with an IPv6 address and routing information such as the default gateway.
- Router solicitation (RS)—Messages sent by IPv6 nodes when they come online to solicit immediate router advertisements from the router. Starting in Junos OS Release 18.1R1, the well-known IPv6 all-routers multicast address, FF02::2, is supported in nondefault routing instances. Without this support, IPv6 router solicitation packets are dropped in nondefault routing instances.
- Neighbor solicitation (NS)—Messages used for duplicate address detection and to test reachability of neighbors.

A host can verify that its address is unique by sending a neighbor solicitation message destined to the new address. If the host receives a neighbor advertisement in reply, the address is a duplicate.

- Neighbor advertisement (NA)—Messages used for duplicate address detection and to test reachability of neighbors. Neighbor advertisements are sent in response to neighbor solicitation messages.

You can specify the information that is sent in router advertisements.

## Dynamic Router Advertisement Configuration Overview

In a network deployment where router interfaces are configured statically, you might need to configure the Router Advertisement Protocol on only a small number of interfaces on which it might run. However, in a subscriber access network, static configuration of the Router Advertisement Protocol becomes impractical because the number of interfaces that potentially need the Router Advertisement Protocol increases substantially. In addition, deploying services in a dynamic environment requires dynamic modifications to interfaces as they are created.

Subscriber access supports the configuration of the Router Advertisement Protocol at the **[edit dynamic-profiles profile-name protocols]** hierarchy level. By specifying Router Advertisement Protocol statements within a dynamic profile, you can dynamically apply a Router Advertisement configuration when a subscriber connects to an interface using a particular access technology (for example, DHCP), enabling the subscriber to access a carrier (multicast) network.

To minimally configure the Router Advertisement Protocol requires that you include the **router-advertisement** statement at the **[edit dynamic-profiles profile-name protocols]** hierarchy level and the **interface** statement along with the *\$junos-interface-name* dynamic variable. All other statements are optional.

.....

**NOTE:** Statements used for Router Advertisement Protocol configuration at the [edit dynamic-profiles *profile-name* protocols] hierarchy level are identical in function to those same statements used for static Router Advertisement Protocol configuration, with the exception of the interface and prefix statements, which use dynamic variables.

.....

## Configuring an Interval Range for Unsolicited Router Advertisements to IPv6 Neighbors

*RFC 4861, Neighbor Discovery for IP version 6 (IPv6)*, defines the Neighbor Discovery protocol, which is used by IPv6 nodes to determine link-layer addresses for neighbors, track reachability of neighbors, and discover routers that can forward packets on behalf of hosts. Routers send router advertisement messages to advertise their presence on the network and their characteristics. Hosts send router solicitation messages to discover routers by requesting that routers respond with router advertisement messages immediately. The router advertisements are sent both periodically (for the life of the interface) and in response to router solicitations received from hosts.

The router sets the interval between all router advertisements at the value specified by the **max-advertisement-interval** statement for the interface that sends the advertisement messages. The default interval is several minutes in duration, 600 seconds, and can be configured up to 1800 seconds.

A shorter interval for the first few advertisements increases the chances that the router is discovered quickly when it first becomes available. Accordingly, for only the first three unsolicited router advertisements, RFC 4861 requires a router to use an interval no greater than 16 seconds. If the router selects a larger interval, the interval is automatically set to 16 seconds for the first three unsolicited router advertisements.

In some customer scenarios, 16 seconds is too large an interval for the initial router advertisements and can result in an unacceptable delay for establishing subscriber sessions. If you want the router to advertise more aggressively for a quicker discovery, you can explicitly configure the **max-advertisement-interval** statement to less than 16 seconds for the interface that sends router advertisements.

However, this statement sets the interval between all advertisements sent on the interface, not just those for the first three unsolicited advertisements. That means that all router advertisement messages are sent at short intervals when you configure a lower range. Some users may find this undesirable, because they prefer to have the router discovered quickly, but once it is known, they want the advertisements to be sent at a slower pace, acting as keepalives for the duration of the interface without generating unnecessary amounts of traffic.

Starting in Junos OS Release 18.2R1, you can configure global override options to set the range from which the router randomly selects an interval for only the initial three router advertisements for all interfaces. Random interval selection reduces the likelihood that messages from one router are synchronized with those of another router. A new random interval value is selected after each advertisement is sent so that the interval varies between successive messages. The range for the interval between subsequent router advertisement messages per dynamic interface is still configured with the **max-advertisement-interval** statement in a dynamic profile.

To configure the interval in a dynamic profile that applies to router advertisement messages on the dynamic interface:

- Configure the interval.

```
[edit dynamic-profiles protocols router-advertisement interface interface-name]
user@host# set max-advertisement-interval seconds
```

To configure an interval range for only the initial three advertisement messages on all interfaces:

1. Configure the low end of the interval range.

```
[edit system services subscriber-management overrides]
user@host# set ra-initial-interval-min seconds
```

2. Configure the high end of the interval range.

```
[edit system services subscriber-management overrides]
user@host# set ra-initial-interval-max seconds
```

Consider the following example, where intervals are configured only for router advertisement messages on a dynamic interface. Because the configured interval value is greater than 16, the interval for the first three unsolicited advertisements is always set to 16 seconds. For all subsequent unsolicited advertisements, the router advertisements are sent at an interval of 60 seconds.

```
[edit dynamic-profiles protocols router-advertisement interface $junos-interface-name]
user@host# set max-advertisement-interval 60
```

Now consider the following example, where intervals are configured globally for the first three unsolicited router advertisement messages on all interfaces. All subsequent unsolicited advertisements are configured per dynamic interface.

```
[edit system services subscriber-management overrides]
user@host# set ra-initial-interval-min 3
user@host# set ra-initial-interval-max 9
[edit dynamic-profiles protocols router-advertisement interface $junos-interface-name]
user@host# set max-advertisement-interval 300
```

In this case, the router generates a random interval between 3 seconds and 9 seconds, inclusive, for the first three router advertisement messages on all interfaces. The router sends all subsequent advertisements at an interval of 300 seconds.

## Methods for Obtaining IPv6 Prefixes for NDRA

You can set up the BNG to select IPv6 prefixes used for NDRA through one of the following methods:

- An external source such as a AAA RADIUS server.

- Dynamic assignment from a local pool of NDRA prefixes that is configured on the BNG

### Using AAA RADIUS Server to Obtain IPv6 Prefixes for NDRA

---

When the BNG needs to obtain a prefix for NDRA, it uses the values in one of the following RADIUS attributes that it receives in Access-Accept messages from the RADIUS server:

- *Framed-IPv6-Prefix*—The attribute contains an IPv6 prefix that the BNG can send to the CPE in router advertisement messages.
- *Framed-IPv6-Pool*—The attribute contains the name of an NDRA pool configured on the BNG from which the BNG can select a prefix to include in router advertisements.

**See Also**   • [Configuring an Address-Assignment Pool Used for Router Advertisements on page 496](#)

### Duplicate Prefix Protection for NDRA

If you are using AAA to supply IPv6 prefixes for NDRA, you can enable duplicate prefix protection for NDRA. If enabled, the BNG checks the following attributes received from external servers:

- *Framed-IPv6-Prefix*
- *Framed-IPv6-Pool*

The router then takes one of the following actions:

- If a prefix overlaps with a prefix in an address pool, the prefix is taken from the pool if it is available.
- If the prefix is already in use, it is rejected as unavailable.
- If the prefix length requested from the external server does not match the pool's prefix length exactly, the authentication request is denied. If configured, the Acct-Stop message includes a termination cause.

**See Also**   • [Configuring Duplicate IPv6 Prefix Protection for Router Advertisement on page 497](#)

Release History Table

Release	Description
18.2R1	Starting in Junos OS Release 18.2R1, you can configure global override options to set the range from which the router randomly selects an interval for only the initial three router advertisements for all interfaces.
18.1R1	Starting in Junos OS Release 18.1R1, the well-known IPv6 all-routers multicast address, FF02::2, is supported in nondefault routing instances. Without this support, IPv6 router solicitation packets are dropped in nondefault routing instances.

## IPv6 WAN Link Addressing with DHCPv6 IA\_NA

You can use DHCPv6 IA\_NA to assign a global IPv6 address to the CPE WAN link. If the CPE sends a Solicit message that contains the IA\_NA option to the BNG, the BNG acts as a DHCPv6 server and assigns a single IPv6/128 address to the WAN interface of the CPE.

- [Methods for Obtaining IPv6 Global Addresses for DHCPv6 IA\\_NA on page 417](#)
- [Configuring an Address-Assignment Pool for Use by DHCPv6 IA\\_NA on page 418](#)

### Methods for Obtaining IPv6 Global Addresses for DHCPv6 IA\_NA

You can set up the BNG to select global IPv6 addresses to be delegated to the requesting router in one of the following ways:

- An external source such as a AAA RADIUS server or a DHCP server using the DHCPv6 relay agent.
- Dynamic assignment from a local pool of addresses that is configured on the BNG

#### Using a AAA RADIUS Server to Obtain IPv6 Addresses for DHCPv6 IA\_NA

When the BNG needs to obtain a global IPv6 for the CPE WAN link and optionally a DHCPv6 prefix, it uses the values in one of the following RADIUS attributes:

- *Framed-IPv6-Prefix*—The attribute contains a global IPv6 address with a prefix length of 128.
- *Framed-IPv6-Pool*—The attribute contains the name of an address-assignment pool configured on the BNG from which the BNG can select a global IPv6 address to send to the CPE.

Both attributes are sent from the RADIUS server to the BNG in RADIUS Access-Accept messages.

## Configuring an Address-Assignment Pool for Use by DHCPv6 IA\_NA

This procedure shows how to configure IPv6 local address pools to allocate global IPv6 addresses to the CPE WAN link.

You must configure separate pools for DHCPv6 prefix delegation, DHCPv6 IA\_NA, and NDRA.

To configure the pool to be used for DHCPv6 IA\_NA:

1. Create a pool and assign a name to it.

```
[edit access]
user@host# edit address-assignment pool v6-ia-na-pool
```

2. Under family inet6, add IPv6 network prefixes to the pool.

```
[edit access address-assignment pool v6-ia-na-pool]
user@host# edit family inet6
user@host# set prefix 2001:db8:0000::/64
```

3. Configure the name of the IPv6 address range, and define the range by setting a low and high range of /128 addresses.

```
[edit access address-assignment pool v6-ia-na-pool family inet6]
user@host# edit range v6-range
user@host# set low 2001:db8::1/128
user@host# set high 2001:db8::ffff:ffff/128
```

- [Specifying the Delegated Address-Assignment Pool to Be Used for DHCPv6 Prefix Delegation on page 424](#)

## Using DHCPv6 Prefix Delegation Overview

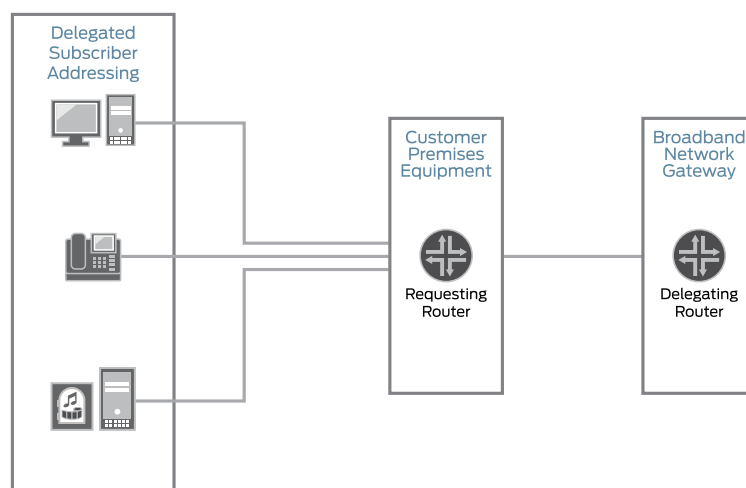

You can use DHCPv6 prefix delegation to automate the delegation of IPv6 prefixes to the CPE. With prefix delegation, a delegating router (the BNG) delegates IPv6 prefixes to a requesting router (the CPE). The requesting router then uses the prefixes to assign global IP addresses to the devices on the subscriber LAN. The requesting router can also assign subnet addresses to subnets on the LAN.

DHCPv6 prefix delegation is useful when the delegating router does not have information about the topology of the networks in which the requesting router is located. In such cases, the delegating router requires only the identity of the requesting router to choose a prefix for delegation.

DHCPv6 prefix delegation replaces the need for NAT in an IPv6 network.

[Figure 8 on page 419](#) shows how DHCPv6 prefix delegation is used in a dual-stack network.

**Figure 8: Delegated Addressing in a Dual-Stack Network Using DHCPv6**

807543

DHCPv6 prefix delegation operates as follows:

1. A delegating router is provided with IPv6 prefixes to be delegated to requesting routers. These prefixes can come from a local address-assignment pool or an external AAA server.  
Each prefix has an associated valid and preferred lifetime, which can be extended.
2. A requesting router requests one or more prefixes from the delegating router.

3. The delegating router chooses prefixes for delegation, and responds with prefixes to the requesting router.
4. The requesting router is then responsible for the delegated prefixes.

The address allocation mechanism in the subscriber network can be performed with ICMPv6 Neighbor Discovery in router advertisements, DHCPv6, or a combination of these two methods.

## Using a Delegated Prefix on the CPE Loopback Interface

For networks in which the service provider directly controls the CPE, a delegated prefix can be used to create an IPv6 address on the loopback interface between the CPE and the BNG. This address can be used to manage the CPE, and the CPE uses it as a source address when it communicates with the BNG.

- See Also**
- [Selecting the Type of Addressing Used on the CPE on page 453](#)

## DHCPv6 Prefix Delegation over PPPoE

The process of DHCPv6 prefix delegation when DHCPv6 is running over a PPPoE access network is as follows:

1. The CPE obtains a link-local address by appending the interface ID that it receives through IPv6CP negotiation to the IPv6 link-local prefix (FE80::/10). The link-local address provides an initial path for protocol communication between the BNG and CPE
2. The CPE sends a DHCPv6 Solicit message that includes an IA\_PD option.
3. The BNG chooses a prefix for the CPE with information from an external AAA server or from a local prefix pool.
4. The BNG sends an Advertise message to the CPE. The message includes the delegated prefix, an IA\_PD option, and an IA\_PD prefix option. The prefix length in the IA\_PD prefix option is 48. The message can also contain other configuration information, such as a maximum lease time.

5. The CPE sends a Request message to the BNG. The message requests the prefix that was advertised.
6. The BNG returns the delegated prefix to the CPE in a Reply message. This message also contains the delegated prefix, an IA\_PD option, and an IA\_PD prefix option. The prefix length in the IA\_PD prefix option is 48. The message can also contain other configuration information, such as a maximum lease time.
7. The CPE uses the delegated prefix to allocate global IPv6 addresses to host devices on the subscriber network. It can use router advertisements, DHCPv6, or a combination of these two methods to allocate addresses on the subscriber LAN.

## Methods for Obtaining IPv6 Prefixes for DHCPv6 Prefix Delegation

You can set up the BNG to select IPv6 prefixes to be delegated to the requesting router in one of the following ways:

- An external source such as a AAA RADIUS server or a DHCP server using the DHCPv6 relay agent.
- Dynamic assignment from a local pool of prefixes that is configured on the BNG

You can specify the name of a delegated pool to use for prefix delegation, which means that you do not need to use AAA to obtain the pool name. In this configuration, if you have also specified a pool match order, the specified delegated pool takes precedence.

### Using a AAA RADIUS Server to Obtain IPv6 Prefixes for Prefix Delegation

When the BNG needs to obtain a prefix for DHCPv6 prefix delegation, it uses the values in one of the following RADIUS attributes:

- *Delegated-IPv6-Prefix*—The attribute (123) contains an IPv6 prefix that the BNG can send to the CPE.
- *Inpr-IPv6-Delegated-Pool-Name*—The attribute (VSA 26-161) contains the name of an address-assignment pool configured on the BNG from which the BNG can select a prefix to send to the CPE.

Both attributes are sent from the RADIUS server to the BNG in RADIUS Access-Accept messages.

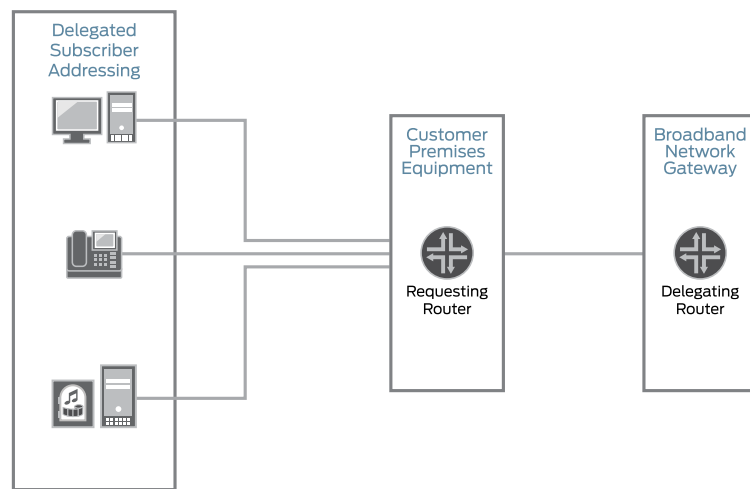

**See Also** • [Selecting the Method of Obtaining IPv6 Prefixes on page 454](#)

## DHCPv6 Prefix Exclusion

You can use the Dynamic Host Configuration Protocol v6 (DHCPv6) prefix delegation to automate the delegation of IPv6 prefixes to the customer premises equipment (CPE) devices. With prefix delegation, a delegating router - the broadband network gateway (BNG) router, delegates IPv6 prefixes to a requesting router such as a CPE device. The requesting router then uses the prefixes to assign global IP addresses to the devices on the subscriber LAN. The requesting router can also assign subnet addresses to subnets on the LAN. DHCPv6 prefix delegation is useful when the delegating router does not have information about the topology of the networks in which the requesting router is located. In such cases, the delegating router requires only the identity of the requesting router to choose a prefix for delegation. DHCPv6 prefix delegation replaces the need for NAT in an IPv6 network.

Figure 9 on page 422 shows how DHCPv6 prefix delegation is used in a dual-stack network.

*Figure 9: Delegated Addressing in a Dual-Stack Network Using DHCPv6*

g017543

DHCPv6 prefix delegation operates as follows:

1. A delegating router is provided with IPv6 prefixes to be delegated to requesting routers. These prefixes can come from a local address-assignment pool or an external AAA server.  
Each prefix has an associated valid and preferred lifetime, which can be extended.
2. A requesting router requests one or more prefixes from the delegating router.
3. The delegating router chooses prefixes for delegation, and responds with prefixes to the requesting router.
4. The requesting router is then responsible for the delegated prefixes.

The address allocation mechanism in the subscriber network can be performed with ICMPv6 Neighbor Discovery Protocol (NDP) in router advertisements, DHCPv6, or a combination of these two methods.

The requesting router cannot use a sub-prefix of the delegated prefix assigned to it by the delegating router to the link between the delegating router and the requesting router. Because of this limitation, there are usually two routes to the CPE device. One is the delegated prefix, for the customer site behind the CPE device and the other for the link between the requesting router and the delegating router. To overcome this, Junos OS allows the exclusion of one specific prefix from a delegated prefix set while using DHCPv6 based prefix delegation as described in RFC 6603. This excluded prefix is used as the link between the delegating router and the requesting router. This prefix link is intended for use in networks where each requesting router is in its own Layer 2 domain.

To support prefix exclude delegation, the requesting router includes the Option Request option (ORO) with the PD\_Exclude option in the solicit, request, renew, or rebind message to inform the delegating router about the support for the prefix delegation. When the Juniper Networks router acting as the DHCP server receives these message and finds the exclude prefix option (option 67) in ORO, it decides the prefix to be excluded. (The length of the prefix to be excluded is bigger than the delegated prefix length.) The excluded prefix is then added in the IA\_Prefix options. The DHCP server acting as relay forwards the requested option to the server and relays the excluded prefix, assigned by the server, back to the client.

To exclude a prefix length in a DHCP server, configure the **exclude-prefix-len** statement at the **[edit access address-assignment pool *pool-name* family dhcpv6 dhcp-attributes]** hierarchy level. The length of the prefix can range from 1 through 128.

If the DHCP server supporting the exclude prefix wants the client to request for a prefix exclude after reconfiguration, then you can configure the **support-option-pd-exclude** statement either at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level or at the **[edit system services dhcp-local-server dhcpv6 group *group-name*]** hierarchy level.

### Configuring DHCPv6 Prefix Exclude Option

To configure DHCPv6 prefix exclude:

1. Configure the prefix length to be excluded from a delegated prefix set pool. This prefix is used as the link between the delegating router and the requesting router. The exclude prefix length is bigger than the given prefix length.

```
[edit access address-assignment pool pool-name family inet6 dhcp-attributes]
user@host# set exclude-prefix-len prefix-length
```

For example, for prefix delegated in 2001:db8::/32, configure the exclude prefix as 2001:db8:ffff:ffc::/72 for delegated pool *prefix\_delegate\_pool*.

```
[edit access address-assignment pool prefix_delegate_pool family inet6 dhcp-attributes]
user@host# set exclude-prefix-len 72
```

2. Configure PD\_Exclude option support in the reconfigure message. In case the server wants the client to request for the prefix to be excluded after reconfiguration then the exclude prefix options are added in the Option Request option (ORO) in the reconfigure message.

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set support-option-pd-exclude
```

3. Configure PD\_Exclude option support in the reconfigure message for a given group.

```
[edit system services dhcp-local-server dhcpv6 group group-name reconfigure]
user@host# set support-option-pd-exclude
```

## Configuring an Address-Assignment Pool for Use by DHCPv6 Prefix Delegation

This procedure shows how to configure IPv6 local address pools to allocate IPv6 prefixes for use by DHCPv6 prefix delegation.

You must configure separate pools for DHCPv6 prefix delegation, DHCPv6 IA\_NA, and NDRA.

To configure the pool to be used for prefix delegation:

1. Create a pool and assign a name to it.

```
[edit access]
user@host# edit address-assignment pool v6-prefix-pool-2001
```

2. Under family inet6, add IPv6 prefixes to the pool.

```
[edit access address-assignment pool v6-prefix-pool-2001]
user@host# edit family inet6
user@host# set prefix 2001:db8:0000:0000:0000::/64
```

3. Configure the name of the IPv6 prefix range, and define the range by setting a prefix length of 64.

```
[edit access address-assignment pool v6-prefix-pool-2001 family inet6]
user@host# edit range prefix-range
user@host# set prefix-length 64
```

## Specifying the Delegated Address-Assignment Pool to Be Used for DHCPv6 Prefix Delegation

You can explicitly specify which address pool the BNG uses to assign IPv6 prefixes for use by DHCPv6 prefix delegation. This feature enables you to identify the address pool without using RADIUS or a network match.

**NOTE:** You can also use by Juniper Networks VSA 26-161 to specify the delegated address pool. The VSA-specified value takes precedence over the delegated-address statement.

To specify the pool to be used for prefix delegation:

1. Specify that you want to configure override options for DHCPv6 local server.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Specify the name of the delegated address pool.

```
[edit system services dhcp-local-server overrides]
user@host# set delegated-pool paris-cable-12
```

### Using DHCPv6 IA\_NA with DHCPv6 Prefix Delegation Overview

You can use DHCPv6 IA\_NA to assign a global IPv6 address to the CPE WAN link and DHCPv6 prefix delegation to provide prefixes for use on the subscriber LAN. DHCPv6 IA\_NA and DHCPv6 prefix delegation are done in a single DHCPv6 session. If the CPE sends both the IA\_NA and IA\_PD options in the same DHCPv6 Solicit message, the BNG returns both a single IPv6/128 address and an IPv6 prefix.

When at least one address is successfully allocated, the router creates a subscriber entry and binds the entry to the assigned address. If both addresses are successfully allocated, the router creates a single subscriber entry and binds both addresses to that entry.

### Lease Times and Session Timeouts for DHCPv6 IA\_NA and DHCPv6 Prefix Delegation

---

When you use DHCPv6 IA\_NA together with DHCPv6 prefix delegation, note the following about session timeouts and lease times:

- A session timeout from AAA has the highest precedence and overrides local pool lease times.
- For DHCPv6 local server, the minimum lease time associated with an address pool takes precedence over pools with longer lease times. For example, if a CPE obtains an IA\_NA address from a pool with a lease time of 3600, and a prefix from a pool with a lease time of 7200, the lease time returned in the Reply message from the BNG is 3600.
- If AAA does not return a session timeout and the address pool does not have a configured lease time, the default setting of 86,400 (one day) is used.

### Behavior When CPE Sends Separate Renew Requests for IA\_NA and IA\_PD Address Types

---

In some networks, the DHCPv6 client CPE device does both of the following:

- Initiates negotiation for both the IA\_NA and IA\_PD address types in a single solicit message.
- Sends separate lease renew requests for the IA\_NA and the IA\_PD and the renew requests are received back-to-back.

Starting in Junos OS Release 17.2R3, 17.4R2, 18.1R3, and 18.3R1, the `jdhcpd` process extends the lease for both address types in this situation.

1. When the reply is received for the first renew request, if a renew request is pending for the second address type, the client stays in the renewing state, the lease is extended for the first IA, and the client entry is updated.
2. When the reply is received for the second renew request, the lease is extended for the second IA and the client entry is updated again.

In earlier releases, the behavior is different for this situation:

1. The client transitions to the bound state instead of staying in the renewing state. The lease is extended for the first IA and the client entry is updated.
2. When the reply is received for the second renew request, the lease is not renewed for the second address type and the reply is forwarded to the client. Consequently, when that lease ages out, the binding for that address type is cleared, the access route is removed, and subsequent traffic is dropped for that address or address prefix.

## DHCPv6 Options in a DHCPv6 Multiple Address Environment

In a DHCPv6 environment, DHCPv6 clients can use a single DHCPv6 Solicit message to request multiple addresses (for example, IA\_NA address, IA\_PD address, or both), as well as the DNS server address (DHCPv6 attribute 23). When a client requests multiple addresses, DHCPv6 uses the following guidelines to determine how options are returned to the client.

- **DNS server address**—Whenever a client requests an IA\_PD address (either alone or with an IA\_NA address) and also requests a DNS server address, DHCPv6 returns a DNS address only when one is specified in the IA\_PD pool. If the IA\_PD pool does not include a DNS address, DHCPv6 ignores any DNS address configured in the IA\_NA pool.  
If the client requests an IA\_NA address (but not an IA\_PD address) and also a DNS server address, DHCPv6 returns a DNS address if one is configured in the IA\_NA pool.
- **Lease time**—DHCPv6 returns the shortest value of the lease times configured in the IA\_NA pool, the IA\_PD pool, and **authd**. DHCPv6 uses this value to set the lifetimes and the Renew and Rebind timers.

**NOTE:** By default, DHCPv6 local server returns the DNS server address as a global DHCPv6 option. You can override the current default behavior if you want DHCPv6 to return the DNS server address at the suboption level.

- See Also**

  - [Overriding How the DNS Server Address Is Returned in a DHCPv6 Multiple Address Environment on page 592](#)

## Methods for Obtaining Addresses for Both DHCPv6 Prefix Delegation and DHCPv6 IA\_NA

You can set up the BNG to select global IPv6 addresses to be delegated to the requesting router in one the following ways:

- An external source such as a AAA RADIUS server or a DHCP server using the DHCPv6 relay agent.
- Dynamic assignment from a local pool of prefixes or global IPv6 addresses that is configured on the BNG

Address assignment for prefix delegation and IA\_NA are independent. For example, you can use AAA RADIUS for DHCPv6 IA\_NA, and use a local pool for prefix delegation.

### Address Pools for DHCPv6 Prefix Delegation and DHCPv6 IA\_NA

You need two separate address pools for prefix delegation and IA\_NA. The pool used for IA\_NA contains /128 addresses, and the pool for prefix delegation contains /56 or /48 addresses.

You can specify the name of a delegated pool to use for prefix delegation, which means that you do not need to use AAA to obtain the pool name. In this configuration, if you have also specified a pool match order, the specified delegated pool takes precedence.

You can configure pool attributes so that the IA\_NA pool and the prefix delegation pool can specify different SIP servers for DNS addresses. DHCPv6 options that the BNG returns to the CPE are based on the pool from which the addresses were allocated. These options that are returned are based on the DHCPv6 Option Request option (ORO), which can be configured globally or within the IA\_NA and IA\_PD request.

### Using a AAA RADIUS Server to Obtain IPv6 Addresses and Prefixes

---

When the BNG needs to obtain a global IPv6 address for the CPE WAN link and a DHCPv6 prefix, it uses the values in one of the following RADIUS attributes:

- *Framed-IPv6-Prefix*—The attribute contains a global IPv6 address and a prefix. A prefix length of 128 is associated with the global IPv6 address. Prefix lengths less than 128 are associated with prefixes.
- *Framed-IPv6-Pool*—The attribute contains the name of an address-assignment pool configured on the BNG, from which the BNG can select a global IPv6 address or an IPv6 prefix to send to the CPE.

Both attributes are sent from the RADIUS server to the BNG in RADIUS Access-Accept messages.

### Junos OS Predefined Variable for Multiple DHCPv6 Address Assignment

---

To configure dynamic DHCPv6 address assignment for both DHCPv6 IA\_NA and DHCPv6 prefix delegation, use the **\$junos-subscriber-ipv6-multi-address** predefined variable in your dynamic profile. You use this variable in place of the **\$junos-subscriber-ipv6-address** variable, which supports a single IPv6 address or prefix. The **\$junos-subscriber-ipv6-multi-address** variable is applied as a demultiplexing source address, and is expanded to include both the host and prefix addresses.

You include the **\$junos-subscriber-ipv6-multi-address** variable at the **[edit dynamic-profile profile-name interfaces interface-name unit logical-unit-number family inet6 demux-source]** hierarchy level.

  - [Configuring an Address-Assignment Pool for Use by DHCPv6 IA\\_NA on page 418](#)

## Multiple DHCPv6 IA\_NA and IA\_PD Requests per Client Interface

DHCPv6 relay agent supports multiple IA\_NA and IA\_PD requests within a single DHCPv6 Solicit message. The requests can be any combination of IA\_NA and IA\_PD addresses, up to a maximum of eight requests. As part of the multiple IA request support, each address lease is assigned its own lease time expiration, independent of the other leases. The use of independent lease timers ensures that when one lease is torn down, the other

active leases are maintained. You can use the **show dhcpv6 relay binding** and **show dhcpv6 relay binding detail** commands to display the status of the individual lease times.

The DHCPv6 support for multiple IA requests enables you to use prefix delegation to designate blocks of addresses, as described in RFC 3633, *IPv6 Prefix Options for DHCPv6*. For example, you might want to delegate multiple address blocks to a customer premises equipment (CPE) router as a means to simplify flow classification and service monetization in your IPv6 environment.

### Example: Configuring a Dual Stack That Uses DHCPv6 IA\_NA and DHCPv6 Prefix Delegation over PPPoE

- [Requirements on page 429](#)
- [Overview on page 429](#)
- [Configuration on page 431](#)
- [Verification on page 448](#)

#### Requirements

---

This example uses the following hardware and software components:

- MX Series 5G Universal Routing Platform
- Junos OS Release 11.4 or later

#### Overview

---

This design uses DHCPv6 IA\_NA and DHCPv6 prefix delegation in your subscriber access network as follows:

- The access network is PPPoE.
- DHCPv6 IA\_NA is used to assign a global IPv6 address on the WAN link. The address comes from a local pool that is specified using AAA RADIUS.
- DHCPv6 prefix delegation is used for subscriber LAN addressing. It used a delegated prefix from a local pool that is specified using AAA RADIUS.
- DHCPv4 is used for subscriber LAN addressing.
- DHCPv6 subscriber sessions are layered over an underlying PPPoE subscriber session.

### Topology

Figure 10: PPPoE Subscriber Access Network with DHCPv6 IA\_NA and DHCPv6 Prefix Delegation

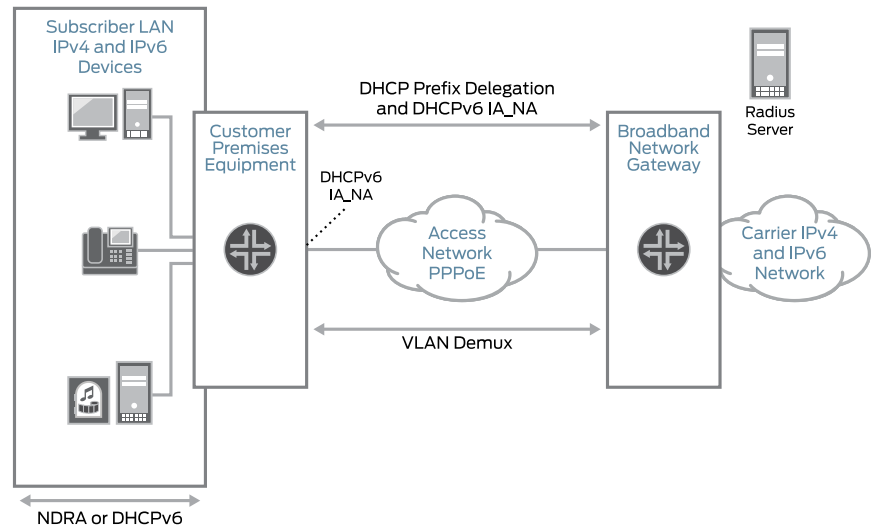

Table 43 on page 430 describes the configuration components used in this example.

Table 43: Configuration Components Used in Dual Stack with DHCPv6 IA\_NA and DHCPv6 Prefix Delegation

Configuration Component	Component Name	Purpose
Dynamic Profile	pppoe-subscriber-profile	Profile that creates a PPPoE logical interface when the subscriber logs in.
Interfaces	ge-0/2/5	Interface used for communication with the RADIUS server.
	ge-0/3/0	Underlying Ethernet interface.
	demux0	VLAN demux interface that runs over the underlying Ethernet interface.
	lo0	Loopback interface for use in the access network. The loopback interface is automatically used for unnumbered interfaces.
Address-Assignment Pools	pool v4-pool	Pool that provides IPv4 addresses for the subscriber LAN.
	pool v6-ia-na-pool	Pool that provides a global IPv6 address to the CPE WAN link.
	pool v6-pd-pool	Pool that provides a pool of prefixes that are delegated to the CPE and used for assigning IPv6 global addresses on the subscriber LAN.

### *Configuring a DHCPv6 Local Server for DHCPv6 over PPPoE*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit system services dhcp-local-server dhcpv6
edit group v6-ppp-subscriber
set interface pp0.0
```

**Step-by-Step Procedure** To layer DHCPv6 above the PPPoE IPv6 family (inet6), associate DHCPv6 with the PPPoE interfaces by adding the PPPoE interfaces to the DHCPv6 local server configuration. Because this example uses a dynamic PPPoE interface, we are using the pp0.0 (PPPoE) logical interface as a wildcard to indicate that a DHCPv6 binding can be made on top of a PPPoE interface.

To configure a DHCPv6 local server:

1. Access the DHCPv6 local server configuration.

```
[edit]
user@host# edit system services dhcp-local-server dhcpv6
```

2. Create a group for dynamic PPPoE interfaces and assign a name.

The group feature groups a set of interfaces and then applies a common DHCP configuration to the named interface group.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit group v6-ppp-subscriber
```

3. Add an interface for dynamic PPPoE logical interfaces.

```
[edit system services dhcp-local-server dhcpv6 group v6-ppp-subscriber]
user@host# set interface pp0.0
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit]
user@host# show
system {
  services {
    dhcp-local-server {
      dhcpv6 {
        group v6-ppp-subscriber {
          interface pp0.0;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring a Dynamic Profile for the PPPoE Logical Interface*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

edit dynamic-profiles pppoe-subscriber-profile
edit routing-instances $junos-routing-instance
set interface $junos-interface-name
exit
edit interfaces pp0 unit $junos-interface-unit
set family inet unnumbered-address "$junos-loopback-interface"
set family inet6 unnumbered-address "$junos-loopback-interface"
set pppoe-options underlying-interface "$junos-underlying-interface"
set pppoe-options server
set ppp-options pap
set ppp-options chap
set keepalives interval 30

```

#### **Step-by-Step Procedure**

Create a dynamic profile for the PPPoE logical interface. This dynamic profile supports both IPv4 and IPv6 sessions on the same logical interface.

To configure the dynamic profile:

1. Create and name the dynamic profile.

```

[edit]
user@host# edit dynamic-profiles pppoe-subscriber-profile

```

2. Add a routing instance to the profile.

```

[edit dynamic-profiles pppoe-subscriber-profile]
user@host# edit routing-instances $junos-routing-instance
user@host# set interface $junos-interface-name

```

3. Configure a PPPoE logical interface (pp0) that is used to create logical PPPoE interfaces for the IPv4 and IPv6 subscribers.

```

[edit dynamic-profiles pppoe-subscriber-profile]
user@host# edit interfaces pp0

```

4. Specify **\$junos-interface-unit** as the predefined variable to represent the logical unit number for the **pp0** interface. The variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0]
user@host# edit unit $junos-interface-unit
```

5. Specify **\$junos-underlying-interface** as the predefined variable to represent the name of the underlying Ethernet interface on which the router creates the dynamic PPPoE logical interface. The variable is dynamically replaced with the actual name of the underlying interface supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

6. Configure the router to act as a PPPoE server when a PPPoE logical interface is dynamically created.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set pppoe-options server
```

7. Configure the IPv4 family for the pp0 interface. Specify the unnumbered address to dynamically create loopback interfaces. Because the example uses routing instances, assign the predefined variable **\$junos-loopback-interface**.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set family inet unnumbered-address $junos-loopback-interface
```

8. Configure the IPv6 family for the pp0 interface. Specify the unnumbered address to dynamically create loopback interfaces. Because the example uses routing instances without router advertisement, assign the predefined variable **\$junos-loopback-interface**.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set family inet6 unnumbered-address $junos-loopback-interface
```

9. Configure one or more PPP authentication protocols for the pp0 interface.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set ppp-options chap
user@host# set ppp-options pap
```

10. Enable keepalives and set an interval for keepalives. We recommend an interval of 30 seconds.

```
[edit dynamic-profiles pppoe-subscriber-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set keepalives interval 30
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit dynamic-profiles pppoe-subscriber-profile]
user@host# show
routing-instances {
  "$junos-routing-instance" {
    interface "$junos-interface-name";
  }
}
interfaces {
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
        server;
      }
      keepalives interval 30;
      family inet {
        unnumbered-address "$junos-loopback-interface";
      }
      family inet6 {
        unnumbered-address "$junos-loopback-interface";
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring a Loopback Interface*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit interfaces lo0
set unit 0 family inet address 203.0.113.1/32 primary
set unit 0 family inet address 203.0.113.1/32 preferred
set unit 0 family inet6 address 2001:db8:0::1/128 primary
```

```
set unit 0 family inet6 address 2001:db8:0::1/128 preferred
```

**Step-by-Step  
Procedure**

To configure a loopback interface:

1. Create the loopback interface and specify a unit number.

```
[edit]  
user@host# edit interfaces lo0 unit 0
```

2. Configure the interface for IPv4.

```
[edit interfaces lo0 unit 0]  
user@host# set family inet address 203.0.113.1/32 primary preferred
```

3. Configure the interface for IPv6.

```
[edit interfaces lo0 unit 0]  
user@host# set family inet6 address 2001:db8:0::1/128 primary preferred
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces lo0]  
user@host# show  
unit 0 {  
  family inet {  
    address 203.0.113.1/32 {  
      primary;  
      preferred;  
    }  
  }  
  family inet6 {  
    address 2001:db8:0::1/128 {  
      primary;  
      preferred;  
    }  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

*Configuring a VLAN Demux Interface over an Ethernet Underlying Interface*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit interfaces
set ge-0/3/0 hierarchical-scheduler maximum-hierarchy-levels 2
set ge-0/3/0 flexible-vlan-tagging
set ge-0/3/0 encapsulation flexible-ethernet-services
exit
edit interfaces demux0 unit 1
set vlan-tags outer 1
set vlan-tags inner 1
set demux-options underlying-interface ge-0/3/0
set family pppoe dynamic-profile pppoe-subscriber-profile
set family pppoe duplicate-protection
set proxy-arp
```

**Step-by-Step Procedure** To configure a VLAN demux interface over an Ethernet underlying interface:

1. Configure the underlying Ethernet interface.

```
[edit]
user@host# edit interfaces ge-0/3/0
user@host# set flexible-vlan-tagging
user@host# set encapsulation flexible-ethernet-services
user@host# set hierarchical-scheduler maximum-hierarchy-levels 2
```

2. Create the VLAN demux interface, and specify a unit number.

```
[edit]
user@host# edit interfaces demux0 unit 1
```

3. Configure the VLAN tags.

```
[edit interfaces demux0 unit 1]
user@host# set vlan-tags outer 1 inner 1
```

4. Specify the underlying Ethernet interface.

```
[edit interfaces demux0 unit 1]
user@host# set demux-options underlying-interface ge-0/3/0
```

5. Specify the dynamic profile.

```
[edit interfaces demux0 unit 1]
```

```
user@host# set family pppoe dynamic-profile pppoe-subscriber-profile
```

6. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on the same VLAN interface.

```
[edit interfaces demux0 unit 1]  
user@host# set family pppoe duplicate-protection
```

7. (Optional) Specify that you want the demux interface to use Proxy ARP.

```
[edit interfaces demux0 unit 1]  
user@host# set proxy-arp
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces]  
user@host# show  
ge-0/3/0 {  
  hierarchical-scheduler maximum-hierarchy-levels 2;  
  flexible-vlan-tagging;  
  encapsulation flexible-ethernet-services;  
}  
demux0 {  
  unit 1 {  
    proxy-arp;  
    vlan-tags outer 1 inner 1;  
    demux-options {  
      underlying-interface ge-0/3/0;  
    }  
    family pppoe {  
      duplicate-protection;  
      dynamic-profile pppoe-subscriber-profile;  
    }  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

*Configuring an Interface for Communication with RADIUS Server*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit interfaces ge-0/2/5
set unit 0 family inet address 203.0.113.99
set gigether-options no-auto-negotiation
```

**Step-by-Step Procedure** To configure the interface:

1. Create the interface, specify a unit number, and configure the address.

```
[edit]
user@host# edit interfaces ge-0/2/5
```

2. Configure the interface for IPv4 and specify the address.

```
[edit interfaces ge-0/2/5]
user@host# set unit 0 family inet address 203.0.113.99
```

3. Specify that Gigabit Ethernet options are not automatically negotiated.

```
[edit interfaces ge-0/2/5]
user@host# set gigether-options no-auto-negotiation
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces ge-0/2/5]
user@host# show
gigether-options {
  no-auto-negotiation;
}
unit 0 {
  family inet {
    address 203.0.113.99/32;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

*Specifying the BNG IP Address*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit routing-options
set router-id 203.0.113.0
```

**BEST PRACTICE:** We strongly recommend that you configure the BNG IP address, thereby avoiding unpredictable behavior if the interface address on a loopback interface changes.

#### Step-by-Step Procedure

To configure the IP address of the BNG:

1. Access the routing-options configuration.

```
[edit]
user@host# edit routing-options
```

2. Specify the IP address of the BNG.

```
[edit routing-options]
user@host# set router-id 203.0.113.0
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit routing-options]
user@host# show
router-id 203.0.113.0;
```

If you are done configuring the device, enter **commit** from configuration mode.

#### Configuring RADIUS Server Access

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access radius-server 203.0.113.99
set secret "$ABC123$ABC123$ABC123"
set timeout 45
set retry 4
set source-address 203.0.113.1
```

**Step-by-Step Procedure**

To configure RADIUS servers:

1. Create a RADIUS server configuration, and specify the address of the server.

```
[edit]
user@host# edit access radius-server 203.0.113.99
```

2. Configure the required secret (password) for the server. Secrets enclosed in quotation marks can contain spaces.

```
[edit access radius-server 203.0.113.99]
user@host# set secret "$ABC123$ABC123$ABC123"
```

3. Configure the source address that the BNG uses when it sends RADIUS requests to the RADIUS server.

```
[edit access radius-server 203.0.113.99]
user@host# set source address 203.0.113.1
```

4. (Optional) Configure the number of times that the router attempts to contact a RADIUS accounting server. You can configure the router to retry from 1 through 16 times. The default setting is 3 retry attempts.

```
[edit access radius-server 203.0.113.99]
user@host# set retry 4
```

5. (Optional) Configure the length of time that the local router or switch waits to receive a response from a RADIUS server. By default, the router or switch waits 3 seconds. You can configure the timeout to be from 1 through 90 seconds.

```
[edit access radius-server 203.0.113.99]
user@host# set timeout 45
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
radius-server {
  203.0.113.99 {
    secret "$ABC123$ABC123$ABC123"; ## SECRET-DATA
    timeout 45;
    retry 4;
    source-address 203.0.113.1;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring RADIUS Server Access Profile*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access profile Access-Profile
set authentication-order radius
set radius authentication-server 203.0.113.99
set radius accounting-server 203.0.113.99
set accounting order radius
set accounting order none
set accounting update-interval 120
set accounting statistics volume-time
```

**Step-by-Step Procedure** To configure a RADIUS server access profile:

1. Create a RADIUS server access profile.

```
[edit]
user@host# edit access profile Access-Profile
```

2. Specify the order in which authentication methods are used.

```
[edit access profile Access-Profile]
user@host# set authentication-order radius
```

3. Specify the address of the RADIUS server used for authentication and the server used for accounting.

```
[edit access profile Access-Profile]
user@host# set radius authentication-server 203.0.113.99
user@host# set radius accounting-server 203.0.113.99
```

4. Configure RADIUS accounting values for the access profile.

```
[edit access profile Access-Profile]
user@host# set accounting order [ radius none ]
user@host# set accounting update-interval 120
user@host# set accounting statistics volume-time
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
profile Access-Profile {
```

```

authentication-order radius;
radius {
    authentication-server 203.0.113.99;
    accounting-server 203.0.113.99;
}
accounting {
    order [ radius none ];
    update-interval 120;
    statistics volume-time;
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Local Address-Assignment Pools

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

edit access address-assignment
set pool v4-pool family inet network 203.0.113.161/32
set pool v4-pool family inet range v4-range-0 low 203.0.113.161
set pool v4-pool family inet range v4-range-0 high 203.0.113.255
set pool v4-pool family inet dhcp-attributes maximum-lease-time 99999
set pool v6-ia-na-pool family inet6 prefix 2001:db8:1000:0000::/64
set pool v6-ia-na-pool family inet6 range v6-range-0 low 2001:db8:1000::1/128
set pool v6-ia-na-pool family inet6 range v6-range-0 high 2001:db8:1000::ffff:ffff/128
set pool v6-pd-pool family inet6 prefix 2001:db8:2012::/48
set pool v6-pd-pool family inet6 range v6-pd prefix-length 64

```

#### Step-by-Step Procedure

Configure three address-assignment pools for DHCPv4, DHCPv6 IA\_NA, and DHCPv6 prefix delegation.

To configure the address-assignment pools:

1. Configure the address-assignment pool for DHCPv4.

```

[edit]
user@host# edit access address-assignment pool v4-pool
user@host# edit family inet
user@host# set network 203.0.113.161
user@host# set range v4-range-0 low 203.0.113.161
user@host# set range v4-range-0 high 203.0.113.255
user@host# set dhcp-attributes maximum-lease-time 99999

```

2. Configure the address-assignment pool for DHCPv6 IA\_NA.

```

[edit]
user@host# edit access address-assignment pool v6-ia-na-pool

```

```

user@host# edit family inet6
user@host# set prefix 2001:db8:1000:0000::/64
user@host# set range v6-range-0 low 2001:db8:1000::1/128
user@host# set range v6-range-0 high 2001:db8:1000::ffff:ffff/128

```

3. Configure the address-assignment pool for DHCPv6 prefix delegation.

```

[edit]
user@host# edit access address-assignment pool v6-pd-pool
user@host# edit family inet6
user@host# set prefix 2001:db8:2012::/48
user@host# set range v6-pd prefix-length 64

```

4. (Optional) Enable duplicate prefix protection.

```

[edit access]
user@host# set address-protection

```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```

[edit access]
user@host# show
address-assignment {
  pool v4-pool {
    family inet {
      network 203.0.113.161/32;
      range v4-range-0 {
        low 203.0.113.161;
        high 203.0.113.255;
      }
      dhcp-attributes {
        maximum-lease-time 99999;
      }
    }
  }
  pool v6-ia-na-pool {
    family inet6 {
      prefix prefix 2001:db8:1000:0000::/64 ;
      range v6-range-0 {
        low 2001:db8:1000::1/128;
        high 2001:db8:1000::ffff:ffff/128;
      }
    }
  }
  pool v6-pd-pool {
    family inet6 {
      prefix 2001:db8:2012::/48;
      range v6-pd prefix-length 64;
    }
  }
}

```

```
    }  
    address-protection;  
  }
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

---

Confirm that the configuration is working properly.

- [Verifying Active Subscriber Sessions on page 448](#)
- [Verifying Both IPv4 and IPv6 Address in Correct Routing Instance on page 448](#)
- [Verifying Dynamic Subscriber Sessions on page 449](#)
- [Verifying DHCPv6 Address Pools Used for DHCPv6 Prefix Delegation on page 450](#)
- [Verifying DHCPv6 Address Bindings on page 451](#)
- [Verifying PPP Options Negotiated with the Remote Peer on page 452](#)

### ***Verifying Active Subscriber Sessions***

**Purpose** Verify active subscriber sessions.

**Action** From operational mode, enter the **show subscribers summary** command.

```
user@host>show subscribers summary
```

```
Subscribers by State
```

```
Active: 2
```

```
Total: 2
```

```
Subscribers by Client Type
```

```
DHCP: 1
```

```
PPPoE: 1
```

```
Total: 2
```

**Meaning** The fields under **Subscribers by State** show the number of active subscribers.

The fields under **Subscribers by Client Type** show the number of active DHCP and PPPoE subscriber sessions.

### ***Verifying Both IPv4 and IPv6 Address in Correct Routing Instance***

**Purpose** Verify that the subscriber has both an IPv4 and IPv6 address and is placed in the correct routing instance.

**Action** From operational mode, enter the **show subscribers** command.

```
user@host>show subscribers
```

Interface	IP Address/VLAN ID	User Name	LS:RI
pp0.1073741825	203.0.113.162	SBRSTATICUSER	default:default
pp0.1073741825	2001:db8:1000::1		default:default

**Meaning** The **Interface** field shows that two subscriber sessions are running on the same interface. The **IP Address** field shows that one session is assigned an IPv4 address, and the second session is assigned an IPv6 address by DHCPv6 IA\_NA.

The **LS:RI** field shows that the subscriber is placed in the correct routing instance and that traffic can be sent and received.

### *Verifying Dynamic Subscriber Sessions*

**Purpose** Verify dynamic PPPoE and DHCPv6 subscriber sessions. In this example configuration the DHCPv6 subscriber session should be layered over the underlying PPPoE subscriber session.

**Action** From operational mode, enter the **show subscribers detail** command.

```
user@host>show subscribers detail
```

```
Type: PPPoE
User Name: SBRSTATICUSER
IP Address: 203.0.113.162
IP Netmask: 255.0.0.0
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Dynamic
Dynamic Profile Name: pppoe-subscriber-profile
MAC Address: 00:00:5E:00:53:01
State: Active
Radius Accounting ID: 2
Session ID: 2
Login Time: 2011-12-08 09:11:41 PST

Type: DHCP
IPv6 Address: 2001:db8:1000::1
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Static
MAC Address: 00:00:5E:00:53:31
State: Active
Radius Accounting ID: 3
Session ID: 3
Underlying Session ID: 2
Login Time: 2011-12-08 09:12:11 PST
DHCP Options: len 42
00 08 00 02 0b b8 00 01 00 0a 00 03 00 01 00 01 02 00 00 01
00 06 00 02 00 03 00 03 00 0c 00 00 00 00 00 00 00 00 00 00
00 00
```

**Meaning** When a subscriber has logged in and started both an IPv4 and an IPv6 session, the output shows the active underlying PPPoE session and the active DHCPv6 session.

The **Session ID** field for the PPPoE session is 2. The **Underlying Session ID** for the DHCP session is 2, which shows that the PPPoE session is the underlying session.

*Verifying DHCPv6 Address Pools Used for DHCPv6 Prefix Delegation*

**Purpose** Verify the delegated address pool used for DHCPv6 prefix delegation and the length of the IPv6 prefix that was delegated to the CPE.

**Action** From operational mode, enter the **show subscribers extensive** command.

```
user@host>show subscribers extensive

Type: PPPoE
User Name: SBRSTATICUSER
IP Address: 203.0.113.162
IP Netmask: 255.0.0.0
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Dynamic
Dynamic Profile Name: pppoe-subscriber-profile
MAC Address: 00:00:5E:00:53:31
State: Active

IPv6 Delegated Address Pool: v6-na-pool
IPv6 Delegated Network Prefix Length: 64
```

**Meaning** The **IPv6 Delegated Address Pool** field shows the name of the pool that DHCPv6 used to assign the IPv6 address for this subscriber session.

*Verifying DHCPv6 Address Bindings*

**Purpose** Display the address bindings in the client table on the DHCPv6 local server.

**Action** From operational mode, enter the **show dhcpv6 server binding detail** command.

```
user@host>show dhcpv6 server binding detail
```

```
Session Id: 580547
  Client IPv6 Address:      2001:db8:1000::4/128
  Client DUID:              LL0x1-00:01:02:00:00:01
  State:                    BOUND(DHCPV6_LOCAL_SERVER_STATE_BOUND)
D) Lease Expires:          2012-01-05 07:06:04 PST
  Lease Expires in:        82943 seconds
  Lease Start:             2012-01-04 07:06:04 PST
  Last Packet Received:    2012-01-04 07:06:04 PST
  Incoming Client Interface: pp0.1073926645
  Server Ip Address:       0.0.0.0
  Client Pool Name:        v6-na-pool-0
  Client Id Length:        10
  Client Id:               /0x00030001/0x00010200/0x0001
```

**Meaning** The **Client IPv6 Address** field shows the /128 address that was assigned to the CPE WAN link using DHCPv6 IA\_NA.

The **Client Pool Name** field shows the name of the address pool that was used to assign the **Client IPv6 Address**.

### *Verifying PPP Options Negotiated with the Remote Peer*

**Purpose** Verify PPP options negotiated with the remote peer.

**Action** From operational mode, enter the **show ppp interface *interface* extensive** command.

```
user@host>show ppp interface pp0.1073741825 extensive
```

```
Session pp0.1073926645, Type: PPP, Phase: Network
LCP
  State: Opened
  Last started: 2012-01-04 07:05:33 PST
  Last completed: 2012-01-04 07:05:33 PST
  Negotiated options:
    Authentication protocol: pap, Magic number: 191301485, Local MRU: 1492,
    Peer MRU: 65531
Authentication: PAP
  State: Grant
  Last started: 2012-01-04 07:05:33 PST
  Last completed: 2012-01-04 07:05:33 PST
IPCP
  State: Opened
  Last started: 2012-01-04 07:05:34 PST
  Last completed: 2012-01-04 07:05:34 PST
  Negotiated options:
    Local address: 203.0.113.1, Remote address: 203.0.113.162
IPV6CP
  State: Opened
  Last started: 2012-01-04 07:05:34 PST
  Last completed: 2012-01-04 07:05:34 PST
  Negotiated options:
    Local interface identifier: 2a0:a50f:fc71:e049,
    Remote interface identifier: 201:2ff:fe00:1
```

**Meaning** The output shows the PPP options that were negotiated with the remote peer.

Under IPCP, the **Negotiated options** field shows the IPv4 local and remote addresses that were negotiated by IPCP.

Under IPV6CP, the **Negotiated options** field shows the IPv6 local and remote interface identifier that were negotiated by IPV6CP.

- [Design 4: IPv6 Addressing with DHCPv6 Prefix Delegation and No NDRA Prefix on page 457](#)

### Selecting the Type of Addressing Used on the CPE

In some networks, you do not need to assign a global IPv6 address on the CPE WAN link. Your decision depends on the type of CPE being used:

- If the CPE is purchased by the subscriber, and is not a device specifically recommended by the service provider, you need to assign a global IPv6 address that can be routed on the Internet.
- If the CPE is supplied by or recommended by the service provider, you can use the loopback interface to manage the CPE.

In this case, you can use a link-local address or you can use an address that is derived from DHCPv6 prefix delegation.

- See Also**
- [IPv6 Addressing Requirements for a Subscriber Access Network on page 409](#)

### Selecting the Method of Provisioning a Global IPv6 Address for the WAN Link

To assign a global IPv6 address to the WAN link of the CPE device, you can choose one of the methods described in [Table 44 on page 454](#).

**Table 44: Choosing the Global IPv6 Address Provisioning Method for the WAN Link**

NDRA Features	DHCPv6 IA_NA Features
Provides address autoconfiguration of the WAN link by means of router advertisements.	Provides a single IPv6/128 address to the WAN interface of the CPE by the BNG acting as a DHCPv6 server.
Supported on PPPoE access networks.	Supported on PPPoE and DHCP access networks.
Provides duplicate prefix prevention.	Provides the ability to use one DHCPv6 message to solicit both a global IPv6 address for the WAN link, and a prefix used to provision addresses on the subscriber LAN.
Use if the CPE does not support DHCP.	--

## Selecting the Method of Assigning Global IPv6 Addresses to Subscribers

**BEST PRACTICE:** For addressing on the subscriber LAN, we recommend that you provision a global IP address for each device on the LAN. IPv6 was designed to allow every IP-capable device on a subscriber LAN to obtain a globally unique address, which avoids the use of NAT between the subscriber LAN and the service provider.

DHCPv6 prefix delegation automates the delegation of IPv6 prefixes to the CPE. The CPE can then use these prefixes to assign global IPv6 addresses for use in a subscriber LAN. DHCPv6 prefix delegation is useful when the delegating router (the BNG) does not have information about the topology of the networks in which the requesting router (the CPE) is located. In such cases, the delegating router requires only the identity of the requesting router to choose a prefix for delegation.

  - [Using DHCPv6 IA\\_NA with DHCPv6 Prefix Delegation Overview on page 425](#)

## Selecting the Method of Obtaining IPv6 Prefixes

You can set up the BNG to select IPv6 prefixes through one of the following methods:

- An external source such as a AAA RADIUS server or a DHCP server using the DHCPv6 relay agent.
- Dynamic assignment from a local pool of global IPv6 addresses or prefixes that is configured on the BNG

### Using a AAA RADIUS Server to Obtain Global IPv6 Addresses and IPv6 Prefixes

Table 45 on page 455 describes the RADIUS attributes used in a dual-stack network. These attributes are sent from the RADIUS server to the BNG in RADIUS Access-Accept messages.

**Table 45: RADIUS Attributes Used to Obtain Global IPv6 Addresses and IPv6 Prefixes**

RADIUS Attribute	Address Assignment Type	Attribute Description
Framed-IPv6-Prefix	NDRA	IPv6 prefix with a prefix length less than 128.
	DHCPv6 IA_NA	IPv6 prefix with a length of 128.
Framed-IPv6-Pool	NDRA	Name of an NDRA pool configured on the BNG from which the BNG selects a prefix.
	DHCPv6 IA_NA	Name of an address-assignment pool configured on the BNG from which the BNG selects a global IPv6 address.
Delegated-IPv6-Prefix	DHCPv6 prefix delegation	IPv6 prefix.
Jnpr-IPv6-Delegated-Pool-Name	DHCPv6 prefix delegation	Name of an address-assignment pool configured on the BNG from which the BNG delegates a prefix.

### Design 1: IPv6 Addressing with DHCPv6 IA\_NA and DHCPv6 Prefix Delegation

This design (Figure 11 on page 456) uses DHCPv6 IA\_NA and DHCPv6 prefix delegation in your subscriber access network as follows:

- DHCPv6 IA\_NA is used to assign a global IPv6 address on the WAN link. The address can come from a local pool or AAA RADIUS.
- DHCPv6 prefix delegation is used for host device addressing. The delegated prefix can come from a local pool or from AAA RADIUS. The CPE uses the delegated prefix for subscriber addressing. The CPE can use NDRA or DHCPv6 to allocate IPv6 addresses on the LAN.

Figure 11: Subscriber Access Network with DHCPv6 IA\_NA and DHCPv6 Prefix Delegation

- [Example: Configuring a Dual Stack That Uses DHCPv6 IA\\_NA and DHCPv6 Prefix Delegation over PPPoE on page 429](#)
  - [Using DHCPv6 IA\\_NA with DHCPv6 Prefix Delegation Overview on page 425](#)

## Design 2: IPv6 Addressing with NDRA and DHCPv6 Prefix Delegation

This design (Figure 12 on page 456) uses NDRA and DHCPv6 prefix delegation in your subscriber access network as follows:

- NDRA addressing is used to provision a global IPv6 address on the WAN link. IPv6 prefixes for NDRA come from a local pool or AAA RADIUS.
- DHCPv6 prefix delegation is used for host device addressing. The delegated prefix can come from a local pool or from AAA RADIUS. The CPE uses the delegated prefix for subscriber addressing. The CPE can use NDRA or DHCPv6 to allocate IPv6 addresses on the LAN.

Figure 12: Subscriber Access Network with NDRA and DHCPv6 Prefix Delegation

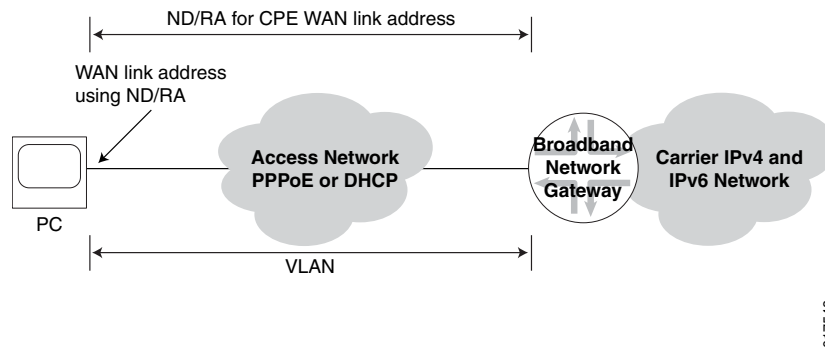

If you have a network with a combination of subscriber LANs and single PCs, you can use a combination of design 2 and design 3.

- See Also**
- [Example: Configuring a Dual Stack That Uses ND/RA and DHCPv6 Prefix Delegation Over PPPoE on page 517](#)
  - [Using DHCPv6 Prefix Delegation Overview on page 419](#)

### Design 3: IPv6 Addressing with NDRA

In this design ([Figure 13 on page 457](#)), NDRA is used for addressing a global IPv6 on the WAN link with prefixes from a local pool or AAA RADIUS. The PC does not need a delegated prefix.

*Figure 13: Subscriber Access Network with NDRA*

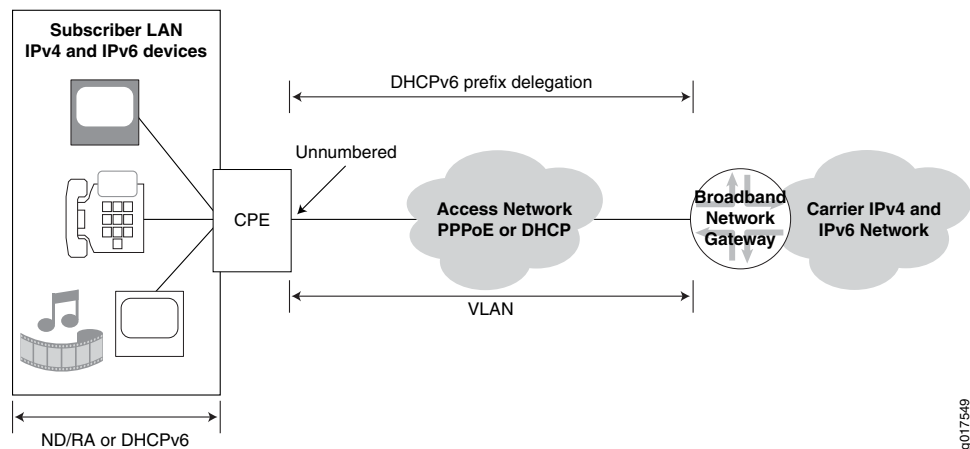

If you have a network with a combination of subscriber LANs and single PCs, you can use a combination of Design 2 and Design 3.

- See Also**
- [Example: Configuring a Dual Stack That Uses ND/RA Over PPPoE on page 498](#)

### Design 4: IPv6 Addressing with DHCPv6 Prefix Delegation and No NDRA Prefix

In this design ([Figure 14 on page 458](#)), the CPE is a model that is sold by or specified by the service provider. The CPE uses an unnumbered WAN interface. The BNG delegates an IPv6 prefix to the CPE with DHCPv6 prefix delegation. The CPE uses the delegated prefix for subscriber addressing. It can use NDRA or DHCPv6 to allocate the IPv6 addresses on the LAN.

- [Configuring Single-Session DHCP Dual-Stack Support on page 464](#)
- [Verifying and Managing DHCP Dual-Stack Configuration on page 467](#)

### IPv4 and IPv6 Dual Stack in a DHCP Access Network

Figure 15 on page 459 shows a dual-stack interface stack in a DHCP access network. The IPv4 family (inet) and the IPv6 family (inet6) can reside on the same VLAN interface.

Figure 15: Dual-Stack Interface Stack over a DHCP Access Network

**NOTE:** When you are using IPv4 and IPv6 dual stack on the same DHCP interface, you must configure one dynamic profile for both the IPv4 and IPv6 subscribers. You cannot run IPv4 and IPv6 subscriber sessions over the same interface if you configure separate dynamic profiles for IPv4 and IPv6.

### Support for Demultiplexing Interfaces

IPv4 and IPv6 dual stack is supported on VLAN demultiplexing (demux) interfaces. Dual stack is not supported on IP demux interfaces.

**See Also** • [Basic Architecture of a Subscriber Access Dual-Stack Network on page 406](#)

## AAA Service Framework in a Dual Stack over a DHCP Access Network

You can use the AAA Service Framework for all authentication, authorization, accounting, address assignment, and dynamic request services that the BNG uses for network access. The framework supports authentication and authorization through external RADIUS servers. It also supports accounting and dynamic-request change of authorization (CoA) and disconnect operations through external servers, and address assignment through a combination of local address-assignment pools and RADIUS servers.

The BNG interacts with external servers to determine how individual subscribers access the broadband network. The BNG can also obtain information from external servers for the following:

- How subscribers are authenticated.
- How accounting statistics are collected and used.
- How dynamic requests, such as CoA, are handled.

As shown in [Figure 16 on page 460](#), an implementation of dual stack over a DHCP access network, there are separate AAA sessions for IPv4 and IPv6 authentication and accounting.

*Figure 16: AAA Service Framework in a Dual Stack over a DHCP Access Network*

### Collection of Accounting Statistics in a DHCP Access Network

AAA provides support for IPv4 and IPv6 statistics in separate accounting sessions.

The following RADIUS attributes are included by default (when available) in Acct-Start, Interim, and Acct-Stop messages:

- Framed-IPv6-Prefix
- Framed-IPv6-Pool
- Delegated-Ipv6-Prefix
- Framed-IPv4-Route
- Framed-IPv6-Route

You can configure the BNG to exclude these attributes in accounting Acct-Start and Acct-Stop messages.

### Change of Authorization (CoA)

RADIUS servers can initiate dynamic requests to the BNG. Dynamic requests include CoA requests, which specify VSA modifications and service changes.

In your access profile configuration, you specify the IP addresses of RADIUS authentication servers that can initiate dynamic requests to the router. The list of authentication servers also provides RADIUS-based dynamic service activation and deactivation during subscriber login.

### Dual-Stack Interface Stack in a DHCP Wholesale Network

Figure 17 on page 461 shows a dual-stack interface stack in a DHCP wholesale network. In this scenario, the IPv4 and IPv6 demux interfaces are configured on the same VLAN interface. The demux interfaces are configured in a separate logical system: routing instance.

Figure 17: Dual-Stack Interface Stack in a DHCP Wholesale Network

## Single-Session DHCP Dual-Stack Overview

Junos OS supports a single-session DHCP dual-stack, which simplifies management of dual-stack subscribers, and improves performance and session requirements when compared to the traditional dual-stack support.

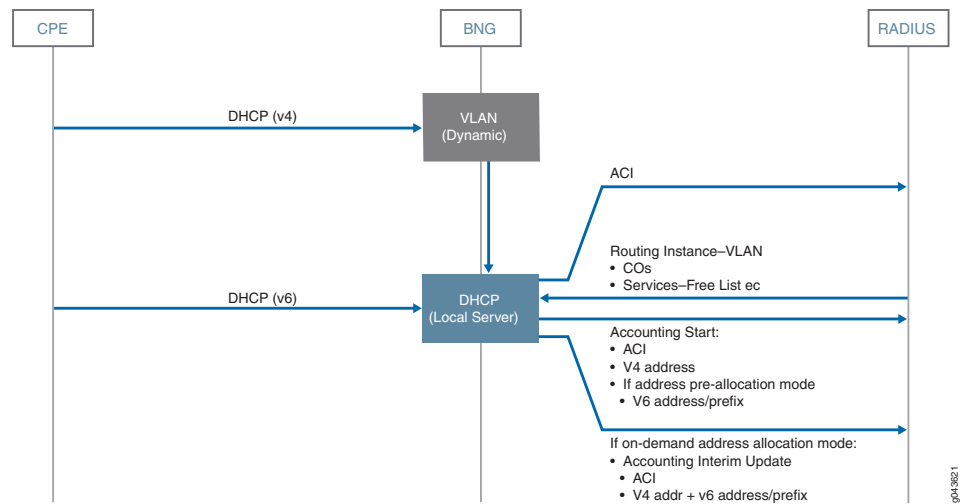

In a DHCP dual-stack environment, a DHCP server supports both DHCPv4 and DHCPv6 subscribers. The DHCP server provides services, such as authentication and accounting, for both the DHCPv4 and DHCPv6 legs of the dual-stack. In a traditional implementation, the two legs of the dual-stack legs are viewed as being independent. The presence of separate legs for DHCPv4 and DHCPv6 creates inefficiencies, since separate, and multiple, sessions can be required to provide similar support for each leg of the dual-stack. For example, to provide authentication for a traditional dual-stack over a dynamic VLAN requires three separate sessions, one for DHCPv4, one for DHCPv6, and one for the authenticated dynamic VLAN. Similarly, multiple sessions might be also required for dual-stack accounting operations.

In the dual-stack over a dynamic VLAN, the single-session dual-stack requires only a single session for authentication, as opposed to the three sessions required for the traditional dual-stack configuration. Accounting support for the dual-stack also uses a single session. In addition to reducing the number of sessions required, the single-session feature also simplifies router configuration, reduces RADIUS message load, and improves accounting session performance for households with dual-stack environments.

In the single-session dual-stack environment, the first DHCP session that negotiates will trigger the dynamic VLAN creation (if required) and is authorized at the DHCP application. The second leg of the dual-stack is held off until the authorization point is complete. When the second leg of the dual stack is established, the DHCP client inherits all common subscriber database values, such as circuit-id, remote-id, username, and interface name from the first leg.

In [Figure 18 on page 462](#), single subscriber session is established for dual-stack user.

Figure 18: DHCP Dual Stack Single-Session Subscriber Deployment Model

You can configure single-session dual-stack subscriber settings for DHCP relay agent and DHCP local server. You use the **dual-stack-group** statement to create a named group that specifies the values for dual stack subscribers. Then, you use the **dual-stack** statement to specify the name of the dual stack group and assign the group to subscribers at the global, group, or interface level.

- For DHCP relay agent, configure these statements at the **[edit forwarding-options dhcp-relay]** hierarchy level and the **[edit forwarding-options dhcp-relay ... overrides]** hierarchy level, respectively,
- For DHCP local server, configure these statements at the **[edit system services dhcp-local-server]** hierarchy level and the **[edit system services dhcp-local-server ... overrides]** hierarchy level, respectively,

You can configure the following common DHCP settings for the single-session dual-stack model. In most cases, these settings are similar to those used for separate DHCPv4 and DHCPv6 legs in a traditional dual-stack configuration. When configured and referenced, the dual-stack configuration takes precedence over the same items configured under the respective family.

- access-profile**—Access profile that provides authentication and accounting parameters for the dual-stack group that take precedence over those configured in a global access profile or in a profile configured for the DHCP relay agent or DHCP local server.
- authentication**—Authentication-related parameters (such as password and username) the router sends to the external AAA server.

The **dual-stack authentication** stanza is similar to the stanza available separately for the v4 and v6 address families. When the **username-include** configuration syntax is used for the DHCPv4 leg of the dual-stack, the **relay-agent-interface-id** option is equivalent to the DHCPv4 **relay-option-82 circuit-id** statement, and the **relay-agent-remote-id** option is equivalent to the DHCPv4 **relay-option-82 remote-id** statement. You do not have to configure the two DHCPv4 options separately.

- **classification-key**—Classification key defines mechanism to be used to identify a dual stack household.
- **dual-stack-interface-client-limit**—Limits the number of dual stack subscribers login per interface.
- **dynamic-profile**—Dynamic profile that is attached to all interfaces, to a named group of interfaces, or to a specific interface.
- **liveness-detection**—Configure an active liveness detection protocol that deletes the binding and releases the resources if the subscriber fails to respond to a configured number of consecutive liveness detection requests, the subscriber.
- **on-demand-address-allocation**—(DHCP local server) Designates whether on-demand address allocation mode is forced for a dual-stack subscriber.

If this configuration is not present, all IP addresses and prefixes for IPv4 and IPv6 families of a dual stack subscriber will be preallocated when the first leg of a dual stack subscriber initially logs in.

If this configuration is present when the first leg of a dual-stack subscriber initially logs in, RADIUS authentication is performed (if configured) and the IP address and prefix of this first family only will be allocated. The IP address and prefix for the other family will not be allocated unless the other family leg subsequently initially logs in.

**NOTE:** The IP address allocation for the second family is informed by the RADIUS authentication previously performed at the time of the first family login.

Starting in Junos OS Release 18.4R1, the method of address allocation is checked to determine subsequent behavior when authd notifies the DHCP process that an address pool is deleted or being drained. [Table 46 on page 463](#) describes the behavior.

**Table 46: Behavior When Address Pool is Deleted or Drained**

Address Allocation Method	Address Pool is Drained	Address Pool is Deleted
On demand	Family with address in pool is logged out gracefully when a DHCP renew or rebind message is received.	Family with address in pool is logged out immediately.
Preallocated	Addresses for both families are deleted gracefully when a DHCP renew or rebind message is received.	Addresses for both families are deleted immediately.

- **protocol-master**—Protocol-master configuration designates either a IPv4 or IPv6 family for a dual stack subscriber. The secondary family client binding login-in will be rejected until a valid client binding is in place for the protocol-master family.

**CAUTION:** If the secondary family binding is logged out for any reason, then only the secondary family binding will be torn down.

If the protocol-master family binding is logged out for any reason, then the corresponding bindings for both the protocol-master and secondary families will be torn down.

- **reauthenticate**—(DHCP local server) Configure reauthentication of the subscriber to initiate change characteristics such as service activations/deactivations and attribute modifications.
- **relay-agent-interface-id**—(DHCP relay agent) Includes Relay Agent Interface-ID (option 18) in DHCPv6 packets destined for the DHCPv6 server. You can configure numerous options to specify what is included in the circuit ID value.

For the DHCPv4 leg of the dual-stack, this statement includes the DHCPv4 **relay-option-82 circuit-id** in packets destined for the DHCPv4 server.

- **relay-agent-remote-id**—(DHCP relay agent) Includes Relay Agent Remote-ID (option 37) in DHCPv6 packets destined for a DHCPv6 server. You can configure numerous options to specify what is included in the remote ID value.

For the DHCPv4 leg of the dual-stack, this statement includes the DHCPv4 **relay-option-82 remote-id** in packets destined for the DHCPv4 server.

- **service-profile**—Dynamic profile for the default subscriber service (or the default DHCP client management service), which is activated when the subscriber (or client) logs in.
- **short-cycle protection**—Detect and lock out short-lived client sessions and clients that repeatedly fail session negotiation to reduce resource usage associated with connection and authentication processing in highly scaled networks.

## Configuring Single-Session DHCP Dual-Stack Support

Configuring single-session dual-stack support is a two-step process. You first create the dual-stack group that specifies the configuration parameters that are shared between the DHCPv4 and DHCPv6 legs of the DHCP dual stack. Then, you attach the dual-stack group to DHCP subscriber interfaces by overriding the default DHCP configurations for the DHCPv4 and DHCPv6 subscribers. You must reference the dual-stack group for both legs of the dual stack. If you attach the group to one leg only, the router rejects the other leg. You can attach the dual-stack group globally, for a specified DHCP group of interfaces, or for a specific interface.

To configure single-session dual-stack group support.

1. Specify that you want to configure DHCP relay agent.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Create and name the dual-stack group.

```
[edit forwarding-options dhcp-relay]
user@host# edit dual-stack-group dual-stack-group-name
```

3. Attach an access profile to the dual-stack group to override the corresponding authentication and accounting properties configured in a global access profile or DHCP relay agent access profile.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
user@host# set access-profile profile-name
```

See [“Attaching Access Profiles to DHCP Subscriber Interfaces or DHCP Client Interfaces”](#) on page 240.

4. Configure the authentication username values and password for the dual-stack group.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
user@host# edit authentication
```

See [“Using External AAA Authentication Services with DHCP”](#) on page 322.

- Configure the unique username.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
authentication]
user@host# set username-include <username-include-configuration>
```

See [“Creating Unique Usernames for DHCP Clients”](#) on page 323.

- Configure the password that authenticates the username to the external authentication service.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
authentication]
user@host# set password password-string
```

See [“Configuring Passwords for Usernames”](#) on page 326.

5. Specify the dynamic profile associated with the dual-stack group.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
user@host# set dynamic-profile <dynamic-profile configuration>
```

See [Attaching Dynamic Profiles to DHCP Subscriber Interfaces or DHCP Client Interfaces](#).

6. Specify the service profile associated with the dual-stack group.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
user@host# set service-profile dynamic-profile-name
```

See [Defining Various Levels of Services for DHCP Subscribers](#).

7. Specify the relay-agent-interface-id for the dual-stack group.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
user@host# set relay-agent-interface-id <relay-agent-interface-id configuration>
```

See [“Inserting DHCPv6 Interface-ID Option \(Option 18\) In DHCPv6 Packets” on page 394.](#)

**NOTE:** For the DHCPv4 leg of the dual-stack, this step specifies the Option 82 Agent Circuit ID (suboption 1) for DHCPv4 clients. See [“Using DHCP Relay Agent Option 82 Information” on page 282.](#)

8. Specify the relay-agent-remote-id for the dual-stack group.

```
[edit forwarding-options dhcp-relay dual-stack-group dual-stack-group-name]
user@host# set relay-agent-remote-id <relay-agent-remote-id-configuration>
```

See [“Inserting DHCPv6 Remote-ID Option \(Option 37\) In DHCPv6 Packets” on page 395.](#)

**NOTE:** For the DHCPv4 leg of the dual-stack, this step specifies the Option 82 Agent Remote ID (suboption 2) for DHCPv4 clients. See [“Using DHCP Relay Agent Option 82 Information” on page 282.](#)

9. Use the override feature to override the default DHCP relay behavior and assign the dual-stack group to DHCPv4 and DHCPv6 clients. You must perform separate steps for each leg of the dual stack.

- To assign the dual-stack group to DHCPv4 clients:

```
[edit forwarding-options dhcp-relay]
user@host# set overrides dual-stack dual-stack-group-name
```

See [“Overriding the Default DHCP Relay Configuration Settings” on page 246.](#)

- To assign the dual-stack group to DHCPv6 clients:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# set overrides dual-stack dual-stack-group-name
```

See [“Overriding the Default DHCP Relay Configuration Settings” on page 246.](#)

10. (Optional) Verify your dual-stack group configuration for DHCPv4 and DHCPv6.

See [“Verifying and Managing DHCP Dual-Stack Configuration” on page 467.](#)

```
user@host> show dhcp relay binding
user@host> show dhcpv6 relay binding
user@host> show subscribers
```

## Verifying and Managing DHCP Dual-Stack Configuration

**Purpose** Display information related to the DHCP single-session dual-stack configuration.

**Action** • To display DHCP relay agent binding information for dual-stack clients:

```
user@host> show dhcp relay binding detail
```

• To display DHCPv6 relay agent binding information for dual-stack clients:

```
user@host> show dhcpv6 relay binding detail
```

• To display assigned IP4 and IPv6 addresses for DHCP dual-stack clients:

```
user@host> show subscribers
```

• To show IPv4 and IPv6 addresses for a specific session:

```
user@host> show network-access aaa subscribers session-id session-id session-id
detail
```

• To all clear DHCPv4 relay bindings and associated DHCPv6 bindings for the dual-stack in the default routing instance. This command does not effect DHCPv6-only stacks that are not associated with the dual-stack.

```
user@host> clear dhcp relay binding dual-stack all
```

Alternatively, you can limit clearing to an address, VLAN interface, logical system, or routing instance.

• To clear all DHCPv6 relay bindings and associated DHCPv4 bindings for the dual-stack in the default routing instance. This command does not effect DHCPv4-only stacks that are not associated with the dual-stack.

```
user@host> clear dhcpv6 relay binding dual-stack all
```

Alternatively, you can limit clearing to an address, VLAN interface, logical system, or routing instance.

### Release History Table

Release	Description
18.4R1	Starting in Junos OS Release 18.4R1, the method of address allocation is checked to determine subsequent behavior when authd notifies the DHCP process that an address pool is deleted or being drained.

### IPv4 and IPv6 Dual Stack in a PPPoE Access Network

In a dual-stack architecture with a PPPoE access network that connects the CPE to the BNG, IPv4 and IPv6 connectivity are provided over a single PPP logical link. The PPP IPv4 control protocol (IPCP) and the IPv6 control protocol (IPv6CP) provide independent IPv4 and IPv6 connectivity over the logical link.

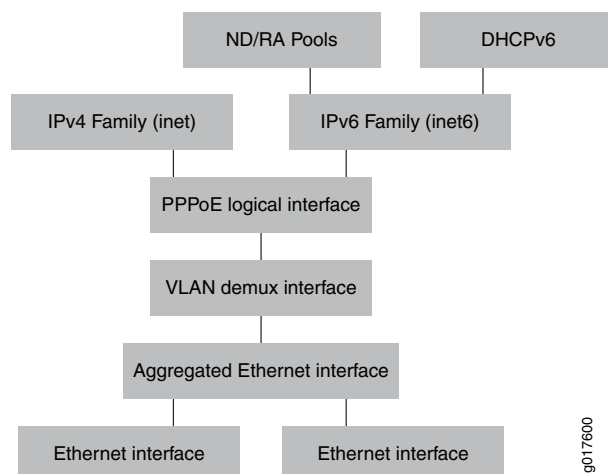

The BNG and the CPE handle both IPCP and IPv6CP identically and simultaneously over a single PPP connection. The BNG or the CPE can open and close any Network Control Protocol (NCP) session without affecting the other sessions. This capability allows for a dynamic setup where IPv4 (family inet) and IPv6 (family inet6) sessions can be brought up and down individually. As long as one family is active, the subscriber remains active.

[Figure 19 on page 468](#) shows a dual-stack interface stack in a PPPoE access network. The IPv4 family (inet) and the IPv6 family (inet6) can reside on the same PPPoE logical interfaces. The family inet and family inet6 parts of dynamic profiles are applied, and services are activated when each individual family is negotiated.

**Figure 19: Dual-Stack Interface Stack over a PPPoE Access Network**

[Figure 20 on page 469](#) shows a dual-stack interface stack over aggregated Ethernet in a PPPoE access network.

*Figure 20: Dual-Stack Aggregated Ethernet Stack over a PPPoE Access Network*

### Support for Demultiplexing Interfaces

IPv4 and IPv6 dual stack is supported on VLAN demultiplexing (demux) interfaces. Dual stack is not supported on IP demux interfaces.

### Determining the Status of CPE in a PPPoE Access Network

In a PPPoE access network, you can enable keepalives to determine the status of the CPE.

### IPv6 Address Provisioning in the PPPoE Access Network

IPv6CP negotiates the interface identifier, which can be used to provision link-local addresses that are used for direct connectivity between the BNG and the CPE. Because PPPoE negotiates only interface IDs and does not negotiate IPv6 addresses, PPPoE relies on other protocols for addressing. The protocols you can use are DHCPv6 and NDRA.

### Authentication in a PPPoE Access Network

In a PPPoE network, you can use PAP and CHAP to identify and authenticate the CPE and subscriber sessions.

You can also use AAA for authentication and authorization through external RADIUS servers.

### Negotiation of Network Control Protocols When Authorized Addresses Are Unavailable

NCP negotiation is initiated for subscriber sessions by default, even when authorized addresses are not available. An example of this situation is when the DHCPv6 local server is configured with an override so that the jpppd process never receives an IPv6 address or prefix from AAA, although the DHCPv6 local server receives a prefix from a delegated pool. In this situation, the client attempts to negotiate IPv6CP with the jpppd process.

By default, when IPCP negotiation is attempted for an IPv4-only PPPoE subscriber session on a dynamic interface, the jpppd process issues a Protocol-Reject message if AAA does

not provide an IPv4 address. However, negotiation is allowed to proceed when the **on-demand-ip-address** statement is included at the **[edit protocols ppp-service]** or **[edit dynamic-profiles *profile-name* interfaces pp0 unit \$junos-interface-unit ppp-options]** hierarchy level.

IPCP negotiation is enabled by default for an IP destination address defined on a static interface.

In contrast, IPv6CP negotiation is enabled to proceed by default for an IPv6-only session when AAA has not provided an appropriate IPv6 address or prefix. To prevent endless client negotiation of IPv6CP, you can alter the behavior by including the **reject-unauthorized-ipv6cp** statement at the **[edit protocols ppp-service]** hierarchy level. This statement enables the jpppd process to reject the negotiation attempt.

When IPv6CP rejection is enabled, jpppd also issues a Protocol-Reject message when router advertisement is not enabled in the dynamic profile that instantiates the interface but only a Framed-IPv6-Prefix attribute is received.

## Shared IPv4 and IPv6 Service Sessions on PPP Access Networks

You can configure one dynamic service profile that supports IPv4, IPv6, or both IPv4 and IPv6. It allows subscribers to share the same service session using IPv4 and IPv6 address families. If you define IPv4 and IPv6 in the dynamic service profile, one address family or both address families can be activated for the service. When the service is activated, matched packets are tagged with the same traffic class and treated the same way for both IPv4 and IPv6 traffic.

### Accounting for Shared IPv4 and IPv6 Service Sessions

---

When service sessions are shared for both IPv4 and IPv6 subscribers, only one Accounting-Start message is sent for each service session regardless of the number of address families that are active. Statistics for each address family of a service session are cumulative across service activations and deactivations of the service.

### Deactivating Shared IPv4 and IPv6 Service Sessions

---

If both IPv4 and IPv6 service sessions are active, and a deactivation message is received for one of the address families (IPv4 or IPv6), all active services for that address family are deactivated. If one address family remains active on the service, the service session remains in the ACTIVE state. If the address family that is deactivated is the only family currently running on the service session, the service returns to the INIT state.

## AAA Service Framework in a Dual Stack over a PPPoE Access Network

You can use the AAA Service Framework for all authentication, authorization, accounting, address assignment, and dynamic request services that the BNG uses for network access. The framework supports authentication and authorization through external RADIUS servers. It also supports accounting and dynamic-request change of authorization (CoA) and disconnect operations through external servers, and address assignment through a combination of local address-assignment pools and RADIUS servers.

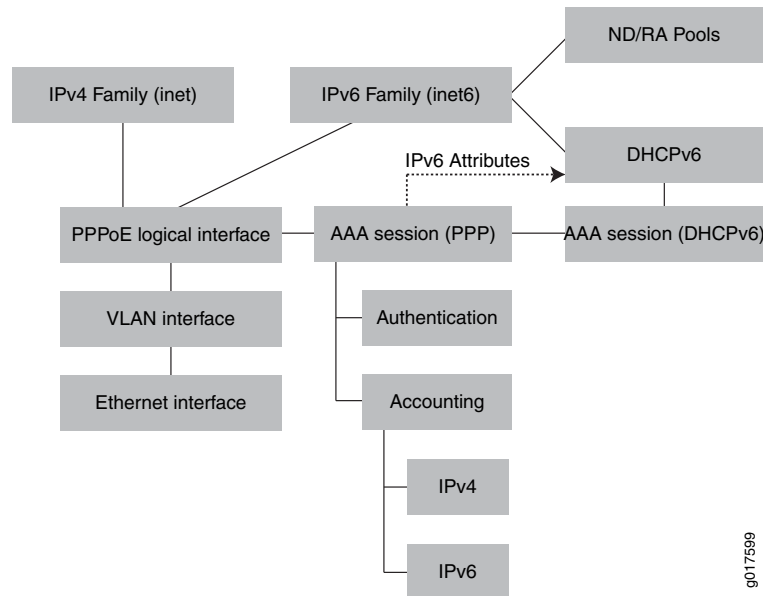

The BNG interacts with external servers to determine how individual subscribers access the broadband network. The BNG can also obtain information from external servers for the following:

- How subscribers are authenticated.
- How accounting statistics are collected and used.
- How dynamic requests, such as CoA, are handled.

As shown in [Figure 21 on page 471](#), implementing a dual stack over a PPPoE access network that uses AAA can have the following characteristics:

- DHCPv6—If used, it runs over the IPv6 family session, and it inherits attributes from the underlying PPPoE session.
- NDRA—If used, it runs over the IPv6 family session.
- IPv4 and IPv6 accounting—One accounting session handles both IPv4 and IPv6 accounting information.

*Figure 21: AAA Service Framework in a Dual Stack over a PPPoE Access Network*

### Collection of Accounting Statistics in a PPPoE Access Network

AAA provides support for both IPv4 and IPv6 statistics in one accounting session. On MX Series 5G Universal Routing Platforms, AAA also provides support for separate IPv4 and IPv6 accounting statistics.

The following RADIUS attributes are included by default (when available) in Acct-Start, Interim, and Acct-Stop messages:

- Framed-IPv6-Prefix
- Framed-IPv6-Pool

- Delegated-Ipv6-Prefix
- Framed-IPv4-Route
- Framed-IPv6-Route

You can configure the BNG to exclude these attributes in Acct-Start and Acct-Stop messages.

### Change of Authorization (CoA)

---

RADIUS servers can initiate dynamic requests to the BNG. Dynamic requests include CoA requests, which specify vendor-specific attribute (VSA) modifications and service changes.

In your access profile configuration, you specify the IP addresses of RADIUS authentication servers that can initiate dynamic requests to the router. The list of authentication servers also provides RADIUS-based dynamic service activation and deactivation during subscriber login.

## RADIUS Accounting Messages for Dual-Stack PPPoE Subscribers

Acct-Start messages sent to the RADIUS server contain all the learned and allocated addresses. Subsequent negotiation or allocation of addresses results in optionally sending immediate Acct-Interim-Update messages that contain all the negotiated and allocated addresses. For the dual-stack PPPoE subscriber, the following types of addresses are provided:

- IP address—negotiated during the IPCP (NCP) phase of PPP
- Interface identifier—negotiated during the IPv6CP (NCP) phase of PPP
- NDRA prefix—sent during router advertisement after IPv6CP
- DHCPv6 IA\_NA address—negotiated by the DHCPv6 Solicit, Advertise, Request, Reply (SARR) phase after IPv6CP
- DHCPv6 IA\_PD prefix—negotiated by the DHCPv6 SARR phase after IPv6CP

The BNG identifies addresses by the following methods:

- Addresses or prefixes returned from an external authority, such as RADIUS
- Addresses allocated locally using the pool names specified by external authority
- Addresses allocated from a local pool not specified for PPP authorization
- Addresses allocated by an external server outside of the BNG or RADIUS, such as a DHCPv6 external server (DHCPv6 relay or relay proxy)

IPCP and IPv6CP negotiation occur at the PPP NCP phase and can occur in any order. However, DHCPv6 PD or DHCPv6 IA\_NA allocation and negotiation occur only after IPv6CP.

The following table lists the RADIUS attributes and their mapping:

Number	RADIUS Attribute	Address Type
1	Framed-IP-Address	IP Address
2	Framed-Pool	IP Address Pool
3	Framed-IPv6-Prefix	NDRA_Prefix (prefix < 128) IA_NA (prefix = 128)
4	Framed-IPv6-Pool	NDRA Prefix pool IA_NA pool
5	Framed-Interface-Id	IPv6 Interface Identifier
6	Delegated-IPv6-Prefix	IA_PD Prefix
7	Jnpr-Delegated-IPv6-Pool (VSA 26-161)	IA_PD Pool
8	Jnpr-IPv6-Ndra-Pool-Name (VSA 26-157)  NOTE. Not supported: Use Framed-IPv6-Pool to specify the NDRA pool. Alternatively, configure it locally by using the <b>neighbor-discovery-router-advertisement pool</b> statement.	NDRA Pool

## Accounting Messages for PPPoE Using NDRA Prefixes

In the following tables, you can compare PPPoE dual-stack address allocation using Stateless Address Autoconfiguration (SLAAC) NDRA.

The following table lists SLAAC (NDRA) prefixes from RADIUS:

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
1	Framed-IPv6-Prefix (used for NDRA Prefix)  Framed-Interface-Id  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD)	IPv6NCP	Because the required attributes are learned prior to the Acct-Start messages, these attributes are sent in Acct-Start messages and no immediate Acct-Interim-Update message is sent.

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
2	Framed-IPv6-Prefix (used for NDRA Prefix)  Framed-Interface-Id  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD)	IPv6NCP + DHCPv6	Because the required attributes are learned prior to the Acct-Start messages, these attributes are sent in Acct-Start messages and no immediate Acct-Interim-Update message is sent.  No immediate Acct-Interim-Update message is sent after DHCPv6.
3	Framed-IPv6-Prefix (used for NDRA Prefix)  Framed-Interface-Id not sent  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD)	IPv6NCP	Acct-Start message contains only iFramed-IPv6-Prefix and Delegated-IPv6-Prefix.  No immediate Acct-Interim-Update message is sent.  Next periodic Acct-Interim-Update message (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix and Delegated-IPv6-Prefix.
4	Framed-IPv6-Prefix (used for NDRA Prefix)  Framed-Interface-Id not sent  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD )	IPv6NCP + DHCPv6	Acct-Start message contains Framed-IPv6-Prefix and Delegated-IPv6-Prefix.  No immediate Acct-Interim-Update message is sent upon IPv6NCP.  No immediate Acct-Interim-Update message is sent upon DHCPv6.  Next periodic Acct-Interim-Update message (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix and Delegated-IPv6-Prefix.

The following table lists prefixes from RADIUS selected pools:

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
1	<p>Framed-IPv6-Pool (used for NDRA Prefix)</p> <p>NOTE: If RADIUS does not return Framed-IPv6-Pool, you can configure this locally using the <del>neighbor-discovery-router-advertisement</del> <b>pool</b> statement, which is used for allocating an NDRA prefix from the local pool.</p> <p>Framed-Interface-Id</p> <p>Jnpr-Delegated-IPv6-pool (used for DHCPv6 IA_PD)</p>	IPv6NCP	<p>Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, Delegated-IPv6-Prefix, and Framed-Interface-Id.</p> <p>Framed-IPv6-Prefix is based on the configuration present in the dynamic profile IPv6 prefix that was allocated and sent in Acct-Start message.</p> <p>Framed-IPv6-Pool is learned from RADIUS.</p> <p>Delegated-IPv6-Prefix is pre-allocated.</p> <p>Framed-Interface-Id is sent in Acct-Start message because it is learned from RADIUS.</p> <p>No Acct-Interim-Update message is sent.</p>
2	<p>Framed-IPv6-Pool (used for NDRA Prefix)</p> <p>NOTE: If RADIUS does not return Framed-IPv6-Pool, you can configure this locally using the <del>neighbor-discovery-router-advertisement</del> <b>pool</b> statement, which is used for allocating an NDRA prefix from the local pool.</p> <p>Framed-Interface-Id</p> <p>Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)</p>	IPv6NCP + DHCPv6	<p>Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, Delegated-IPv6-Prefix, and Framed-Interface-Id.</p> <p>Framed-IPv6-Prefix and Framed-IPv6-Pool are based on the configuration present in dynamic profile IPv6 prefix and is allocated prior and sent in Acct-Start message.</p> <p>Delegated-IPv6-Prefix is pre-allocated.</p> <p>Framed-Interface-Id is sent in Acct-Start message because it is learned from RADIUS.</p> <p>No immediate Acct-Interim-Update message is sent upon IPv6NCP.</p> <p>No immediate Acct-Interim-Update message is sent upon DHCPv6.</p>

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
3	<p>Framed-IPv6-Pool (used for NDRA Prefix)</p> <p>NOTE: If RADIUS does not return Framed-IPv6-Pool, you can configure this locally using the <del>neighbor-discovery-router-advertisement</del> <b>pool</b> statement, which is used for allocating an NDRA prefix from the local pool.</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)</p>	IPv6NCP	<p>Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix.</p> <p>Delegated-IPv6-Prefix is pre-allocated.</p> <p>No immediate Acct-Interim-Update message is sent.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix. (This value is learned during IPv6NCP negotiation with the peer.)</p>
4	<p>Framed-IPv6-Pool (used for NDRA Prefix)</p> <p>NOTE: If RADIUS does not return Framed-IPv6-Pool, you can configure this locally using the <del>neighbor-discovery-router-advertisement</del> <b>pool</b> statement, which is used for allocating an NDRA prefix from the local pool.</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)</p>	IPv6NCP + DHCPv6	<p>Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix.</p> <p>Delegated-IPv6-Prefix is pre-allocated.</p> <p>No immediate Acct-Interim-Update message is sent upon IPv6NCP.</p> <p>No immediate Acct-Interim-Update message is sent upon DHCPv6.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix. (This value is learned during IPv6NCP negotiation with the peer.)</p>

The following table lists prefixes from a local pool or an external server:

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
1	<p>Framed-IPv6-Pool (used for NDRA Prefix)</p> <p>NOTE: If RADIUS does not return Framed-IPv6-Pool, you can configure this locally using the <del>neighbor-discovery-router-advertisement</del> <b>pool</b> statement, which is used for allocating an NDRA prefix from the local pool.</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool not sent</p>	IPv6NCP	<p>Acct-Start message contains Framed-IPv6-Prefix and Framed-IPv6-Pool.</p> <p>No immediate Acct-Interim-Update message is sent.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix and Framed-IPv6-Pool.</p>
2	<p>Framed-IPv6-Pool (used for NDRA Prefix)</p> <p>NOTE: If RADIUS does not return Framed-IPv6-Pool, you can configure this locally using the <del>neighbor-discovery-router-advertisement</del> <b>pool</b> statement, which is used for allocating an NDRA prefix from the local pool.</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool not sent</p> <p>[IA_PD prefix is learned from DHCPv6 External Server (DHCPv6 Relay / Relay Proxy model) or reservation from a local pool by DHCPv6]</p>	IPv6NCP + DHCPv6	<p>Acct-Start message contains Framed-IPv6-Prefix and Framed-IPv6-Pool.</p> <p>No immediate Acct-Interim-Update message is sent upon DHCPv6.</p> <p>Upon DHCPv6, immediate Acct-Interim-Update is sent which contains Framed-IPv6-Pool, Framed-IPv6-Prefix, Framed-Interface-Id, and DHCPv6 IA_PD Prefix.</p> <p>Framed-Interface-Id value is learned during IPv6NCP negotiation with the peer.</p> <p>DHCPv6 IA_PD is learned by DHCPv6 either by DHCPv6 external server or reservation from a local pool during DHCPv6 SARR phase.</p> <p>Any periodic Acct-Interim-Update before DHCPv6 completion contains Framed-Interface-Id in addition to the attributes of the Acct-Start message. (This can occur if DHCPv6 occurs after periodic interval.)</p>

### Accounting Messages for PPPoE Subscribers That Use DHCPv6 IA\_NA Prefixes

In the following tables, you can compare PPPoE dual-stack address allocation using DHCPv6 IA\_NA prefixes.

The following table lists DHCPv6 IA\_NA prefixes from RADIUS:

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
1	Framed-IPv6-Prefix (used for IA_NA prefix)  Framed-Interface-Id  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD)	IPv6NCP	Because the required attributes are learned prior to Acct-Start message, these attributes are sent in Acct-Start message and no immediate Acct-Interim-Update message is sent.
2	Framed-IPv6-Prefix (used for IA_NA Prefix)  Framed-Interface-Id  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD)	IPv6NCP + DHCPv6	Because the required attributes are learned prior to Acct-Start message, these attributes are sent in Acct-Start message and no immediate Acct-Interim-Update message is sent.  There is no immediate Acct-Interim-Update message sent after DHCPv6.
3	Framed-IPv6-Prefix (used for IA_NA Prefix)  Framed-Interface-Id not sent  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD )	IPv6NCP	Acct-Start message message contains Framed-IPv6-Prefix and Delegated-IPv6-Prefix.  No immediate Acct-Interim-Update message is sent.  Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix and Delegated-IPv6-Prefix.
4	Framed-IPv6-Prefix (used for IA_NA Prefix)  Framed-Interface-Id not sent  Delegated-IPv6-Prefix (used for DHCPv6 IA_PD)	IPv6NCP + DHCPv6	Acct-Start message message contains iFramed-IPv6-Prefix and Delegated-IPv6-Prefix.  No immediate Acct-Interim-Update message is sent upon IPv6NCP.  No immediate Acct-Interim-Update message is sent upon DHCPv6.  Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix and Delegated-IPv6-Prefix.

The following table lists prefixes from RADIUS selected pools:

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
1	Framed-IPv6-Pool (used for IA_NA Prefix)  Framed-Interface-Id  Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)	IPv6NCP	Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, Delegated-IPv6-Prefix, and Framed-Interface-Id .  Framed-IPv6 Prefix is pre-allocated.  Framed-IPv6-Pool is learned from RADIUS.  Delegated-IPv6-Prefix is pre-allocated .  Framed-Interface-Id is sent in Acct-Start message because it is learned from RADIUS.  No Acct-Interim-Update message is sent.
2	Framed-IPv6-Pool (used for IA_NAPrefix)  Framed-Interface-Id  Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)	IPv6NCP + DHCPv6	Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, Delegated-IPv6-Prefix, and Framed-Interface-Id.  Framed-IPv6 is pre-allocated.  Framed-IPv6-Pool is learned from RADIUS.  Delegated-IPv6-Prefix is pre-allocated.  Framed-Interface-Id is sent in Acct-Start message because it is learned from RADIUS.  No immediate Acct-Interim-Update message is sent upon IPv6NCP.  No immediate Acct-Interim-Update message is sent upon DHCPv6.

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
3	<p>Framed-IPv6-Pool (used for IA_NA Prefix)</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)</p>	IPv6NCP	<p>Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix.</p> <p>Framed-IPv6-Prefix is pre-allocated.</p> <p>Framed-IPv6-Pool is learned from RADIUS.</p> <p>Delegated-IPv6-Prefix is pre-allocated.</p> <p>No immediate Acct-Interim-Update message is sent.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix. (This value is learned during IPv6NCP negotiation with the peer.)</p>
4	<p>Framed-IPv6-Pool (used for IA_NA Prefix)</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool (used for DHCPv6 IA_PD)</p>	IPv6NCP + DHCPv6	<p>Acct-Start message contains Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix.</p> <p>Framed-IPv6-Prefix is pre-allocated.</p> <p>Framed-IPv6-Pool is learned from RADIUS.</p> <p>Delegated-IPv6-Prefix is pre-allocated.</p> <p>No immediate Acct-Interim-Update message is sent upon IPv6NCP.</p> <p>No immediate Acct-Interim-Update message is sent upon DHCPv6.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix, Framed-IPv6-Pool, and Delegated-IPv6-Prefix. (This value is learned during IPv6NCP negotiation with the peer.)</p>

The following table lists prefixes from a local pool or an external server:

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
1	<p>Framed-IPv6-Pool (used for IA_NA Prefix)</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool not sent</p>	IPv6NCP	<p>Acct-Start message contains Framed-IPv6-Prefix and Framed-IPv6-Pool.</p> <p>Framed-IPv6-Prefix is pre-allocated.</p> <p>Framed-IPv6-Pool is learned from RADIUS.</p> <p>No immediate Acct-Interim-Update message is sent.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id in addition to Framed-IPv6-Prefix and Framed-IPv6-Pool. (This value is learned during IPv6NCP negotiation with the peer.)</p>
2	<p>Framed-IPv6-Pool (used for IA_NA Prefix)</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool not sent</p> <p>[IA_PD prefix is learned from DHCPv6 External Server (DHCPv6 Relay / Relay Proxy model) or reservation from a local pool by DHCPv6]</p>	IPv6NCP + DHCPv6	<p>Acct-Start message contains Framed-IPv6-Prefix and Framed-IPv6-Pool.</p> <p>Framed-IPv6-Prefix is pre-allocated.</p> <p>Framed-IPv6-Pool is learned from RADIUS.</p> <p>No immediate Acct-Interim-Update message is sent upon DHCPv6.</p> <p>Upon DHCPv6, an immediate Acct-Interim-Update is sent that contains Framed-IPv6-Pool, Framed-IPv6-Prefix, Framed-Interface-Id, and DHCPv6 IA_PD Prefix.</p> <p>Framed-Interface-Id value is learned during IPv6NCP negotiation with the peer.</p> <p>DHCPv6 IA_PD is learned by DHCPv6 either by DHCPv6 External Server or reservation from a local pool during DHCPv6 SARR phase.</p> <p>Any periodic Acct-Interim-Update before DHCPv6 completion contains Framed-Interface-Id in addition to the attributes of Acct-Start message. (This can occur if DHCPv6 occurs after periodic interval.)</p>

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
3	<p>Framed-IPv6-Pool not sent</p> <p>[IA_NA Prefix is learned from DHCPv6 External Server (DHCPv6 Relay / Relay Proxy model) or reservation from a local pool by DHCPv6]</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool not sent</p> <p>[IA_PD prefix is learned from DHCPv6 External Server (DHCPv6 Relay / Relay Proxy model) or reservation from a local pool by DHCPv6]</p>	IPv6NCP	<p>Acct-Start message does not contain any of the IPv6-related prefixes and addresses or pool names.</p> <p>No immediate Acct-Interim-Update message is sent upon IPv6NCP.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id. (This value is learned during IPv6NCP negotiation with the peer.)</p>

Number	RADIUS Attributes	IPv6 Address Negotiation Type	RADIUS Accounting Messages
4	<p>Framed-IPv6-Pool not sent</p> <p>[IA_NA Prefix is learned from DHCPv6 External Server (DHCPv6 Relay / Relay Proxy model) or reservation from a local pool by DHCPv6 ]</p> <p>Framed-Interface-Id not sent</p> <p>Jnpr-Delegated-IPv6-Pool not sent</p> <p>[IA_PD prefix is learned from DHCPv6 External Server (DHCPv6 Relay / Relay Proxy model) or reservation from a local pool by DHCPv6]</p>	IPv6NCP+DHCPv6	<p>Acct-Start message does not contain any of the IPv6-related prefixes and addresses or pool names.</p> <p>No immediate Acct-Interim-Update message is sent upon IPv6NCP.</p> <p>Next periodic Acct-Interim-Update (based on interval) contains Framed-Interface-Id. (This value is learned during IPv6NCP negotiation with the peer.)</p> <p>Upon DHCPv6, immediate Acct-Interim-Update is sent which contains Framed-IPv6-Prefix, Framed-IPv6-Pool, Framed-Interface-Id, and DHCPv6 IA_PD.</p> <p>Framed-IPv6-Prefix is the IA_NA prefix learned by DHCPv6 (either by external server or reservation from a local pool).</p> <p>Framed-IPv6-Pool is sent only if there is a reservation of an IA_NA prefix from local pool by DHCPv6.</p> <p>Framed-Interface-Id value is learned during IPv6NCP negotiation with the peer.</p> <p>DHCPv6 IA_PD prefix is learned by DHCPv6 either by DHCPv6 external server or reservation from a local pool during DHCPv6 SARR phase.</p> <p>Any periodic Acct-Interim-Update before DHCPv6 completion contains Framed-Interface-Id only. (This can occur if DHCPv6 occurs after periodic interval.)</p>

### Suppressing Accounting Information That Comes from AAA

The following standard and vendor-specific IPv6 RADIUS attributes are included by default (when available) in Acct-Start and Acct-Stop messages:

- Framed-IPv6-Prefix
- Framed-IPv6-Pool
- Delegated-Ipv6-Prefix
- Framed-IPv4-Route
- Framed-IPv6-Route

You can configure the software to exclude these attributes from Acct-Start or Acct-Stop messages. To do so, configure the access profile:

1. Access the access profile.

```
[edit]
user@host# edit access profile dual-stack radius attributes
```

2. The following examples show how to use the **exclude** statement to exclude attributes from messages.

```
[edit access profile dual-stack radius attributes]
user@host# set exclude delegated-ipv6-prefix accounting-start
```

```
[edit access profile dual-stack radius attributes]
user@host# set exclude framed-ipv6-pool [accounting-start accounting-stop]
```

```
[edit access profile dual-stack radius attributes]
user@host# set exclude framed-ipv6-prefix accounting-start framed-ipv6-route
accounting-start
```

```
[edit access profile dual-stack radius attributes]
user@host# set exclude framed-ipv6-prefix accounting-start framed-ipv6-route
accounting-start
```

## Avoiding Negotiation of IPv6CP in the Absence of an Authorized Address

You can control the behavior of the router in a situation where IPv6CP negotiation is initiated for subscriber sessions when no authorized addresses are available.

By default, IPv6CP negotiation is enabled to proceed for an IPv6-only session when AAA has not provided an appropriate IPv6 address or prefix. In the absence of the address, the negotiation cannot successfully complete. To prevent endless client negotiation of IPv6CP, include the **reject-unauthorized-ipv6cp** statement at the **[edit protocols ppp-service]** hierarchy level, which enables the jpppd process to reject the negotiation attempt.

To configure the router to reject IPv6CP negotiation messages when no IPv6 address is available for a dynamic interface:

- Enable rejection of unauthorized IPv6CP negotiation messages.

```
[edit protocols ppp-service]
user@host# set reject-unauthorized-ipv6cp
```

**NOTE:** The `reject-unauthorized-ipv6cp` statement does not prevent IPv6CP negotiation for static interfaces, because the `jpppd` process cannot determine whether router advertisement of DHCPv6 is configured to run above the PPP interface.

## Best Practices for Configuring IPv4 and IPv6 Dual Stack in a PPPoE Access Network

- [Best Practice: Static PPPoE Interfaces with NDRA on page 485](#)
- [Best Practice: DHCPv6 Prefix Delegation over a PPPoE Access Network on page 486](#)
- [Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic Profiles with NDRA on page 486](#)
- [Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic Profiles with DHCPv6 on page 487](#)
- [Best Practice: IPv4 Addressing for Logical Interfaces in PPPoE Dynamic Profiles on page 487](#)
- [Best Practice: Configuring Authentication for DHCP Subscribers on a PPPoE Access Network on page 488](#)

### Best Practice: Static PPPoE Interfaces with NDRA

When you use static PPPoE interfaces with NDRA, the prefix configured for router advertisement must match the source address specified under family `inet6` in the logical `pp0` interface configuration. If these values do not match, the prefix is not advertised correctly.

For example:

```
[edit protocols router-advertisement]
interface pp0.2004 {
  prefix 2001:db8:2040:2004::/64;
}
```

```
[edit interface pp0]
unit 2004 {
  family inet6 {
    address 2001:db8:2040:2004::1:1/64;
  }
}
```

To view the prefix in the ICMPv6 packet, use the **monitor traffic interface pp0.xxx extensive** command. If the prefix is missing, make sure that there is not a mismatch between the family inet6 address configured for the interface and the prefix configured for the interface in the router advertisement configuration.

### Best Practice: DHCPv6 Prefix Delegation over a PPPoE Access Network

When you use DHCPv6 prefix delegation over a PPPoE access network, you need to enable unnumbered addressing in the family inet6 configuration.

For dynamic PPPoE interfaces, enable unnumbered addressing in the dynamic profile. For example:

```
[edit dynamic-profiles]
PPPoE-dyn-ipv4v6-dhcp {
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        ...
        family inet6 {
          unnumbered-address lo0.0;
        }
      }
    }
  }
}
```

For static PPPoE interfaces, enable unnumbered addressing in the interface configuration. For example:

```
[edit interface pp0]
unit 2004 {
  family inet6 {
    unnumbered-address lo0.0;
```

### Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic Profiles with NDRA

When you use NDRA, always set the IPv6 internet address in dynamic profiles to the **\$junos-ipv6-address** predefined variable. This variable is replaced with the IPv6 address of the interface used for router advertisements.

```
[edit dynamic-profiles]
dyn-v4v6-ndra {
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        family inet6 {
          address "$junos-ipv6-address ";
        }
      }
    }
  }
}
```

## Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic Profiles with DHCPv6

The IPv6 address configuration for logical interfaces in PPPoE dynamic profiles when you are using DHCPv6 depends on whether or not you are using routing instances.

If you are using routing instances, use the **\$junos-loopback-interface** predefined variable for the IPv6 address. For example:

```
[edit dynamic-profiles]
dyn-v4v6-ri {
  routing-instances {
    "$junos-routing-instance" {
      interface "$junos-interface-name";
    }
  }
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        family inet6 {
          unnumbered-address "$junos-loopback-interface";
        }
      }
    }
  }
}
```

If you are not using routing instances, use the unnumbered address for the IPv6 address. The unnumbered address enables the local address to be derived from the specified interface and allows IP processing on the interface without assigning an explicit IP address to the interface. For example:

```
[edit dynamic-profiles]
dyn-v4v6-ndra {
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        pppoe-options {
          underlying-interface "$junos-underlying-interface";
          server;
        }
        family inet6 {
          unnumbered-address lo0.0;
        }
      }
    }
  }
}
```

## Best Practice: IPv4 Addressing for Logical Interfaces in PPPoE Dynamic Profiles

The IPv4 address configuration for logical interfaces in PPPoE dynamic profiles depends on whether or not you are using routing instances.

If you are using routing instances, use the `$junos-loopback-interface` variable for the IPv6 address.

```
[edit dynamic-profiles]
dyn-v4v6-ri {
  routing-instances {
    "$junos-routing-instance" {
      interface "$junos-interface-name";
    }
  }
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        family inet {
          unnumbered-address "$junos-loopback-interface";
        }
      }
    }
  }
}
```

If you are not using routing instances, use the unnumbered address for the IPv6 address. The unnumbered address enables the local address to be derived from the specified interface and allows IP processing on the interface without assigning an explicit IP address to the interface.

```
[edit dynamic-profiles]
dyn-v4v6-ndra {
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        pppoe-options {
          underlying-interface "$junos-underlying-interface";
          server;
        }
        family inet {
          unnumbered-address lo0.0;
        }
      }
    }
  }
}
```

### Best Practice: Configuring Authentication for DHCP Subscribers on a PPPoE Access Network

In most cases PPPoE is used to authenticate subscribers in a PPPoE access network. However, if you wish to use DHCP to perform the authentication, do not configure subscriber authentication at the `[edit system services dhcp-local-server]` or the `[edit system services dhcp-local-server dhcpv6]` hierarchy levels. Instead configure subscriber authentication at the `[edit system services dhcp-local-server dhcpv6 group]` hierarchy level. For example:

```
[edit system services dhcp-local-server dhcpv6]
group v6-dhcp-client {
  authentication {
    password $ABC123;
    username-include {
      user-prefix StaticUser;
    }
  }
}
```

### Configuring a DHCPv6 Local Server for DHCPv6 over PPPoE

To layer DHCPv6 above the PPPoE IPv6 family (inet6), create a DHCPv6 local server and associate DHCPv6 with the PPPoE interfaces by adding the PPPoE interfaces to the DHCPv6 local server configuration. Specify static and dynamic PPPoE interfaces as follows:

- Dynamic—Use the pp0.0 (PPPoE) logical interface as a wildcard to indicate that a DHCPv6 binding can be made on top of a PPPoE interface.
- Static—Use unit numbers to explicitly specify static interfaces; for example, pp0.2000.

To configure a DHCPv6 local server:

1. Access the DHCPv6 local server configuration.

```
[edit]
user@host# edit system services dhcp-local-server dhcpv6
[edit system services dhcp-local-server dhcpv6]
```

2. Create a group for dynamic PPPoE interfaces and assign a name.

The group feature groups a set of interfaces and then applies a common DHCP configuration to the named interface group.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit group group-pppoe
```

3. For dynamic PPPoE logical interfaces, add an interface.

```
[edit system services dhcp-local-server dhcpv6 group group-pppoe]
user@host# set interface pp0.0
```

4. For static PPPoE, add a range of interfaces.

```
[edit system services dhcp-local-server dhcpv6 group group-pppoe]
user@host# set interface pp0.2000 upto pp0.2999
```

## Configuring a PPPoE Dynamic Profile for Use with DHCP Addressing in a Dual-Stack Network

Configure a dynamic profile for IPv4 and IPv6 subscribers that access the network. The dynamic profile defines the attributes of the dynamic PPPoE logical subscriber interface.

To configure a PPPoE dynamic profile for both IPv4 and IPv6 subscribers:

1. Create and name the dynamic profile.

```
[edit]
user@host# edit dynamic profiles PPPOE-dyn-ipv4v6
```

2. If you are using routing instances, add a routing instance to the profile, and add an interface to the routing instance.
  - Specify the **\$junos-routing-instance** variable for the routing instance. The routing instance variable is dynamically replaced with the routing instance the accessing subscriber uses when connecting to the BNG.
  - Specify the **\$junos-interface-name** variable for the interface. The interface variable is dynamically replaced with the interface that the accessing subscriber uses when connecting to the BNG.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6]
user@host# set routing-instances $junos-routing-instance interface
$junos-interface-name
```

3. Add a PPPoE logical interface (pp0) to the profile, and specify **\$junos-interface-unit** as the predefined variable to represent the logical unit number for the interface. The variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6]
```

```
user@host# edit interfaces pp0 unit $junos-interface-unit
```

4. Configure the IPv4 family for the pp0 interface as follows:

- If you are not using routing instances, assign an unnumbered address. The unnumbered address enables the local address to be derived from the specified interface and allows IP processing on the interface without an explicit IP address assigned to the interface.

For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet unnumbered-address lo0.0
```

- If you are using routing instances, assign the predefined variable **\$junos-loopback-interface**.

For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet unnumbered-address $junos-loopback-interface
```

5. Configure the IPv6 family for the pp0 interface as follows:

- If you are not using routing instances, assign an unnumbered address that specifies the loopback interface. The unnumbered address enables the local address to be derived from the loopback interface and allows IP processing on the interface without an explicit IP address assigned to the interface.

For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet6 unnumbered-address lo0.0
```

- If you are using routing instances, assign the predefined variable **\$junos-loopback-interface**.

For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet6 unnumbered-address $junos-loopback-interface
```

6. Specify **\$junos-underlying-interface** as the predefined variable to represent the name of the underlying Ethernet interface on which the router creates the dynamic PPPoE logical interface. The variable is dynamically replaced with the actual name of the underlying interface.

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

7. Define the router to act as a PPPoE server when a PPPoE logical interface is dynamically created.

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options server
```

8. (Optional) Configure the PPP authentication protocol for the pp0 interface. Specify either **chap** or **pap** (or both).

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set ppp-options chap
user@host# set ppp-options pap
```

9. (Optional) Enable keepalives and set an interval for keepalives. We recommend an interval of 30 seconds. For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6 interfaces pp0 unit "$junos-interface-unit"]
user@host# set keepalives interval 30
```

## Configuring a PPPoE Dynamic Profile for Use with NDRA in a Dual-Stack Network

Configure a dynamic profile for IPv4 and IPv6 PPPoE subscribers that access the network. The dynamic profile defines the attributes of the dynamic PPPoE logical subscriber interface.

This dynamic profile is for configurations that use NDRA to assign a global IP address to the CPE WAN link.

To configure a PPPoE dynamic profile for NDRA:

1. Create and name the dynamic profile.

```
[edit]
user@host# edit dynamic profiles PPPOE-dyn-ipv4v6-ndra
```

2. If you are using routing instances, add a routing instance to the profile and add an interface to the routing instance.
  - Specify the **\$junos-routing-instance** variable for the routing instance. The routing instance variable is dynamically replaced with the routing instance the accessing subscriber uses when connecting to the BNG.
  - Specify the **\$junos-interface-name** variable for the interface. The interface variable is dynamically replaced with the interface that the accessing subscriber uses when connecting to the BNG.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6-ndra]
user@host# set routing-instances $junos-routing-instance interface
$junos-interface-name
```

3. Add a PPPoE logical interface (pp0) to the profile, and specify **\$junos-interface-unit** as the predefined variable to represent the logical unit number for the interface. The variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6-ndra]
user@host# edit interfaces pp0 unit $junos-interface-unit
```

4. Configure the IPv4 family for the pp0 interface as follows:
  - If you are not using routing instances, assign an unnumbered address. The unnumbered address enables the local address to be derived from the specified interface and allows IP processing on the interface without assigning an explicit IP address to the interface.

For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra interfaces pp0 unit
"$junos-interface-unit"]
```

```
user@host# set family inet unnumbered-address lo0.0
```

- If you are using routing instances, assign the predefined variable **\$junos-loopback-interface**.

For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra interfaces pp0 unit
 "$junos-interface-unit"]
user@host# set family inet unnumbered-address $junos-loopback-interface
```

5. Configure the IPv6 family for the pp0 interface, and assign **\$junos-ipv6-address** as the predefined variable. Use this variable when you are using router advertisement with or without routing instances. This variable is replaced with the IPv6 address of the interface used for router advertisements.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6-ndra interfaces pp0 unit
 "$junos-interface-unit"]
user@host# set family inet6 address $junos-ipv6-address
```

6. Specify **\$junos-underlying-interface** as the predefined variable to represent the name of the underlying Ethernet interface on which the router creates the dynamic PPPoE logical interface. The variable is dynamically replaced with the actual name of the underlying interface.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6-ndra pp0 interfaces pp0 unit
 "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

7. Define the router to act as a PPPoE server when a PPPoE logical interface is dynamically created.

```
[edit dynamic profiles PPPOE-dyn-ipv4v6-ndra interfaces pp0 unit
 "$junos-interface-unit"]
user@host# set pppoe-options server
```

8. (Optional) Configure the PPP authentication protocol that is used to identify and authenticate the CPE. Specify either **chap** or **pap** (or both).

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra interfaces pp0 unit
 "$junos-interface-unit"]
user@host# set ppp-options chap
user@host# set ppp-options pap
```

9. (Optional) Enable keepalives and set an interval for keepalives. We recommend an interval of 30 seconds. For example:

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra interfaces pp0 unit
"$junos-interface-unit"]
user@host# set keepalives interval 30
```

10. Configure the router advertisement protocol.

- a. Access the router advertisement configuration.

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra]
user@host# edit protocols router-advertisement
```

- b. Specify the interface on which the NDRA configuration is applied. Assign **\$junos-interface-name** as the predefined variable. The variable is replaced with the actual name of the interface.

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra protocols router-advertisement]
user@host# edit interface $junos-interface-name
```

- c. Specify a prefix value contained in router advertisement messages sent to the CPE on interfaces created with this dynamic profile.

If you specify the `$junos-ipv6-ndra-prefix` predefined variable, the actual value is obtained from a local pool or through AAA.

```
[edit dynamic-profiles PPPOE-dyn-ipv4v6-ndra protocols router-advertisement]
user@host# set prefix $junos-ipv6-ndra-prefix
```

- See Also**
- [Best Practice: IPv6 Addressing for Logical Interfaces in PPPoE Dynamic Profiles with NDRA on page 486](#)
  - [IPv4 and IPv6 Dual Stack in a PPPoE Access Network on page 468](#)

## Configuring a Static PPPoE Logical Interface for NDRA

To configure a static PPPoE logical interface for static NDRA configurations:

1. Specify the name and logical unit number of the interface.

```
[edit]
user@host# edit interfaces pp0 unit 1000
```

2. Configure a description for the interface.

```
[edit interfaces pp0 unit 1000]
```

```
user@host# set description "static IPv4v6 dual stack, NDRA"
```

3. Specify the family inet6 source address.

```
[edit interfaces pp0 unit 1000]
user@host# set family inet6 address 2001:db8:2040:2004::1.1.1/64
```

4. Configure an unnumbered address for family inet.

```
[edit interfaces pp0 unit 1000]
user@host# set family inet unnumbered-address lo0.0
```

5. Specify the underlying Ethernet interface.

```
[edit interfaces pp0 unit 1000]
user@host# set pppoe-options underlying-interface ge-1/0/0.1000
```

6. Define the router to act as a PPPoE server when the PPPoE logical interface is created.

```
[edit interfaces pp0 unit 1000]
user@host# set pppoe-options server
```

7. Access the router advertisement configuration, and specify the prefixes that the BNG sends in router advertisements for the static interface. Make sure that the prefixes match the source address configured for the static PPPoE logical interface configured in Step 3.

```
[edit]
user@host# edit protocols router-advertisement
user@host# set interface pp0.1000 prefix 2001:db8:2040:2004::/64
```

**See Also** • [Best Practice: Static PPPoE Interfaces with NDRA on page 485](#)

## Configuring an Address-Assignment Pool Used for Router Advertisements

If you are using local address-assignment pools to be used for router advertisement, create a pool and add IPv6 prefixes to the pool.

You must configure separate pools for DHCPv6 prefix delegation, DHCPv6 IA\_NA, and router advertisement.

To configure an NDRA address-assignment pool.

1. Create a pool for IPv6 prefixes used by NDRA.

```
[edit]
```

```
user@host# edit access address-assignment pool ndra-2010 family inet6
```

2. Add IPv6 network prefixes to the pool.

```
[edit access address-assignment pool ndra-2010 family inet6]
user@host# set prefix 2001:db8::/64
```

3. Configure the name of the IPv6 address range and define the range. For NDRA pools, specify the range by setting a prefix length of 64.

```
[edit access address-assignment pool ndra-2010 family inet6]
user@host# set range ndra-range prefix-length 64
```

4. Specify that the address-assignment pool is used for NDRA.

```
[edit access address-assignment]
user@host# set neighbor-discovery-router-advertisement ndra-2010
```

- See Also**
- *How NDRA Works in a Subscriber Access Network*
  - [Methods for Obtaining IPv6 Prefixes for NDRA on page 415](#)

## Configuring Duplicate IPv6 Prefix Protection for Router Advertisement

If you are using AAA to supply IPv6 prefixes for router advertisement, you can enable duplicate prefix protection to prevent prefixes from being used more than once. If enabled, the following attributes received from external servers are checked:

- *Framed-IPv6-Prefix*
- *Framed-IPv6-Pool*

The router then takes one of the following actions:

- If a prefix matches a prefix in an address pool, the prefix is taken from the pool if it is available.
- If the prefix is already in use, it is rejected as unavailable.
- If the prefix length requested from the external server does not match the pool's prefix length exactly, the authentication request is denied. If configured, the Acct-Stop message will include a termination cause.

To configure duplicate prefix protection:

1. Enter the **access** configuration.

```
[edit]
user@host# edit access
```

2. Enable duplicate prefix protection.

```
[edit access]
user@host# address-protection
```

- See Also**
- [How NDRA Works in a Subscriber Access Network](#)
  - [Duplicate Prefix Protection for NDRA on page 416](#)

## Configuring the IPv6 Link-Local Address for Dynamic Demux Interfaces over Static Demux VLAN Interfaces

When you are using Router Advertisement for IPv6 subscribers on dynamic demux interfaces that run over underlying static demux interfaces, both interfaces should use the same link-local address.

The link local address should be assigned using a unique 64-Bit IPv6 interface identifier (EUI-64), which is obtained based on the MAC address of the underlying interface.

To cause the system to implement the link-local address based on the MAC address of the underlying interface and to comply with the 64-bit Extended Unique Identifier (EUI-64):

1. Access the hierarchy that configures all static demux interfaces on the router.

```
[edit]
edit system demux-options
```

2. Configure the system to use the MAC address of the underlying static interface as the basis for the link-local address of the demux interface.

```
[edit system demux-options]
set use-underlying-interface-mac
```

## Example: Configuring a Dual Stack That Uses ND/RA Over PPPoE

This example shows a dual stack configuration for a residential subscriber with a single PC. It uses ND/RA to provide a prefix used to obtain a global IPv6 address for the PC.

- [Requirements on page 498](#)
- [Overview on page 499](#)
- [Configuration on page 500](#)
- [Verification on page 514](#)

---

### Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Router

- Junos OS Release 11.4 or later

### Overview

This design uses ND/RA in your subscriber access network as follows:

- The access network is PPPoE.
- ND/RA is used to assign a global IPv6 address on the WAN link. The prefixes used in router advertisements come from a local pool that is specified using AAA RADIUS.

### Topology

**Figure 22: PPPoE Subscriber Access Network with NDRA**

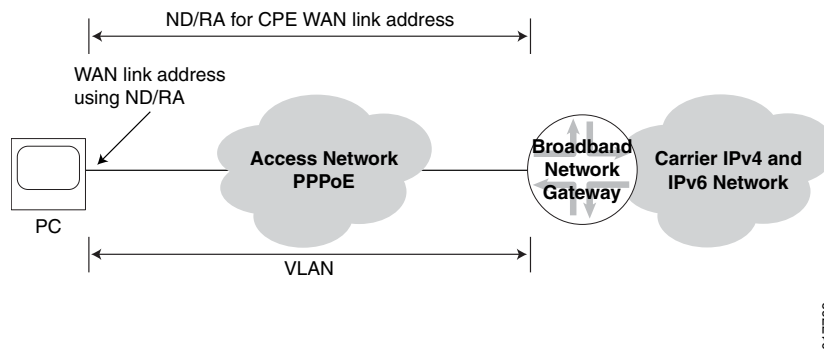

Table 47 on page 499 describes the configuration components used in this example.

**Table 47: Configuration Components Used in Dual Stack with ND/RA and DHCPv6 Prefix Delegation**

Configuration Component	Component Name	Purpose
Dynamic Profiles	DS-dyn-ipv4v6-ndra	Profile that creates a PPPoE logical interface when the subscriber logs in.
Interfaces	ge-3/3/0	Underlying Ethernet interface.
	lo0	Loopback interface for use in the access network. The loopback interface is automatically used for unnumbered interfaces.
Address-Assignment Pools	default-ipv4-pool-2	Pool that provides IPv4 addresses for the subscriber LAN.
	ndra-2010	Pool that provides IPv6 prefixes used in router advertisements. These prefixes are used to create a global IPv6 address that is assigned to the CPE WAN link.

## Configuration

To configure this example, perform these tasks:

- [Configuring a Dynamic Profile for the PPPoE Logical Interface on page 502](#)
- [Configuring a Loopback Interface on page 505](#)
- [Configuring a Static Underlying Ethernet Interface for Dynamic PPPoE Subscriber Interfaces on page 506](#)
- [Specifying the BNG IP Address on page 507](#)
- [Configuring RADIUS Server Access on page 508](#)
- [Configuring RADIUS Server Access Profile on page 510](#)
- [Specifying the RADIUS Server Access Profile to Use on page 511](#)
- [Configuring Local Address-Assignment Pools on page 511](#)

### CLI Quick Configuration

The following is the complete configuration for this example:

```
dynamic-profiles {
  DS-dyn-ipv4v6-ra {
    interfaces {
      pp0 {
        unit "$junos-interface-unit" {
          ppp-options {
            chap;
            pap;
          }
          pppoe-options {
            underlying-interface "$junos-underlying-interface";
            server;
          }
          keepalives interval 30;
          family inet {
            unnumbered-address lo0.0;
          }
          family inet6 {
            address $junos-ipv6-address;
          }
        }
      }
    }
  }
  protocols {
    router-advertisement {
      interface "$junos-interface-name" {
        prefix $junos-ipv6-ndra-prefix;
      }
    }
  }
}
system {
  services {
```

```

dhcp-local-server {
  dhcpv6 {
    group DHCPv6-over-pppoe {
      interface pp0.0;
    }
  }
}
}
access-profile Access-Profile;
interfaces {
  ge-3/3/0 {
    unit 1004 {
      description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd";
      encapsulation ppp-over-ether;
      vlan-id 1004;
      pppoe-underlying-options {
        duplicate-protection;
        dynamic-profile DS-dyn-ipv4v6-ra;
      }
    }
  }
}
lo0 {
  description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd";
  unit 0 {
    family inet {
      address 192.0.2.77/32 {
        primary;
      }
    }
    family inet6 {
      address 2001:db8:2030:0:0:0::1/64 {
        primary;
      }
    }
  }
}
}
routing-options {
  router-id 203.0.113.0;
}
access {
  radius-server {
    203.0.113.99 {
      secret "$ABC123$ABC123ABC123"; ## SECRET-DATA
      timeout 45;
      retry 4;
      source-address 203.0.113.1;
    }
  }
}
profile Access-Profile {
  authentication-order radius;
  radius {
    authentication-server 203.0.113.99;
    accounting-server 203.0.113.99;
  }
}

```

```

    }
    accounting {
        order [ radius none ];
        update-interval 120;
        statistics volume-time;
    }
}
address-assignment {
    neighbor-discovery-router-advertisement ndra-2010;
    pool default-ipv4-pool-2 {
        family inet {
            network 203.0.113.10/16;
            range r5 {
                low 203.0.113.11;
                high 203.0.113.150;
            }
        }
    }
    pool ndra-2010 {
        family inet6 {
            prefix 2001:db8:2010:0:0:0::/48;
            range L prefix-length 64;
        }
    }
}
address-protection;
}

```

### *Configuring a Dynamic Profile for the PPPoE Logical Interface*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

edit dynamic-profiles DS-dyn-ipv4v6-ra
edit interfaces pp0 unit $junos-interface-unit
set family inet unnumbered-address lo0.0
set family inet6 address $junos-ipv6-address
set pppoe-options underlying-interface "$junos-underlying-interface"
set pppoe-options server
set ppp-options pap
set ppp-options chap
set keepalives interval 30
up 3
edit protocols router-advertisement
edit interface $junos-interface-name
set prefix $junos-ipv6-ndra-prefix

```

**Step-by-Step Procedure** Create a dynamic profile for the PPPoE logical interface. This dynamic profile supports both IPv4 and IPv6 sessions on the same logical interface.

To configure the dynamic profile:

1. Create and name the dynamic profile.

```
[edit]
user@host# edit dynamic-profiles DS-dyn-ipv4v6-ra
```

2. Configure a PPPoE logical interface (pp0) that is used to create logical PPPoE interfaces for the IPv4 and IPv6 subscribers.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra]
user@host# edit interfaces pp0
```

3. Specify **\$junos-interface-unit** as the predefined variable to represent the logical unit number for the pp0 interface. The variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0]
user@host# edit unit $junos-interface-unit
```

4. Specify **\$junos-underlying-interface** as the predefined variable to represent the name of the underlying Ethernet interface on which the router creates the dynamic PPPoE logical interface. The variable is dynamically replaced with the actual name of the underlying interface supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

5. Configure the router to act as a PPPoE server when a PPPoE logical interface is dynamically created.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options server
```

6. Configure the IPv4 family for the pp0 interface. Specify the unnumbered address to dynamically create loopback interfaces.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet unnumbered-address lo0.0
```

7. Configure the IPv6 family for the pp0 interface. Because the example uses router advertisement, assign the predefined variable **\$junos-ipv6-address**.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
```

```
user@host# set family inet6 unnumbered-address $junos-ipv6-address
```

8. Configure one or more PPP authentication protocols for the pp0 interface.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set ppp-options chap
user@host# set ppp-options pap
```

9. Enable keepalives and set an interval for keepalives. We recommend an interval of 30 seconds.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set keepalives interval 30
```

10. Access the router advertisement configuration.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra]
user@host# edit protocols router-advertisement
```

11. Specify the interface on which the ND/RA configuration is applied.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra protocols router-advertisement]
user@host# edit interface $junos-interface-name
```

12. Specify a prefix value contained in router advertisement messages sent to the CPE on interfaces created with this dynamic profile. If you specify the \$junos-ipv6-ndra-prefix predefined variable, the actual value is obtained from a local pool or through AAA.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra protocols router-advertisement interface
 "$junos-interface-name"]
user@host# set prefix $junos-ipv6-ndra-prefix
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra]
user@host# show
interfaces {
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
      }
    }
  }
}
```

```

        server;
    }
    keepalives interval 30;
    family inet {
        unnumbered-address lo0.0;
    }
    family inet6 {
        address $junos-ipv6-address;
    }
}
}
}
protocols {
    router-advertisement {
        interface "$junos-interface-name" {
            prefix $junos-ipv6-ndra-prefix;
        }
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring a Loopback Interface*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

edit interfaces lo0 unit 0
set family inet address 192.0.2.77/32 primary
set family inet6 address 2001:db8:2030:0:0::1/64 primary

```

#### **Step-by-Step Procedure**

To configure a loopback interface:

1. Create the loopback interface and specify a unit number.

```

[edit]
user@host# edit interfaces lo0 unit 0

```

2. Configure the interface for IPv4.

```

[edit interfaces lo0 unit 0]
user@host# set family inet address 192.0.2.77/32 primary

```

3. Configure the interface for IPv6.

```

[edit interfaces lo0 unit 0]
user@host# set family inet6 address 2001:db8:2030:0:0::1/64 primary

```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces lo0]
user@host# show
unit 0 {
  family inet {
    address 192.0.2.77/32 {
      primary;
    }
  }
  family inet6 {
    address 2001:db8:2030:0:0::1/64 {
      primary;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

#### *Configuring a Static Underlying Ethernet Interface for Dynamic PPPoE Subscriber Interfaces*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit interfaces ge-3/3/0 unit 1004
set description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd"
set encapsulation ppp-over-ether
set vlan-id 1004
set pppoe-underlying-options duplicate-protection
set pppoe-underlying-options dynamic-profile DS-dyn-ipv4v6-ra
```

#### **Step-by-Step Procedure**

To configure the underlying Ethernet interface:

1. Specify the name and logical unit number of the static underlying Ethernet interface to which you want to attach the IPv4 and IPv6 dynamic profile.

```
[edit]
user@host# edit interfaces ge-3/3/0 unit 1004
```

2. Configure a description for the interface.

```
[edit interfaces ge-3/3/0 unit 1004]
user@host# set description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd"
```

3. Configure PPPoE encapsulation on the underlying interface.

```
[edit interfaces ge-3/3/0 unit 1004]
```

```
user@host# set encapsulation ppp-over-ether
```

4. Configure the VLAN Id.

```
[edit interfaces ge-3/3/0 unit 1004]
user@host# set vlan-id 1004
```

5. Attach the dynamic profile to the underlying interface.

```
[edit interfaces ge-3/3/0 unit 1004]
user@host# set pppoe-underlying-options dynamic-profile DS-dyn-ipv4v6-ra
```

6. (Optional) Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on the same VLAN interface.

```
[edit interfaces ge-3/3/0 unit 1004]
user@host# set pppoe-underlying-options duplicate-protection
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces]
user@host# show
ge-3/3/0 {
  unit 1004 {
    description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd";
    encapsulation ppp-over-ether;
    vlan-id 1004;
    pppoe-underlying-options {
      duplicate-protection;
      dynamic-profile DS-dyn-ipv4v6-ra;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Specifying the BNG IP Address*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit routing-options
set router-id 203.0.113.0
```

**BEST PRACTICE:** We strongly recommend that you configure the BNG IP address to avoid unpredictable behavior if the interface address on a loopback interface changes.

**Step-by-Step Procedure**

To configure the IP address of the BNG:

1. Access the routing-options configuration.

```
[edit]
user@host# edit routing-options
```

2. Specify the IP address or the BNG.

```
[edit routing-options]
user@host# set router-id 203.0.113.0
```

**Results**

From configuration mode, confirm your configuration by entering the **show** command.

```
[edit routing-options]
user@host# show
router-id 203.0.113.0;
```

If you are done configuring the device, enter **commit** from configuration mode.

**Configuring RADIUS Server Access****CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access radius-server 203.0.113.99
set secret "$ABC123$ABC123ABC123"
set timeout 45
set retry 4
set source-address 203.0.113.1
```

**Step-by-Step Procedure**

To configure RADIUS servers:

**Step-by-Step Procedure**

To configure RADIUS servers:

1. Create a RADIUS server configuration, and specify the address of the server.

```
[edit]
user@host# edit access radius-server 203.0.113.99
```

2. Configure the required secret (password) for the server. Secrets enclosed in quotation marks can contain spaces.

```
[edit access radius-server 203.0.113.99]
user@host# set secret "$ABC123$ABC123ABC123"
```

3. Configure the source address that the BNG uses when it sends RADIUS requests to the RADIUS server.

```
[edit access radius-server 203.0.113.99]
user@host# set source address 203.0.113.1
```

4. (Optional) Configure the number of times that the router attempts to contact a RADIUS accounting server. You can configure the router to retry from 1 through 16 times. The default setting is 3 retry attempts.

```
[edit access radius-server 203.0.113.99]
user@host# set retry 4
```

5. (Optional) Configure the length of time that the local router or switch waits to receive a response from a RADIUS server. By default, the router or switch waits 3 seconds. You can configure the timeout to be from 1 through 90 seconds.

```
[edit access radius-server 203.0.113.99]
user@host# set timeout 45
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
radius-server {
  203.0.113.99 {
    secret "$ABC123$ABC123ABC123"; ## SECRET-DATA
    timeout 45;
    retry 4;
    source-address 203.0.113.1;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring RADIUS Server Access Profile*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access profile Access-Profile
set authentication-order radius
set radius authentication-server 203.0.113.99
set radius accounting-server 203.0.113.99
set accounting order radius
set accounting order none
set accounting update-interval 120
set accounting statistics volume-time
```

**Step-by-Step Procedure** To configure a RADIUS server access profile:

1. Create a RADIUS server access profile.

```
[edit]
user@host# edit access profile Access-Profile
```

2. Specify the order in which authentication methods are used.

```
[edit access profile Access-Profile]
user@host# set authentication-order radius
```

3. Specify the address of the RADIUS server used for authentication and the server used for accounting.

```
[edit access profile Access-Profile]
user@host# set radius authentication-server 203.0.113.99
user@host# set radius accounting-server 203.0.113.99
```

4. Configure RADIUS accounting values for the access profile.

```
[edit access profile Access-Profile]
user@host# set accounting order [ radius none ]
user@host# set accounting update-interval 120
user@host# set accounting statistics volume-time
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
profile Access-Profile {
```

```

authentication-order radius;
radius {
    authentication-server 203.0.113.99;
    accounting-server 203.0.113.99;
}
accounting {
    order [ radius none ];
    update-interval 120;
    statistics volume-time;
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### *Specifying the RADIUS Server Access Profile to Use*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following command and paste it into the CLI at the **[edit]** hierarchy level.

```
set access-profile Access-Profile
```

#### **Step-by-Step Procedure**

To specify the RADIUS server access profile to use for authentication:

1. Specify the access profile.

```

[edit]
user@host# set access-profile Access-Profile

```

#### **Results**

From configuration mode, confirm your configuration by entering the **show** command.

```

[edit]
user@host# show
...
access-profile Access-Profile;
...

```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring Local Address-Assignment Pools*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

edit access
set address-assignment pool default-ipv4-pool-2 family inet network 203.0.113.10/16
set address-assignment pool default-ipv4-pool-2 family inet range r5 low 203.0.113.11

```

```

set address-assignment pool default-ipv4-pool-2 family inet range r5 high 203.0.113.150
set address-assignment pool ndra-2010 family inet6 prefix 2001:db8:2010:0:0:0::/48
set address-assignment pool ndra-2010 family inet6 range L prefix-length 64
set address-assignment neighbor-discovery-router-advertisement ndra-2010
set address-protection

```

**Step-by-Step Procedure** Configure three address-assignment pools for DHCPv4, DHCPv6 prefix delegation, and ND/RA.

To configure the address-assignment pools:

1. Configure the address-assignment pool for DHCPv4.

```

[edit]
user@host# edit access address-assignment pool default-ipv4-pool-2
user@host# edit family inet
user@host# set network 203.0.113.10/16
user@host# set range r5 low 203.0.113.11
user@host# set range r5 high 203.0.113.150

```

2. Configure the address-assignment pool for ND/RA.

```

[edit]
user@host# edit access address-assignment pool ndra-2010
user@host# edit family inet6
user@host# set prefix 2001:db8:2010:0:0:0::/48
user@host# set range L prefix-length 64

```

3. Specify that the address-assignment pool is used for NDRA.

```

[edit]
user@host# edit access address-assignment
user@host# set neighbor-discovery-router-advertisement ndra-2010

```

4. (Optional) Enable duplicate prefix protection.

```

[edit access]
user@host# set address-protection

```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```

[edit access]
user@host# show
address-assignment {
  neighbor-discovery-router-advertisement ndra-2010;
  pool default-ipv4-pool-2 {
    family inet {
      network 203.0.113.10/16;

```

```
    range r5 {  
        low 203.0.113.11;  
        high 203.0.113.150;  
    }  
}  
pool ndra-2010 {  
    family inet6 {  
        prefix 2001:db8:2010:0:0:0::/48;  
        range L prefix-length 64;  
    }  
}  
address-protection;
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Active Subscriber Sessions on page 514](#)
- [Verifying Both IPv4 and IPv6 Address in Correct Routing Instance on page 514](#)
- [Verifying Dynamic Subscriber Sessions on page 515](#)
- [Verifying the ND/RA Prefix Pool and Prefix Length on page 515](#)
- [Verifying the Status of the PPPoE Logical Interface on page 516](#)
- [Verifying Router Advertisements on page 517](#)

### *Verifying Active Subscriber Sessions*

**Purpose** Verify active subscriber sessions.

**Action** From operational mode, enter the **show subscribers summary** command.

```
user@host>show subscribers summary
```

```
Subscribers by State
  Active: 2
  Total: 2
```

```
Subscribers by Client Type
  DHCP: 1
  PPPoE: 1
  Total: 2
```

**Meaning** The fields under **Subscribers by State** show the number of active subscribers.

The fields under **Subscribers by Client Type** show the number of active DHCP and DHCPoE subscriber sessions.

### *Verifying Both IPv4 and IPv6 Address in Correct Routing Instance*

**Purpose** Verify that the subscriber has both an IPv4 and IPv6 address and is placed in the correct routing instance.

**Action** From operational mode, enter the **show subscribers** command.

```
user@host>show subscribers
```

Interface	IP Address/VLAN ID	User Name	LS:RI
pp0.1073741864	192.0.2.5	dual-stack-v4v6-pd	default:default
*	2001:db8:2010:0:0:8::/64		
pp0.1073741864	2001:db8:2040:2000:2000:5::/64		
default:default			

**Meaning** The **Interface** field shows that there are two subscriber sessions running on the same interface. The **IP Address** field shows that one session is assigned an IPv4 address, and one session is assigned on IPv6 address.

The **LS:RI** field shows that the subscriber is placed in the correct routing instance and that traffic can be sent and received.

### *Verifying Dynamic Subscriber Sessions*

**Purpose** Verify that the dynamic subscriber session is active, and the IPv6 prefix obtained from the ND/RA pool.

**Action** From operational mode, enter the **show subscribers detail** command.

```
user@host>show subscribers detail
Type: PPPoE
User Name: dual-stack-v4v6-nas
IP Address: 192.0.2.4
IP Netmask: 255.255.0.0
IPv6 User Prefix: 2001:db8:2010:0:0:6::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741859
Interface type: Dynamic
Dynamic Profile Name: DS-dyn-ipv4v6-ra
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 81
Session ID: 81
Login Time: 2012-01-17 14:19:41 PST
```

**Meaning** The **IPv6 User Prefix** field shows the prefix that was obtained from the ND/RA pool. The **State** field shows that the session is active.

### *Verifying the ND/RA Prefix Pool and Prefix Length*

**Purpose** Verify the pool used for ND/RA and the prefix length used with the pool

**Action** From operational mode, enter the **show subscribers extensive** command.

```
user@host>show subscribers extensive
Type: PPPoE
User Name: dual-stack-v4v6-nas
IP Address: 192.0.2.4
IP Netmask: 255.255.0.0
IPv6 User Prefix: 2001:db8:2010:0:0:6::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741859
Interface type: Dynamic
```

```

Dynamic Profile Name: DS-dyn-ipv4v6-ra
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 81
Session ID: 81
Login Time: 2012-01-17 14:19:41 PST
IPv6 Delegated Address Pool: ndra-2010
IPv6 Delegated Network Prefix Length: 48
IPv6 Interface Address: 2001:db8:2010:0:0:6::1/64

```

**Meaning** Under the PPPoE session, the **IPv6 Delegated Address Pool** field shows the name of the pool used for ND/RA prefixes. The **IPv6 Delegated Network Prefix Length** field shows the length of the prefix used to assign the IPv6 address for this subscriber session. The **IPv6 Interface Address** field shows the IPv6 address assigned to the CPE interface from the ND/RA pool.

#### *Verifying the Status of the PPPoE Logical Interface*

**Purpose** Display status information about the PPPoE logical interface (pp0).

**Action** From operational mode, enter the **show interfaces pp0.logical** command.

```

user@host>show interfaces pp0.1073741859

Logical interface pp0.1073741859 (Index 388) (SNMP ifIndex 674)
  Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
  PPPoE:
    State: SessionUp, Session ID: 10,
    Session AC name: almach, Remote MAC address: 00:00:5E:00:53:02,
    Underlying interface: ge-3/3/0.1004 (Index 354)
    Bandwidth: 1000mbps
    Input packets : 15
    Output packets: 44
    Keepalive settings: Interval 30 seconds, Up-count 1, Down-count 3
    LCP state: Opened
    NCP state: inet: Opened, inet6: Opened, iso: Not-configured, mpls: Not-configured

  CHAP state: Closed
  PAP state: Success
  Protocol inet, MTU: 65531
    Flags: Sendbcst-pkt-to-re
    Addresses, Flags: Is-Primary
      Local: 192.0.2.77
  Protocol inet6, MTU: 65531
    Addresses, Flags: Is-Preferred Is-Primary
      Destination: 2001:db8:2010:0:0:6::/64, Local: 2001:db8:2010:0:0:6::1
      Local: fe80::2a0:a50f:fc63:a842

```

**Meaning** The **Local** field under **Protocol inet** shows the IPv4 address of the pp0 interface. This is the IPv4 address configured for the loopback interface.

The **Destination** field under **Protocol inet6** shows the IPv6 address obtained through ND/RA. This is the value of the `$junos-ipv6-ndra-prefix` variable configured in the dynamic profile.

The **Local** field under **Protocol inet6** shows the value of the `$junos-ipv6-address` variable configured for family inet6 in the pp0 configuration of the dynamic profile.

### **Verifying Router Advertisements**

**Purpose** Verify that router advertisements are being sent, and router solicits are being received.

**Action** From operational mode, enter the **show ipv6 router-advertisement** command.

```
user@host>show ipv6 router-advertisement
Interface: pp0.1073741859
  Advertisements sent: 3, last sent 00:09:53 ago
  Solicits received: 0
  Advertisements received: 0
```

If you have a large number of subscriber interfaces, you can display router advertisements for a specific interface.

```
user@host>show ipv6 router-advertisement interface pp0.1073741859
Interface: pp0.1073741859
  Advertisements sent: 3, last sent 00:10:31 ago
  Solicits received: 0
  Advertisements received: 0
```

**Meaning** The display shows the number of advertisements that the router sent, the number of solicits and advertisements that the router received.

## **Example: Configuring a Dual Stack That Uses ND/RA and DHCPv6 Prefix Delegation Over PPPoE**

- [Requirements on page 518](#)
- [Overview on page 518](#)
- [Configuration on page 520](#)
- [Verification on page 536](#)

## Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Router
- Junos OS Release 11.4 or later

## Overview

This design uses ND/RA and DHCPv6 prefix delegation in your subscriber access network as follows:

- The access network is PPPoE.
- ND/RA is used to assign a global IPv6 address on the WAN link. The prefixes used in router advertisements come from a local pool that is specified using AAA RADIUS.
- DHCPv6 prefix delegation is used for subscriber LAN addressing. It used a delegated prefix from a local pool that is specified using AAA RADIUS.
- DHCPv4 is used for subscriber LAN addressing.
- DHCPv6 subscriber sessions are layered over an underlying PPPoE subscriber session.

## Topology

*Figure 23: PPPoE Subscriber Access Network with ND/RA and DHCPv6 Prefix Delegation*

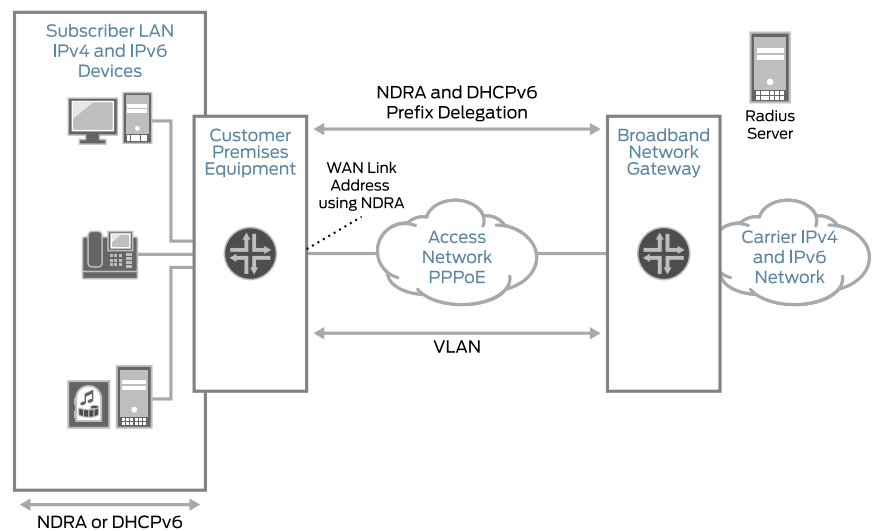

Table 48 on page 519 describes the configuration components used in this example.

*Table 48: Configuration Components Used in Dual Stack with ND/RA and DHCPv6 Prefix Delegation*

Configuration Component	Component Name	Purpose
Dynamic Profiles	DS-dyn-ipv4v6-ndra	Profile that creates a PPPoE logical interface when the subscriber logs in.
Interfaces	ge-3/3/0	Underlying Ethernet interface.
	lo0	Loopback interface for use in the access network. The loopback interface is automatically used for unnumbered interfaces.
Address-Assignment Pools	default-ipv4-pool-2	Pool that provides IPv4 addresses for the subscriber LAN.
	ndra-2010	Pool that provides IPv6 prefixes used in router advertisements. These prefixes are used to create a global IPv6 address that is assigned to the CPE WAN link.
	delegated-pool	Pool that provides a pool of prefixes that are delegated to the CPE and are used for assigning IPv6 global addresses on the subscriber LAN.

### CLI Quick Configuration

The following is the complete configuration for this example:

```
dynamic-profiles {
  DS-dyn-ipv4v6-ra {
    interfaces {
      pp0 {
        unit "$junos-interface-unit" {
          ppp-options {
            chap;
            pap;
          }
          pppoe-options {
            underlying-interface "$junos-underlying-interface";
            server;
          }
          keepalives interval 30;
          family inet {
            unnumbered-address lo0.0;
          }
          family inet6 {
            address $junos-ipv6-address;
          }
        }
      }
    }
  }
  protocols {
    router-advertisement {
      interface "$junos-interface-name" {
        prefix $junos-ipv6-ndra-prefix;
      }
    }
  }
}
```

```

system {
  services {
    dhcp-local-server {
      dhcpv6 {
        overrides {
          delegated-pool dhcpv6-pd-pool;
        }
        group DHCPv6-over-pppoe {
          interface pp0.0;
        }
      }
    }
  }
}
access-profile Access-Profile;
interfaces {
  ge-3/3/0 {
    unit 1109 {

      range L prefix-length 64;
    }
  }
}
address-protection;
}

```

### *Configuring a DHCPv6 Local Server for DHCPv6 over PPPoE*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

edit system services dhcp-local-server dhcpv6
edit group DHCPv6-over-pppoe
set interface pp0.0

```

**Step-by-Step Procedure** To layer DHCPv6 above the PPPoE IPv6 family (inet6), associate DHCPv6 with the PPPoE interfaces by adding the PPPoE interfaces to the DHCPv6 local server configuration. Because this example uses a dynamic PPPoE interface, we are using the pp0.0 (PPPoE) logical interface as a wildcard to indicate that a DHCPv6 binding can be made on top of a PPPoE interface.

To configure a DHCPv6 local server:

1. Access the DHCPv6 local server configuration.

```
[edit]
user@host# edit system services dhcp-local-server dhcpv6
```

2. Create a group for dynamic PPPoE interfaces and assign a name.

The group feature groups a set of interfaces and then applies a common DHCP configuration to the named interface group.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit group DHCPv6-over-pppoe
```

3. Add an interface for dynamic PPPoE logical interfaces.

```
[edit system services dhcp-local-server dhcpv6 group DHCPv6-over-pppoe]
user@host# set interface pp0.0
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit]
user@host# show
system {
  services {
    dhcp-local-server {
      dhcpv6 {
        group DHCPv6-over-pppoe {
          interface pp0.0;
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

#### *Configuring a Dynamic Profile for the PPPoE Logical Interface*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit dynamic-profiles DS-dyn-ipv4v6-ra
edit interfaces pp0 unit $junos-interface-unit
set family inet unnumbered-address lo0.0
set family inet6 address $junos-ipv6-address
set pppoe-options underlying-interface "$junos-underlying-interface"
set pppoe-options server
set ppp-options pap
set ppp-options chap
set keepalives interval 30
up 3
edit protocols router-advertisement
edit interface $junos-interface-name
set prefix $junos-ipv6-ndra-prefix
```

**Step-by-Step Procedure** Create a dynamic profile for the PPPoE logical interface. This dynamic profile supports both IPv4 and IPv6 sessions on the same logical interface.

To configure the dynamic profile:

1. Create and name the dynamic profile.

```
[edit]
user@host# edit dynamic-profiles DS-dyn-ipv4v6-ra
```

2. Configure a PPPoE logical interface (pp0) that is used to create logical PPPoE interfaces for the IPv4 and IPv6 subscribers.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra]
user@host# edit interfaces pp0
```

3. Specify **\$junos-interface-unit** as the predefined variable to represent the logical unit number for the **pp0** interface. The variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0]
user@host# edit unit $junos-interface-unit
```

4. Specify **\$junos-underlying-interface** as the predefined variable to represent the name of the underlying Ethernet interface on which the router creates the dynamic PPPoE logical interface. The variable is dynamically replaced with the actual name of the underlying interface supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

5. Configure the router to act as a PPPoE server when a PPPoE logical interface is dynamically created.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options server
```

6. Configure the IPv4 family for the pp0 interface. Specify the unnumbered address to dynamically create loopback interfaces.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet unnumbered-address lo0.0
```

7. Configure the IPv6 family for the pp0 interface. Because the example uses router advertisement, assign the predefined variable `$junos-ipv6-address`.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set family inet6 unnumbered-address $junos-ipv6-address
```

8. Configure one or more PPP authentication protocols for the pp0 interface.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set ppp-options chap
user@host# set ppp-options pap
```

9. Enable keepalives and set an interval for keepalives. We recommend an interval of 30 seconds.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra interfaces pp0 unit "$junos-interface-unit"]
user@host# set keepalives interval 30
```

10. Access the router advertisement configuration.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra]
user@host# edit protocols router-advertisement
```

11. Specify the interface on which the ND/RA configuration is applied.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra protocols router-advertisement]
user@host# edit interface $junos-interface-name
```

12. Specify a prefix value contained in router advertisement messages sent to the CPE on interfaces created with this dynamic profile. If you specify the `$junos-ipv6-ndra-prefix` predefined variable, the actual value is obtained from a local pool or through AAA.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra protocols router-advertisement interface
"$junos-interface-name"]
user@host# set prefix $junos-ipv6-ndra-prefix
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit dynamic-profiles DS-dyn-ipv4v6-ra]
user@host# show
interfaces {
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
        server;
      }
      keepalives interval 30;
      family inet {
        unnumbered-address lo0.0;
      }
      family inet6 {
        address $junos-ipv6-address;
      }
    }
  }
}
protocols {
  router-advertisement {
    interface "$junos-interface-name" {
      prefix $junos-ipv6-ndra-prefix;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring a Loopback Interface*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit interfaces lo0 unit 0
set family inet address 192.0.2.77/32 primary
set family inet6 address 2001:db8:2030:0:0::1/64 primary
```

**Step-by-Step Procedure**

To configure a loopback interface:

1. Create the loopback interface and specify a unit number.

```
[edit]
user@host# edit interfaces lo0 unit 0
```

2. Configure the interface for IPv4.

```
[edit interfaces lo0 unit 0]
user@host# set family inet address 192.0.2.77/32 primary
```

3. Configure the interface for IPv6.

```
[edit interfaces lo0 unit 0]
user@host# set family inet6 address 2001:db8:2030:0:0::1/64 primary
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces lo0]
user@host# show
unit 0 {
  family inet {
    address 192.0.2.77/32 {
      primary;
    }
  }
  family inet6 {
    address 2001:db8:2030:0:0::1/64 {
      primary;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring a Static Underlying Ethernet Interface for Dynamic PPPoE Subscriber Interfaces*

**CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit interfaces ge-3/3/0 unit 1109
set description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd"
set encapsulation ppp-over-ether
set vlan-id 1109
set pppoe-underlying-options duplicate-protection
```

```
set pppoe-underlying-options dynamic-profile DS-dyn-ipv4v6-ra
```

### Step-by-Step Procedure

To configure the underlying Ethernet interface:

1. Specify the name and logical unit number of the static underlying Ethernet interface to which you want to attach the IPv4 and IPv6 dynamic profile.

```
[edit]
user@host# edit interfaces ge-3/3/0 unit 1109
```

2. Configure a description for the interface.

```
[edit interfaces ge-3/3/0 unit 1109]
user@host# set description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd"
```

3. Configure PPPoE encapsulation on the underlying interface.

```
[edit interfaces ge-3/3/0 unit 1109]
user@host# set encapsulation ppp-over-ether
```

4. Configure the VLAN Id.

```
[edit interfaces ge-3/3/0 unit 1109]
user@host# set vlan-id 1109
```

5. Attach the dynamic profile to the underlying interface.

```
[edit interfaces ge-3/3/0 unit 1109]
user@host# set pppoe-underlying-options dynamic-profile DS-dyn-ipv4v6-ra
```

6. (Optional) Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on the same VLAN interface.

```
[edit interfaces ge-3/3/0 unit 1109]
user@host# set pppoe-underlying-options duplicate-protection
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit interfaces]
user@host# show
ge-3/3/0 {
  unit 1109 {
    description "dynamic ipv4v6 dual stack, ndra, dhcpv6 pd";
    encapsulation ppp-over-ether;
    vlan-id 1109;
```

```
pppoe-underlying-options {
  duplicate-protection;
  dynamic-profile DS-dyn-ipv4v6-ra;
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Specifying the BNG IP Address*

#### **CLI Quick Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit routing-options
set router-id 203.0.113.0
```

**BEST PRACTICE:** We strongly recommend that you configure the BNG IP address to avoid unpredictable behavior if the interface address on a loopback interface changes.

#### **Step-by-Step Procedure**

To configure the IP address of the BNG:

1. Access the routing-options configuration.

```
[edit]
user@host# edit routing-options
```

2. Specify the IP address or the BNG.

```
[edit routing-options]
user@host# set router-id 203.0.113.0
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit routing-options]
user@host# show
router-id 203.0.113.0;
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring RADIUS Server Access*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access radius-server 203.0.113.99
set secret "$ABC123$ABC123ABC123"
set timeout 45
set retry 4
set source-address 203.0.113.1
```

**Step-by-Step Procedure** To configure RADIUS servers:

**Step-by-Step Procedure** To configure RADIUS servers:

1. Create a RADIUS server configuration, and specify the address of the server.

```
[edit]
user@host# edit access radius-server 203.0.113.99
```

2. Configure the required secret (password) for the server. Secrets enclosed in quotation marks can contain spaces.

```
[edit access radius-server 203.0.113.99]
user@host# set secret "$ABC123$ABC123ABC123"
```

3. Configure the source address that the BNG uses when it sends RADIUS requests to the RADIUS server.

```
[edit access radius-server 203.0.113.99]
user@host# set source address 203.0.113.1
```

4. (Optional) Configure the number of times that the router attempts to contact a RADIUS accounting server. You can configure the router to retry from 1 through 16 times. The default setting is 3 retry attempts.

```
[edit access radius-server 203.0.113.99]
user@host# set retry 4
```

5. (Optional) Configure the length of time that the local router or switch waits to receive a response from a RADIUS server. By default, the router or switch waits 3 seconds. You can configure the timeout to be from 1 through 90 seconds.

```
[edit access radius-server 203.0.113.99]
```

```
user@host# set timeout 45
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
radius-server {
  203.0.113.99 {
    secret "$ABC123$ABC123ABC123"; ## SECRET-DATA
    timeout 45;
    retry 4;
    source-address 203.0.113.1;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring RADIUS Server Access Profile

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access profile Access-Profile
set authentication-order radius
set radius authentication-server 203.0.113.99
set radius accounting-server 203.0.113.99
set accounting order radius
set accounting order none
set accounting update-interval 120
set accounting statistics volume-time
top
set access-profile Access-Profile
```

**Step-by-Step Procedure** To configure a RADIUS server access profile:

1. Create a RADIUS server access profile.

```
[edit]
user@host# edit access profile Access-Profile
```

2. Specify the order in which authentication methods are used.

```
[edit access profile Access-Profile]
user@host# set authentication-order radius
```

3. Specify the address of the RADIUS server used for authentication and the server used for accounting.

```
[edit access profile Access-Profile]
user@host# set radius authentication-server 203.0.113.99
user@host# set radius accounting-server 203.0.113.99
```

4. Configure RADIUS accounting values for the access profile.

```
[edit access profile Access-Profile]
user@host# set accounting order [ radius none ]
user@host# set accounting update-interval 120
user@host# set accounting statistics volume-time
```

5. At the top of the configuration hierarchy, enter the following command to enable the access profile.

```
[edit]
user@host# set access-profile Access-Profile
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
profile Access-Profile {
  authentication-order radius;
  radius {
    authentication-server 203.0.113.99;
    accounting-server 203.0.113.99;
  }
  accounting {
    order [ radius none ];
    update-interval 120;
    statistics volume-time;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

#### *Specifying the RADIUS Server Access Profile to Use*

**CLI Quick Configuration** To quickly configure this example, copy the following command and paste it into the CLI at the **[edit]** hierarchy level.

```
set access-profile Access-Profile
```

**Step-by-Step Procedure** To specify the RADIUS server access profile to use for authentication:

1. Specify the access profile.

```
[edit]
user@host# set access-profile Access-Profile
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit]
user@host# show
...
access-profile Access-Profile;
...
```

If you are done configuring the device, enter **commit** from configuration mode.

### *Configuring Local Address-Assignment Pools*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit access
set address-assignment pool default-ipv4-pool-2 family inet network 203.0.113.10/16
set address-assignment pool default-ipv4-pool-2 family inet range r5 low 203.0.113.11
set address-assignment pool default-ipv4-pool-2 family inet range r5 high 203.0.113.150
set address-assignment pool delegated-pool family inet6 prefix
2001:db8:2040:2000:2000::/48
set address-assignment pool delegated-pool family inet6 range r1 prefix-length 64
set address-assignment pool ndra-2010 family inet6 prefix 2001:db8:2010:0:0:0::/48
set address-assignment pool ndra-2010 family inet6 range L prefix-length 64
set address-protection
```

**Step-by-Step Procedure** Configure three address-assignment pools for DHCPv4, DHCPv6 prefix delegation, and ND/RA.

To configure the address-assignment pools:

1. Configure the address-assignment pool for DHCPv4.

```
[edit]
user@host# edit access address-assignment pool default-ipv4-pool-2
user@host# edit family inet
user@host# set network 203.0.113.10/16
user@host# set range r5 low 203.0.113.11
user@host# set range r5 high 203.0.113.150
```

2. Configure the address-assignment pool for DHCPv6 prefix delegation

```
[edit]
user@host# edit access address-assignment pool delegated-pool
user@host# edit family inet6
user@host# set prefix 2001:db8:2040:2000:2000::/48
user@host# set range r1 prefix-length 64
```

3. Configure the address-assignment pool for ND/RA.

```
[edit]
user@host# edit access address-assignment pool ndra-2010
user@host# edit family inet6
user@host# set prefix 2001:db8:2010:0:0:0::/48
user@host# set range L prefix-length 64
```

4. (Optional) Enable duplicate prefix protection.

```
[edit access]
user@host# set address-protection
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit access]
user@host# show
address-assignment {
  pool default-ipv4-pool-2 {
    family inet {
      network 203.0.113.10/16;
      range r5 {
        low 203.0.113.11;
        high 203.0.113.150;
      }
    }
  }
  pool delegated-pool {
    family inet6 {
      prefix 2001:db8:2040:2000:2000::/48;
      range r1 prefix-length 64;
    }
  }
  pool ndra-2010 {
    family inet6 {
      prefix 2001:db8:2010:0:0:0::/48;
      range L prefix-length 64;
    }
  }
}
address-protection;
```

If you are done configuring the device, enter **commit** from configuration mode.

*Specifying the Address-Assignment Pool to Be Used for DHCPv6 Prefix Delegation*

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
edit system services dhcp-local-server dhcpv6
set overrides delegated-pool dhcpv6-pd-pool
```

**Step-by-Step Procedure** To specify that the dhcp-pd-pool is used for DHCPv6 prefix delegation:

1. Access the DHCPv6 local server configuration.

```
[edit]
user@host# edit system services dhcp-local-server dhcpv6
```

2. Specify the address pool that assigns the delegated prefix.

```
[edit system services dhcp-local-server dhcpv6]
user@host# set overrides delegated-pool dhcpv6-pd-pool
```

**Results** From configuration mode, confirm your configuration by entering the **show** command.

```
[edit system]
user@host# show
services {
  dhcp-local-server {
    dhcpv6 {
      overrides {
        delegated-pool dhcpv6-pd-pool;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Active Subscriber Sessions on page 536](#)
- [Verifying Both IPv4 and IPv6 Address in Correct Routing Instance on page 536](#)
- [Verifying Dynamic Subscriber Sessions on page 537](#)
- [Verifying DHCPv6 Address Pools Used for NDRA and DHCPv6 Prefix Delegation on page 539](#)
- [Verifying DHCPv6 Address Bindings on page 540](#)
- [Verifying Router Advertisements on page 540](#)
- [Verifying the Status of the PPPoE Logical Interface on page 541](#)

### *Verifying Active Subscriber Sessions*

**Purpose** Verify active subscriber sessions.

**Action** From operational mode, enter the **show subscribers summary** command.

```
user@host>show subscribers summary
```

```
Subscribers by State
```

```
Active: 2
Total: 2
```

```
Subscribers by Client Type
```

```
DHCP: 1
PPPoE: 1
Total: 2
```

**Meaning** The fields under **Subscribers by State** show the number of active subscribers.

The fields under **Subscribers by Client Type** show the number of active DHCP and DHCPoE subscriber sessions.

### *Verifying Both IPv4 and IPv6 Address in Correct Routing Instance*

**Purpose** Verify that the subscriber has both an IPv4 and IPv6 address and is placed in the correct routing instance.

**Action** From operational mode, enter the **show subscribers** command.

```
user@host>show subscribers
```

Interface	IP Address/VLAN ID	User Name	LS:RI
pp0.1073741864	203.0.113.5	dual-stack-v4v6-pd	default:default
*	2001:db8:2010:0:0:8::/64		
pp0.1073741864	2001:db8:2040:2000:2000:5::/64		
default:default			

**Meaning** The **Interface** field shows that there are two subscriber sessions running on the same interface. The **IP Address** field shows that one session is assigned an IPv4 address, and one session is assigned on IPv6 address.

The **LS:RI** field shows that the subscriber is placed in the correct routing instance and that traffic can be sent and received.

### *Verifying Dynamic Subscriber Sessions*

**Purpose** Verify dynamic PPPoE and DHCPv6 subscriber sessions. In this example configuration the DHCPv6 subscriber session should be layered over the underlying PPPoE subscriber session.

**Action** From operational mode, enter the **show subscribers detail** command.

```
user@host>show subscribers detail

Type: PPPoE
User Name: dual-stack-v4v6-pd
IP Address: 203.0.113.5
IP Netmask: 255.255.0.0
IPv6 User Prefix: 2001:db8:2010:0:0:8::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741864
Interface type: Dynamic
Dynamic Profile Name: DS-dyn-ipv4v6-ra
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 87
Session ID: 87
Login Time: 2012-01-17 14:45:30 PST

Type: DHCP
IPv6 Prefix: 2001:db8:2040:2000:2000:5::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741864
Interface type: Static
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 88
Session ID: 88
Underlying Session ID: 87
Login Time: 2012-01-17 14:46:00 PST
DHCP Options: len 42
00 08 00 02 0b b8 00 01 00 0a 00 03 00 01 00 07 64 11 07 02
00 06 00 02 00 19 00 19 00 0c 00 00 00 00 00 00 00 00 00 00
00 00
```

**Meaning** When a subscriber has logged in and started both an IPv4 and an IPv6 session, the output shows the active underlying PPPoE session and the active DHCPv6 session.

The **Session ID** field for the PPPoE session is 87. The **Underlying Session ID** for the DHCP session is 87, which shows that the PPPoE session is the underlying session.

*Verifying DHCPv6 Address Pools Used for NDRA and DHCPv6 Prefix Delegation*

**Purpose** Verify the pool used for ND/RA, the delegated address pool used for DHCPv6 prefix delegation and the length of the IPv6 prefixes that were delegated to the CPE.

**Action** From operational mode, enter the **show subscribers extensive** command.

```

user@host>show subscribers extensive

Type: PPPoE
User Name: dual-stack-v4v6-pd
IP Address: 203.0.113.5
IP Netmask: 255.255.0.0
IPv6 User Prefix: 2001:db8:2010:0:0:8::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741864
Interface type: Dynamic
Dynamic Profile Name: DS-dyn-ipv4v6-ra
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 87
Session ID: 87
Login Time: 2012-01-17 14:45:30 PST
IPv6 Delegated Address Pool: delegated-pool
IPv6 Delegated Address Pool: ndra-2010
IPv6 Delegated Network Prefix Length: 48
IPv6 Interface Address: 2010:0:0:8::1/64

Type: DHCP
IPv6 Prefix: 2001:db8:2040:2000:2000:5::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741864
Interface type: Static
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 88
Session ID: 88
Underlying Session ID: 87
Login Time: 2012-01-17 14:46:00 PST
DHCP Options: len 42
00 08 00 02 0b b8 00 01 00 0a 00 03 00 01 00 07 64 11 07 02
00 06 00 02 00 19 00 19 00 0c 00 00 00 00 00 00 00 00 00
00 00
IPv6 Delegated Address Pool: delegated-pool
IPv6 Delegated Network Prefix Length: 64
IPv6 Delegated Network Prefix Length: 48

```

**Meaning** Under the PPPoE session, the **IPv6 Delegated Address Pool** fields show the names of the pools used for DHCPv6 prefix delegation and for ND/RA prefixes. The **IPv6 Delegated Network Prefix Length** field shows the length of the prefix used to assign the IPv6 address for this subscriber session. The **IPv6 Interface Address** field shows the IPv6 address assigned to the CPE interface from the ND/RA pool.

Under the DHCP session, the **IPv6 Delegated Address Pool** fields show the name of the pool used for DHCPv6 prefix delegation. The **IPv6 Delegated Network Prefix Length** fields shows the length of the prefix used in DHCPv6 prefix delegation.

### *Verifying DHCPv6 Address Bindings*

**Purpose** Display the address bindings in the client table on the DHCPv6 local server.

**Action** From operational mode, enter the **show dhcpv6 server binding** command.

```
user@host>show dhcpv6 server binding
```

Prefix	Session Id	Expires	State	Interface	Client DUID
2001:db8:2040:2000:2000:5::/64	88		86189	BOUND	pp0.1073741864
LL0x1-00:07:64:11:07:02					

If you have many active subscriber sessions, you can display the server binding for a specific interface.

```
user@host>show dhcpv6 server binding interface pp0.1073741864
```

Prefix	Session Id	Expires	State	Interface	Client DUID
2001:db8:2040:2000:2000:5::/64	88		86182	BOUND	pp0.1073741864
LL0x1-00:07:64:11:07:02					

**Meaning** The **Prefix** field shows the DHCPv6 prefix assigned to the subscriber session from the pool used for DHCPv6 prefix delegation.

### *Verifying Router Advertisements*

**Purpose** Verify that router advertisements are being sent, and router solicits are being received.

**Action** From operational mode, enter the **show ipv6 router-advertisement** command.

```
user@host>show ipv6 router-advertisement
```

```
Interface: pp0.1073741864
  Advertisements sent: 3, last sent 00:03:29 ago
  Solicits received: 0
  Advertisements received: 0
```

If you have a large number of subscriber interfaces, you can display router advertisements for a specific interface.

```
user@host>show ipv6 router-advertisement interface pp0.1073741864
```

```
Interface: pp0.1073741864
  Advertisements sent: 3, last sent 00:03:34 ago
  Solicits received: 0
  Advertisements received: 0
```

**Meaning** The display shows the number of advertisements that the router sent, the number of solicits and advertisements that the router received.

### *Verifying the Status of the PPPoE Logical Interface*

**Purpose** Display status information about the PPPoE logical interface (pp0).

**Action** From operational mode, enter the **show interfaces pp0.logical** command.

```
user@host>show interfaces pp0.1073741864
```

```
Logical interface pp0.1073741864 (Index 388) (SNMP ifIndex 681)
Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
PPPoE:
  State: SessionUp, Session ID: 10,
  Session AC name: almach, Remote MAC address: 00:00:5E:00:53:02,
  Underlying interface: ge-3/3/0.1109 (Index 367)
Bandwidth: 1000mbps
Input packets : 22
Output packets: 50
Keepalive settings: Interval 30 seconds, Up-count 1, Down-count 3
LCP state: Opened
NCP state: inet: Opened, inet6: Opened, iso: Not-configured, mpls: Not-configured

CHAP state: Closed
PAP state: Success
Protocol inet, MTU: 65531
  Flags: Sendbcst-pkt-to-re
  Addresses, Flags: Is-Primary
  Local: 192.0.2.77
Protocol inet6, MTU: 65531
  Addresses, Flags: Is-Preferred Is-Primary
  Destination: 2001:db8:2010:0:8::/64, Local: 2001:db8:2010:0:8::1
  Local: fe80::2a0:a50f:fc63:a842
```

**Meaning** The **Underlying interface** field shows the underlying Ethernet interface configured in the example.

The **Destination** field under **Protocol inet6** shows the IPv6 address obtained through ND/RA. This is the value of the *\$junos-ipv6-ndra-prefix* variable configured in the dynamic profile.

The **Local** field under **Protocol inet6** shows the value of the *\$junos-ipv6-address* variable configured for family inet6 in the pp0 configuration of the dynamic profile.

## IP demultiplexing interfaces on Packet-Triggered Subscribers Services Overview

Packet triggered subscribers feature creates IP demultiplexing interfaces (IP demux IFL) on receiving a data packet from clients with preassigned IP address. On receiving the first packet, the control plane checks the IP address. If the source IP address matches one of the configured IP address ranges, the subscriber is authenticated with authenticating server. On successful authentication, the IP demux IFL is created using the dynamic profile specified in the CLI. The IP demux IFL adds the framed route and demux source for subscriber using the mask passed by the authenticating server. If the mask is not sent by the authenticating server, access and demux routes are installed using the mask specified in the CLI.

For IPv4, all traffic from single household has same source IPv4 public address. Hence, for every household only one IP demux IFL is created. For business subscribers, multiple public IP addresses are created using framed-routes. For IPv6, the source address of traffic coming from same household is different as each device has different source address. For scaling reason, it is not possible to have one IP demux IFL for each device in each household. Hence, all devices from the same household share the same IP demux IFL.

**NOTE:** During IP demux IFL creation if the authentication fails, the IP demux IFL is still created but such IP demux IFL cannot forward any traffic. Any received traffic for the associated subscriber is dropped. All such rejected IP demux IFLs remains in configured state and is referred as configured subscribers. Creating IP demux IFL even if the authentication fails will avoid thrashing as subsequent packets will be dropped on the PFE and will not be punted to the RE. All subscribers in 'Configured' state will be periodically removed. Once these subscribers are removed any new packets received from the same source will get punted to the RE.

---

### Benefits of IP demultiplexing interfaces on Packet-Triggered Subscribers Services feature:

- Supports packet triggered subscribers using authentication and service selection by RADIUS server and allows a maximum of 16 IPv4 and 16 IPv6 address ranges per underlying IFL.
- Allows the authenticating server to pass in the dynamic-profile to use. When the authenticating server passes these values, they take precedence over values configured through CLI.
- Provides throttling mechanism to mitigate DoS-like attack and limit the rate of exception packets sent to RE for IP demux authentication and creation. The throttling mechanism uses the existing DDoS mechanism.

## Configuring Packet Triggered Subscribers Using IP Demux Interfaces in Dynamic Profiles

You can configure the packet triggered subscribers for demux interfaces for both IPv4 and IPv6 addresses. The packet triggered subscribers feature creates IP demux IFL on receiving a data packet from clients with preassigned IP address. Once the IP demux IFL is created framed route and demux source are added for subscriber using the mask passed by the authenticating server.

To enable the packet triggered subscribers feature, configure the demux options in a dynamic profile. Dynamic profiles enable you to dynamically apply configured values to the dynamic interfaces, making them easier to manage.

Before you begin:

- Configure the dynamic profile.

See *Configuring a Basic Dynamic Profile*.

After you configure the dynamic profile, configure the packet triggered subscribers interfaces beginning with the demux interface:

1. Specify that you want to configure the **demux** interface.

```
[edit interfaces interface-name unit unit-number]
user@host# edit demux
```

2. Configure the family for the demux interfaces.

- a. Specify that you want to configure the family.

For IPv4:

```
[edit interfaces interface-name unit unit-number demux]
user@host# edit inet
```

For IPv6:

```
[edit interfaces interface-name unit unit-number]
user@host# edit inet6
```

3. Configure the address-source and auto-configure details for the family.

```
[edit interfaces interface-name unit unit-number inet]
user@host# edit address-source auto-configure
```

4. Configure the address range for the demux interface for the family.

```
[edit interfaces interface-name unit unit-number inet address-source]
```

```
user@host# edit address-range
```

5. Under address range configure the:

- a. Dynamic profile includes the details for network address, and the range for the demux interface for the family.

```
[edit interfaces interface-name unit unit-number inet address-source address-range]  
user@host# edit dynamic-profile
```

- b. Authentication includes the details for password to be included and the username profiles such as, delimiter, domain name, interface name, authentication server, source address and user prefix for the demux interface for the family.

```
[edit interfaces interface-name unit unit-number inet address-source address-range]  
user@host# edit authentication
```

## Conserving IPv4 Addresses for Dual-Stack PPP Subscribers Using On-Demand IPv4 Address Allocation

In a dual stack over PPP access network scenario, the dual-stack session remains running as long as either the IPv4 or IPv6 session is active. By default, when a subscriber terminates the IPv4 session, the BNG retains the IPv4 address that was allocated by AAA at login. The address is not released while the dual-stack PPP session is running. If the IPv4 session is renegotiated while the session is running, the same IPv4 address is assigned to the subscriber's IPv4 session. This functionality results in inefficient use of IPv4 addresses.

You can conserve IPv4 addresses by configuring the router to release the IPv4 address if a subscriber is no longer using an IPv4 service. This feature provides on-demand IP address allocation or de-allocation after the initial PPP authentication and IPv6 address or prefix allocation.

The on-demand configuration does not take effect when the destination (peer) IP address is statically configured in the inet family of the PPP interface.

## On-Demand IPv4 Address Negotiation and Release for Static PPP Subscribers Overview

This topic describes how on-demand IPv4 address allocation and de-allocation works for static dual-stack PPP subscribers.

- [IPv4 Address Negotiation for Static PPP Subscribers on page 545](#)
- [IPv4 Address Release for Static PPP Subscribers on page 547](#)

### IPv4 Address Negotiation for Static PPP Subscribers

The process for IPv4 address negotiation for a static inet family and address over a static PPP interface is as follows:

1. PPP Link Control Protocol (LCP) is established and an IPv6 control protocol is successfully negotiated.
2. The broadband network gateway (BNG) receives an Internet Protocol Control Protocol (IPCP) Configure Request with a 0.0.0.0 IPv4 address option from the customer premises equipment (CPE).
3. The BNG sends an IPCP Configure Request with a local IPv4 address option to the CPE.

4. The BNG sends an Access-Request message with the IPv4-Release-Control VSA (26-164) (if configured) to the RADIUS server.
5. The BNG receives an IPCP Configure ACK from the CPE.
6. The BNG receives an Access-Accept message from the RADIUS server.
  - If a Framed-IP-Address attribute is received, the BNG performs a duplicate address check (if configured). If a duplicate address check is completed successfully, PPP continues IPCP negotiation with the CPE. Otherwise, the entire PPP session is brought down by sending an LCP terminate request to the CPE.
  - If a Framed-Pool attribute is received, then the IPv4 address is allocated from the specified local address pool configured in the BNG. If the IP pool is not configured in the BNG and there is no other IP pool available, the BNG sends an LCP Protocol-Reject message to the CPE.
  - If neither a Framed-IP-Address attribute nor a Framed-Pool attribute is received, then the BNG allocates an IPv4 address from one of the configured local address pools. If the BNG cannot allocate an IPv4 address, the BNG sends an LCP Protocol-Reject message to the CPE.
  - If ADFv4 filters are present in the Access-Accept message, they need to be reinstalled for that subscriber in the BNG.
  - If both IPv4 primary and secondary DNS addresses are present in the Access-Accept message, then both need to be updated for that subscriber in the BNG. If either an IPv4 primary DNS address or an IPv4 secondary DNS address is present in the Access-Accept message, then only the corresponding DNS address needs to be updated for that subscriber.

If an IPv4 address is not available, and the BNG receives an Access-Reject message from the RADIUS server, the following occurs:

- If the Access-Reject message includes the IPv4-Release-Control VSA (26-164), the BNG sends an IPCP terminate request to the CPE. The CPE is then allowed to renegotiate IP NCP.
- If the Access-Reject message does not include the IPv4-Release-Control VSA (26-164), the BNG sends an LCP Protocol-Reject message to the CPE. The CPE must renegotiate the LCP link before it is allowed to renegotiate IP NCP.

If the RADIUS Access-Reject message includes the IPCP Terminate-Request field, the text of Reply Message attribute (18) is appended to the information in the Terminate-Request field, and will be shown in PPP data.

If there is no response from the RADIUS server, then IPCP is terminated.

7. The BNG sends an IPCP Configure NACK with the new IPv4 address option to the CPE.
8. The subscriber secure policy service (if present for inet family) is activated.

The BNG sends an immediate Interim-Accounting message (if configured) with the IPv4-Release-Control VSA (26-164) (if configured) and the Framed-IP-Address attribute to the RADIUS server.

9. The BNG receives an IPCP Configure Request with new IPv4 address option from the CPE.
10. The BNG receives an Interim-Accounting response from the RADIUS server.
11. The BNG sends an IPCP Configure ACK to the CPE.

#### **IPv4 Address Release for Static PPP Subscribers**

---

The process for IPv4 address release for static inet family and address over static PPP interface is as follows:

1. The BNG receives an IPCP terminate request from the CPE.
2. The BNG sends an IPCP terminate ACK to the CPE.
3. The following actions occur:
  - The subscriber secure policy service (if present for inet family) is de-instantiated.
  - If an IPv4 address was allocated from local address pool, the address then becomes available.
  - The IPv4 address entry is cleared from the subscriber record.
  - The BNG sends an immediate Interim-Accounting message (if configured) with the IPv4-Release-Control VSA (26-164) (if configured) to the RADIUS server and the Framed-IP-Address attribute is not included.
  - User Session Statistics are retained for the entire PPP session and are not cleared when the IPv4 address is released.
4. The BNG receives an Interim-Accounting response from the RADIUS server.

No action is taken in the BNG whether or not it receives a response from the RADIUS server.

### **On-Demand IPv4 Address Negotiation and Release for Dynamic PPP Subscribers Overview**

This topic describes how on-demand IPv4 address allocation and de-allocation works for dynamic dual-stack PPP subscribers.

- [IPv4 Address Negotiation for Dynamic PPP Subscribers on page 548](#)
- [IPv4 Address Release for Dynamic PPP Subscribers on page 549](#)

### IPv4 Address Negotiation for Dynamic PPP Subscribers

---

The process for IPv4 address negotiation for a dynamic inet family and address over a static PPP interface is as follows:

1. PPP Link Control Protocol (LCP) is established and IPv6 control protocol is successfully negotiated.
2. The broadband network gateway (BNG) receives an Internet protocol Control Protocol (IPCP) Configure Request with a 0.0.0.0 IPv4 address option from the CPE.
3. The BNG sends an Access-Request message with the IPv4-Release-Control VSA (26-164) (if configured) to the RADIUS server.
4. The BNG receives an Access-Accept message from the RADIUS server.
  - If a Framed-IP-Address attribute is received, then a duplicate address check (if configured) is performed on the BNG. If a duplicate address check is completed successfully, then PPP continues IPCP negotiation with the CPE. Otherwise, the entire PPP session is brought down by sending an LCP terminate request to the CPE.
  - If Framed-Pool attribute is received, then the IPv4 address is allocated from the specified local address pool configured in the BNG. If the pool is not configured in the BNG and there is no other IP pool available, then an IPCP protocol reject is sent to the CPE.
  - If neither a Framed-IP-Address attribute nor a Framed-Pool attribute is received, then the BNG allocates an IPv4 address from one of the configured local address pools. If the BNG cannot allocate an IPv4 address, then an IPCP protocol reject is sent to the CPE.
  - If ADFv4 filters are present in the Access-Accept message, then they need to be reinstalled for that subscriber in the BNG.
  - If both IPv4 primary and secondary DNS addresses are present in the Access-Accept message, then both of them need to be updated for that subscriber in the BNG. If either an IPv4 primary DNS address or an IPv4 secondary DNS address is present in the Access-Accept message, then only the corresponding DNS address needs to be updated for that subscriber.

If an IPv4 address is not available, and the BNG receives an Access-Reject message from the RADIUS server, the following occurs:

- If the Access-Reject message includes the IPv4-Release-Control VSA (26-164), the BNG sends an IPCP terminate request to the CPE. The CPE is then allowed to renegotiate IP NCP.
- If the Access-Reject message does not include the IPv4-Release-Control VSA (26-164), the BNG sends an LCP Protocol-Reject message to the CPE. The CPE must renegotiate the LCP link before it is allowed to renegotiate IP NCP.

If the RADIUS Access-Reject message includes the IPCP Terminate-Request field, the text of Reply Message attribute #18 is appended to the information in the Terminate-Request field, and will be shown in PPP data.

If an Access-Challenge message is received instead of an Access-Accept, then the IPCP protocol reject is sent to the CPE.

If there is no response from the RADIUS server, then IPCP is terminated.

5. The BNG sends an IPCP Configure NACK with the new IPv4 address option to the CPE.
6. The dynamic inet family and local address are added and all IPv4 (family inet) services for the dynamic client profile are instantiated.  
  
The BNG sends an IPCP Configure Request with a local IPv4 address option to the CPE.
7. The BNG sends an immediate Interim-Accounting message (if configured) with the IPv4-Release-Control VSA (26-164) (if configured) and a Framed-IP-Address attribute to the RADIUS server.
8. All IPv4 services, such as ascend data filters (ADF) and firewall filters, for the dynamic service profile and the lawful intercept service (if present for inet family) are instantiated and the Service Accounting-Start messages (if service accounting is configured and IPv4 service is not part of a multi-family service profile) are sent to the RADIUS server. If service instantiation fails, then IPCP is terminated and an IPv4 address release process is initiated.
9. The BNG receives an IPCP Configure Request with a new IPv4 address option from the CPE.
10. The BNG sends an IPCP Configure ACK to the CPE.
11. The BNG receives a Service Accounting-Start response from the RADIUS server.
12. The BNG receives an Interim-Accounting response from the RADIUS server.
13. The BNG receives an IPCP Configure ACK from the CPE.

---

#### IPv4 Address Release for Dynamic PPP Subscribers

---

The process for IPv4 address release for dynamic inet family and address over static PPP interface is as follows:

1. The BNG receives an IPCP terminate request from the CPE.
2. The BNG sends an IPCP terminate ACK to the CPE.

3. The following actions occur:

- All IPv4 (family inet) services for the dynamic client profile are de-instantiated and the dynamic inet family and local address are removed.
- All IPv4 services, such as ascend data filters (ADF) and firewall filters, for a dynamic service profile and the lawful intercept service (if present for inet family) are de-instantiated. The Service Accounting-Stop messages (if service accounting is configured and IPv4 service is not part of a multi-family service profile) is sent to the RADIUS server.
- If an IPv4 address was allocated from a local address pool, then it is available.
- The IPv4 address entry is cleared from the subscriber record

4. The BNG sends an immediate Interim-Accounting message (if configured) with the IPv4-Release-Control VSA (26-164) (if configured) to the RADIUS server and the Framed-IP-Address attribute must not be included.

User Session Statistics and service session statistics for multi-family service are retained for the entire PPP session and is not cleared when the IPv4 address is released.

5. The BNG receives an Interim-Accounting response from the RADIUS server.

No action taken in the BNG whether or not it receives a response from the RADIUS server.

## IPCP Negotiation with Optional Peer IP Address

During normal operation for an Internet Protocol Control Protocol (IPCP) negotiation, if the Point-to-Point Protocol (PPP) client does not request a specific IP address, the MX Series server sends an IP address obtained from RADIUS or from the local address pool.

Typically, when the CPE negotiates a statically provisioned IP address, the BNG receives a Framed-IP-Address of 255.255.255.255, and optionally a Framed Route, during PPP authorization. The CPE presents the configured IP WAN address in the IP Address option of the IPCP confReq message. The BNG then accepts the peer's proposed address.

In some other cases, however, the subscriber's public IP address is provisioned locally on the CPE but not explicitly negotiated via IPNCP. If the PPP client seeks a specific IP address, on receiving a NAK from the server, it sends a confReq message without specifying the IP address option. In this case, even though the server sends an IPCP confAck message, the server terminates the client because the server requires an IP address from the client.

You can configure the [peer-ip-address-optional](#) statement to enable the IPCP negotiation to succeed even though the peer does not include the IP address option in an IPCP configuration request for static and dynamic, and terminated and tunneled, Point-to-Point Protocol over Ethernet (PPPoE) subscribers. By default, this statement is disabled. This feature also supports high availability (HA) and unified in-service software upgrade (unified ISSU).

If the client does not include the IP address option in an IPCP configuration request and the IPCP negotiation succeeds by configuring the **peer-ip-address-optional** statement, then the server does not have the client IP address.

**NOTE:** If the client does include the IP address option in an IPCP configuration request, it does not matter whether the **peer-ip-address-optional** statement is configured because the subscriber is always available and the server has the client IP address.

An IP address from RADIUS or from the local pool is allocated to the client and the route towards this is added on the server even though the client is not assigned with this address. IPCP is successful and the subscriber becomes available. If you want the server to have the route to the client-requested IP address, use the Framed-Route RADIUS attribute or configure static routes. The client adds or configures static routes towards the server for proper forwarding.

## How RADIUS Attributes Are Used During Authentication When On-Demand Address Allocation is Enabled

The following describes the behavior of the border network gateway (BNG) during authentication when on-demand IP address allocation is enabled:

- If the RADIUS server returns a Framed-IP-Address attribute, the BNG does not go to the RADIUS server for address allocation on the first Internet Protocol Control Protocol (IPCP) negotiation. It uses the Framed-IP-Address attribute returned in the initial Access-Accept message. Accounting-Start and periodic Interim-Accounting messages include the Framed-IP-Address attribute. Immediate Interim Accounting messages are not sent to RADIUS server. Address allocation is similar to the process described for a static or dynamic subscriber.

When a Framed-IP-Address is returned from the RADIUS server during authentication and the customer premises equipment (CPE) does not negotiate IPCP, the IPv4 address is not released whether or not the on-demand IP address allocation is enabled.

- If the RADIUS server returns a Framed-Pool attribute, the BNG does not go to the RADIUS server for address allocation upon first IPCP negotiation and it allocates an IPv4 address from the specified local address pool. Accounting-Start and periodic Interim-Accounting messages do not include the Framed-IP-Address attribute until IPCP negotiation. Immediate Interim Accounting messages (if configured) are sent to the RADIUS server. Address allocation is similar to the process described for a static or dynamic subscriber.
- If the RADIUS server does not return either the Framed-IP-Address attribute or the Framed-Pool attribute, address allocation is similar to the process described for a static or dynamic subscriber. Because IPCP is the only Network Control Protocol (NCP) active for these subscribers, the entire PPP session is terminated upon an IPCP terminate request and an Accounting-stop message is sent to the RADIUS server.

Immediate Interim-Accounting messages to release the IPv4 address are not sent in this case.

### Configuring Static On-Demand IPv4 Address Allocation for Dual-Stack PPP Subscribers

To configure static on-demand IPv4 address allocation for dual-stack PPP subscribers:

1. Specify the name and logical unit number of the interface.

```
[edit]
user@host# edit interfaces pp0 unit 1000
```

2. Enable on-demand IP address allocation.

```
[edit interfaces pp0 unit 1000]
user@host# set ppp-options on-demand-ip-address
```

### Configuring Dynamic On-Demand IPv4 Address Allocation for Dual-Stack PPP Subscribers

To configure dynamic on-demand IPv4 address allocation for dual-stack PPP subscribers:

1. Access the dynamic profile.

```
[edit]
user@host# edit dynamic profiles ppp-dyn-ipv4
```

2. Specify the name and logical unit number of the interface.

```
[edit dynamic profiles ppp-dyn-ipv4]
user@host# edit interfaces ppp unit 1000
```

3. Enable on-demand IP address allocation.

```
[edit dynamic profiles ppp-dyn-ipv4 interfaces pp0 unit 1000]
user@host# set ppp-options on-demand-ip-address
```

### Configuring Global On-Demand IPv4 Address Allocation for Dual-Stack PPP Subscribers

To configure static on-demand IP address IPv4 address allocation for dual-stack PPP subscribers at the system level:

1. Specify the protocol.

```
[edit]
user@host# edit protocols
```

2. Specify the ppp-service option.

```
[edit protocols]
user@host# edit ppp-service
```

3. Enable on-demand IP address allocation.

```
[edit protocols ppp-service]
user@host# set on-demand-ip-address
```

## Enabling Immediate Interim Accounting Messages for On-Demand IPv4 Address Changes

To enable the BNG to send an immediate interim accounting message:

1. Create a profile and assign a name to it.

```
[edit access]
user@host# edit profile profile1
```

2. Under accounting, specify the address-change-immediate-update option.

```
[edit access profile profile1]
user@host# edit accounting
user@host# set address-change-immediate-update
```

## Enabling IPv4 Release Control VSA (26–164) in RADIUS Messages

When you are using on-demand address allocation for dual-stack PPP subscribers, you can configure the BNG to include the IPv4-Release-Control VSA (26–164) in the Access-Request that is sent during on-demand IP address allocation and in the Interim-Accounting messages that are sent to report an address change.

If no IPv4 address is available during negotiation for static or dynamic PPP subscribers, the RADIUS server includes this VSA in the Access-Reject message it sends to the BNG. The consequence is that the BNG sends an IPCP terminate request to the CPE and the CPE can then renegotiate IPCP.

If you have not enabled VSA 26–164 to be sent, then the Access-Reject message does not include the VSA, and the BNG sends an LCP Protocol-Reject message to the CPE. The CPE must renegotiate the LCP link before it is allowed to renegotiate IP NCP.

The configuration of this statement has no effect when on-demand IP address allocation or deallocation is not configured.

You can optionally configure a message that is included in the VSA when it is sent to the RADIUS server.

To enable the IPv4-Release-Control VSA (26–164) in RADIUS messages:

1. Create a profile and assign a name to it.

```
[edit access]
user@host# edit profile profile1
```

2. Specify that you want to configure RADIUS.

```
[edit access profile profile1]
user@host# edit radius
```

3. (Optional) Configure the VSA to be sent and optionally specify a text message to be included in the VSA.

```
user@host# set ip-address-change-notify message message
```

### Monitoring Active Subscriber Sessions

**Purpose** View a summary of active subscriber sessions.

**Action** From operational mode, enter the **show subscribers summary** command.

```
user@host>show subscribers summary
```

```
Subscribers by State
  Active: 2
  Total: 2
```

```
Subscribers by Client Type
  DHCP: 1
```

```
PPPoE: 1
Total: 2
```

**Meaning** The output under **Subscribers by State** shows the number of active subscriber sessions.

The output under **Subscribers by Client Type** shows the number of active sessions by type. The two subscriber sessions above represent a DHCPv6 subscriber on a PPPoE access network. When DHCPv6 is layered over PPPoE, two separate subscriber sessions are created for a subscriber.

## Monitoring Both IPv4 and IPv6 Address in Correct Routing Instance

**Purpose** Verify that the subscriber has both an IPv4 and an IPv6 address and is placed in the correct routing-instance.

**Action** From operational mode, enter the **show subscribers** command.

```
user@host>show subscribers
```

Interface	IP Address/VLAN ID	User Name	LS:RI
pp0.1073741825	203.0.113.162	ipv4-v6-subscriber	default:default
pp0.1073741825	2001:DB8::1		default:default

**Meaning** The **Interface** field shows that there are two subscriber sessions running on the same interface. The **IP Address** field shows that one session is assigned an IPv4 address, and one session is assigned on IPv6 address.

The **LS:RI** field shows that the subscriber is placed in the correct routing instance and that traffic can be sent and received.

## Monitoring Dynamic Subscriber Sessions

**Purpose** Display dynamic PPPoE and DHCPv6 subscriber sessions.

**Action** From operational mode, enter the **show subscribers detail** command.

```
user@host>show subscribers detail
```

```
Type: PPPoE
User Name: SBRSTATICUSER
IP Address: 203.0.113.162
IP Netmask: 255.0.0.0
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Dynamic
Dynamic Profile Name: pppoe-subscriber-profile
MAC Address: 00:00:5E:00:53:01
```

```

State: Active
Radius Accounting ID: 2
Session ID: 2
Login Time: 2011-12-08 09:11:41 PST

Type: DHCP
IPv6 Address: 2001:DB8::1
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Static
MAC Address: 00:00:5E:00:53:01
State: Active
Radius Accounting ID: 3
Session ID: 3
Underlying Session ID: 2
Login Time: 2011-12-08 09:12:11 PST
DHCP Options: len 42
00 08 00 02 0b b8 00 01 00 0a 00 03 00 01 00 01 02 00 00 01
00 06 00 02 00 03 00 03 00 0c 00 00 00 00 00 00 00 00 00
00 00

```

**Meaning** If you are using DHCPv6 over a PPPoE access network, the output shows the relationship of the DHCPv6 subscriber session with its underlying PPPoE subscriber session. In the output for the PPPoE session, the **Session ID** is 2. The output of the DHCP session shows that the **Underlying Session ID** is 2.

## Monitoring Address Pools Used for Subscribers

**Purpose** Verify the pool used for NDRA, the delegated address pool used for DHCPv6 prefix delegation, and the length of the IPv6 prefixes that were delegated to the CPE.

**Action** From operational mode, enter the **show subscribers extensive** command.

```

user@host>show subscribers extensive

Type: PPPoE
User Name: dual-stack-v4v6-pd
IP Address: 203.0.113.5
IP Netmask: 255.255.0.0
IPv6 User Prefix: 2001:db8:2010:0:0:8::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741864
Interface type: Dynamic
Dynamic Profile Name: DS-dyn-ipv4v6-ra
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 87
Session ID: 87
Login Time: 2012-01-17 14:45:30 PST
IPv6 Delegated Address Pool: dhcpv6-pd-pool
IPv6 Delegated Address Pool: ndra-2010
IPv6 Delegated Network Prefix Length: 48

```

```

IPv6 Interface Address: 2001:db8:2010:0:0:8::1/64

Type: DHCP
IPv6 Prefix: 2001:db8:2040:2000:2000:5::/64
Logical System: default
Routing Instance: default
Interface: pp0.1073741864
Interface type: Static
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 88
Session ID: 88
Underlying Session ID: 87
Login Time: 2012-01-17 14:46:00 PST
DHCP Options: len 42
00 08 00 02 0b b8 00 01 00 0a 00 03 00 01 00 07 64 11 07 02
00 06 00 02 00 19 00 19 00 0c 00 00 00 00 00 00 00 00 00 00
00 00
IPv6 Delegated Address Pool: dhcpv6-pd-pool
IPv6 Delegated Network Prefix Length: 64
IPv6 Delegated Network Prefix Length: 48

```

**Meaning** Under the PPPoE session, the **IPv6 Delegated Address Pool** fields show the names of the pools used for DHCPv6 prefix delegation and for NDRA prefixes. The **IPv6 Delegated Network Prefix Length** field shows the length of the prefix used to assign the IPv6 address for this subscriber session. The **IPv6 Interface Address** field shows the IPv6 address assigned to the CPE interface from the NDRA pool.

Under the DHCP session, the **IPv6 Delegated Address Pool** fields show the name of the pool used for DHCPv6 prefix delegation. The **IPv6 Delegated Network Prefix Length** fields shows the length of the prefix used in DHCPv6 prefix delegation.

## Monitoring Specific Subscriber Sessions

**Purpose** Display information about specific subscriber sessions. If you have many subscriber sessions running, you can use this command to display specific sessions.

**Action** From operational mode, enter the **show subscribers extensive id** command.

```

user@host>show subscribers extensive id 2

Type: PPPoE
User Name: SBRSTATICUSER
IP Address: 203.0.113.162
IP Netmask: 255.0.0.0
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Dynamic
Dynamic Profile Name: pppoe-subscriber-profile
MAC Address: 00:00:5E:00:53:01
State: Active
Radius Accounting ID: 2

```

```

Session ID: 2
Login Time: 2011-12-08 09:11:41 PST

user@host> show subscribers extensive id 3
Type: DHCP
IPv6 Address: 2001:DB8::1
Logical System: default
Routing Instance: default
Interface: pp0.1073741825
Interface type: Static
MAC Address: 00:00:5E:00:53:01
State: Active
Radius Accounting ID: 3
Session ID: 3
Underlying Session ID: 2
Login Time: 2011-12-08 09:12:11 PST
DHCP Options: len 42
00 08 00 02 0b b8 00 01 00 0a 00 03 00 01 00 01 02 00 00 01
00 06 00 02 00 03 00 03 00 0c 00 00 00 00 00 00 00 00 00
00 00

```

**Meaning** The output shows details about specific subscriber sessions.

## Monitoring the Status of the PPPoE Logical Interface

**Purpose** Display status information about the PPPoE logical interface.

**Action** user@host> show interfaces pp0.1073741888

```

Logical interface pp0.1073741888 (Index 123) (SNMP ifIndex 707)
Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
PPPoE:
  State: SessionUp, Session ID: 16,
  Session AC name: centaurus, Remote MAC address: 00:00:5E:00:53:02,
  Underlying interface: ge-1/0/0.1104 (Index 95)
Input packets : 8
Output packets: 51816
LCP state: Opened
NCP state: inet: Opened, inet6: Opened, iso: Not-configured, mpls:
Not-configured
CHAP state: Closed
PAP state: Success
Protocol inet, MTU: 1500
  Flags: Sendbroadcast-pkt-to-re
  Addresses, Flags: Is-Primary
    Local: 192.0.2.77
Protocol inet6, MTU: 1500
  Addresses, Flags: Is-Preferred Is-Primary
    Destination: 2001:DB8:0:21::/64, Local: 2001:DB8:0:21::1
  Addresses, Flags: Is-Preferred
    Destination: fe80::/64, Local: fe80::2a0:a50f:fc61:6d0

```

**Meaning** Displays session information about the ppp0 interface.

## Monitoring Service Sessions for Subscribers

**Purpose** Display a details about dual-stack subscriber session.

**Action** `user@host> show subscribers interface pp0.1073741888 extensive`

```
Type: PPPoE
User Name: dual-stack-v4v6-2svc-good
IP Address: 203.0.113.140
Logical System: default
Routing Instance: default
Interface: pp0.1073741888
Interface type: Dynamic
Dynamic Profile Name: DS-dyn-ipv4v6-ra
MAC Address: 00:00:5E:00:53:02
State: Active
Radius Accounting ID: 155
Session ID: 155
Login Time: 2011-01-30 20:36:53 PST
Service Sessions: 2

Service Session ID: 174
Service Session Name: l3-v4-service
State: Active
IPv4 Input Filter Name: upstrm-filter-ge-1/0/0.1104-in
IPv4 Output Filter Name: dwnstrm-filter-ge-1/0/0.1104-out

Service Session ID: 175
Service Session Name: l3-v6-service
State: Active
IPv6 Input Filter Name: v6-up-filter-ge-1/0/0.1104-in
IPv6 Output Filter Name: v6-dn-filter-ge-1/0/0.1104-out
```

**Meaning** The highlighted output includes details about a subscriber's service sessions.

## Monitoring PPP Options Negotiated with the Remote Peer

**Purpose** Display the PPP options that were negotiated with the CPE. You can also view the IPv4 address that was negotiated with the remote peer. This address matches the address returned from AAA. You can also see this address by using the **show subscribers** command.

Note that this is the only command that will provide the details about the negotiated interface IDs.

**Action** user@host> show ppp interface pp0.1073741888 extensive

```
Session pp0.1073741888, Type: PPP, Phase: Network
LCP
  State: Opened

## Address-Assignment Pools Overview

The address-assignment pool feature supports subscriber management and DHCP management functionality by enabling you to create centralized IPv4 and IPv6 address pools independently of the client applications that use the pools. The authd process manages the pools and the address allocation, whether the addresses come from local pools or from a RADIUS server. For example, multiple client applications, such as DHCP, can use the same address-assignment pool to provide addresses for their particular clients. Client applications can acquire addresses for either authenticated or unauthenticated clients. The pool selected for a subscriber, based on the RADIUS server or network matching or other rule, is called the matching pool for the subscriber.

Address-assignment pools support both dynamic and static address assignment. In dynamic address assignment, a client is automatically assigned an address from the

address-assignment pool. In static address assignment, which is supported for IPv4 pools only, you reserve an address that is then always used by a particular client. Addresses that are reserved for static assignment are removed from the dynamic address pool and cannot be assigned to other clients.

You can configure named address ranges within an address-assignment pool. A named range is a subset of the overall address range. A client application can use named ranges to manage address assignment based on client-specific criteria. For example, for IPv4 address-assignment pools, you might create a named range that is based on a specific DHCP option 82 value. Then, when a DHCP client request matches the specified option 82 value, an address from the specified range is assigned to the client.

Starting in Junos OS Release 18.1R1, you can exclude a specified address or range of consecutive addresses to prevent them from being allocated from an address pool. For example, you might want to reserve certain addresses or ranges to be used only for static subscribers. When you configure an address or range to be excluded, and the address or an address within the range, has already been allocated, that subscriber is logged out, the address is deallocated, and the address is marked for exclusion.

You can link address-assignment pools together to provide backup pools for address assignment. When no addresses are found to be available in the primary or matching address pool, the router or switch automatically proceeds to the linked (secondary) address pool to search for an available address to allocate.

Although the first pool in a chain of linked pools is generally considered the primary pool, a matching pool is not necessarily the first pool in the chain. For example, in a chain of three pools, A, B, and C, where A is the primary pool, pool B might be matched for certain subscribers based on information returned by the RADIUS server. The search for an available address for those subscribers begins in pool B.

Starting in Junos OS Release 18.1R1, the behavior changes for how the search for an available address proceeds through a chain of linked pools. By default, the matching pool is searched first, then the search moves to the first pool in the chain and proceeds through the chain until an available address is found and allocated, or until the search determines no addresses are free. In each pool, all address ranges are fully searched for an address. This behavior enables addresses to be assigned contiguously.

Alternatively, you can configure the **linked-pool-aggregation** statement to search first within a block of addresses in each range in the matching pool and then successively through the linked pools. The search then moves back to the first pool in the chain and searches all addresses in all ranges in each pool through the last pool in the chain.

The address-assignment pool hold-down feature enables you to specify that no additional address are allocated from an existing active address-assignment pool. This configuration gracefully transforms the active pool to an inactive state as the previously allocated addresses are returned to the pool. When the pool is inactive, you can safely perform maintenance on the pool without affecting any active subscribers.

You can also explicitly identify that an address-assignment pool is used for NDRA.

**NOTE:** This feature requires a license. To understand more about Subscriber Access Licensing, see [Subscriber Access Licensing Overview](#). Please refer to the [Juniper Licensing Guide](#) for general information about License Management. Please refer to the product [Data Sheets](#) for details, or contact your Juniper Account Team or Juniper Partner.

### Benefits of Address Assignment Pools

- You can create centralized pools of addresses independent of client applications.
- You can specify blocks of addresses, named ranges, so that a given address pool can be used to supply different addresses for different client applications or for subscribers that match different sets of criteria.
- You can link pools together to ensure that pools are searched for free addresses in a specific manner, contiguously or noncontiguously.
- You can gracefully transition an address pool from active to inactive by specifying that no further addresses are allocated from the pool.

### Address Allocation from Linked Address Pools

You can link address-assignment pools together into a chain to provide backup pools for address assignment. The pool selected for a subscriber, based on the RADIUS server or network matching or some other rule, is called the matching or matched pool for the subscriber. The matching pool might not be the first (primary) pool in the chain. When no addresses are available for allocation from the matching or primary address pool, the router or switch automatically proceeds to another address pool to search for an available address to allocate. When the search discovers no available addresses anywhere, the search stops and no address is allocated for the subscriber.

The search behavior determines not only how the search progresses along a chain of linked pools, but which address ranges within each pool are searched. Depending on where the search starts, your configuration, and whether previously allocated addresses have been freed, the search may continue in the next linked address pool in the chain, or move back to the first pool in the chain.

The search for an available address starts in the pool that matches the subscriber. In many cases, the matching pool is also the first pool in the chain. For some subscribers, the matching pool is farther down the chain. For example, you might configure the RADIUS server to specify the second pool of a chain rather than the first based on some criteria that it matches during authentication. For another example, you might specify different address ranges for different subscriber groups; whether a particular pool matches a subscriber then depends on which pools are configured for the different address ranges.

The following terms are used to explain the details of the search behavior:

- **lowAddress**—The lowest address in a given range within an address pool.
- **highAddress**—The highest address in a given range within an address pool.

- **nextAddress**—The next address after the last address allocated in a given range within an address pool. This is the address expected to be allocated next. This address, as well as the last range used, is saved as a starting point for searches.

For example, suppose Pool A has a single range that includes the following addresses: 192.0.2.1, 192.0.2.2, 192.0.2.3, 192.0.2.4. In this case, 192.0.2.1 is the **lowAddress** and 192.0.2.4 is the **highAddress**. If 192.0.2.2 was the last address allocated from this pool, then **nextAddress** is 192.0.2.3.

Starting in Junos OS Release 18.1R1, you can configure linked pools to be searched in one of two ways:

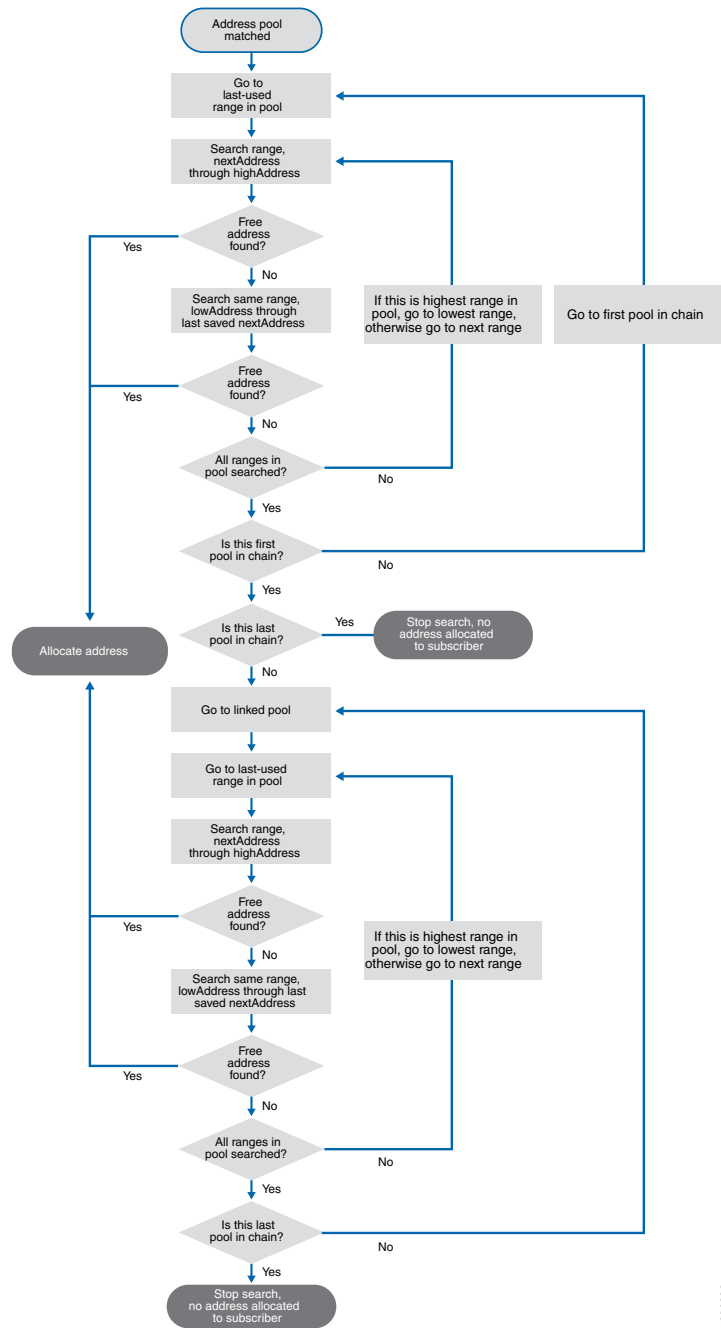

- **Contiguous address allocation**—This is the default behavior. All addresses in each range of a pool are searched. The search starts in the matched pool, then moves to the first pool in the chain and, if necessary, continues through each linked pool successively to the last pool in the chain. In each pool, all addresses in all ranges are searched for a free address. This method enables addresses to be assigned contiguously; each pool has to be full before another pool is searched.
- **Noncontiguous (aggregated) address allocation**—Behavior when the **linked-pool-aggregation** statement is configured. Initially, only certain addresses (from **nextAddress** to **highAddress**) are searched in each range of the matched pool. The same search is performed in the linked pool and, if necessary, continues through each linked pool successively to the last pool in the chain.

The search then restarts at the first pool in the chain (not necessarily the matched pool). This time, all addresses in all ranges are searched, in all pools through the end of the chain.

That is the basic functionality, but the details of both searches are fairly complex.

[Figure 24 on page 567](#) shows the default search behavior.

Figure 24: Default Address Assignment from Linked Address Pools

For example, suppose the following conditions exist:

- Linked address pools A, B, C, and D. Pool C is matched.
- Each pool has three address ranges, r1, r2, r3. The last used range was r2 in each pool.

If no free address is found, the search proceeds like this: C > A > B > C > D, then stops.

1. Pool C is searched, nextAddress through highAddress in range r2.
2. Pool C is searched, lowAddress through nextAddress in range r2.
3. Pool C is searched, nextAddress through highAddress in range r3.
4. Pool C is searched, lowAddress through nextAddress in range r3.
5. Pool C is searched, nextAddress through highAddress in range r1.
6. Pool C is searched, lowAddress through nextAddress in range r1.

All ranges and addresses in pool C have been searched, so the search moves to the first pool in the chain, A.

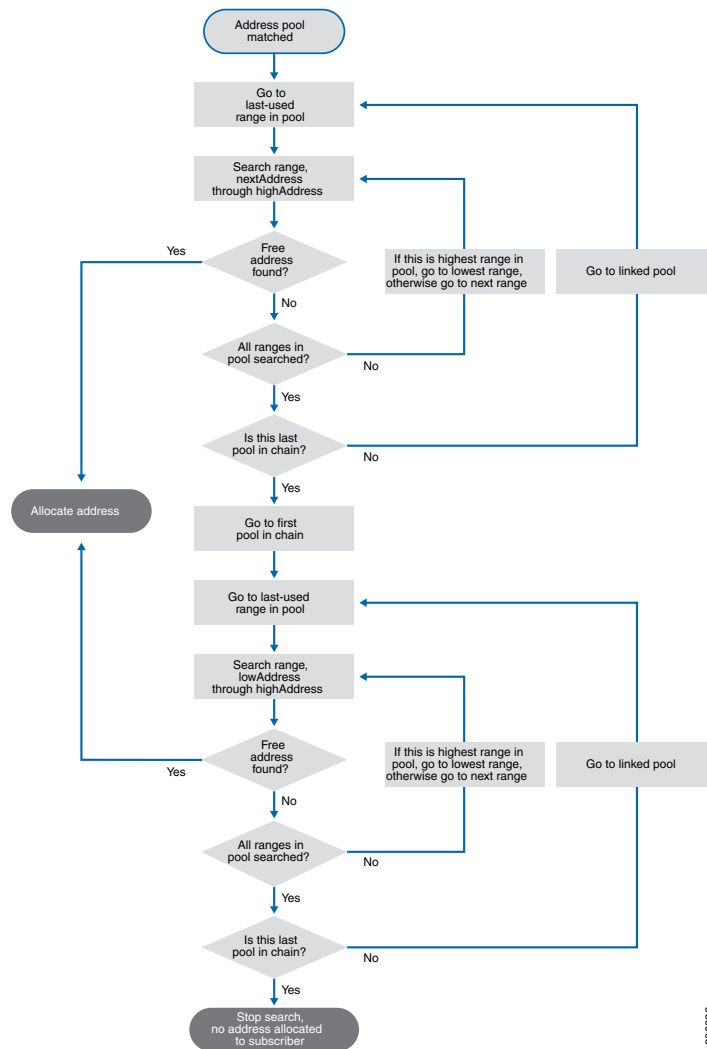

7. Pool A is searched, nextAddress through highAddress in range r2.
8. Pool A is searched, lowAddress through nextAddress in range r2.
9. Pool A is searched, nextAddress through highAddress in range r3.
10. Pool A is searched, lowAddress through nextAddress in range r3.
11. Pool A is searched, nextAddress through highAddress in range r1.
12. Pool A is searched, lowAddress through nextAddress in range r1.

All ranges and addresses in pool A have been searched, so the search moves to the next linked pool in the chain, B.

This process continues until all addresses in all ranges in all pools have been searched. The pool search order is C > A > B > C > D, then stops. Depending on where and whether an address is found, the matching pool might be searched twice. This is true unless the matching pool is the first pool in the chain. For example, if pool A is the matching pool in this set of conditions, then the complete search (assuming no address is found) would be A > B > C > D.

[Figure 25 on page 569](#) shows the search behavior when you include the **linked-pool-aggregation** statement.

Figure 25: Aggregated Address Assignment from Linked Address Pools

For example, consider the same conditions exist as for the default example:

- Linked address pools A, B, C, and D. Pool C is matched.
- Each pool has three address ranges, r1, r2, r3. The last used range was r2 in each pool.

If no free address is found, the search proceeds like this: C > D > A > B > C > D, then stops.

1. Pool C is searched, nextAddress through highAddress in range r2.
2. Pool C is searched, nextAddress through highAddress in range r3.
3. Pool C is searched, nextAddress through highAddress in range r1.

All ranges in pool C have been searched from nextAddress to highAddress, so the search moves to the next linked pool in the chain, D.

4. Pool D is searched, nextAddress through highAddress in range r2.
5. Pool D is searched, nextAddress through highAddress in range r3.
6. Pool D is searched, nextAddress through highAddress in range r1.

All ranges in pool D have been searched from nextAddress to highAddress. Pool D is the last pool in the chain, so the search moves to the first pool in the chain, A.

7. Pool A is searched, lowAddress through highAddress in range r2.
8. Pool A is searched, lowAddress through highAddress in range r3.
9. Pool A is searched, lowAddress through highAddress in range r1.

All ranges and addresses in pool A have been searched, so the search moves to the next linked pool in the chain, B.

10. Pool B is searched, lowAddress through highAddress in range r2.
11. Pool B is searched, lowAddress through highAddress in range r3.
12. Pool B is searched, lowAddress through highAddress in range r1.

All ranges and addresses in pool B have been searched, so the search moves to the next linked pool in the chain, C.

This process continues until all addresses in all ranges in all pools have been searched. The pool search order is C > D > A > B > C > D, then stops. Depending on where and whether an address is found, all pools might be searched twice, even when the matching pool is the first pool in the chain. For example, if pool A is the matching pool in this set of conditions, then the complete search (assuming no address is found) would be A > B > C > D > A > B > C > D.

## Address-Assignment Pool Configuration Overview

The address-assignment pool feature supports subscriber management functionality by enabling you to create address pools that can be shared by different client applications. An address-assignment pool can support either IPv4 address or IPv6 addresses. You cannot use the same pool for both types of address.

**NOTE:** Address-assignment pools are completely separate from services PIC-based L2TP LNS address pools, which you create with the `address-pool` statement at the `[edit access]` hierarchy level, and NAT pools, which you create with the `pool` statement at the `[edit services nat]` hierarchy level.

---

To configure an address-assignment pool:

1. Configure the address-assignment pool name and specify the addresses for the pool.  
See [“Configuring an Address-Assignment Pool Name and Addresses” on page 571](#).
2. (Optional) Configure named ranges (subsets) of addresses.

See [“Configuring a Named Address Range for Dynamic Address Assignment”](#) on page 572.

3. (Optional) Exclude addresses or a range of addresses in address pools from being allocated.

See [“Preventing Addresses from Being Allocated from an Address Pool”](#) on page 573.

4. (Optional) Configure address-assignment pool linking and specify the secondary pool to use when the primary pool is fully allocated.

See [“Configuring Address-Assignment Pool Linking”](#) on page 576.

5. (Optional) Configure address-assignment pool hold-down, so that no additional addresses are allocated from the identified pool. This is also known as passive drain.

See [“Configuring Address-Assignment Pool Hold-Down”](#) on page 577.

6. (Optional) Configure address-assignment pool rapid drain, also known as active drain, to gracefully prevent additional address allocation from the pool and prevent existing clients from renewing leases for addresses from the pool.

See [“Configuring DHCP Local Address Pool Rapid Drain”](#) on page 578.

7. (Optional) Create static address bindings (IPv4 only).

See [“Configuring Static Address Assignment”](#) on page 581.

8. (Optional) Enable duplicate address protection to prevent addresses from being used more than once.

See [“Configuring Duplicate IPv4 Address Protection for AAA”](#) on page 582.

9. (Optional) Configure attributes for DHCP clients.

See [“Configuring DHCP Client-Specific Attributes Applied When Clients Obtain an Address”](#) on page 299.

**See Also** • [DHCP Attributes Overview on page 295](#)

## Configuring an Address-Assignment Pool Name and Addresses

To configure an address-assignment pool, you must specify the name of the pool and configure the addresses for the pool.

To configure an IPv4 address-assignment pool:

1. Configure the name of the pool and specify the IPv4 family.

[edit access]

```
user@host# edit address-assignment pool isp_1 family inet
```

2. Configure the network address and the prefix length of the addresses in the pool.

```
[edit access address-assignment pool isp_1 family inet]  
user@host# set network 192.168.0.0/16
```

To configure an IPv6 address-assignment pool:

1. Configure the name of the pool and specify the IPv6 family.

```
[edit access]  
user@host# edit address-assignment pool isp_2 family inet6
```

2. Configure the IPv6 network prefix for the address pool. The prefix specification is required when you configure an IPv6 address-assignment pool.

```
[edit access address-assignment pool isp_2 family inet6]  
user@host# set prefix 2001:db8:2008:2009::/32
```

## Configuring a Named Address Range for Dynamic Address Assignment

You can optionally configure multiple named ranges, or subsets, of addresses within an address-assignment pool. During dynamic address assignment, a client can be assigned an address from a specific named range. To create a named range, you specify a name for the range and define the address range.

To create a named range within an IPv4 address-assignment pool:

1. Specify the name of the address-assignment pool and the IPv4 family.

```
[edit access]  
user@host# edit address-assignment pool isp_1 family inet
```

2. Configure the name of the range and the lower and upper boundaries of the addresses in the range.

```
[edit access address-assignment pool isp_1 family inet]  
user@host# set range southeast low 192.168.102.2 high 192.168.102.254
```

To create a named range within an IPv6 address-assignment pool:

1. Specify the name of the address-assignment pool and the IPv6 family.

```
[edit access]  
user@host# edit address-assignment pool isp_2 family inet6
```

2. Configure the name of the range and define the range. You can define the range based on the lower and upper boundaries of the prefixes in the range, or based on the length of the prefixes in the range.

```
[edit access address-assignment pool isp_2 family inet6]
user@host# set range dsl-range low 2001:db8:2008:2010:2011:0100::/64 high
2001:db8:2008:2010:2011:ffff::/64
user@host# set range fiber-east prefix-length 48
```

## Preventing Addresses from Being Allocated from an Address Pool

You can exclude specified addresses or address ranges to prevent them from being allocated from an address pool. For example, you might want to reserve certain addresses or ranges to be used only for static subscribers. When you configure an address or range of addresses to be excluded, and the address or an address within the range has already been allocated, that the subscriber allocated that address is logged out, the address is deallocated, and the address is marked for exclusion.

To exclude an address or range of addresses in an address pool from being allocated:

- Specify an individual address.

```
[edit access address-assignment pool-name family (inet | inet6)]
user@host# set excluded-address ip-address
```

- Specify and name a range of consecutive addresses.

```
[edit access address-assignment pool-name family (inet | inet6)]
user@host# set excluded-range name low minimum-value high maximum-value
```

For example, the following partial configuration for an IPv4 address pool defines a range, *r1*, of addresses to allocate, from 192.168.0.10 through 192.168.128.250. It excludes a single address, 192.168.110.10. It further defines two ranges, *exclude1* and *exclude2*, that specify two sets of consecutive addresses that cannot be allocated from the pool.

```
pool v4-pool {
  family inet {
    network 192.168.0.0/16;
    range r1 {
      low 192.168.0.10;
      high 192.168.128.250;
    }
    excluded-address 192.168.110.10
    excluded-range exclude1 {
      low 192.168.12.0
      high 192.168.12.255
    }
    excluded-range exclude2 {
      low 192.168.98.10
      high 192.168.98.200
    }
  }
}
```

```
}
```

Similarly, the configuration for pool v6-pool defines a range of addresses to allocate and a range of addresses that are excluded from allocation.

```
pool v6-pool {
  family inet6 {
    prefix 2016::/64;
    range r2 {
      low 2016::1;
      high 2016::80:ffff;
    }
    excluded-range exclude3 {
      low 2016::7c:a
      high 2016::7c:ff
    }
  }
}
```

To view information about excluded addresses, you can use either of the following commands:

```
user@host> show network-access address-assignment pool pool-name
```

IP address/prefix	Hardware address	Host/User	Type
192.168.2.1	00:00:5e:00:53:01	user1	DHCP
192.168.2.2	00:00:5e:00:53:02	user2	DHCP
192.168.2.3	00:00:5e:00:53:03	user3	DHCP
<b>192.168.2.4</b>	<b>NA</b>	<b>EXCLUDED</b>	<b>unknown</b>

```
user@host> show network-access aaa statistics address-assignment pool pool-name
```

```
Address-assignment statistics
...
Addresses excluded: 1000
...
```

## Configuring Address-Assignment Pool Usage Threshold Traps

You can receive advanced warning that an address pool or linked set of address pools is running short on available addresses by setting usage threshold traps. An address pool has SNMP thresholds associated with it that allow the local address server to signal SNMP traps when certain conditions exist. These thresholds include high utilization threshold and abated utilization threshold. If a pool's outstanding addresses exceed the high utilization threshold and the SNMP trap signaling is enabled, SNMP is notified. Likewise, when a pool's utilization drops below the abated threshold utilization threshold, SNMP is notified. When the system reaches the high utilization value, it sends warning messages. When memory usage falls to the abated utilization value, the system stops sending warning messages.

To set the usage for threshold traps:

- Specify the percentage after which the address pool usage is exceeded that an SNMP trap is generated.

```
[edit access]  
user@host# edit address-assignment high-utilization 95
```

To set the abated value for the trap:

- Specify the percentage below which the address pool usage is abated that an SNMP trap is generated.

```
[edit access]  
user@host# edit address-assignment abated-utilization 80
```

## Configuring Address-Assignment Pool Linking

Address-assignment pool linking enables you to specify a secondary address pool for the router to use when the matching or primary address-assignment pool is fully allocated. You can create a chain of multiple linked pools. For example, you can link Pool A to Pool B, and link Pool B to Pool C. You can link any number of pools serially in a chain, but you cannot create multiple links to or from the same pool. For example, you cannot create links from Pool A to both Pool B and Pool C. Similarly, Pool C cannot be linked from both Pool A and Pool B. An additional consideration is that all address pools in a chain must be of the same family type, IPv4 or IPv6.

When the address pool that matches the subscribers has no available addresses, the router automatically switches over to the linked pool and allocates addresses from that pool. The router uses a linked pool only when the matching address-assignment pool is fully allocated.

Starting in Junos OS Release 18.1, the behavior changes for how to find and allocate a free address in a chain of address pools. You can configure linked pools to be searched in one of two ways:

- **Contiguous address allocation**—Default behavior. All addresses in each range of a pool are searched. The search starts in the matched pool, then moves to the first pool in the chain and, if necessary, continues through each linked pool successively to the last pool in the chain. In each pool, all addresses in all ranges are searched for a free address. This method enables addresses to be assigned contiguously; each pool has to be full before another pool is searched.
- **Noncontiguous (aggregated) address allocation**—Behavior when **linked-pool-aggregation** is configured. Initially, only certain addresses (from `nextAddress` to `highAddress`) are searched in each range of the matched pool. The same search is performed in the linked pool, if necessary, and continues through each successive linked pool through the last pool in the chain.

The search then restarts at the first pool in the chain (not necessarily the matched pool). This time, all addresses in all ranges are searched, in all pools through the end of the chain.

Including the **linked-pool-aggregation** statement might be desirable if you configure your RADIUS server to use the IP address alone to identify subscribers. Typically, subscribers are identified by the RADIUS server using the subscriber session ID and other criteria. If you use only the IP address, you might encounter the following issue with the default behavior when the **linked-pool-aggregation** statement is not configured. A subscriber can disconnect and that address can be assigned to the next subscriber. The `Acct-Start` message for the second subscriber might be sent before the `Acct-Stop` message is sent for the disconnected subscriber. When the `Acct-Stop` is received, the new subscriber, identified only by the IP address, can be disconnected.

You can avoid this situation by either including the **linked-pool-aggregation** statement or configuring your RADIUS server to use the subscriber session ID (instead of the IP address) for identification.

Before you begin, configure your address pools. See [“Address-Assignment Pool Configuration Overview” on page 570](#).

To link an address-assignment pool to a secondary pool:

1. Specify the names of the pools to be linked.

```
[edit access address-assignment pool-name]
user@host# set link secondary-pool-name
```

2. (Optional) Configure searching to allow for noncontiguous address allocation.

```
[edit access]
user@host# set linked-pool-aggregation
```

For example, the following configuration links Pool\_A to Pool\_B and then links Pool\_B to Pool\_C.

```
[edit access]
user@host# set address-assignment pool Pool_A link Pool_B
user@host# set address-assignment pool Pool_B link Pool_C
```

## Configuring Address-Assignment Pool Hold-Down

The address-assignment pool hold-down feature—also known as passive drain—enables you to gracefully transition an active address pool to an inactive state. When the pool is in the inactive state, you can safely perform maintenance on the pool without affecting any current subscribers (such as adding, changing, or deleting addresses).

When an address-assignment pool is in the hold-down state, no additional addresses are allocated from that pool. However, the hold-down state does not affect any existing subscribers that are using addresses previously assigned from the pool. As the existing subscribers disconnect, their IP addresses are marked as free in the pool, but the addresses are not reallocated due to the pool's hold-down state. Eventually, when all subscribers have disconnected and their addresses are returned to the pool, the pool becomes inactive.

To place an active address-assignment pool in the hold-down state:

1. Specify the name of the address-assignment pool.

```
[edit access]
user@host# edit address-assignment pool isp_1
```

2. Specify that the pool is in the hold-down state so that no additional addresses can be allocated from the pool.

```
[edit access address-assignment pool isp_1]
user@host# set hold-down
```

## Configuring DHCP Local Address Pool Rapid Drain

You can force the DHCP local server to stop allocating addresses from a specific local address pool by configuring the pool to active-drain mode. This mode enables the server to gracefully terminate subscribers that are already using addresses assigned from that pool and transition them to another pool. When a DHCP subscriber attempts to renew (at the T1 renewal time) the lease on an IP address from a pool now configured for active-drain mode, the DHCP local server replies with a NAK to the subscriber's renewal request. This response forces the subscriber to renegotiate a lease. The server then allocates a new IP address from an alternative address pool that is not configured for active drain.

The active-drain mode provides a way to rapidly drain subscribers from an address pool. Consequently, the longer the configured lease time for subscribers, the more useful active-drain mode may be. If you do not configure active-drain mode for a pool, then to stop the allocation of its addresses, you must either configure passive-drain mode or delete the pool.

- Passive-drain mode places the address pool in a hold-down state. No more addresses are allocated from the pool, but subscribers currently using an assigned address from the pool are not affected. Existing subscribers are allowed to age out. When the subscriber disconnects (or is disconnected by an operator) the address is released, but cannot be reassigned. Eventually, all subscribers have released their addresses, and the pool is no longer active. Because leases for active subscribers are renewed on request, passive-drain mode can take much longer than active-drain mode to recover all addresses in the pool.
- Pool deletion disrupts the traffic for each current subscriber using a pool address for as long as it takes for the lease to expire and for the subscriber to renegotiate and obtain a new lease. The server removes all subscribers with an address from the deleted pool. The subscribers attempt to extend the lease but fail because the lease was deleted at the server. When the subscribers subsequently attempt to renegotiate a new lease, it may be granted with an address from a different pool or from RADIUS.

You can delete the active-drain configuration before the address pool is emptied. In this case, lease extensions may be granted for subscribers still having addresses from this pool. This recovery is best effort, because some subscribers are in the process of being logged out by the server when the configuration is deleted. These subscribers cannot be recovered to the pool and must renegotiate a lease. These subscribers might then be assigned an address either from this pool (because it is active again) or from an alternate pool.

If the DHCP client fails to receive notification that the address pool is being drained, it may continue to grant lease extensions to subscribers using this pool. This condition is indicated when the address remains bound to the client beyond the T1 time (up to the T2 time) when it should have been recovered by the pool. In this situation, delete the active-drain configuration, then reconfigure it for the pool to ensure the pool is drained in a timely manner.

In the event of an authd or jdncpd restart, or of a graceful Routing Engine switchover, pool addresses might still be used by some subscribers for whom a NAK has not been sent to initiate the logout. When the restart or GRES completes, authd sends jdncpd a

notification with a list of subscribers still having addresses from the pool that is configured for active drain. Pool draining can then continue.

**NOTE:** Starting in Junos OS Release 18.4R1, the method of address allocation determines the subsequent behavior when authd notifies the DHCP process that an address pool is deleted or being drained.

- When addresses are allocated on demand, the family with the address in that pool is logged out immediately when the pool is deleted, or logged out gracefully by the draining process when a DHCP renew or rebind message is received.
- When the addresses are preallocated, the addresses for both families are deleted immediately when the pool is deleted, or deleted gracefully by the draining process when a DHCP renew or rebind message is received.

To configure the DHCP local server to stop allocating addresses from an address pool:

1. Access the address pool configuration.

```
[edit access]
user@host# edit address-assignment pool pool-name
```

2. Specify active drain mode for the pool.

```
[edit access address-assignment pool pool-name]
user@host# set active-drain
```

You can use the **show network-access aaa statistics** command to confirm that active drain is configured for a pool.

```
user@host> show network-access aaa statistics address-assignment pool pool1
```

```
Address assignment statistics
Pool Name: pool1
Out of Memory: 0
Out of Addresses: 0
Address total: 33009
Addresses in use: 1
Address Usage (percent): 0
Pool drain configured: yes
```

**NOTE:** The active-drain feature takes precedence over preservation of the prefix address. Address preservation may ensure that the same delegated prefix is assigned to the subscriber based on the access circuit identifier (ACI). When a subscriber with a preserved prefix logs out, the ACI and prefix are stored in the address preservation table. When that subscriber tries to log in again, the address and ACI are looked up in the table.

Active drain mode affects this behavior. When the prefix is currently part of a pool set to active-drain mode, it is removed from the table and is not assigned to the subscriber when the subscriber tries to log in again.

If active drain is cancelled while the client is in the process of logging out, then the prefix and ACI string are preserved in the table. In this case, the prefix can be assigned to that ACI string when the subscriber logs in again. However, if active drain is cancelled after the client has already logged out and the table has been cleared of the prefix/ACI association, then the subscriber at a subsequent login gets a prefix from the pool that is reactivated and the prefix could be different.

## Configuring Static Address Assignment

You can optionally create a static IPv4 address binding by reserving a specific address for a particular client. The address is removed from the address-assignment pool so that it is not assigned to another client. When you reserve an address, you identify the client host and create a binding between the client MAC address and the assigned IP address. IPv6 address-assignment pools do not support static address binding.

To configure a static binding for an IPv4 address:

1. Specify the name of the IPv4 address-assignment pool containing the IP address you want to reserve for the client.

```
[edit access]
user@host# edit address-assignment pool isp_1 family inet
```

2. Specify the name of the client for the static binding, the client MAC address, and the IP address to reserve for the client. This configuration specifies that the client with MAC address 00:00:5E:00:53:90 is always assigned IP address 192.168.44.12.

```
[edit access address-assignment pool isp_1 family inet]
user@host# set host svale6_boston_net hardware-address
00:00:5E:00:53:90ip-address 192.168.44.12
```

## Configuring Duplicate IPv4 Address Protection for AAA

Starting in Junos OS Release 14.1, if you are using AAA to supply IPv4 addresses, you can enable duplicate address protection to prevent addresses from being used more than once. If enabled, the following attributes received from external servers are checked:

- *Framed-IP-Address*
- *Framed-Pool*

The router then takes one of the following actions:

- If an address matches an address in an address pool, the address is taken from the pool, provided it is available.
- If the address is already in use, it is rejected as unavailable and the existing subscriber using the address remains intact.

To configure duplicate address protection:

1. Enter the **access** configuration.

```
[edit]  
user@host# edit access
```

2. Enable duplicate address protection.

```
[edit access]  
user@host# set address-protection
```

Starting in Junos OS Release 18.4R1, you can optionally enable the reassignment of an address that is currently in use when address protection is configured by including the **reassign-on-match** option. When configured, the router disconnects the existing subscriber and allows the new subscriber to renegotiate. The effect of this configuration is that the address in use is always reassigned to the new subscriber.

One use case for this override capability occurs when a mobile subscriber is accidentally dropped from the gateway GPRS support node (GGSN), but the GGSN keeps the subscriber's L2TP session up for some period of time. When the customer tries to reconnect through a different node, the session cannot connect because the original session is still up. Address reassignment enables the new session to preempt the existing session, allowing the subscriber to reconnect.

**NOTE:** The existing subscriber is disconnected only when the address is from a RADIUS-sourced address pool. When the address is from a locally configured address pool, the existing subscriber session remains intact.

---

**BEST PRACTICE:** Do not use the **reassign-on-match** option when RADIUS is allocating addresses that are contained in a locally configured address pool because there is a greater chance of address collision. We recommend that you do not overlap RADIUS-sourced addresses with local address pools.

The **reassign-on-match** option works in the following way:

1. A subscriber negotiates access with a given IP address.
2. The router determines whether that address is in use and where it came from.
  - When a subscriber is already logged in with that address, the address is not part of a locally configured pool, and address protection is enabled:
    - The router sends a NAK to the new subscriber, rejecting the request.
    - The router sends a disconnect request to the existing subscriber. The disconnect request includes a termination ID to report the cause of the logout.
    - The new (rejected) subscriber can renegotiate and is assigned the IP address.
  - When a subscriber is already logged in with that address and the address was allocated from a local address pool:
    - The router sends a NAK to the new subscriber, rejecting the request.
    - The router does not send a disconnect request to the existing subscriber.

When you add **reassign-on-match** to an existing duplicate address protection configuration, it takes effect immediately for the existing subscribers. Similarly, if you remove **reassign-on-match** from a configuration, it takes effect immediately, so that a subsequent request for access with an in-use address does not result in termination of the existing subscriber.

To enable address reassignment:

- ```
[edit access address-protection]
user@host# set reassign-on-match
```

## Example: Configuring an Address-Assignment Pool

This example shows an address-assignment pool configuration that creates two pools, one for IPv4 DHCP clients (**isp\_1**), and a second pool (**chi-fiber-ra**) that is used for router advertisement.

```
[edit access]
address-assignment {
```

```

network-discovery-router-advertisement chi-fiber-ra;
pool isp_1 {
  family inet {
    network 192.168.0.0/16;
    range southeast {
      low 192.168.102.2 high 192.168.102.254;
    }
    range northeast {
      low 192.168.119.2 high 192.168.119.250;
    }
    host sval6.boston.example.net {
      hardware-address 00:00:5E:00:53:90;
      ip-address 192.168.44.12;
    }
    dhcp-attributes {
      option-match {
        option-82 {
          circuit-id fiber range northeast;
        }
        option-82 {
          circuit-id cable_net range southeast;
        }
      }
      boot-file boot.client;
      boot-server 192.168.200.100;
      grace-period 3600;
      maximum-lease-time 18000;
      netbios-node-type p-node;
      router 192.168.44.44 192.168.44.45;
    }
  }
}
pool chi-fiber-ra {
  family inet6 {
    prefix 2001:db8:2008:2009:2010::/48;
    range fiber3 {
      low 2001:db8:2008:2009:2010::1/64;
      high 2001:db8:2008:2009:2010::5/64;
    }
  }
}
}

```

This example creates an IPv4 address-assignment pool named **isp-1**, which contains two named address ranges, **southeast** and **northeast**. The address-assignment pool also contains a static binding for client **host sval6.boston.example.net**. The **ISP\_1** pool configuration also includes the **dhcp-attributes** statement, indicating that the pool is used for DHCP clients. If the option 82 **circuit-id** entry matches the string **fiber**, then DHCP assigns the client an address from the **northeast** range. If the option 82 **circuit-id** matches the string **cable\_net**, DHCP assigns an address from the **southeast** range.

The second address-assignment pool created in this example is **chi-fiber-ra**. The **neighbor-discovery-router-advertisement** statement at the beginning of the syntax specifies

that this named address-assignment pool is used for router advertisement. The syntax at the end of the example configures the address-assignment pool named **chi-fiber-ra**.

- [Configuring a DNS Server Address for IPv6 Hosts on page 593](#)

## DNS Name Server Address Overview

When a client attempts to access a domain—for example, `www.example.com`—a request is sent to a Domain Name System (DNS) name server. The name server stores information that correlates domain names with IP addresses; the IP address is used to reach the requested domain. In response to the client request, the name server looks up the IP address for the domain—`192.0.2.10` for `www.example.com`—and returns it to the client.

In your network configuration, you must configure the address of one or more name servers locally on the router or on your RADIUS server. The local configuration supports the following subscriber types:

- DHCPv4 or DHCPv6
- IP over Ethernet (VLAN)
- Terminated PPPoE (IPv4 or IPv6)
- Tunneled PPPoE (IPv4 or IPv6)

You can configure the name server addresses globally (per routing instance), per access profile, or, for DHCP only, per address pool. You can configure more than one name server in a routing instance or access profile by repeating the statement for each address.

Because you can configure name server addresses at more than one level, the address returned to the client is determined by the order of preference among the levels. The preference depends on the client type.

- For DHCP subscribers, the preference in descending order is  
RADIUS > DHCP address pool > access profile > global
- For non-DHCP subscribers, the preference in descending order is  
RADIUS > access profile > global

According to the preference order, a name server address configured in RADIUS is preferred by all subscriber types over all other configuration levels. For all subscriber types, the global name server address is used only when no other name server addresses are configured. When a name server address is configured only in a DHCP address pool, then no address is available to non-DHCP subscribers.

When you configure multiple addresses for a name server, the order in which you configure them determines the preference within that configuration. The preference according to configuration level supersedes this ordering.

There is no restriction on the number of DNS name server addresses that you can configure. For DHCP subscribers, all the addresses are sent in DHCP messages. However, only two addresses—determined by preference order—are sent to PPP subscribers.

All changes in these locally configured DNS name servers affect only new subscribers that subsequently log in. Existing subscribers are not affected by the changes.

## Configuring DNS Name Server Addresses for Subscriber Management

This topic describes the procedure for configuring DNS name server addresses at the access profile and routing instance levels. For information about configuring addresses in DHCP address pools, see the DHCP topics referenced in the *Related Documentation* section. For information about configuring addresses on your RADIUS server, refer to your RADIUS software documentation. The order in which the name server configurations at different levels are preferred is described in “[DNS Name Server Address Overview](#)” on [page 589](#).

**BEST PRACTICE:** In practice, choose either the `domain-name-server` statement or the `domain-name-server-inet` statement for IPv4 addresses. They both have the same effect and there is no need to use both statements. If you do use both statements, addresses configured with `domain-name-server-inet` are preferred over addresses configured with `domain-name-server`.

For example, the following sample configuration specifies two IPv4 domain name servers. The server configured with the `domain-name-server-inet` statement, 192.0.2.23, is preferred over the server configured with the `domain-name-server` statement, 198.51.100.31.

```
[edit access]
user@host# set domain-name-server 198.51.100.31
user@host# set domain-name-server-inet 192.0.2.23
```

To configure DNS name server addresses globally:

- Configure an IPv4 address.

```
[edit access]
user@host# set domain-name-server-inet dns-address
```

Alternatively, you can use a different statement to configure an IPv4 address.

```
[edit access]
user@host# set domain-name-server dns-address
```

- Configure an IPv6 address.

```
[edit access]
user@host# set domain-name-server-inet6 dns-address
```

For example, to configure multiple addresses of each type:

```
[edit access]
user@host# set domain-name-server-inet 198.51.100.31
user@host# set domain-name-server-inet 198.51.100.100
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:81ca
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:7334
```

To configure DNS name server addresses in an access profile:

- Configure an IPv4 address.

```
[edit access profile profile-name]
user@host# set domain-name-server-inet dns-address
```

Alternatively, you can use a different statement to configure an IPv4 address.

```
[edit access profile profile-name]
user@host# set domain-name-server dns-address
```

- Configure an IPv6 address.

```
[edit access profile profile-name]
user@host# set domain-name-server-inet6 dns-address
```

For example, to configure multiple addresses of each type:

```
[edit access profile vrf-s-access]
user@host# set domain-name-server-inet 198.51.100.01
user@host# set domain-name-server-inet 198.51.100.100
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:ac81
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:71bfd
```

## Overriding How the DNS Server Address Is Returned in a DHCPv6 Multiple Address Environment

In a DHCPv6 environment, DHCPv6 clients can use a single Solicit message to request multiple addresses (an IA\_NA address, an IA\_PD address, or both), as well as the DNS server address (DHCPv6 attribute 23). By default, the DHCPv6 local server returns the DNS server address as a global DHCPv6 option.

You can override the default behavior and specify that the DHCPv6 local server returns DNS server addresses as their respective IA\_NA and IA\_PD suboptions. You can configure the DHCPv6 local server to support the override globally, for a specific group, or for a specific interface.

**CAUTION:** Some customer premises equipment (CPE) cannot recognize the DNS server address when the address is returned as an IA\_NA or IA\_PD suboption, which can create interoperability issues.

To configure the DHCPv6 local server to return the DNS server address as an IA\_NA or IA\_PD suboption.

1. Specify that you want to configure DHCPv6 override options.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Override the default behavior. DHCPv6 local server now returns DNS server addresses as the respective IA\_PD or IA\_NA suboption.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set multi-address-embedded-option-response
```

- See Also**
- [Using DHCPv6 IA\\_NA with DHCPv6 Prefix Delegation Overview on page 425](#)
  - [DHCPv6 Options in a DHCPv6 Multiple Address Environment on page 427](#)

## DNS Resolver for IPv6 DNS Overview

In a network that uses Neighbor Discovery Router Advertisement (NDRA) to provide IPv6 addressing, the DNS server address can be provided in Router Advertisements sent to IPv6 hosts. The address is included in a field called Recursive DNS Server (RDNSS). This feature is useful in networks that are not running DHCPv6.

RADIUS can populate the RDNSS field dynamically when an IPv6 subscriber logs in. On the RADIUS server, you can configure a primary and secondary DNS address in the following VSAs, which are stored in the `$junos-ipv6-dns-server` variable:

- Ipv6-Primary-DNS (26-47)
- Ipv6-Secondary-DNS (26-48)

When a subscriber logs in, RADIUS provides the actual DNS server address in the Access-Accept message.

You can also configure a static IPv6 address for DNS servers.

After the subscriber session is established, the DNS address is stored in the session database. When the router sends IPv6 router advertisements, it uses this DNS address in the RDNSS field in the Router Advertisement option.

## Configuring a DNS Server Address for IPv6 Hosts

To configure a dynamic DNS server address for IPv6 hosts:

1. Specify that the router receives the DNS server address in the `$junos-ipv6-dns-server-address` variable sent from RADIUS servers in the Access-Accept message when the subscriber logs in.

```
[edit dynamic-profiles dynamic-profile-name protocols router-advertisement interface
interface-name]
user@host# set dns-server-address $junos-ipv6-dns-server-address
```

2. Specify the time in seconds for which the DNS server address remains valid.

```
[edit dynamic-profiles dynamic-profile-name protocols router-advertisement interface
interface-name dns-server-address address]
user@host# set lifetime 2400
```

The default value of the lifetime is 1800 seconds.

To configure a static DNS server address for IPv6 hosts:

1. Specify the IPv6 address of the DNS server.

```
[edit dynamic-profiles dynamic-profile-name protocols router-advertisement interface
interface-name]
user@host# set dns-server-address ipv6-address
```

2. Specify the time in seconds for which the DNS server address remains valid.

```
[edit dynamic-profiles dynamic-profile-name protocols router-advertisement interface  
interface-name dns-server-address address]  
user@host# set lifetime 2400
```

The default value of the lifetime is 1800 seconds.

## ANCP and the ANCP Agent Overview

This topic describes the Access Node Control Protocol (ANCP) and the *ANCP agent*. The ANCP agent is the Junos OS process that manages subscriber access lines with ANCP. The agent monitors subscriber access lines, reports subscriber traffic rates on the access lines between the subscribers and the access nodes, and modifies the traffic rates, all in support of CoS traffic shaping.

---

### Overview

ANCP acts as a control plane between a service-oriented Layer 3 edge device and a Layer 2 access node. The access nodes—ANCP *neighbors*—are network devices that terminate access loops from subscribers; for DSL access loops, the access node is a DSL access multiplexer (DSLAM). Queuing and scheduling mechanisms for subscriber traffic must avoid congestion within the access network while contending with multiple flows and distinct CoS requirements. These mechanisms require the edge device—a router acting as a broadband network gateway (BNG), often also called a network access server (NAS)—to provide information about the access network and subscriber traffic.

The ANCP agent can map an access line to an interface or interface set either statically or dynamically. The agent provides that information to both CoS and AAA. The agent passes on to both CoS and AAA the traffic shaping attributes for each subscriber access line that the access node sent to the ANCP agent. In addition, the agent sends to AAA all DSL Forum attributes that were sent by the access node. AAA can use these attributes during RADIUS accounting and authentication for both DHCP IP demux and PPPoE subscriber sessions. The traffic rates can also be used for shaping L2TP tunnel traffic.

You can monitor ANCP agent events and operations by including the **traceoptions** statement at the **[edit protocols ancp]** hierarchy level.

Junos OS supports Class of Service (CoS) traffic shaping on the following interface types for ANCP:

- Static VLAN interfaces, except those created by Extensible Subscriber Services Manager (ESSM)
- Static VLAN demux interfaces, except those created by ESSM
- Static interface sets, including those created by ESSM

- Dynamic interface sets
- Dynamic VLAN-tagged interface sets
- Dynamic agent circuit identifier (ACI) interface sets, also known as ACI sets or ACI VLANs
- Dynamic PPPoE and DHCP IP demux subscriber interfaces
- Dynamic VLAN demux interfaces with Ethernet-VPLS encapsulation

ANCP was developed as an extension of *RFC 3292, General Switch Management Protocol (GSMP) V3*, but is now defined in *RFC 6320, Protocol for Access Node Control Mechanism in Broadband Networks*.

### Topology Discovery

---

The router uses topology discovery to collect information from the access node. The information includes the following:

- Topology of the access network
- DSL line state
- Actual upstream and downstream net data rates of a synchronized DSL link
- Maximum attainable upstream and downstream net data rates
- Interleaving delay

### Subscriber Services

---

The router receives the service profile for the subscribers from a RADIUS server. Most of the services are enforced by the router itself. The router shapes the aggregate egress traffic to subscribers based on the local loop throughput reported by the DSLAM. This traffic shaping optimizes traffic flow while avoiding traffic drops in the access node.

Some service attributes, such as interleaving delay and multicast channel information, are enforced at the access node. The ANCP agent provides the line configuration mechanism that the edge device can use to pass the line configuration to the access nodes. Typically, multiple profiles are provisioned on the access node. The router instructs the access node which profile to use for a given subscriber.

Subscribers typically receive some combination of voice, data, and video services. Each service can be provisioned on a VLAN. A subscriber might receive only a single service over a single VLAN configured on a logical interface. A group of VLANs carrying services to a subscriber is an *interface set*.

Subscribers have operational states, but they do not have administrative states because they cannot be configured in the CLI.

Subscribers have one of the following operational states which represent the DSL line state as it is reported in the ANCP Port Up and Port Down messages sent by an access node:

- Idle—Ports are not configured and the subscriber cannot log in.

- Silent—Ports are configured and the subscriber is connected, but the DSL modem is not ready to transfer data.
- Showtime—Ports are configured, the subscriber is connected, and the DSL modem is online and ready to transfer data.

**NOTE:** For information about ANCP for business subscribers and services, see *Layer 2 Wholesale with ANCP-Triggered VLANs Overview*.

---

### ANCP Interfaces and Access Loop Circuit Identifiers

---

The access loop or access line in an ANCP topology consists of the physical elements between the subscriber device (CPE) and the access node. An identifier associated with the access loop serves to identify the subscriber as well. This identifier is an alphanumeric string that actually identifies the interface on the DSLAM from which subscriber requests originate. It can be referred to by various names.

- In ANCP messages, a TLV carries the access loop circuit ID, also referred to as the access line identifier, access loop circuit identifier, or access identifier.
- DHCP discovery packets can identify the line with the Agent Circuit ID suboption in the Option 82 field.
- PPPoE discovery packets can identify the line with the Agent-Circuit-ID subattribute in the DSL Forum vendor-specific tag.

Each of these identifiers is abbreviated as ACI. When the ANCP agent receives a port management message from an access node, it uses the access loop circuit identifier contained in the message to determine which logical interface or interface set corresponds to the subscriber.

You can associate an identifier with an ANCP access line by static configuration. When you configure a logical interface by specifying the interface name at the **[edit protocols ancp interfaces]** hierarchy level, include the **access-identifier** statement to associate the access loop circuit identifier with the interface. When you configure an interface set by including the **interface-set** statement at the **[edit protocols ancp interfaces]** hierarchy level, associate the access loop circuit identifier with the interface set by including the **access-identifier** statement at the **[edit protocols ancp interfaces interface-set interface-set-name]** hierarchy level.

When the DHCP or PPPoE discovery packet includes an ACI, the ANCP agent can dynamically map the ACI to the subscriber interface or interface set. VLANs for the subscribers are created according to a dynamic profile; these are called agent circuit identifier-based or ACI-based dynamic VLANs.

ANCP agent support for RADIUS authentication and accounting requires that both static and dynamic ACIs must be unique across the network. No two interfaces across multiple neighbors (access nodes) can share the same identifier. The DHCP and PPPoE processes do not have information about the access node IP addresses and consequently cannot distinguish between duplicate identifiers. This situation prevents the AAA services

framework from correlating a DHCP or PPPoE client session with an access line for RADIUS authentication and accounting.

### Mapping Access Lines to Interfaces and Interface Sets

---

The ANCP agent maps the ACI for subscriber access lines to an interface or interface set to apply DSL attributes received from the access node to CoS traffic shaping for the access line. The access line mapping can be statically configured with the `access-identifier` statement, or dynamically derived during subscriber authentication. Static mapping always supersedes dynamic mapping.

The ANCP agent can remap an access line to a different interface or interface set than its original mapping. Remapping can also be static or dynamic. For example, an access line might be first dynamically mapped to a subscriber interface and then statically configured to an interface set.

You can statically configure mapping with the statement only for interface and interface set types that have configured or deterministic names:

- Static VLAN interfaces
- Static VLAN demux interfaces
- Static interface sets
- Dynamic interface sets
- Dynamic VLAN-tagged interface sets

Static configuration with the statement is required for mapping an access line to static interface sets, dynamic interface sets, and dynamic VLAN-tagged interface sets. This is true regardless of the presence of an ACI in the PPPoE or DHCP IP demux subscriber's discovery packet, because the use of the ACI is irrelevant to the creation of these types of interface sets.

You cannot statically configure mapping with the statement for the following interface and interface set types, because they have nondeterministic, automatically generated names:

- Dynamic VLAN demux interfaces
- Dynamic ACI interface sets (ACI VLANs)
- Dynamic PPPoE and DHCP IP demux subscriber interfaces

In the context of Layer 2 wholesale services, the ANCP agent can map access lines to dynamic VLAN demux interfaces that have Ethernet-VPLS encapsulation. The ANCP agent triggers the creation of these interfaces with the ANCP Port UP message, which always includes the ACI for the access line. The agent can then dynamically map the interface to an access line for CoS traffic shaping.

Dynamic mapping works as follows:

- If the subscriber interface is a member of an interface set, the ANCP agent maps the ACI for the access line to the interface set.

- If the subscriber interface is not a member of an interface set, the ANCP agent maps the ACI for the access line to the subscriber interface.

The ANCP agent does not support static or dynamic mapping for the following interface types, regardless of the presence of the access line's ACI in the subscriber's discovery packet:

- Static VLAN interfaces created by ESSM.
- Static VLAN demux interfaces created by ESSM.
- Dynamic VLAN interfaces.
- Dynamic VLAN demux interfaces that do not have Ethernet-VPLS encapsulation.

### ANCP Neighbors

---

The ANCP agent can report traffic only for access nodes that are configured as ANCP neighbors (also referred to as ANCP peers). Neighbors can establish TCP connections with the router. Include the **neighbor** statement at the **[edit protocols ancp]** hierarchy level to configure an access node as an ANCP neighbor.

The ANCP agent exchanges adjacency messages with neighbors. If an adjacency message is not received from a neighbor within the expected period, then the neighbor is considered to be down and is disconnected. You can adjust how long the ANCP agent waits for adjacency messages from all neighbors by including the **adjacency-timer** statement at the **[edit protocols ancp]** hierarchy level. The interval between adjacency messages is negotiated between router and the neighbor during adjacency establishment. The larger of two timer values—either the value received in the ANCP SYN message or the configured value—is selected. Loss of synchronization between the router and a neighbor is declared when no valid messages are received for a period of time that exceeds three times the negotiated value.

#### NOTE:

The ANCP TCP connection is not established and consequently ANCP neighbors do not come up in either of the following circumstances:

- When the neighbor address (numbered or unnumbered) has a /32 mask.
- When the unnumbered local address for ANCP dynamic logical interfaces is configured to use a preferred source address.

---

ANCP neighbors have one of the following administrative states, which simply represent the configuration of the neighbor:

- enabled—The neighbor is configured in the CLI.
- disabled—The neighbor is not configured, meaning either that it has never been configured or that the configuration has been deleted.

ANCP neighbors in the enabled state have one of the following operational states, which represent the state of adjacency negotiations:

- **Configured**—The neighbor has been configured, but has never established an adjacency.
- **Establishing**—Adjacency negotiations are in progress.
- **Established**—Adjacency negotiations have succeeded and an ANCP session has been established.
- **Not Established**—The neighbor has lost a previously established adjacency, but is ready to begin negotiations.

You can also configure parameters for a specific neighbor that override global or default configurations by including any of the following statements at the **[edit protocols ancp neighbor ip-address]** hierarchy level:

- **adjacency-timer**—Adjust the interval between adjacency messages exchanged with this neighbor.
- **ietf-mode**—Prevent the ANCP agent from operating in a backward-compatible mode for this neighbor; for neighbors that use the current IETF implementation of ANCP.
- **maximum-discovery-table-entries**—Specify how many discovery table entries are accepted from this neighbor. Include this statement at the **[edit protocols ancp]** hierarchy level to set the number of entries globally for all neighbors.
- **pre-ietf-mode**—Enable the ANCP agent to operate in a backward-compatible mode for this neighbor; for neighbors that use the original IETF implementation of ANCP (GSMPv2) rather than the current implementation. Include this statement at the **[edit protocols ancp]** hierarchy level to operate in backward-compatible mode globally for all neighbors.

*RFC 6320, Protocol for Access Node Control Mechanism in Broadband Networks*, defines ANCP Version 1. ANCP was originally implemented based on General Switch Management Protocol (GSMP) version 3, sub-version 1. However, the Internet community has made so many extensions and modifications to GSMPv3 in the course of developing ANCP that ANCP is no longer interoperable with GSMPv3. Consequently, ANCP neighbors must be able to dynamically detect the version that each peer supports. A joint registry codifies the GSMP and ANCP version numbers.

When an ANCP neighbor opens adjacency negotiations, it indicates the highest version of ANCP that it supports, either 0x31 for GSMPv3 or 0x32 for ANCP Version 1. (Version 1 may also be called Version 50, referring to the decimal conversion from the hexadecimal value.) If the receiving neighbor supports that version of ANCP, it returns that value when it responds to the sending neighbors. If it does not support that version, the receiving neighbor simply drops the message.

The ANCP agent stores information about active ANCP subscribers in the Junos shared database, including DSL attributes for the access lines. This storage is persistent and is removed from the database only when you delete the interface or interface set for the access line or issue one of the following commands:

- **clear ancp neighbor**

- **clear ancp subscriber**

The persistence of the storage enables PPPoE and DHCP IP demux subscribers to be properly managed by RADIUS for authentication and accounting, with their DSL attributes, even when the ANCP connection has been temporarily terminated.

### Partitions

---

ANCP supports the division of an access node into logical partitions. Each partition creates an adjacency with a router; each partition on an access node can form adjacencies with different routers. Partition negotiation takes place during ANCP adjacency negotiation. ANCP messages carry the following fields relating to the partition negotiation:

- The partition type (PType) field indicates whether the access node is partitioned and how the partition identifier is negotiated. The field has one of the following values negotiated during the formation of the adjacency:
  - 0—The access node is not partitioned or does not support partitions.
  - 1—The number of partitions is fixed and the router requests the access node to use the identifier it places in the partition identifier field.
  - 2—The number of partitions is fixed and the access node has assigned the partition identifier.
- The partition ID field that indicates one of the following scenarios for ANCP agent support of the neighbor:
  - Zero partition ID—The ANCP agent supports each neighbor on an IP address over a single TCP session with a partition ID of zero. This is the default support case. This value is required when the partition type is zero.
  - Single nonzero partition ID—The ANCP agent supports each neighbor on an IP address over a single TCP session with a nonzero partition ID. This case requires partition ID learning to be enabled with the **gsmp-syn-wait** statement at the **[edit protocols ancp]** hierarchy level.
- The partition flag (PFlag) field indicates the type of partition request being made. A value of one specifies a new adjacency.

The following partitioning schemes are supported

- Each partition has an independent ANCP session and channel to an adjacent router. All partitions have a fixed partition ID of zero.
- Each partition has an independent ANCP session and channel to an adjacent router. Each partition has a dedicated, nonzero partition ID.

### Adjacency Update Messages

---

After an adjacency has been established, the ANCP agent uses adjacency update messages to inform routers that control the same partition about each other. Once more than one router has established an adjacency to a given partition, the ANCP agent sends an adjacency update message to each of these routers to report how many established

adjacencies the partition currently supports. When an adjacency is lost, an update message is sent to the remaining routers to report the change in status. You can use the **show ancp neighbor detail** command to display the number of adjacencies currently established on a particular partition.

### Generic Response Messages and Result Codes

ANCP neighbors and the router can reply to messages either with a specific response message or a generic response message. A generic response message is typically sent when no information needs to be sent to the peer other than a success or failure result. If the response is about a failure, then a result code is included that specifies the kind of failure; a limited amount of diagnostic data can also be included. A generic response message can also be sent independently of a request if the adjacency is being shut down because of the failure. In this case, the sender of the message zeros out the Transaction ID field in the message header and the Message Type field in the Status-Info TLV.

Table 49 on page 605 describes the result codes that can be included in a generic response message.

**Table 49: ANCP Failure Result Codes**

| Code Value | Description                                                                                                                                                                                                      | Detected By                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| 0x02       | Although the request message is properly formed, it is invalid because it violates the protocol, either because of timing issues such as a race condition or the direction in which the message was transmitted. | ANCP agent                                                       |
| 0x06       | One or more of the specified ports is down because of a state mismatch between the router and an ANCP control application.                                                                                       | Control applications (none yet available)                        |
| 0x13       | ANCP is out of resources. This result code is sent only by the access node; the problem is probably not related to the access lines, but can be related to a specific request.                                   | ANCP protocol layer or control applications (none yet available) |
| 0x51       | The type of request message is not implemented because of a mismatch in protocol versions or capability state between the peers, or possibly because the message type is optional for an ANCP capability.        | ANCP agent                                                       |
| 0x53       | The message is malformed either because it was corrupted in transit or an implementation error occurred at one end of the connection.                                                                            | ANCP agent                                                       |
| 0x54       | One or more mandatory TLVs is missing from the request.                                                                                                                                                          | ANCP agent                                                       |

Table 49: ANCP Failure Result Codes (continued)

| Code Value | Description                                                                                                                                                 | Detected By                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| 0x55       | The contents of one or more TLVs in the request are invalid because they do not match the TLV specification.                                                | ANCP agent                                |
| 0x500      | One or more of the ports specified in a request does not exist, possibly because of a configuration mismatch between the access node and the router or AAA. | Control applications (none yet available) |

**NOTE:** Although Junos OS supports both sending and receiving generic response messages, currently the ANCP agent only receives these messages. When one of these messages is received, the router generates a system log, increments the generic message counters, and increments the result code counters. When the ANCP agent receives an incorrect or unexpected generic response message from an ANCP neighbor, it immediately drops the packet, generates a system log notice message, and takes no further action.

Generic response messages usually include the Status-Info TLV, which includes supplemental information about a warning or error condition. The Status-Info TLV is required when the result code indicates any of the following: a port is down or does not exist, a mandatory TLV is missing, or a TLV is invalid. The Status-Info TLV can also be included in other ANCP message types.

## ANCP Operations in Different Network Configurations

This topic describes different types of supported network configurations and the sequence of events for ANCP operations in representative sample network topologies.

You can configure the ANCP agent for any of the following interface types:

- Static VLAN interfaces, except those created by Extensible Subscriber Services Manager (ESSM)
- Static VLAN demux interfaces, except those created by ESSM
- Static interface sets, including those created by ESSM
- Dynamic interface sets
- Dynamic VLAN-tagged interface sets
- Dynamic agent circuit identifier (ACI) interface sets, also known as ACI sets or ACI VLANs

- Dynamic PPPoE and DHCP IP demux subscriber interfaces
- Dynamic VLAN demux interfaces with Ethernet-VPLS encapsulation

Subscriber sessions are dynamically created as needed for each of the devices in a household. Each household can include multiple CPE devices that access the Internet. In all cases, each household is identified by a unique ACI that is assigned by the access node. Additional identifiers are used in some configurations.

### 1:1 and N:1 Traffic Shaping Models

The 1:1 and N:1 traffic shaping models determine how VLANs are correlated with households. These models are also referred to as access models or configuration models. A network can include one or both of the models:

- 1:1 model—A household has only one PPPoE or DHCP IP demux subscriber session. One or more such households can exist on a single VLAN or VLAN demux interface. In the case of a single household, either the subscriber interface or its underlying VLAN or VLAN demux interface can represent the household. In the case of multiple households, the corresponding subscriber interfaces represent the households. In either case, the interface representing a household must be mapped to the ACI for its access line.

[Table 50 on page 607](#) describes the types of interfaces supported for the ANCP 1:1 access model when interface sets are not involved, and whether the PPPoE or DHCP IP demux discovery packets must include the ACI for the subscriber access lines.

**Table 50: ACI Mapping by Interface Type for the ANCP 1:1 Model**

| Interface Type                           | Description                                                                                                                                                                      | Presence of ACI in Discovery Packets |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Dynamic PPPoE or DHCP IP demux interface | When ACI is present in discovery packets, the ANCP agent maps the ACI to the subscriber interface. The name of the interface is automatically generated and nondeterministic.    | Required.                            |
| Static VLAN or VLAN demux interface      | The name of the interface is statically configured. The ANCP agent configuration must include the <b>access-identifier</b> statement to statically map the ACI to the interface. | Not present.                         |

- N:1 model—A household can have more than one PPPoE or DHCP IP demux subscriber session. The household can have more than one VLAN or VLAN demux interface. In either case, all the interfaces must be grouped into an interface set. The interface set in turn must be mapped to the ACI for the household's access line.

An interface set groups the dynamic PPPoE or DHCP IP demux sessions for a household. The subscribers are placed into interface sets by one several methods.

[Table 51 on page 608](#) describes the types of interface sets supported in the ANCP N:1 access model, how they are created, and how the ACI is mapped to the interface set.

**Table 51: ACI Mapping by Interface Set Type for the ANCP N:1 Access Model**

| Type of Interface Set         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Interface Type                                                                        | Presence of ACI in Discovery Packets |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|--------------------------------------|
| ACI-based VLAN interface sets | <p>When the router receives a DHCP or PPPoE discovery packet that includes an ACI embedded within the DSL Forum vendor-specific tag, it dynamically creates the VLAN and the interface set. The router generates a nondeterministic name for the interface set, such as aci-1003-ge-1/0/0.1073741832.</p> <p>The ANCP agent automatically maps the ACI from the discovery packet to the dynamically created interface set.</p> <p>All DHCP IP demux or PPPoE sessions that have the same ACI are mapped to the same interface set.</p>                                                                                                         | Dynamic VLAN and VLAN demux interfaces.                                               | Required.                            |
| Dynamic interface sets        | <p>A dynamic profile dynamically creates the interface set and places interfaces in the set. The profile can either have the name of the interface set explicitly configured or a variable that represents the interface set name. If a variable is used, then the interface set name is provided by RADIUS when it returns an Access-Accept message for the subscriber.</p> <p>The ANCP agent configuration must include the <b>access-identifier</b> statement to statically map the ACI to the interface set.</p> <p>All DHCP IP demux and PPPoE sessions are mapped to an interface set according to the rules of the dynamic profile.</p> | DHCP IP demux subscriber interfaces, PPPoE subscriber interfaces, or VLAN interfaces. | Irrelevant.                          |
| Static interface sets         | <p>The interface set and set name are statically configured and include multiple static interfaces.</p> <p>The ANCP agent configuration must include the <b>access-identifier</b> statement to statically map the ACI to the interface set.</p>                                                                                                                                                                                                                                                                                                                                                                                                | Static VLAN and VLAN demux interfaces.                                                | Irrelevant.                          |
| VLAN-tagged interface sets    | <p>When the router receives a DHCP or PPPoE discovery packet that includes a VLAN ID, it dynamically creates the VLAN and the interface set. The interface set is given a deterministic name consisting of the physical interface name and the VLAN tags, for example, ge-1/0/0-101.</p> <p>The ANCP agent configuration must include the <b>access-identifier</b> statement to statically map the ACI to the interface set.</p> <p>All DHCP IP demux or PPPoE sessions that have the same VLAN ID tag are mapped to the same interface set.</p>                                                                                               | Dynamic VLAN and VLAN demux interfaces.                                               | Irrelevant.                          |

CoS traffic shaping is based on the subscriber downstream traffic rate that the ANCP agent receives from the access node and then passes to CoS. CoS can shape subscriber traffic at the level of the household or the session:

- Household shaping—Only aggregate traffic to the household is shaped. Household shaping results from applying a CoS traffic-control profile to the static VLAN or VLAN demux interface or to the interface set.

- Session shaping—The traffic rate to individual devices in the household is shaped. Session shaping results from specifying a CoS traffic-control profile in the dynamic PPPoE profile that creates the subscriber session. Depending on the network configuration, session shaping may employ shared priority queues to shape all sessions identically or individual priority queues to shape the sessions separately.

### Business Services Traffic Shaping Model

---

In addition to the N:1 and 1:1 traffic shaping models, the ANCP agent also supports a business services traffic shaping model. In this model, the Extensible Subscriber Services Manager (ESSM) classifies a PPPoE session as either residential household or business subscriber. Classification occurs during RADIUS authentication and authorization. The ANCP agent applies CoS traffic shaping differently depending on the classification.

Before RADIUS authentication and authorization, the PPPoE session represents a residential household in the ANCP 1:1 model. The ANCP agent dynamically maps the household's access line to the corresponding subscriber interface and applies CoS traffic shaping to that interface. The household line's ACI is present in the PPPoE discovery packet.

When ESSMD subsequently classifies a PPPoE session as a business subscriber session during RADIUS authentication and authorization, it creates and groups multiple management and data plane static VLAN interfaces into a static interface set. then it statically maps the access line for the PPPoE session to this interface set according to the CLI configuration. The ANCP agent removes CoS traffic shaping from the subscriber interface and applies it to the static interface set. Removing the CoS traffic shaping means that the CoS application applies the next rate in its default or configured adjustment control profile to the interface or interface set. The new business subscriber interface set cannot contain a mix of static and dynamic interfaces. That prohibition is not limited to dynamic VLANs and the PPPoE session that triggered the creation of the interface set.

**NOTE:** An exception to the ANCP agent's general support for CoS traffic shaping and RADIUS authentication and accounting on static VLAN and VLAN Demux interfaces is that it does not support these interfaces if they are created by ESSM. These interfaces are different from the ESSM-created interface sets, which are supported by the ANCP agent.

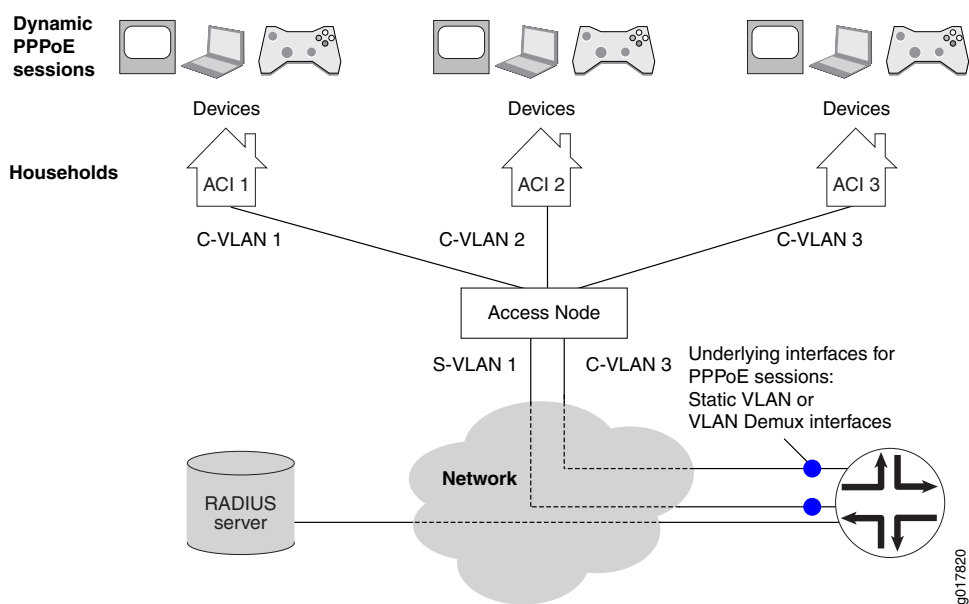

From the perspective of the ANCP agent, the business services model effectively overrides a dynamically derived access-line-to-interface mapping with a statically configured access-line-to-interface-set mapping. This action triggers the ANCP agent to reapply CoS traffic shaping accordingly.

The business services model is typically used in a Layer 2 wholesale network. For detailed information, see *Layer 2 Wholesale with ANCP-Triggered VLANs Overview*.

### ANCP Network Using N:1 and 1:1 Configuration Models without Interface Sets

In this sample topology, two households are configured for one underlying static VLAN or VLAN demux interface (N:1; dual-tagged VLAN) and a single household is configured for another underlying interface (1:1; single-tagged VLAN) (Figure 26 on page 610). In addition to the unique ACI assigned by the access node, each household is further identified by the VLAN, which is mapped to the identifier in the ANCP agent configuration. CoS traffic shaping for sessions can employ only shared priority queues to shape all sessions identically; individual priority queues to shape the sessions separately are not supported.

Figure 26: Sample ANCP Topology Without Interface Sets (1:1 and N:1 Model)

### Sequence of ANCP Events: Static VLAN or VLAN Demux Interfaces over Ethernet Without Interface Sets

---

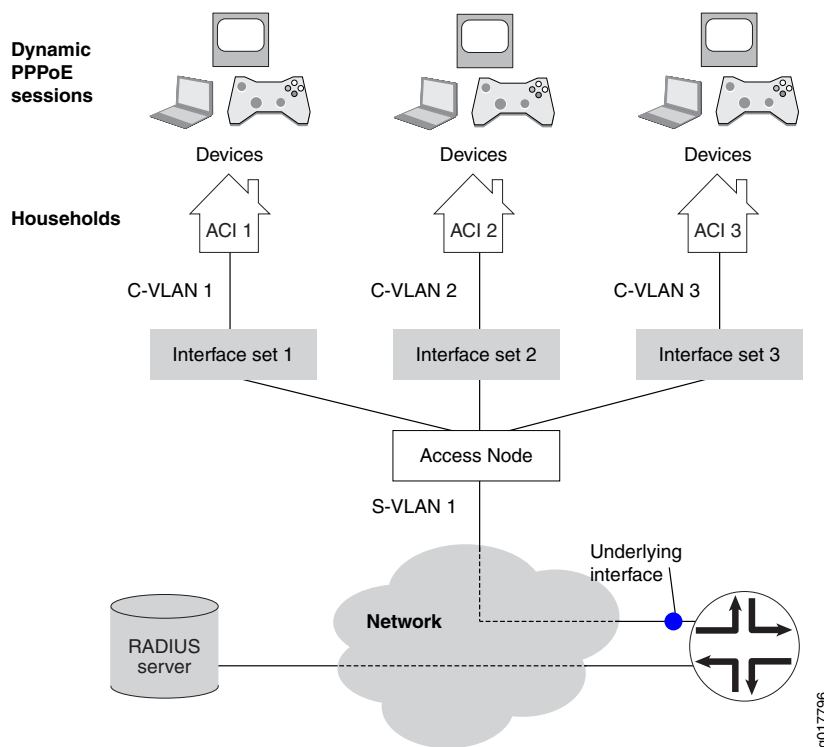

The following sequence of events is for the topology in [Figure 26 on page 610](#) with static VLAN interfaces over Ethernet without interface sets.

1. A network device in the household initiates PPPoE discovery.
2. PPPoE creates a dynamic PPPoE session on the underlying static VLAN or VLAN demux interface and applies the advisory options configured on the VLAN to the session.
3. The access node independently provides the ANCP agent with the ANCP DSL attributes for an access line identified by an ACI.
4. The ANCP agent sends CoS the adjusted downstream data rate for the static VLAN or demux VLAN mapped to the ACI. The ANCP agent stores all DSL attributes, including the adjusted upstream data rate, in the router's shared database.
5. AAA correlates the dynamic PPPoE session with the access line by matching the underlying interface of the session to the static VLAN or VLAN demux interface associated with the ACI in the ANCP agent configuration.
6. AAA retrieves the ANCP DSL attributes for the access line from the router's shared database and maps them to the Juniper Networks DSL VSAs in the RADIUS Access-Request and Accounting-Request messages. If the DSL attributes are unavailable, the session's advisory upstream and downstream data rates are mapped to the Upstream-Calculated-Qos-Rate VSA (26-142) and Downstream-Calculated-Qos-Rate (26-141) VSAs, respectively. These VSAs are then included in the RADIUS messages.

### ANCP Network Using N:1 Configuration Model with Interface Sets

In this topology, multiple households are configured for each underlying static VLAN or VLAN demux interface (Figure 27 on page 612). The VLANs are dual-tagged. Each household includes several CPE devices that access the Internet. In addition to the unique ACI assigned by the access node, the household is further identified by the interface set. The interface set groups the dynamic PPPoE sessions for the individual subscriber devices. It is either explicitly configured in the dynamic PPPoE profile or specified in the RADIUS Access-Accept message during PPPoE session authentication. Session shaping can employ shared priority queues to shape all sessions identically or individual queues to shape the sessions separately.

Figure 27: Sample ANCP Topology with Interface Sets (N:1 Model)

In this N:1 model with interface sets, the access node must add the DSL Forum VSA to the PPPoE PADI and PADR discovery packets that it passes to the router during the establishment of dynamic PPPoE sessions. The VSA includes the ACI for the household. This inclusion enables AAA to correlate the PPPoE sessions with their respective subscriber access lines and DSL attributes during RADIUS authentication and accounting. If the ACI is not present, AAA cannot make the correlation and subsequently reports only the advisory upstream and downstream data rates to RADIUS Authentication and Accounting.

When the dynamic PPPoE profile is configured with the **\$junos-interface-set-name** predefined variable, the configuration of the access node, router, and RADIUS server must be synchronized with regard to the ACI and interface set:

- The RADIUS Access-Accept message must contain the Juniper Networks Qos-Interface-Set-Name VSA (26-130).
- The CoS Layer 2 configuration must explicitly identify the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).
- The ANCP agent configuration must map an ACI to the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).

### Sequence of ANCP Events: Static VLAN Interfaces over Ethernet with Interface Sets

---

The following sequence of events is for the topology in [Figure 27 on page 612](#) with static VLAN interfaces over Ethernet with interface sets.

1. A network device in the household initiates PPPoE discovery.
2. The access node adds the DSL Forum VSA tag with the ACI for the household to the PPPoE PADI and PADR discovery packets. (The identifier is known to PPPoE as the agent circuit identifier.)
3. PPPoE creates a dynamic PPPoE session with the provided ACI on the underlying static VLAN and applies the advisory options configured on the VLAN to the session.
4. The access node independently provides the ANCP agent with the ANCP DSL attributes for an access line identified by an ACI.
5. The ANCP agent provides CoS with the adjusted downstream data rate for the interface set mapped to the ACI. The ANCP agent stores all ANCP DSL attributes, including the adjusted upstream and downstream data rates, in the router's shared database.
6. AAA correlates the dynamic PPPoE session with the access line by matching the session identifier received in the DSL Forum VSA to the ACI configured for the interface set in the ANCP agent configuration.
7. AAA retrieves the ANCP DSL attributes for the access line from the router's shared database and maps them to the Juniper Networks DSL VSAs in the RADIUS Access-Request and Accounting-Request messages. If the DSL attributes are unavailable, the session's advisory upstream and downstream data rates are mapped to the Upstream-Calculated-Qos-Rate VSA (26-142) and

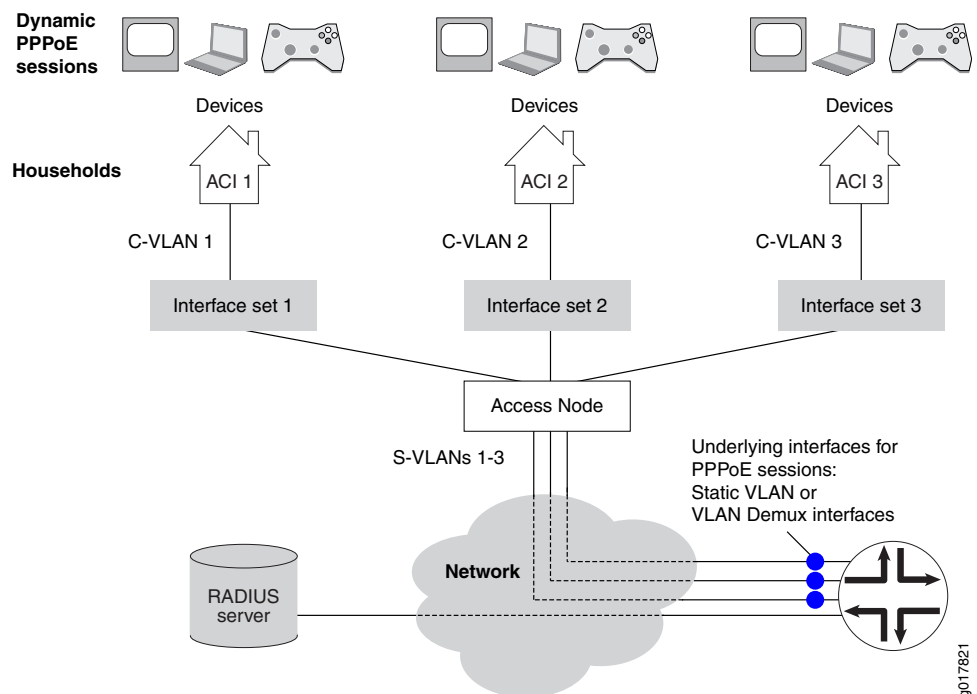

Downstream-Calculated-Qos-Rate (26–141) VSAs, respectively. These VSAs are then included in the RADIUS messages.

8. When authentication is completed, the dynamic PPPoE session is placed into the interface set configured in the dynamic PPPoE profile. The profile specifies a named interface set or the `$junos-interface-set-name` predefined variable, which indicates that the interface set is named in the RADIUS Access-Accept message.

### ANCP Network Using 1:1 Configuration Model with Interface Sets

In this topology, a single household is configured for each underlying static VLAN or VLAN demux interface (Figure 28 on page 614). The VLANs are dual-tagged. Each household includes several CPE devices that access the Internet. In addition to the unique ACI assigned by the access node, the household is further identified by the interface set. The interface set is either explicitly configured in the dynamic PPPoE profile or specified in the RADIUS Access-Accept message during PPPoE session authentication. Session shaping can employ shared priority queues to shape all sessions identically or individual queues to shape the sessions separately.

Figure 28: Sample ANCP Topology with Interface Sets (1:1 Model)

In this 1:1 model with interface sets, the ANCP agent configuration must map the underlying interface for the PPPoE sessions in an interface set to both the ACI and the interface set. This configuration enables AAA to correlate the PPPoE sessions with their respective subscriber access lines and DSL attributes during RADIUS authentication and accounting.

When the dynamic PPPoE profile is configured with the **\$junos-interface-set-name** predefined variable, the configuration of the access node, router, and RADIUS server must be synchronized with regard to the ACI and interface set:

- The RADIUS Access-Accept message must contain the Juniper Networks Qos-Interface-Set-Name VSA (26-130).
- The CoS Layer 2 configuration must explicitly identify the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).
- The ANCP agent configuration must map an ACI to the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).

### Sequence of ANCP Events: Static VLAN Demux Interfaces over Aggregated Ethernet with Interface Sets

---

The following sequence of events is for the topology in [Figure 28 on page 614](#) with static VLAN demux interfaces over aggregated Ethernet with interface sets.

1. A network device in the household initiates PPPoE discovery.
2. PPPoE creates a dynamic PPPoE session with the provided ACI on the underlying static VLAN demux interface and applies the advisory options configured on the VLAN to the session.
3. The access node independently provides the ANCP agent with the ANCP DSL attributes for an access line identified by an ACI.
4. The ANCP agent provides CoS with the adjusted downstream data rate for the interface set mapped to the ACI. The ANCP agent stores all ANCP DSL attributes, including the adjusted upstream and downstream data rates, in the router's shared database.
5. AAA correlates the dynamic PPPoE session with the access line by matching the underlying interface of the session to the underlying interface configured for the interface set in the ANCP agent configuration.
6. AAA retrieves the ANCP DSL attributes for the access line from the router's shared database and maps them to the Juniper Networks DSL VSAs in the RADIUS Access-Request and Accounting-Request messages. If the DSL attributes are unavailable, the session's advisory upstream and downstream data rates are mapped to the Upstream-Calculated-Qos-Rate VSA (26-142) and Downstream-Calculated-Qos-Rate (26-141) VSAs, respectively. These VSAs are then included in the RADIUS messages.
7. When authentication is completed, the dynamic PPPoE session is placed into the interface set configured in the dynamic PPPoE profile. The profile specifies a named interface set or the **\$junos-interface-set-name** predefined variable, which indicates that the interface set is named in the RADIUS Access-Accept message.

## Configuring the ANCP Agent

You can configure the ANCP agent to enable a service-oriented Layer 3 edge device to discover information about the topology of a connected access network. The ANCP agent can also provide details about subscriber traffic and enable the adjustment of QoS traffic shaping for subscribers.

To configure the ANCP agent:

1. Specify each ANCP neighboring access node to be monitored and optionally configure neighbor parameters.

See [“Configuring ANCP Neighbors” on page 617](#).

2. Specify the subscribers reached by a VLAN or a set of VLANs through a particular access node.

See [“Associating an Access Node with Subscribers for ANCP Agent Operations” on page 619](#).

3. (Optional) Configure the adjacency timer.

See [“Specifying the Interval Between ANCP Adjacency Messages” on page 620](#).

4. (Optional) Specify the maximum number of discovery table entries that are accepted.

See [“Specifying the Maximum Number of Discovery Table Entries” on page 620](#).

5. (Optional) Configure the ANCP agent to work with an early IETF draft.

See [“Configuring the ANCP Agent for Backward Compatibility” on page 621](#).

6. (Optional) Configure the graceful restart timer.

See [“Specifying How Long Processes Wait for the ANCP Agent Restart to Complete” on page 621](#).

7. (Optional) Configure the ANCP agent to learn partition IDs from neighbors.

See [“Configuring the ANCP Agent to Learn ANCP Partition IDs” on page 622](#).

8. (Optional) Configure an adjustment factor per DSL line type for the downstream and upstream data rates that the ANCP agent reports to AAA.

See [“Setting a Global Adjustment Factor per DSL Subscriber Line for ANCP Agent-Reported Traffic Rates” on page 654](#).

9. (Optional) Configure the ANCP agent to report unadjusted downstream traffic rates to CoS.

See [“Configuring the ANCP Agent to Report Traffic Rates to CoS” on page 650](#).

10. (Optional) Specify a recommended shaping rate to be applied by RADIUS to downstream or upstream traffic per ANCP interface.

See [“Setting a Recommended Shaping Rate for Traffic on ANCP Interfaces” on page 652.](#)

11. (Optional) Configure AAA to Include or Exclude Juniper Networks DSL VSAs in RADIUS authentication and accounting messages.

See [“Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages” on page 660.](#)

12. (Optional) Configure AAA to send an immediate interim accounting update to the RADIUS server when AAA receives a rate change notification from the ANCP agent on the router.

See [“Configuring Immediate Interim Accounting Updates to RADIUS in Response to ANCP Notifications” on page 661.](#)

13. (Optional) Configure the ANCP agent to associate a neighbor with an access-facing physical interface for the creation of autosensed dynamic VLANs on the interface.

See *Configuring the ANCP Agent for ANCP-Triggered, Autosensed Dynamic VLANs.*

14. (Optional) Configure the ANCP agent to dampen the effect of short-term adjacency losses for all neighbors.

See *Configuring the ANCP Agent to Dampen the Effects of Short-Term Adjacency Losses.*

15. (Optional) Configure trace options for troubleshooting the configuration.

See *Tracing ANCP Agent Operations for Subscriber Access.*

## Configuring ANCP Neighbors

You must configure each neighboring access node that you want the ANCP agent to monitor and potentially shape traffic for. Some neighbor settings override globally configured values.

To configure an ANCP neighbor:

1. Specify the IP address of the neighbor.

```
[edit protocols ancp]
user@host# set neighbor 203.0.113.234
```

2. (Optional) Configure the neighbor to operate in a backward-compatible mode when it does not support the current IETF standard and the backward-compatible mode is not configured globally.

```
[edit protocols ancp neighbor 203.0.113.234]
```

```
user@host# set pre-ietf-mode
```

3. (Optional) Override the globally configured backward-compatible mode when the neighbor supports the current IETF standard.

```
[edit protocols ancp neighbor 203.0.113.234]  
user@host# set ietf-mode
```

4. (Optional) Configure the interval in seconds between ANCP adjacency messages exchanged with this neighbor.

```
[edit protocols ancp neighbor 203.0.113.234]  
user@host# set adjacency-timer 20
```

5. (Optional) Specify the maximum number of discovery table entries that are accepted from this neighbor.

```
[edit protocols ancp neighbor 203.0.113.234]  
user@host# set maximum-discovery-table-entries 10000
```

6. (Optional) Enable out-of-band ANCP triggering of autosensed, dynamic VLANs on the physical interface.

```
[edit protocols ancp neighbor 203.0.113.234]  
user@host# set auto-configure-trigger interface ge-1/0/0
```

7. (Optional) Configure how long the ANCP agent maintains a Layer 2 wholesale session when an adjacency loss occurs.

```
[edit protocols ancp neighbor 203.0.113.234]  
user@host# set adjacency-loss-hold-time 10
```

## Associating an Access Node with Subscribers for ANCP Agent Operations

The ANCP agent on the router uses the access loop circuit identifier (ACI) to distinguish individual ANCP subscribers. Because the agent uses the ACI to associate (map) each subscriber to an interface or interface set, each ACI must be unique across all ANCP neighbors connected to the router.

**BEST PRACTICE:** We recommend that the ACIs be unique across your ANCP network.

Access lines can be statically or dynamically mapped to interfaces or interface set. When the subscriber's DHCP or PPPoE discovery packets contain the ACI, then the agent can dynamically map it to the interface or interface set. Otherwise, the ACI must be statically configured. A static configuration overrides dynamic mapping of ACIs—and therefore subscribers—to interfaces or sets.

You can use the **access-identifier** statement only for interface and interface set types that have configured or deterministic names: static VLAN interfaces, static VLAN demux interfaces, static interface sets, dynamic interface sets, and dynamic VLAN-tagged interface sets.

The **access-identifier** statement is required for mapping an access line to static interface sets, dynamic interface sets, and dynamic VLAN-tagged interface sets. This is true regardless of the presence of an ACI in the PPPoE or DHCP IP demux subscriber's discovery packet, because the use of the ACI is irrelevant to the creation of these types of interface sets.

You cannot use the **access-identifier** statement for the following interface and interface set types, because they have nondeterministic, automatically generated names: dynamic VLAN demux interfaces, dynamic ACI interface sets (ACI VLANs), and dynamic PPPoE and DHCP IP demux subscriber interfaces.

To associate an ACI with a set of VLAN interfaces for subscribers:

- Specify the name of the interface set and the unique ACI for the access node.

```
[edit protocols ancp interfaces]
user@host# set interface-set vlan5 access-identifier "dslam port 2/3"
```

To associate an ACI with a single VLAN:

- Specify the logical interface and the unique ACI for the access node.

```
[edit protocols ancp interfaces]
user@host# set ge-1/0/4.12 access-identifier "dslam port-2-10"
```

To associate an ACI with a static VLAN demux interface:

- Specify the logical interface and the unique ACI for the access node.

```
[edit protocols ancp interfaces]
user@host# set demux0.100 access-identifier aci_100_1_0
```

## Specifying the Interval Between ANCP Adjacency Messages

When the ANCP agent and a neighbor negotiate to establish an adjacency, each proposes a value for the interval between the adjacency messages that they exchange after it is established. The larger of the values proposed by the agent and the neighbor is selected for the interval between subsequent adjacency messages exchanged by the agent and the neighbor. You can specify the interval value that the ANCP agent proposes for either all neighbors or a specific neighbor.

To configure the proposed interval between ANCP adjacency messages for all neighbors:

- Specify the time in seconds.

```
[edit protocols ancp]
user@host# set adjacency-timer 20
```

To configure the proposed interval between ANCP adjacency messages for a specific neighbor:

- Specify the time in seconds.

```
[edit protocols ancp neighbor 203.0.113.234]
user@host# set adjacency-timer 20
```

## Specifying the Maximum Number of Discovery Table Entries

You can specify the maximum number of discovery table entries accepted from all neighbors or from a particular neighbor.

To configure the maximum number of entries for all neighbors:

- Specify the number of entries.

```
[edit protocols ancp]
user@host# set maximum-discovery-table-entries 5000
```

To configure the maximum number of entries for a specific neighbor:

- Specify the number of entries.

```
[edit protocols ancp neighbor 203.0.113.234]
user@host# set maximum-discovery-table-entries 5000
```

## Configuring the ANCP Agent for Backward Compatibility

You can configure the ANCP agent to operate in a mode compatible with the protocol as it was initially proposed to operate. This backward-compatible or pre-IETF mode is compatible with Internet draft *draft-wadhwa-gsmp-l2control-configuration-00.txt*, *GSMP extensions for layer2 control (L2C)*. Setting this backward-compatible mode enables interoperation with devices that are not compatible with the later ANCP Internet drafts or RFC 6320, *Protocol for Access Node Control Mechanism in Broadband Networks*.

When this mode is configured globally for all neighbors, you can override it for a particular neighbor that supports the IETF draft or standard.

To configure the ANCP agent to operate in a backward-compatible mode for all neighbors:

- Specify the pre-IETF mode.

```
[edit protocols ancp]
user@host# set pre-ietf-mode
```

To configure the ANCP agent to operate in a backward-compatible mode for a specific neighbor:

- Specify the pre-IETF mode.

```
[edit protocols ancp neighbor 203.0.113.234]
user@host# set pre-ietf-mode
```

- To override the globally configured backward-compatible mode for a specific neighbor:

Specify the IETF mode.

```
[edit protocols ancp neighbor 203.0.113.234]
user@host# set ietf-mode
```

## Specifying How Long Processes Wait for the ANCP Agent Restart to Complete

You can specify how long other processes wait for the ANCP agent to restart. The ANCP agent sends a keepalive message to CoS at intervals equal to one-third the value of the maximum helper restart time. For example, when you configure the maximum restart time to 120 seconds, the ANCP agent sends a keepalive message every 40 seconds.

If CoS does not receive a keepalive message within the maximum helper restart time, it considers the ANCP agent to be down and immediately reverts any traffic shaping updates that were implemented as a result of ANCP agent monitoring to the configured values. Consequently, traffic to the subscribers is not effectively shaped, potentially resulting in traffic drops in the DSLAMs. The configured values are maintained until the ANCP agent comes back up and sends fresh traffic shaping updates to CoS.

To configure how long other processes wait for the ANCP agent to restart:

- Specify the time in seconds.

```
[edit protocols ancp]
user@host# set maximum-helper-restart-time 150
```

## Configuring the ANCP Agent to Learn ANCP Partition IDs

By default, the ANCP agent expects ANCP partition IDs to be zero, meaning that the access node is not divided into logical partitions that can each form adjacencies with routers. You can configure the ANCP agent to support nonzero partition IDs. When you do so, the agent waits a configurable period to receive a SYN message from a neighbor during adjacency initiation. When the agent receives such a message, it uses the partition information contained in the Partition ID, PType, and PFlag fields to generate in turn a SYN message that it sends to the neighbor to continue adjacency negotiation.

To configure the ANCP agent to learn partition ID information from neighbors:

1. Enable partition ID learning.

```
[edit protocols ancp]
user@host# set gsmp-syn-wait
```

2. (Optional) Specify the maximum time the ANCP agent waits to receive a SYN message from a neighbor during the formation of an adjacency.

```
[edit protocols ancp]
user@host# set gsmp-syn-timeout seconds
```

For example, to enable partition ID learning and force the ANCP agent to wait 45 seconds for a SYN message:

```
[edit protocols ancp]
user@host# set gsmp-syn-wait
user@host# set gsmp-syn-timeout 45
```

## Example: Configuring an ANCP Network with Interface Sets and N:1 Static Demux VLANs over Aggregated Ethernet

This example describes how to configure an ANCP network topology that manages subscriber access for several households by grouping individual devices into interface sets, providing access and services through one dedicated C-VLAN per household, and shaping traffic on a per-household basis. In this N:1 configuration, dual-tagged VLANs are configured over a single, underlying, static VLAN demux interfaces over aggregated Ethernet.

- [Requirements on page 623](#)
- [Overview on page 623](#)
- [Configuration on page 628](#)
- [Verification on page 641](#)

## Requirements

---

This example uses the following hardware and software components:

- MX Series 5G Universal Routing Platform with only MPCs installed for VLAN demux support
- RADIUS server
- DSLAM access node

Before you begin configuring the example, be sure you have:

- Thoroughly read and understood the following topics:
  - [ANCP and the ANCP Agent Overview on page 598](#)
  - [ANCP Operations in Different Network Configurations on page 606](#)
- Configured your access node.
- Configured your RADIUS server.

## Overview

---

ANCP provides a means to configure, maintain, and monitor local access lines between access nodes (DSLAMs) and subscribers. Associated CoS configurations shape the downstream subscriber traffic. ANCP can enable more accurate traffic shaping by adjusting net data rates to discount the packet overhead of the access lines and then providing these adjusted rates to CoS.

The network topology in this example includes a dual-tagged (C-VLAN/S-VLAN) VLAN configuration over a static VLAN demux interface that is in turn configured over aggregated Ethernet for redundancy. This topology is an N:1 configuration model because—although each C-VLAN corresponds to one subscriber household—all the C-VLANs are configured over the same underlying VLAN demux interface. Multiple end-user devices in each household—or rather the dynamic PPPoE sessions established by each device—are grouped by household into interface sets. The grouping is accomplished by a separate dynamic profile configured for each C-VLAN. The ANCP agent configuration maps the ACI for the household's access line to an interface set. CoS applies a traffic-control profile to each interface set to shape the subscriber-directed traffic on a per-household basis. The CoS shaping rate is dynamically updated based upon the DSL attributes provided by the access node for each household's access line.

[Figure 29 on page 624](#) shows S-VLAN 103, configured on demux0, servicing the access node. C-VLANs 1, 2, and 3 each service a single household (subscriber). The respective households are identified by unique ACIs. The dynamic PPPoE sessions for devices in each household are grouped for monitoring and traffic shaping into interface sets 10301, 10302, and 10303.

Figure 29: N:1 ANCP Topology with Interface Sets and VLAN Demux Interface over Aggregated Ethernet

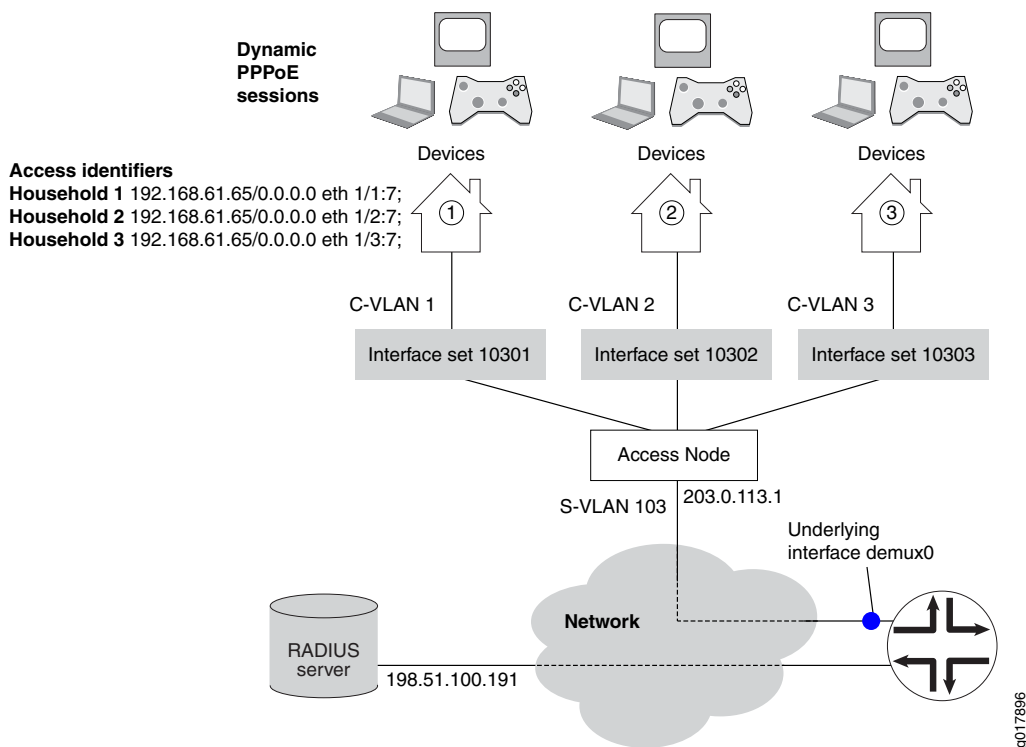

Table 52 on page 624 describes the configuration components used in this example.

Table 52: Configuration Components used in ANCP N:1 Topology Example with Interface Sets

| Configuration Component or Property | Component Name or Setting | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                     | ge-1/0/2                  | Backup member link in the aggregated Ethernet bundle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                     | lo0.0                     | Loopback interface for use in the access network. The loopback interface is automatically used for unnumbered interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                     | pp0                       | PPP interface on which the PPPoE subscriber logical interfaces are created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 52: Configuration Components used in ANCP N:1 Topology Example with Interface Sets (continued)**

| Configuration Component or Property | Component Name or Setting        | Description                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface sets                      | 10301                            | Set of interfaces in which the sessions for the devices in a particular household are created. Each interface set is specified in a dynamic profile for that household. ANCP associates each interface set with an ACI and a VLAN demux logical interface (C-VLAN). CoS applies a traffic-control profile to each interface set. |
|                                     | 10302                            |                                                                                                                                                                                                                                                                                                                                  |
|                                     | 10303                            |                                                                                                                                                                                                                                                                                                                                  |
| Advisory traffic rates              | downstream-rate                  | Recommended rate for downstream traffic in the absence of traffic rate information from the access node.                                                                                                                                                                                                                         |
|                                     | upstream-rate                    | Recommended rate for upstream traffic in the absence of traffic rate information from the access node.                                                                                                                                                                                                                           |
| Traffic-control profile             | tcp1                             | CoS profile that shapes the downstream subscriber traffic rate; in this example, shaping is adjusted for ATM packet overhead. The profile is applied to the interface sets.                                                                                                                                                      |
| IP addresses                        | 203.0.113.1                      | Address of the ANCP access node that monitors the subscriber households.                                                                                                                                                                                                                                                         |

|                                     | 192.168.61.65/0.0.0.0 eth 1/3:7; |                                                                                                                                                                                                                                                                                                                                  |

The ANCP agent configuration includes the following elements:

- The IP address for the access node (DSLAM) is specified as 203.0.113.1. The interval between ANCP adjacency messages sent between neighbors is set to 5 seconds.
- The ANCP agent is enabled to report adjusted data rates to CoS to improve the accuracy of downstream traffic shaping. The ANCP agent adjusts the net data rates for ADSL lines by ninety percent and for ADSL2 lines by ninety-five percent.
- Each interface set is associated with both the ACI unique to the subscriber household and the relevant underlying VLAN demux interface.

The RADIUS configuration on the router includes the following elements:

- The IP address (198.51.100.191) for the authentication and accounting server, as well as the secret password for accessing the server.
- The subscriber access profile, radius-profile, specifies that RADIUS is used for authentication.
- Juniper Networks DSL VSAs are included in RADIUS request messages, but the DSL Forum VSA attributes are excluded from RADIUS messages
- Accounting sessions are configured to be recognized in decimal format.

---

### Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure an ANCP network with static N:1 demux VLANs to the subscriber households, perform these tasks:

- [Configuring the Dynamic PPPoE Profiles on page 630](#)
- [Configuring the Static VLAN Demux Interface over Aggregated Ethernet on page 633](#)
- [Configuring Class of Service on page 637](#)
- [Configuring ANCP on page 638](#)
- [Configuring RADIUS Authentication and Accounting on page 640](#)

#### CLI Quick Configuration

To quickly configure the ANCP network described in this example, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
# Dynamic Profiles
edit dynamic-profiles ancp-10301
set interfaces interface-set 10301 interface pp0 unit "$junos-interface-unit"
edit interfaces pp0 unit "$junos-interface-unit"
set ppp-options chap

### *Configuring the Dynamic PPPoE Profiles*

**Step-by-Step Procedure** In this procedure, you configure a dynamic profile for each C-VLAN: ancp-10301, ancp-10302, and ancp-1033.

1. Configure the interface set that the PPPoE sessions on this C-VLAN are placed in.

```
[edit dynamic-profiles ancp-10301]
user@host1# edit interfaces interface-set 10301
```

2. Configure the logical interfaces to be dynamically instantiated for the interface set.

```
[edit dynamic-profiles ancp-10301 interfaces interface-set 10301]
user@host1# set interface pp0 unit "$junos-interface-unit"
```

3. Configure CHAP and PAP authentication as properties of the dynamic PPPoE logical interfaces.

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set ppp-options chap
user@host1# set ppp-options pap
```

4. Configure the logical underlying interface on which the router creates the dynamic PPPoE logical interface; this is the interface on which the subscriber logs in.

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set pppoe-options underlying-interface "$junos-underlying-interface"
```

5. Specify the interval between successive keepalive requests.

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set keepalives interval 30
```

6. Configure the IPv4 protocol family and that the local (unnumbered) address can be derived from the loopback address for the dynamic PPPoE logical interfaces.

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set family inet unnumbered-address lo0.0
```

7. Repeat Steps 1 through 6 for the second dynamic profile, ancp-10302, and the third dynamic profile, ancp-10303.

**Results** From configuration mode, confirm the dynamic profile configuration by entering the **show dynamic-profiles** command.

```
[edit]
user@host# show dynamic-profiles
ancp-10301 {
  interfaces {
    interface-set 10301 {
      interface pp0 {
        unit "$junos-interface-unit";
      }
    }
  }
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
      }
      keepalives interval 30;
      family inet {
        unnumbered-address lo0.0;
      }
    }
  }
}
```

*Configuring the Static VLAN Demux Interface over Aggregated Ethernet***Step-by-Step Procedure**

1. Enable hierarchical scheduling on this interface.

```
[edit interfaces ge-1/0/1]
user@host1# set hierarchical-scheduler
```

2. Specify this interface as the primary member of the aggregated Ethernet bundle.

```
[edit interfaces ge-1/0/1]
user@host1# set gigether-options 802.3ad ae0 primary
```

3. Enable hierarchical scheduling on a second interface.

```
[edit interfaces ge-1/0/2]
user@host1# set hierarchical-scheduler
```

4. Specify this interface as the backup member of the aggregated Ethernet bundle.

```
[edit interfaces ge-1/0/2]
user@host1# set gigether-options 802.3ad ae0 backup
```

5. Enable hierarchical scheduling on the aggregated Ethernet interface.

```
[edit interfaces ae0]
user@host1# set hierarchical-scheduler
```

6. Enable stacked VLAN tagging for all logical interfaces on the aggregated Ethernet interface.

```
[edit interfaces ae0]
user@host1# set stacked-vlan-tagging
```

7. Enable link protection as a property of the aggregated Ethernet interface.

```
[edit interfaces ae0]
user@host1# set aggregated-ether-options link-protection
```

8. Configure VLAN demux interface demux0.10301.

- a. Configure the router to respond to ARP requests on the interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set proxy-arp
```

- b. Configure the outer VLAN tag to identify the access node (S-VLAN) and the inner VLAN tag to identify the subscriber port on the access node (C-VLAN).

```
[edit interfaces demux0 unit 10301]
user@host1# set vlan tags outer 103 inner 1
```

- c. Specify that the VLAN demux interface runs on the underlying aggregated Ethernet interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set demux-options underlying-interface ae0
```

- d. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on this VLAN demux interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set family pppoe duplicate-protection
```

- e. Configure the dynamic profile that is instantiated on the VLAN demux interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set family pppoe dynamic-profile ancp-10301
```

- f. Configure the recommended upstream and downstream traffic rates.

```
[edit interfaces demux0 unit 10301]
user@host1# set advisory-options upstream-rate 1m
user@host1# set advisory-options downstream-rate 16m
```

- 9. Configure VLAN demux interface demux0.10302.

- a. Configure the router to respond to ARP requests on the interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set proxy-arp
```

- b. Configure the outer VLAN tag to identify the access node (S-VLAN) and the inner VLAN tag to identify the subscriber port on the access node (C-VLAN).

```
[edit interfaces demux0 unit 10302]
user@host1# set vlan tags outer 103 inner 2
```

- c. Specify that the VLAN demux interface runs on the underlying aggregated Ethernet interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set demux-options underlying-interface ae0
```

- d. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on this VLAN demux interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set family pppoe duplicate-protection
```

- e. Configure the dynamic profile that is instantiated on the VLAN demux interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set family pppoe dynamic-profile ancp-10302
```

- f. Configure the recommended upstream and downstream traffic rates.

```
[edit interfaces demux0 unit 10302]
user@host1# set advisory-options upstream-rate 1m
user@host1# set advisory-options downstream-rate 16m
```

10. Configure VLAN demux interface demux0.10303.

- a. Configure the router to respond to ARP requests on the interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set proxy-arp
```

- b. Configure the outer VLAN tag to identify the access node (S-VLAN) and the inner VLAN tag to identify the subscriber port on the access node (C-VLAN).

```
[edit interfaces demux0 unit 10303]
user@host1# set vlan tags outer 103 inner 3
```

- c. Specify that the VLAN demux interface runs on the underlying aggregated Ethernet interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set demux-options underlying-interface ae0
```

- d. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on this VLAN demux interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set family pppoe duplicate-protection
```

- e. Configure the dynamic profile that is instantiated on the VLAN demux interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set family pppoe dynamic-profile ancp-10303
```

- f. Configure the recommended upstream and downstream traffic rates.

```
[edit interfaces demux0 unit 10303]
user@host1# set advisory-options upstream-rate 1m
user@host1# set advisory-options downstream-rate 16m
```

11. Configure the IPv4 protocol family and the address of the loopback interface.

```
[edit interfaces lo0]
user@host1# set unit 0 family inet address 127.0.50.1/28
```

**Results** From configuration mode, confirm the static VLAN demux configuration by entering the **show interfaces** command.

```
[edit]
user@host# show interfaces

```

When you are done configuring the device, enter **commit** from configuration mode.

### Configuring Class of Service

- Step-by-Step Procedure**
1. Configure the traffic-control profile with the shaping rate and specify the overhead accounting mode to account for ATM cell encapsulation.

```

[edit class-of-service]
user@host1# set traffic-control-profiles tcp1 shaping-rate 16m
user@host1# set traffic-control-profiles tcp1 overhead-accounting cell-mode

```

2. Apply the traffic-control profile to the interface sets.

```

[edit class-of-service]
user@host1# set interfaces interface-set 10301 output-traffic-control-profile tcp1
user@host1# set interfaces interface-set 10302 output-traffic-control-profile tcp1
user@host1# set interfaces interface-set 10303 output-traffic-control-profile tcp1

```

- Results** From configuration mode, confirm the class of service configuration by entering the **show class-of-service** command.

```

[edit]
user@host# show class-of-service

```

```

traffic-control-profiles {
  tcp1 {
    shaping-rate 16m;
    overhead-accounting cell-mode;
  }
}
interfaces {
  interface-set 10301 {
    output-traffic-control-profile tcp1;
  }
  interface-set 10302 {
    output-traffic-control-profile tcp1;
  }
  interface-set 10303 {
    output-traffic-control-profile tcp1;
  }
}

```

When you are done configuring the device, enter **commit** from configuration mode.

### Configuring ANCP

#### Step-by-Step Procedure

1. Configure the access node address.

```

[edit protocols ancp]
user@host1# set neighbor 203.0.113.1

```

2. Configure the ANCP agent to report adjusted downstream traffic rates to CoS.

```

[edit protocols ancp]
user@host1# set qos-adjust

```

3. Specify an overhead adjustment of the traffic on ADSL and ADSL2 lines to 90 percent and 95 percent, respectively, of the net data rate.

```

[edit protocols ancp]
user@host1# set qos-adjust-adsl 90
user@host1# set qos-adjust-adsl2 95

```

4. Specify an interval of 5 seconds between adjacency messages sent to all ANCP neighbors.

```

[edit protocols ancp]
user@host1# set adjacency-timer 5

```

5. Associate the ACI with the interface sets for each C-VLAN.

```

[edit protocols ancp]

```

```

user@host1# set interfaces interface-set 10301 access-identifier
"192.168.61.65/0.0.0.0 eth 1/1:7;"
user@host1# set interfaces interface-set 10302 access-identifier
"192.168.61.65/0.0.0.0 eth 1/2:7;"
user@host1# set interfaces interface-set 10303 access-identifier
"192.168.61.65/0.0.0.0 eth 1/3:7;"

```

6. Specify the underlying interface for the interface sets.

```

[edit protocols ancp]
user@host1# set interfaces interface-set 10301 underlying-interface demux0.10301
user@host1# set interfaces interface-set 10302 underlying-interface demux0.10302
user@host1# set interfaces interface-set 10303 underlying-interface demux0.10303

```

7. Configure the size of the ANCP trace log files.

```

[edit protocols ancp traceoptions]
user@host1# set file ancpd size 512m

```

8. Configure flags for tracing ANCP configuration and CoS operations.

```

[edit protocols ancp traceoptions]
user@host1# set flag config
user@host1# set flag cos

```

**Results** From configuration mode, confirm the ANCP agent configuration by entering the **show ancp** command.

```

[edit]
user@host# show ancp
traceoptions {
  file ancpd size 512m;
  flag config;
  flag cos;
}
qos-adjust;
adjacency-timer 5;
qos-adjust-adsl 90;

```

When you are done configuring the device, enter **commit** from configuration mode.

### *Configuring RADIUS Authentication and Accounting*

#### **Step-by-Step Procedure**

1. Configure the password for the RADIUS server.

```

[edit access]
user@host1# set radius-server 198.51.100.191 secret "$ABC123$ABC123$ABC123"

```

2. Specify that RADIUS is used to authenticate subscribers.

```

[edit access]
user@host1# set profile radius-profile authentication-order radius

```

3. Configure the RADIUS authentication and accounting server.

```

[edit access]
user@host1# set profile radius-profile radius authentication-server 198.51.100.191
user@host1# set profile radius-profile radius accounting-server 198.51.100.191

```

4. Configure options for the RADIUS server: The format used to identify the accounting session and that Juniper Networks DSL VSAs are added to RADIUS request messages.

```

[edit access]
user@host1# set profile radius-profile radius options accounting-session-id-format decimal
user@host1# set profile radius-profile radius options juniper-dsl-attributes

```

5. Exclude DSL Forum VSA attributes from being included in RADIUS messages.

```

[edit access]
user@host1# set profile radius-profile radius attribute exclude dsl-forum-attributes access-request
user@host1# set profile radius-profile radius attribute exclude dsl-forum-attributes accounting-start
user@host1# set profile radius-profile radius attribute exclude dsl-forum-attributes accounting-stop

```

**Results** From configuration mode, confirm the RADIUS configuration by entering the **show access** command.

```
[edit]
user@host# show access
radius-server {
  198.51.100.191 secret "$ABC123$ABC123$ABC123"; ## SECRET-DATA
}
profile radius-profile {
  radius {
    authentication-server 198.51.100.191;
    accounting-server 198.51.100.191;
    options {
      accounting-session-id-format decimal;
      juniper-dsl-attributes;
    }
    attributes {
      exclude {
        dsl-forum-attributes [ access-request accounting-start accounting-stop ];
      }
    }
  }
}
```

When you are done configuring the device, enter **commit** from configuration mode.

### Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Aggregated Ethernet Interface Configuration on page 641](#)
- [Verifying the Traffic Scheduling and Shaping Parameters for the Interface Set on page 642](#)
- [Verifying the demux0 Interface Configuration on page 642](#)
- [Verifying the pp0 Interface Configuration on page 643](#)
- [Verifying the ANCP Agent Configuration on page 644](#)

#### *Verifying the Aggregated Ethernet Interface Configuration*

**Purpose** Verify that the interface values match your configuration, the link is up, and traffic is flowing.

**Action** From operational mode, enter the **show interfaces redundancy** command.

```
user@host> show interfaces redundancy
```

| Interface | State      | Last change | Primary  | Secondary | Current status |
|-----------|------------|-------------|----------|-----------|----------------|
| ae0       | On primary |             | ge-1/0/1 | ge-1/0/2  | both up        |

From operational mode, enter the **show interfaces ae0** command.

```
user@host> show interfaces ae0
```

```
Physical interface: ae0, Enabled, Physical link is Up
  Interface index: 128, SNMP ifIndex: 606
  Link-level type: Ethernet, MTU: 1522, Speed: 1Gbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Disabled, Source filtering: Disabled,
  Flow control: Disabled, Minimum links needed: 1, Minimum bandwidth needed: 0
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Current address: 00:00:5E:00:53:c0, Hardware address: 00:00:5E:00:53:c0
  Last flapped   : 2012-03-11 13:24:18 PST (2d 03:34 ago)
  Input rate      : 1984 bps (2 pps)
  Output rate     : 0 bps (0 pps)

Logical interface ae0.32767 (Index 69) (SNMP ifIndex 709)
  Flags: SNMP-Traps 0x4004000 VLAN-Tag [ 0x0000.0 ] Encapsulation: ENET2
  Statistics          Packets          pps          Bytes          bps
  Bundle:
    Input :           371259             2       46036116       1984
    Output:              0             0           0           0
  Protocol multiservice, MTU: Unlimited
  Flags: Is-Primary
```

**Meaning** The **show interfaces redundancy** output shows the redundant link configuration and that both link interfaces are up. The **show interfaces ae0** output shows that the aggregated Ethernet interface is up and that traffic is being received on the logical interface.

#### *Verifying the Traffic Scheduling and Shaping Parameters for the Interface Set*

**Purpose** Verify that the traffic scheduling and shaping parameters are configured and applied properly.

**Action** user@host> show class-of-service

#### *Verifying the demux0 Interface Configuration*

**Purpose** Verify that the VLAN demux interface displays the configured PPPoE family attributes and the member links in the aggregated Ethernet bundle.

**Action** From operational mode, enter the **show interfaces demux0** command for each VLAN.

```
user@host> show interfaces demux0.10301
```

```
Logical interface demux0.10301 (Index 76) (SNMP ifIndex 61160)
  Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.100 ]
  Encapsulation: ENET2
  Demux:
    Underlying interface: ae0 (Index 199)
  Link:
```

```

ge-1/0/1
ge-1/0/2
Input packets : 2
Output packets: 18575
Protocol pppoe
  Dynamic Profile: ancp-10301,
  Service Name Table: None,
  Max Sessions: 16000, Duplicate Protection: On,
  AC Name: pppoe-server-1

```

Alternatively, you can enter **show pppoe underlying-interfaces detail** to display the state and PPPoE family configuration for all configured underlying interfaces.

**Meaning** The output shows the name of the underlying interface, the member links of the aggregated bundle, and the PPPoE family configuration. The output shows packet counts when traffic is present on the logical interface.

#### *Verifying the pp0 Interface Configuration*

**Purpose** Verify that the interface values match your configuration.

**Action** From operational mode, enter the **show interfaces pp0** command.

```
user@host> show interfaces pp0.100
```

```

Logical interface pp0.100 (Index 71) (SNMP ifIndex 710)
Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
PPPoE:
  State: SessionUp, Session ID: 1,
  Session AC name: pppoe-server-1, Remote MAC address: 00:00:5E:00:53:34,
  Underlying interface: demux0.10301 (Index 70)
Link:
  ge-5/0/3.32767
  ge-5/1/2.32767
  Input packets : 18572
  Output packets: 18572
Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
Keepalive: Input: 0 (never), Output: 18566 (00:00:02 ago)
LCP state: Opened
NCP state: inet: Opened, inet6: Not-configured, iso: Not-configured, mpls:
Not-configured
CHAP state: Closed
PAP state: Success
Protocol inet, MTU: 1500
  Flags: Sendbroadcast-pkt-to-re
  Addresses, Flags: Is-Primary
    Local: 203.0.113.45

```

**Meaning** This output shows information about the PPPoE logical interface created on the underlying VLAN demux interface. The output includes the PPPoE family and aggregated Ethernet redundant link information, and shows input and output traffic for the PPPoE interface.

**Verifying the ANCP Agent Configuration**

**Purpose** Verify that the ANCP values match your configuration and that traffic is flowing.

**Action** From operational mode, enter the **show ancp subscriber** command.

```
user@host> show ancp subscriber detail
```

| Interface | State      | Last change | Primary  | Secondary | Current status |
|-----------|------------|-------------|----------|-----------|----------------|
| ae0       | On primary |             | ge-1/0/1 | ge-1/0/2  | both up        |

From operational mode, enter the **show ancp cos** command.

```
user@host> show ancp cos
```

```
Qos Adjust Flag:      TRUE
Keepalive Timer:      30 secs
Cos State:             WRITE_READY
Connect Time:         Mon Mar 19 15:03:01 2012
Session Time:         Mon Mar 19 15:03:13 2012
Routing Instance Time: Mon Mar 19 15:03:14 2012
Keepalive Time:       Not Set
Rate Update Time:     Mon Mar 19 15:03:15 2012
```

| Type   | Name  | Index | Pending Update | Last Update |
|--------|-------|-------|----------------|-------------|
| iflset | 10301 | 1     | None           | 64 Kbps     |
| iflset | 10302 | 2     | None           | 64 Kbps     |
| iflset | 10303 | 71    | None           | 64 Kbps     |

**Meaning** The **show ancp subscriber** output shows subscriber line information such as state and the various traffic rates collected by the ANCP agent—displayed for each subscriber as identified by the ACI. The **show ancp cos** output shows that the ANCP agent is configured to send adjusted rate data to CoS, that keepalives are configured for a 30-second interval, and that the interface sets 10301, 10302, and 10303 are configured and their traffic rates are updating

### Traffic Rate Reporting and Adjustment by the ANCP Agent

The ANCP agent monitors the subscriber access lines and reports to AAA and CoS information about the lines that it receives from the access node. Starting in Junos OS Release 17.4R1, the ANCP agent can use access line information that it receives in the PPPoE intermediate agent (PPPoE-IA) tags. This information is carried in the Vendor-Specific-Tags TLV in subattribute DSL-Type (0x0091) in PADI or PADO packets. In earlier releases, the ANCP agent can use only access line information that it receives in ANCP messages. The access line information for both carriers is logically sourced from the same data on the access node; it represents a current, accurate snapshot of the values at the moment that the subscriber connection is initiated.

It is theoretically possible for ANCP and PPPoE subscribers to specify different data rates in the Vendor-Specific-Tags TLV when the connection is first established. This is an unlikely occurrence, but when the dynamic profile is configured to accept these values, the most recently received value takes precedence. The rates announced on the PPPoE connection are expected to be used only when ANCP is either not used or does not include rates. However, network dynamics make it impossible to guarantee the source from which the information arrives first. If the values conflict, a subsequent Port Up message from the access node forces the resolution to the ANCP values.

- [Overview on page 645](#)
- [Traffic Rate Adjustment on page 647](#)
- [Recommended Traffic Shaping Rates on page 649](#)
- [ANCP Agent Keepalives for CoS on page 649](#)

---

#### Overview

---

The ANCP agent reports two kinds of data rates:

- The *net data rate* is the portion of the total data rate that can be used to transmit user information. The net data rate is also called the *unadjusted* traffic rate.
- Because each DSL line type has a certain technology overhead, the actual rate for user data is less than the net data rate. The *adjusted* or *calculated* rate is the net data rate

reduced by the amount of technology overhead incurred by each DSL line type. The result is a closer approximation of the actual rate of subscriber data traffic.

The ANCP agent reports traffic rates differently to AAA and CoS:

- The agent always reports unadjusted rates for both upstream and downstream traffic to AAA in response to a AAA request. When configured, the agent adjusts the traffic rates and reports the adjusted values in addition to the unadjusted rate.
- The ANCP agent reports traffic rates to CoS only when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level. The agent reports only downstream traffic rates to CoS in support of CoS traffic shaping. It never reports upstream traffic rates to CoS because CoS does not shape upstream traffic. The agent also reports to CoS the overhead mode and bytes for the access line; CoS can use this information when it subsequently shapes the traffic.

When you remove a shaping rate configuration that the ANCP agent previously applied, the traffic shaping rate reverts to the CoS session shaping as determined by the CoS traffic-control profiles specified in the dynamic profile. However, if the ANCP agent remains running but loses a connection to a particular neighbor whose subscriber traffic has been adjusted as a result of ANCP agent action, the adjusted rate remains in effect. The rate currently in effect changes only when the ANCP agent restores the connection and sends fresh updates to CoS, or when you remove the **qos-adjust** statement.

Because CoS can perform traffic shaping only when a traffic-control profile has been applied to the interface or interface set, you might expect the ANCP agent to always influence traffic shaping when the ANCP subscriber interface or interface set has a traffic-control profile. This behavior does not always occur.

Consider a configuration where a subscriber logical interface is a member of an ACI-based VLAN (interface set); all members share the same ACI. The dynamic profile that instantiates the subscriber interface applies a traffic-control profile to the interface. The profile that instantiates the VLAN applies an interface-shared filter instead of a traffic-control profile.

The following sequence of events takes place when the subscriber logs in.

1. The first packet creates the auto-sensed, underlying VLAN.
2. The second packet creates the ACI-based subscriber VLAN
3. The third packet creates the subscriber logical interface.

Because the VLAN comes up first, the ANCP agent attaches to the VLAN and not to the interface. Consequently, the agent reports to CoS the downstream data rate only for the VLAN, not for the logical interface. CoS has no information to adjust the shaping rate for the interface, so it shapes traffic for the interface only according to the interface's traffic-control profile.

Although the agent does report the downstream rate for the VLAN, CoS cannot use that information to shape the VLAN traffic, because the VLAN does not have a traffic-control profile. Consequently, the VLAN rate does not affect the logical interface's rate even though the logical interface is a member of that interface set.

### Traffic Rate Adjustment

When a DSLAM determines the data rate on the subscriber local loop, it ignores the additional headers on the DSL line that are associated with the overhead of the access mode (ATM or Ethernet) and the technology of the DSL line type. When the ANCP agent subsequently reports a net data rate, by default it includes this overhead, reporting a slightly higher value than the actual subscriber data rate seen by the DSLAM.

You can configure the ANCP agent to additionally report an adjusted rate to account for the traffic overhead. The ANCP agent dynamically adjusts the net data rate by applying a fixed percentage value to the net data rate received from the DSLAM. The percentage adjustment factor applies globally for all subscribers of the particular DSL line type as follows:

- The agent can adjust the rates it reports to AAA for all DSL types.
- The agent can adjust the rates it reports to CoS for only frame-mode DSL types (SDSL, VDSL, VDSL2, and OTHER). It cannot adjust the rates reported to CoS for cell-mode DSL types (ADSL, ADSL2, and ADSL2+).

You can also configure the ANCP agent to adjust the number of overhead bytes that it reports to CoS per cell or frame. The agent can add or subtract the specified value from the actual number of overhead bytes for all DSL types. The agent does not report the number of overhead bytes (adjusted or unadjusted) to AAA.

Table 53 on page 647 summarizes how adjusted rates and overheads are reported.

**Table 53: Traffic Adjustment Reporting by Access Line Type**

| DSL Access Line Type | Upstream and Downstream Adjusted Rate Reported to AAA | Downstream-Only Adjusted Rate Reported to CoS | Adjusted Overhead Byte Count Reported to CoS |
|----------------------|-------------------------------------------------------|-----------------------------------------------|----------------------------------------------|
| ADSL                 | ✓                                                     | –                                             | ✓                                            |

The ANCP agent reports traffic rates to CoS only when you have included the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level. By default, these are unadjusted rates. CoS attempts to avoid traffic drops in the access node by itself adjusting the traffic shaping rate that it applies to downstream traffic for a particular VLAN or set of VLANs.

The discrepancy between the actual user data rate and the agent-reported net data rate reduces the accuracy of CoS traffic shaping. You increase the accuracy of CoS traffic shaping by configuring the ANCP agent to report adjusted rate and byte values to CoS.

If you are running Junos OS Release 17.3 or earlier, use the CLI configuration statements in [Table 54 on page 648](#) to make traffic adjustments. The CoS statements are at the **[edit protocols ancp qos-adjust]** hierarchy level. The AAA statements are at the **[edit protocols ancp]** hierarchy level.

**Table 54: Statements for Adjusting Traffic Rate and Overhead by Access Line Type Through Junos OS Release 17.3**

| Access Line Type | Adjust Net Downstream and Upstream Rates for AAA | Adjust Net Downstream Rates for CoS | Adjust Overhead Bytes for CoS |
|------------------|--------------------------------------------------|-------------------------------------|-------------------------------|
| ADSL             | qos-adjust-adsl                                  | –                                   | adsl-bytes                    |
| ADSL2            | qos-adjust-adsl2                                 | –                                   | adsl2-bytes                   |
| ADSL2+           | qos-adjust-adsl2-plus                            | –                                   | adsl2-plus-bytes              |
| OTHER            | qos-adjust-other                                 | other-overhead-adjust               | other-bytes                   |
| SDSL             | qos-adjust-sdsl                                  | sdsl-overhead-adjust                | sdsl-bytes                    |
| VDSL             | qos-adjust-vdsl                                  | vdsl-overhead-adjust                | vdsl-bytes                    |
| VDSL2            | qos-adjust-vdsl2                                 | vdsl2-overhead-adjust               | vdsl2-bytes                   |

If you are running Junos OS Release 17.4R1 or later, use the **access-line** configuration statement options in [Table 55 on page 648](#) to make traffic adjustments for CoS and AAA options. The **access-line** statement is at the **[edit system]** hierarchy level.

**Table 55: Statements for Adjusting Traffic Rate and Overhead by Access Line Type Starting in Junos OS Release 17.4R1**

| Access Line Type | Adjust Net Downstream and Upstream Rates for AAA | Adjust Net Downstream Rates for CoS | Adjust Overhead Bytes for CoS |
|------------------|--------------------------------------------------|-------------------------------------|-------------------------------|
| ADSL             | adsl-total-adjust                                | –                                   | adsl-overhead-bytes           |
| ADSL2            | adsl2-total-adjust                               | –                                   | adsl2-overhead-bytes          |
| ADSL2+           | adsl2-plus-total-adjust                          | –                                   | adsl2-plus-overhead-bytes     |
| OTHER            | other-total-adjust                               | other-overhead-adjust               | other-overhead-bytes          |
| SDSL             | sdsl-total-adjust                                | sdsl-overhead-adjust                | sdsl-overhead-bytes           |
| VDSL             | vdsl-total-adjust                                | vdsl-overhead-adjust                | vdsl-overhead-bytes           |
| VDSL2            | vdsl-total-adjust                                | vdsl2-overhead-adjust               | vdsl2-overhead-bytes          |

### Recommended Traffic Shaping Rates

---

To handle a situation where the router does not receive information from the access node about the downstream and upstream calculated traffic rates for an interface, you can specify recommended *advisory* values for shaping the traffic sent to the interface so that it matches the subscriber local loop speed.

The transmit speed is the recommended traffic value in bits per second used for downstream traffic for an ANCP interface, and is conveyed in the Juniper Networks VSA, Downstream-Calculated-Qos-Rate (IANA 4874, 26-141). The receive speed is the recommended traffic value in bits per second used for upstream traffic for an ANCP interface, and is conveyed in the Juniper Networks VSA, Upstream-Calculated-Qos-Rate VSA (IANA 4874, 26-142).

To set the recommended shaping rates that are used as the default values for these VSAs in static configurations, include the **downstream-rate** and **upstream-rate** statements at the **[edit interfaces interface-name unit logical-unit-number advisory-options]** hierarchy level.

To configure the recommended rates on dynamically created VLAN interfaces, include the **upstream-rate** or **downstream-rate** statements at the **[edit dynamic-profiles profile-name interfaces \$junos-interface-ifd-name unit \$junos-interface-unit advisory-options]** hierarchy level.

To configure the recommended rates on dynamically created ACI interface sets, include the **upstream-rate** or **downstream-rate** statements at the **[edit dynamic-profiles profile-name interface-set \$junos-interface-set-name interfaces \$junos-interface-ifd-name advisory-options]** hierarchy level.

### ANCP Agent Keepalives for CoS

---

The ANCP agent sends a keepalive message to CoS at specific intervals. If CoS does not receive a keepalive in the expected time, it reverts the shaping rate changes it made in response to the ANCP agent. You can adjust how long CoS waits for a keepalive message by including the **maximum-helper-restart-time** statement at the **[edit protocols ancp]** hierarchy level. The interval between keepalive messages is automatically set to one-third the value of the maximum helper restart time. For example, if you set the maximum helper restart time to 120 seconds, then the ANCP agent sends keepalive messages every 40 seconds. In this example, if CoS does not receive a keepalive message within 120 seconds, then it reverts any policy changes derived from the ANCP agent.

### Preservation of CoS Shaping Across ANCP Agent Restarts

When the ANCP agent stops due to a process or GRES, CoS enforces the ANCP downstream shaping-rates until the CoS keepalive timer expires. When the timer expires, CoS reverts to the CoS shaping-rate configured for the interfaces.

You configure the CoS keepalive timer by including the **maximum-helper-restart-time seconds** statement at the **[edit protocols ancp]** hierarchy level. It specifies how much time other daemons such as CoS wait for the ANCP agent to restart and is used to configure the CoS rate update keepalive timer.

The ANCP agent does not maintain TCP sessions from neighbors across the restart or GRES. When it restarts, it must re-establish sessions with neighbors and subscriber sessions before the timer expires. For all the re-established sessions, the ANCP agent updates CoS with the updated downstream shaping rates and provides DSL line attributes to the session database for AAA.

If CoS stops or restarts while ANCP is up, the ANCP agent retransmits all known subscriber downstream rates to CoS. Any existing adjusted shaping rates that have not been updated revert to the configured CoS shaping rates when the CoS restart timer expires.

**See Also** • [Specifying How Long Processes Wait for the ANCP Agent Restart to Complete on page 621](#)

## Configuring the ANCP Agent to Report Traffic Rates to CoS

By default, the ANCP agent does not report the traffic rate on subscriber access lines to CoS. You must include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level to configure the ANCP agent to report downstream data rates received in ANCP Port Up messages to CoS for all subscribers in the network. This information enables CoS to subsequently shape the traffic on these access lines—but only if a shaping rate is configured in a CoS traffic-control profile for the access lines.

When a DSLAM calculates the data rate on the subscriber local loop, it ignores the additional headers on the DSL line that are associated with the overhead of the access mode (ATM or Ethernet). The unadjusted downstream data rate includes these headers in its calculation and reports a slightly higher value than that calculated by the DSLAM. The ANCP agent also reports to CoS the traffic mode and the traffic rate overhead.

**NOTE:** The ANCP agent never reports upstream traffic rates to CoS.

---

You can also configure the ANCP agent to adjust the actual (net) downstream data rates for individual DSL types as follows:

- For frame-mode DSL types (SDSL, VDSL, VDSL2, and OTHER), you can configure an adjustment in the number of overhead bytes to account for encapsulation differences. You can also specify a percentage value that is applied to the actual, unadjusted data rate received in ANCP Port Up messages.
- For cell-mode DSL types (ADSL, ADSL2, and ADSL2+), you can configure only an adjustment in the number of overhead bytes for the traffic to account for encapsulation differences.

The ANCP agent adjusts the rate by the specified percentage. It adjusts the cell or frame overhead by adding or subtracting the specified number of bytes. By default the adjustment is 100 percent and 0 bytes, meaning that the agent does not adjust the net values before it reports them to CoS.

If CoS does not receive a keepalive message within the maximum helper restart time, it considers the ANCP agent to be down and immediately reverts to the configured values

for any traffic shaping updates that were modified as a result of traffic reports from the ANCP agent. The configured values are maintained until the ANCP agent comes back up and sends fresh traffic updates to CoS.

If the ANCP agent remains running but loses the connection to a neighbor, CoS does not revert to its configured values. In this case, CoS changes the shaping rate for the subscriber traffic only if the ANCP agent restores the connection to that neighbor and reports new traffic rates to CoS or if you remove the **qos-adjust** statement.

**NOTE:** Starting in Junos OS Release 17.4R1, the previously supported rate- and byte-adjustment statements at the [edit protocols ancp] and [edit protocols ancp qos-adjust] hierarchy levels are deprecated. They are replaced by the access-line statement and its many options at the [edit system] hierarchy level. The ANCP agent ignores the deprecated statements if they are present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing rate or byte adjustment configuration, you must reconfigure your adjustment with the access-line statement.

The exception to this change is that the **qos-adjust** statement remains supported, but no longer has any subordinate statements. Always configure the **qos-adjust** statement for normal ANCP operations. You may want to disable it for debugging purposes.

To configure the ANCP agent to report traffic rates to CoS:

1. Enable rate reporting to CoS.

```
[edit protocols ancp]
user@host# set qos-adjust
```

2. (Optional) Specify the number of bytes to add or subtract per cell or frame for one or more line types.

- In Junos OS Release 17.3 or earlier:

```
[edit protocols ancp qos-adjust]
user@host# set adsl-bytes bytes
user@host# set adsl2-bytes bytes
user@host# set adsl2-plus-bytes bytes
user@host# set sdsl-bytes bytes
user@host# set vdsl-bytes bytes
user@host# set vdsl2-bytes bytes
user@host# set other-bytes bytes
```

- In Junos OS Release 17.4R1 or later:

```
[edit system access-line]
user@host# set adsl-overhead-bytes bytes
user@host# set adsl2-overhead-bytes bytes
user@host# set adsl2-plus-overhead-bytes bytes
```

```

user@host# set other-overhead-bytes bytes
user@host# set sdsl-overhead-bytes bytes
user@host# set vdsl-overhead-bytes bytes
user@host# set vdsl2-overhead-bytes bytes

```

3. (Optional) Specify a percentage rate adjustment for one or more frame-mode DSL line types.

- In Junos OS Release 17.3 or earlier:

```

[edit protocols ancp qos-adjust]
user@host# set other-overhead-adjust percentage;
user@host# set sdsl-overhead-adjust percentage
user@host# set vdsl-overhead-adjust percentage
user@host# set vdsl2-overhead-adjust percentage;

```

- In Junos OS Release 17.4R1 or later:

```

[edit system access-line]
user@host# set other-overhead-adjust percentage
user@host# set sdsl-overhead-adjust percentage
user@host# set vdsl-overhead-adjust percentage
user@host# set vdsl2-overhead-adjust percentage

```

## Setting a Recommended Shaping Rate for Traffic on ANCP Interfaces

When the access node sends information about the downstream and upstream calculated traffic rates for an interface, those values are used to shape the traffic sent to the interface so that it matches the subscriber local loop speed. You can specify recommended values that are used when the router does not receive this information from the access node. In this event, these recommended values are used as the default values for the following Juniper VSAs:

- Downstream-Calculated-Qos-Rate (IANA 4871, 26–141)—Conveys the transmit speed, which is the recommended traffic value in bits per second used for downstream traffic for an ANCP interface.
- Upstream-Calculated-Qos-Rate (IANA 4874, 26–142)—Conveys the receive speed, which is the recommended traffic value in bits per second used for upstream traffic for an ANCP interface.

You can configure the recommended rates either on static VLAN and VLAN demux interfaces, or you can specify them in a dynamic profile for dynamic VLAN and VLAN demux interfaces or interface sets.

To configure recommended traffic shaping values for a static interface:

1. Set the rate in bits per second for downstream traffic for the interface.

```
[edit interfaces interface-name unit logical-unit-number advisory-options]
user@host# set downstream-rate rate
```

2. Set the rate in bits per second for upstream traffic for the interface.

```
[edit interfaces interface-name unit logical-unit-number advisory-options]
user@host# set upstream-rate rate
```

For example, to set the recommended downstream rate to 16 Mbps and the recommended upstream rate to 1 Mbps on VLAN demux interface demux0.10301:

```
[edit interfaces demux0 unit 10301 advisory-options]
user@host# set downstream-rate 16M
user@host# set upstream-rate 1M
```

To configure recommended traffic shaping values for a dynamic interface:

1. Set the rate in bits per second for downstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit
  $junos-interface-unit advisory-options]
user@host# set downstream-rate rate
```

2. Set the rate in bits per second for upstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit
  $junos-interface-unit advisory-options]
user@host# set upstream-rate rate
```

For example, to configure the dynamic profile ancp-dyn-vlan2 to set the recommended downstream rate to 10 Mbps and the recommended upstream rate to 1 Mbps on all interfaces in the dynamically created interface set:

```
[edit dynamic-profiles ancp-dyn-vlan2 interfaces $junos-interface-ifd-name unit
  $junos-interface-unit advisory-options]
user@host# set downstream-rate 10M
user@host# set upstream-rate 1M
```

To configure recommended traffic shaping values for a dynamic interface set:

1. Set the rate in bits per second for downstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-set $junos-interface-set-name
  interface $junos-interface-ifd-name advisory-options]
user@host# set downstream-rate rate
```

2. Set the rate in bits per second for upstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-set $junos-interface-set-name
  interface $junos-interface-ifd-name advisory-options]
user@host# set upstream-rate rate
```

For example, to configure the dynamic profile `ancp-dyn-vlan1` to set the recommended downstream rate to 12 Mbps and the recommended upstream rate to 2 Mbps on all interfaces in the dynamically created interface set:

```
[edit dynamic-profiles ancp-dyn-vlan1 interfaces interface-set $junos-interface-set-name
  interface $junos-interface-ifd-name advisory-options]
user@host# set downstream-rate 12M
user@host# set upstream-rate 2M
```

## Setting a Global Adjustment Factor per DSL Subscriber Line for ANCP Agent-Reported Traffic Rates

The ANCP agent always reports both upstream and downstream rates to AAA. When a DSLAM calculates the data rate on the subscriber local loop, it ignores the additional headers on the DSL line that are associated with the overhead of the access mode (ATM or Ethernet). When the ANCP agent reports the net upstream data rate or the net downstream data rate, it includes the headers in its calculation and reports a slightly higher value than that calculated by the DSLAM; this is the unadjusted data rate.

The ANCP agent can optionally report adjusted data rates to AAA. Configure the agent to adjust the traffic rate to account for the header overhead by specifying an adjustment factor for one or more DSL line types. The adjustment factor is a percentage that is applied to the total downstream and upstream data rates reported by the ANCP agent. The adjustment factor applies globally for all subscribers of that DSL line type. By default, the ANCP agent applies an adjustment factor of 100 percent to all DSL lines, meaning that no adjustment is made. The ANCP agent simply passes on the DSL line rates that include the header information.

**NOTE:** These adjustment factors affect only the rates reported to AAA. The ANCP agent reports downstream data rates to CoS only when you include the `qos-adjust` statement at the `[edit protocols ancp]` hierarchy level.

**NOTE:** Starting in Junos OS Release 17.4R1, the previously supported `qos-adjust-line-type` rate adjustment statements at the `[edit protocols ancp]` hierarchy level are deprecated. They are replaced by the `line-type-total-adjust` options for the `access-line` statement at the `[edit system]` hierarchy level. The ANCP agent ignores the deprecated statements if they are present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing rate adjustment configuration, you must reconfigure your adjustment with the `access-line` statement.

To apply a global adjustment factor for DSL subscriber lines to be reported to AAA:

- Specify the adjustment factor percentage for the desired subscriber line.
  - In Junos OS Release 17.3 or earlier:

```
[edit protocols ancp]
user@host# set qos-adjust-adsl percentage
user@host# set qos-adjust-adsl2 percentage
user@host# set qos-adjust-adsl2-plus percentage
user@host# set qos-adjust-other percentage
user@host# set qos-adjust-sdsl percentage
user@host# set qos-adjust-vdsl percentage
user@host# set qos-adjust-vdsl2 percentage
```

- In Junos OS Release 17.4 or later:

```
[edit system access-line]
user@host# set adsl-total-adjust percentage
user@host# set adsl2-total-adjust percentage
user@host# set adsl2-plus-total-adjust percentage
user@host# set other-total-adjust percentage
user@host# set sdsl-total-adjust percentage
user@host# set vdsl-total-adjust percentage
user@host# set vdsl2-total-adjust percentage
```

## Verifying and Monitoring CoS for ANCP Subscribers

**Purpose** View ANCP CoS state information:

**Action** • To display summary information about the CoS state for all ANCP subscribers:

```
user@host> show ancp cos
```

- To display information about the CoS state for an ANCP subscriber specified by the ACI:

```
user@host> show ancp cos "port-2-11"
```

- To display the most recently updated CoS information:

```
user@host> show ancp cos last-update
```

- To display the CoS information that is pending (will be used to update the fields):

```
user@host> show ancp cos pending-update
```

- [Configuring Immediate Interim Accounting Updates to RADIUS in Response to ANCP Notifications on page 661](#)

### ANCP Agent Interactions with AAA

The ANCP agent reports both unadjusted (net) data rates and adjusted data rates for subscriber traffic to AAA for RADIUS authentication and accounting of subscriber sessions. The adjusted data rate enables RADIUS to allocate the appropriate services (including class of service) to PPPoE sessions during authentication. The rate reports also enable RADIUS accounting to track the class of service actually provided for the PPPoE sessions, which in turn enables accurate billing for subscriber services.

The access nodes send ANCP DSL attributes in ANCP messages to the router, where they are stored in the shared database. AAA maps the ANCP DSL attributes to both the Juniper Networks DSL VSAs (used by RADIUS) and the DSL Forum VSA subattributes

(also called the DSL Forum VSAs). RADIUS uses these attributes during authentication and accounting for PPPoE sessions on the subscriber access line. The attributes persist even when the ANCP session to a given node has ended, enabling RADIUS to later apply these attributes to new sessions on that subscriber access line. To remove the attributes, you must delete the interface or interface set for the access line from the ANCP agent configuration.

The RADIUS profile must be configured to include the **juniper-dsl-attributes** option, or AAA does not report the attributes to RADIUS. If the ANCP DSL attributes are unavailable, AAA maps the session's advisory upstream and downstream data rates (as configured on the session's underlying interface) to the Juniper Networks VSAs, Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141], respectively. AAA subsequently provides only these VSAs to RADIUS.

For successful authentication and accounting by RADIUS, AAA has to correlate PPPoE and DHCP IP demux sessions with their access lines and their associated DSL attributes. Some access nodes provide the ACI in PADI/PADR packets for the PPPoE sessions or in the DHCP discovery packets for DHCP IP demux sessions.

When the ACI is not provided in a 1:1 VLAN model with interface sets, you must associate the underlying interface for the sessions with the identifier and the interface set. If you do not configure this association, then only the advisory traffic rates are provided to RADIUS. This configuration has no effect when the identifier is provided by the access node.

For the N:1 VLAN model with interface sets, the access node must provide the ACI. If you configure the underlying interface for this model when the access node does not provide the identifier, the subscriber sessions can be incorrectly correlated with access lines.

AAA reports values to RADIUS for the Juniper Networks VSAs 26-141 and 26-142 according to the following scheme:

1. When the PPPoE or DHCP IP demux subscriber session can be correlated with an access line, then the ANCP agent adjusts the downstream and upstream traffic rates reported by the access node according to the ANCP agent CoS configuration. The agent then maps the adjusted rates to Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141].
2. If the session cannot be correlated with an access line, but the PPPoE or DHCP discovery packet includes the DSL Forum VSA and the Access-Loop-Encapsulation subattribute includes a value for the AAL5 data link, then the ANCP agent adjusts the Actual-Data-Rate-Downstream and Actual-Data-Rate-Upstream subattributes to account for the ATM 48/53 cell tax. The adjusted rates mapped to Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141].
3. If neither of the preceding sets of conditions is satisfied, then the ANCP agent simply maps the recommended downstream and upstream data rates to Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141]. The recommended rates are either configured statically for the VLAN or VLAN demux interfaces or are in the dynamic profile that creates the interfaces.

To map an ACI to a static VLAN demux interface, include the **access-identifier** *identifier* statement at the **[edit protocols ancp interfaces demux0.logical-unit-number]** hierarchy level.

To configure advisory upstream and downstream data rates on a static VLAN demux interface, include the **upstream-rate** *rate* or **downstream-rate** *rate* statements at the **[edit interfaces demux0 unit logical-unit-number]** hierarchy level.

To configure an underlying interface for the PPPoE sessions in an interface set, include the **underlying-interface** *interface-name* statement at the **[edit protocols ancp interfaces interface-set interface-set-name]** hierarchy level.

When an ACI, and therefore a subscriber access line, has been mapped to an interface or interface set, the ACI can be re-mapped to a different interface or set. When this happens, traffic shaping is adjusted accordingly for the interfaces or interface sets involved. This capability is useful for the Business Services model, where a PPPoE session that is initially classified as a residential household can be reclassified as a business subscriber during RADIUS authentication by using a Junos OS ICE AAA framework Op-Script application.

In the Business Services Model, the PPPoE session initially represents a residential household until RADIUS authentication and authorization takes place. The ANCP agent dynamically maps the household's access line to the appropriate subscriber interface and applies CoS traffic shaping to the interface. During authentication and authorization, the Op-Script application may classify the PPPoE session as a business subscriber rather than a residential subscriber. If this occurs, the application creates multiple static VLANs and groups them into an interface set. Based on the ANCP agent configuration, the application then statically maps the subscriber's access line to this static interface set. This interface set can include only static interfaces.

The ANCP agent reverts CoS traffic shaping from the interface previously used by the subscriber and instead applies the shaping to the interface set. This reversion means that the CoS process applies to the interface the next shaping rate in its adjustment control profile.

## ANCP DSL Attributes Mapped to Juniper Networks DSL Vendor-Specific Attributes

Digital Subscriber Line (DSL) attributes are RADIUS vendor-specific attributes (VSAs) that are defined by the DSL Forum in RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes*. The attributes transport DSL information that is not supported by standard RADIUS attributes and which conveys details about the associated DSL subscriber line and traffic. These attributes are contained as subattributes in the single DSL Forum VSA (IANA vendor ID 3561). An ANCP access node can provide this information to the router in a PPPoE PADI message during PPPoE subscriber discovery.

The access node can also report the same information about the DSL subscriber line and traffic information by means of the ANCP DSL TLVs or attributes carried in ANCP messages to the router. The ANCP attributes are defined in RFC 6320, *Protocol for Access Node Control Mechanism in Broadband Networks*. These ANCP DSL attributes correspond to Juniper Networks (IANA vendor ID 4874) DSL VSAs and to DSL Forum VSAs.

The router simply passes the DSL line and traffic information that it receives from the access node to the RADIUS server, without performing any parsing or manipulation. A RADIUS authentication or accounting message can contain any combination of the DSL Forum VSAs and the Juniper Networks DSL VSAs. You can configure the RADIUS access profile to exclude one or more individual attributes, or all DSL Forum attributes, from being included in RADIUS messages.

The DSL Forum attribute and subattributes received by the router during PPPoE and DHCP client discovery are not updated after discovery, whereas the equivalent ANCP DSL attributes are updated whenever there is a change to the access line.

[Table 56 on page 659](#) shows the relationship between the ANCP DSL attributes, Juniper Networks DSL VSAs, and DSL Forum VSAs.

**Table 56: Mapping ANCP DSL Attributes to Juniper Networks DSL VSAs and DSL Forum VSAs**

| ANCP DSL Attribute Name [Type Number]         | Juniper Networks VSA (Vendor ID 4874) Name [RADIUS Attribute Number]                                                                                                                                                        | DSL Forum VSA (Vendor ID 3561) Name [RADIUS Attribute Number] |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| Access-Aggregation-Circuit-ID-ASCII [0x0003]  | Acc-Aggr-Cir-Id-Asc [26-112]                                                                                                                                                                                                | -                                                             |
| Access-Aggregation-Circuit-ID-Binary [0x0006] | Acc-Aggr-Cir-Id-Bin [26-111]                                                                                                                                                                                                | -                                                             |
| Access-Loop-Circuit-ID [0x0001]               | Acc-Loop-Cir-Id [26-110]                                                                                                                                                                                                    | Agent-Circuit-Id [26-1]                                       |

## Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages

You can include the **juniper-dsl-attributes** statement to configure AAA to add the set of Juniper Networks DSL VSAs to the RADIUS authentication and accounting request messages for subscribers. By default, these VSAs are not added to any RADIUS message. See [“ANCP DSL Attributes Mapped to Juniper Networks DSL Vendor-Specific Attributes” on page 658](#) for a table of the Juniper Networks DSL VSAs.

After you have configured the inclusion of the Juniper Networks VSAs, you can subsequently exclude one or more of the VSAs from being transmitted. To do so, include the **exclude** statement at the **[edit access profile *profile-name* radius attributes]** hierarchy level, and specify which VSAs to exclude.

In contrast to the Juniper Networks DSL VSAs (vendor ID 4874), the DSL Forum VSA (vendor ID 3561) is added to all RADIUS messages by default. The DSL Forum VSA conveys individual DSL Forum attributes. See [“DSL Forum Vendor-Specific Attributes” on page 45](#) for a table of these VSAs. You can use the **exclude** statement at the **[edit access profile *profile-name* radius attributes]** hierarchy level to prevent this VSA from being included in any RADIUS message.

To add the Juniper Networks DSL VSAs to RADIUS messages:

- Configure the inclusion trigger.

```
[edit access profile profile-name radius options]
user@host# set juniper-dsl-attributes
```

To exclude specific Juniper Networks DSL VSAs from RADIUS messages:

- Configure the exclusion trigger.

```
[edit access profile profile-name radius attributes]
user@host# set exclude vsa-option
```

For example, to exclude the interleaving delay VSAs, configure the following statements:

```
[edit access profile profile-name radius attributes]
user@host# set exclude max-interlv-delay-dn
user@host# set excludemax-interlv-delay-up
```

To exclude the DSL Forum (RFC 4679) VSA from RADIUS messages:

- Configure the exclusion trigger.

```
[edit access profile profile-name radius attributes]
user@host# set exclude dsl-forum-attributes
```

## Configuring Immediate Interim Accounting Updates to RADIUS in Response to ANCP Notifications

When an ANCP neighbor reports a change in the upstream traffic rate or downstream traffic rate of an access line, the ANCP agent immediately passes the information to AAA. By default, AAA does not pass this information on to the RADIUS server until the next accounting update. However, you can configure AAA to report the rate change immediately.

When you include the **ancp-speed-change-immediate-update** statement in the subscriber session access profile, receipt of the notification from the ANCP agent triggers AAA to send an interim update Accounting-Request message to the RADIUS server for the PPPoE and DHCP IP demux subscribers associated with that access line. The interim update request includes the new access line parameters and the adjusted upstream and downstream traffic rates.

To configure AAA to immediately send rate change information from the ANCP agent to the RADIUS server with interim accounting updates:

- Specify the immediate update.

```
[edit access profile profile-name accounting]
user@host# set ancp-speed-change-immediate-update
```

## ANCP Monitoring and Management

---

- [Triggering ANCP OAM to Test the Local Loop on page 662](#)
- [Verifying and Monitoring ANCP Neighbors on page 663](#)
- [Clearing ANCP Neighbors on page 663](#)
- [Verifying and Monitoring ANCP Subscribers on page 664](#)
- [Clearing ANCP Subscribers on page 664](#)
- [Clearing and Verifying ANCP Statistics on page 665](#)

### Triggering ANCP OAM to Test the Local Loop

You can trigger ANCP OAM to perform a loopback test on the local loop between the access node and the CPE to help isolate simple faults. On an ATM-based local loop, the ANCP operation triggers the access node to generate ATM (F4/F5) loopback cells on the local loop. On an Ethernet-based local loop, the ANCP operation triggers the access node to generate an Ethernet loopback message on the local loop. When the test completes, the access node sends a message to the router with the results.

Issue the **request ancp oam neighbor** command from CLI operational mode to initiate testing of a local loop identified by the IP address or system name of the ANCP neighbor and the ACI for a subscriber on that access node.

Issue the **request ancp oam interface** command from CLI operational mode to initiate testing of a local loop identified by the ANCP interface or interface set associated with a subscriber and the ACI for a subscriber on that access node.

With both commands, you can also specify how many times the test must be run and how long the router waits for a response to the OAM request.

To initiate ANCP local loop testing:

- Identify the loop by the subscriber identifier and the neighbor's IP address; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam neighbor ip-address 192.168.32.5 subscriber "dslam  
port-2-10" count 5 timeout 600
```

- Identify the loop by the subscriber identifier and the neighbor's system name; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam neighbor system-name 00:00:5E:00:53:ba subscriber  
"dslam port-2-10" count 10 timeout 600
```

- Identify the loop by the subscriber identifier and the interface associated with the subscriber; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam interface ge-1/0/2.12 identifier-string timeout 15
```

- Identify the loop by the subscriber identifier and the set of interfaces associated with the subscriber; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam interface interface-set vlan5 identifier-string count 3
```

## Verifying and Monitoring ANCP Neighbors

**Purpose** View ANCP neighbor information:

**Action** • To display summary information about all ANCP neighbors:

```
user@host> show ancp neighbor
```

- To display information about a specific ANCP neighbor, add the IP address or MAC address to the command:

```
user@host> show ancp neighbor ip-address 203.0.113.64
user@host> show ancp neighbor system-name 00:00:5E:00:53:ba
```

- To display detailed information, add **detail** to the command:

```
user@host> show ancp neighbor detail
```

```
user@host> show ancp neighbor system-name 00:00:5E:00:53:ba detail
```

- To display a count of ANCP neighbors in various states and the total number of neighbors, or a count of DSL lines in various states for all subscribers for a particular neighbor:

```
user@host> show ancp summary neighbor
user@host> show ancp summary neighbor 203.0.113.64
```

- To display total and state-wise counts of both ANCP neighbors and subscribers:

```
user@host> show ancp summary
```

## Clearing ANCP Neighbors

**Purpose** Clear ANCP neighbor information.

**Action** • To clear connections with all ANCP neighbors:

```
user@host> clear ancp neighbor
```

- To clear the connection with a specific ANCP neighbor, add the IP address or MAC address to the command:

```
user@host> clear ancp neighbor ip-address 203.0.113.64
```

```
user@host> clear ancp neighbor system-name 00:00:5E:00:53:ba
```

- To verify that the connection has been cleared:

```
user@host> show ancp neighbor
```

```
user@host> show ancp neighbor 203.0.113.64
```

```
user@host> show ancp neighbor 00:00:5E:00:53:ba
```

## Verifying and Monitoring ANCP Subscribers

**Purpose** View ANCP subscriber (local access loop) information:

- Action**
- To display summary information about all ANCP subscribers:

```
user@host> show ancp subscriber
```

- To display information about all ANCP subscribers connected through a particular ANCP neighbor:

```
user@host> show ancp subscriber neighbor 203.0.113.64
```

- To display information about an ANCP subscriber specified by the ACI:

```
user@host> show ancp subscriber "port-2-11"
```

- To display detailed information, add **detail** to the command:

```
user@host> show ancp subscriber detail
```

```
user@host> show ancp subscriber neighbor 203.0.113.64 detail
```

- To display a count of subscribers in various states and the total number of subscribers:

```
user@host> show ancp summary subscriber
```

- To display total and state-wise counts of both ANCP neighbors and subscribers:

```
user@host> show ancp summary
```

## Clearing ANCP Subscribers

**Purpose** Clear ANCP subscriber information.

- Action**
- To clear connections with all ANCP subscribers that are not mapped:

```
user@host> clear ancp subscriber
```

- To clear connections with all ANCP subscribers that are mapped:

```
user@host> clear ancp neighbor
```

- To clear the connection with an ANCP subscriber identified by a particular ACI on all neighbors, add the identifier to the command:

```
user@host> clear ancp subscriber identifier port-2-10
```

- To clear the connection with an ANCP subscriber identified by a particular ACI on a specific neighbor, add the identifier and either the IP address or MAC address to the command:

```
user@host> clear ancp subscriber identifier port-2-10 ip-address 203.0.113.64
```

```
user@host> clear ancp subscriber identifier port-2-10 system-name 00:00:5E:00:53:ba
```

- To verify that the connection has been cleared:

```
user@host> show ancp subscriber
```

## Clearing and Verifying ANCP Statistics

**Purpose** Clear ANCP statistics.

**Action** • To clear all ANCP statistics:

```
user@host> clear ancp statistics
```

- To clear statistics for a specific ANCP neighbor, add the IP address or MAC address to the command:

```
user@host> clear ancp statistics ip-address 203.0.113.64
```

```
user@host> clear ancp statistics system-name 00:00:5E:00:53:ba
```

- To verify that the statistics have been cleared:

```
user@host> show ancp statistics
```

## Tracing ANCP Events for Troubleshooting

The Junos OS trace feature tracks ANCP agent operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `ancpd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the [System Log Explorer](#).)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

The following topics describe how to configure all aspects of tracing ANCP agent operations:

- [Configuring the ANCP Trace Log Filename on page 666](#)
- [Configuring the Number and Size of ANCP Log Files on page 666](#)
- [Configuring Access to the ANCP Log File on page 667](#)
- [Configuring a Regular Expression for ANCP Messages to Be Logged on page 667](#)
- [Configuring the ANCP Tracing Flags on page 668](#)
- [Configuring the Severity Level to Filter Which ANCP Messages Are Logged on page 668](#)

## Configuring the ANCP Trace Log Filename

By default, the name of the file that records trace output for ANCP is `ancpd`. You can specify a different name with the `file` option.

To configure the filename for ANCP tracing operations:

- Specify the name of the file used for the trace output.

```
[edit protocols ancp traceoptions]  
user@host# set file ancp_1
```

## Configuring the Number and Size of ANCP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format *.number.gz*. The newest archived file is *.0.gz* and the oldest archived file is *.(maximum number)-1.gz*. When the

current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.

```
[edit protocols ancp traceoptions]
user@host# set file ancp_1_logfile_1 files 20 size 2097152
```

## Configuring Access to the ANCP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit protocols ancp traceoptions]
user@host# set file ancp_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit protocols ancp traceoptions]
user@host# set file ancp_1_logfile_1 no-world-readable
```

## Configuring a Regular Expression for ANCP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit protocols ancp traceoptions]  
user@host# set file ancp_1 _logfile_1 match regex
```

## Configuring the ANCP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit protocols ancp traceoptions]  
user@host# set flag restart
```

## Configuring the Severity Level to Filter Which ANCP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

```
[edit protocols ancp traceoptions]  
user@host# set level severity
```

## Diameter Base Protocol Overview

The Diameter protocol is defined in *RFC 3588, Diameter Base Protocol*, and provides an alternative to RADIUS that is more flexible and extensible. The Diameter base protocol provides basic services to one or more applications (also called functions) that each runs in a different Diameter instance. The individual application provides the extended AAA functionality. Applications that use Diameter include Gx-Plus, JSRC, NASREQ, and

PTSP. Starting in Junos OS Release 13.1R1, the packet-triggered subscribers and policy control (PTSP) feature is no longer supported.

Diameter peers communicate over a reliable TCP transport layer connection by exchanging Diameter messages that convey status, requests, and acknowledgments by means of standard Diameter AVPs and application-specific AVPs. The Diameter transport layer configuration is based on Diameter network elements (DNEs); multiple DNEs per Diameter instance are supported. Currently only the predefined *master* Diameter instance is supported, but you can configure alternative values for many of the master Diameter instance values.

Each DNE consists of a prioritized list of peers and a set of routes that define how traffic is forwarded. Each route associates a destination with a function (application), a function partition, and a metric. When an application sends a message to a routed destination, all routes within the Diameter instance are examined for a match. When the best route to the destination has been selected, the message is forwarded by means of the DNE that includes that route.

Multiple routes to the same destination can exist within a given DNE and in different DNEs. In the case of multiple routes that match a request for forwarding, the best route is selected as follows:

1. The route with the lowest metric is selected.
2. In the event of a tie, the route with the highest specification score is selected.
3. In the event of another tie, then the names of the DNEs are compared in lexicographical order. The route in the DNE with the lowest value is selected. For example, dne-austin has a lower value than dne-boston.
4. If the routes are tied within the same DNE, then the route names are compared in lexicographical order. The route with the lowest value is selected.

The specification score of a route is 0 by default. Points are added to the score as follows:

- If the destination realm matches the request, add 1.
- If the destination host matches the request, add 2.
- If the function matches the request, add 3.
- If the function partition matches the request, add 4.

Multiple routes to the same destination can exist within a given DNE and in different DNEs. In the case of multiple routes that match a request for forwarding, Diameter selects the best route as follows:

1. Diameter compares the metric of the routes and selects the route with the lowest metric.
2. If multiple routes have the same lowest metric, then Diameter selects the most-qualified route. Diameter evaluates multiple attributes of the route to determine a score that reflects how specifically each route matches the request. By default, the score of a route is 0. Points are added to the score as follows:
  - If the destination realm matches the request, add 1.
  - If the destination host matches the request, add 2.
  - If the function matches the request, add 3.
  - If the function partition matches the request, add 4.
3. If multiple routes are equally qualified, then Diameter compares the names of the DNEs in lexicographical order and selects the route in the DNE that has the lowest value. For example, dne-austin has a lower value than dne-boston.
4. If the routes are tied within the same DNE, then Diameter compares the route names in lexicographical order and selects the route with the lowest value.

When the state of any DNE changes, the route lookup for all destinations is reevaluated. All outstanding messages to routed destinations are rerouted as needed, or discarded.

To configure a Diameter network element, include the **network-element** statement at the **[edit diameter]** hierarchy level, then include the **route** statement at the **[edit diameter network-element element-name forwarding]** hierarchy level.

To configure a route for the DNE, include the **destination** (optional), **function** (optional), and **metric** statements at the **[edit diameter network-element element-name forwarding route dne-route-name]** hierarchy level.

Specify the Diameter peers associated with the DNE by including one or more **peer** statements at the **[edit diameter network-element element-name]** hierarchy level.

Specify the Diameter peers associated with the DNE by including one or more **peer** statements at the **[edit diameter network-element element-name]** hierarchy level.

Set the priority for each peer with the **priority** statement at the **[edit diameter network-element element-name peer peer-name]** hierarchy level.

Diameter requires you to configure information about the origin node; this is the endpoint node that originates Diameter for the Diameter instance. Include the **host** and **realm** statements at the **[edit diameter]** hierarchy level to configure the Diameter origin.

You can optionally configure one or more *transports* to specify the source (local) address of the transport layer connection. To configure a Diameter transport, include the **transport** statement at the **[edit diameter]** hierarchy level. Then include the **address** statement at the **[edit diameter transport transport-name]** hierarchy level.

You can optionally specify a logical system and routing instance for the connection by including the **logical-system** and **routing-instance** statements at the **[edit diameter transport transport-name]** hierarchy level. By default, Diameter uses the *default* logical system and *master* routing instance. The logical system and routing instance for the transport connection must match that for the peer, or a configuration error is reported.

Each Diameter peer is specified by a name. Peer attributes include address and the destination TCP port used by active connections to this peer. To configure a Diameter peer, include the **peer** statement at the **[edit diameter]** hierarchy level, and then include the **address** and **connect-actively** statements at the **[edit diameter peer peer-name]** hierarchy level.

To configure the active connection, include the **port** and **transport** statements at the **[edit diameter peer peer-name connect-actively]** hierarchy level. The assigned transport identifies the transport layer source address used to establish active connections to the peers. **transport** statements.

---

### Benefits of Using Diameter

Diameter is an enhanced AAA protocol that compared to RADIUS offers reliable transport, error handling, capability negotiation, and extensibility. Diameter has a peer-to-peer architecture compared to the RADIUS client-server design. Diameter enables dynamic peer discovery rather than requiring manual configuration of servers and supports secure, scalable roaming. Diameter applications can be defined for specific needs that operate on top of the Diameter base protocol. Diameter applications have authentication and authorization messages and corresponding attributes appropriate to the functionality of the application. Diameter supports authorization without authentication.

### Messages Used by Diameter Applications

Junos OS supports the following Diameter applications:

- JSRC—A Juniper Networks Diameter application registered with the IANA (<http://www.iana.org>) as Juniper Policy-Control-JSRC, with an ID of 16777244. It communicates with the SAE (remote SRC peer).
- PTSP—A Juniper Networks Diameter application registered with the IANA (<http://www.iana.org>) as Juniper JGx, with an ID of 16777273. It communicates with the SAE (remote SRC peer). Starting in Junos OS Release 13.1R1, the packet-triggered subscribers and policy control (PTSP) feature is no longer supported.
- Gx-Plus—An application that extends the 3GPP Gx interface for wireline use cases. 3GPP Gx is registered with the IANA (<http://www.iana.org>). It communicates with a PCRF.

If data for a particular AVP included in a message is not available to the router, Gx-Plus simply omits the AVP from the message it sends to the PCRF. If the PCRF determines it has insufficient information to make a determination, it may deny the request. The

Diameter answer messages include the Result-Code AVP (AVP 268); the values of this AVP convey success, failure, or errors to the requestor.

- NASREQ—A Diameter-based authentication, authorization, and accounting protocol defined in RFC 7155. Junos OS supports authentication and authorization only.

Juniper Networks has also registered the Juniper-Session-Recovery application (16777296) and two new command codes (8388628 for Juniper-Session-Events and 8388629 for Juniper-Session-Discovery) with the IANA (<http://www.iana.org>).

Table 57 on page 675 describes Diameter messages the applications use.

**Table 57: Diameter Messages and Diameter Applications**

| Diameter Message                  | Code | Application        | Description                                                                                                                                                                                                                                     |
|-----------------------------------|------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AA-Request (AAR)                  | 265  | JSRC, NASREQ, PTSP | Request from the application to the SAE at new subscriber login or during SAE-application synchronization. The request can be one of three types: address-authorization, provisioning-request, or synchronization.                              |
| AA-Answer (AAA)                   | 265  | JSRC, NASREQ, PTSP | Response from the SAE to the application's AA-Request message.                                                                                                                                                                                  |
| Abort-Session-Request (ASR)       | 274  | JSRC, NASREQ, PTSP | Request from the SAE to the application to log out a provisioned subscriber.                                                                                                                                                                    |
| Abort-Session-Answer (ASA)        | 274  | JSRC, NASREQ, PTSP | Response from the application to the SAE's ASR message. If the application sends the logout request to AAA, the ASA message includes a success notification (ACK). If the logout failed, the ASA message includes a failure notification (NAK). |
| Accounting-Request (ACR)          | 271  | JSRC, PTSP         | Request from the SAE to the application or from the application to the SAE for statistics.                                                                                                                                                      |
| Accounting-Answer (ACA)           | 271  | JSRC, PTSP         | Response to the ACR message to provide statistics for each installed policy (service).                                                                                                                                                          |
| Capability Exchange Request (CER) | 257  | Gx-Plus            | Request from one peer to another when the peers establish a transport connection; initiates the capability negotiation. The CER announces the peer's identity and capabilities, such as applications and security mechanisms supported.         |

*Table 57: Diameter Messages and Diameter Applications (continued)*

| Diameter Message                 | Code | Application | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------|------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Capability Exchange Answer (CEA) | 257  | Gx-Plus     | Response to the CER message to announce this peer's capabilities. If this peer has no capabilities in common with the peer that sent the CER, then it must set the Result-Code AVP to <code>DIAMETER_NO_COMMON_APPLICATION</code> and should drop the connection. Otherwise, the CEA details establish common capabilities between the peers and enable them to further establish communication. |

Table 57: Diameter Messages and Diameter Applications (continued)

| Diameter Message             | Code | Application | Description |
|------------------------------|------|-------------|-------------|
| Credit-Control-Request (CCR) | 272  | Gx-Plus     |             |

Table 57: Diameter Messages and Diameter Applications (continued)

| Diameter Message | Code | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |      |             | Request from Gx-Plus to the PCRF at subscriber login, logout, or update.                                                                                                                                                                                                                                                                                                                                                                                        |
|                  |      |             | An initial request (CCR-I) is sent when a subscriber logs in and AAA is requested to activate the subscriber's session. Gx-Plus retries the CCR-I message if a CCA-I message is not received from the PCRF within 10 seconds. The CCR-I message is retried up to 3 times.                                                                                                                                                                                       |
|                  |      |             | The CCR-I message includes the Diameter AVP Subscription-Id attribute (443) with the Subscription-Id-Type Diameter AVP sub-attribute (450) set to 4 (END_USER_PRIVATE) and the Subscription-Id-Data Diameter AVP sub-attribute (444) set to <b>reserved</b> .                                                                                                                                                                                                   |
|                  |      |             | If no CCA-I is received after the 4 CCR-I messages have been sent—the first message plus 3 retries—then Gx-Plus starts sending CCR-N messages. CCR-N messages are retried forever until a success or failure response is received from the PCRF. CCR-N messages include the Juniper-Provisioning-Source AVP (AVP code 2101) set to local to notify the PCRF that the router has the authority to make a local decision regarding subscriber service activation. |
|                  |      |             | An update request (CCR-U) message is sent when a usage threshold is reached. The CCR-U reports the actual usage for all statistics. The PCRF may return a CCA-U message that includes new monitoring thresholds, service activations, service deactivations.                                                                                                                                                                                                    |
|                  |      |             | If the PCRF times out on the CCR-U report, the router sets the threshold default to 10 minutes. When the change in threshold values is less than the minimum, the values are adjusted to the minimums. For example, the minimum increase for duration is 10 minutes.                                                                                                                                                                                            |
|                  |      |             | A CCR-U is also sent to report the status of service activation or deactivation. When a monitored service is deactivated separate from a subscriber logout, the CCR-U indicates that the service is no longer active and includes the service's usage data.                                                                                                                                                                                                     |
|                  |      |             | A CCR-U is sent to the PCRF after the                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 57: Diameter Messages and Diameter Applications (continued)

| Diameter Message                         | Code    | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------|---------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          |         |             | <p>router sends an RAA message in response to an RAR message that requests service activations or deactivations.</p> <p>A termination request (CCR-T) is sent at subscriber logout to inform the PCRF that a provisioned subscriber session is being terminated. CCR-T messages are retried forever until a success response is received from the PCRF.</p> <p>When a monitored service is deactivated as part of the subscriber logout, the CCR-T message includes monitored usage data for the service, such as bytes used.</p>                                                                                              |
| Credit-Control-Answer (CCA)              | 272     | Gx-Plus     | <p>Reply from the PCRF to a CCR message.</p> <p>In response to a CCR-I, the PCRF returns a CCA-I message that indicates success (DIAMETER_SUCCESS) or failure (DIAMETER_AUTHORIZATION_REJECTED) depending on whether the subscriber has sufficient credit for the requested services. All other responses are ignored and the CCR-I is retried.</p> <p>In response to a CCR-T, the PCRF returns a CCA-T message that indicates a successful termination with a value of 2001 (DIAMETER_SUCCESS) in the Result-Code AVP. All other responses are ignored and the CCR-T is retried.</p> <p>A CCA-N is a response to a CCR-N.</p> |
| Juniper-Session-Discovery-Request (JSDR) | 8388629 | Gx-Plus     | Discovery request from the PCRF to Gx-Plus to discover subscriber sessions on the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Juniper-Session-Discovery-Answer (JSDA)  | 8388629 | Gx-Plus     | <p>Reply from router to a JSDR message; describes session information. The Result-Code AVP includes one of the following values, or an error value:</p> <ul style="list-style-type: none"> <li>• 2001—DIAMETER_SUCCESS; the end of the database was reached, meaning all information has been sent.</li> <li>• 2002—DIAMETER_LIMITED_SUCCESS; some of the session information was sent, but more remains to be sent.</li> </ul>                                                                                                                                                                                                |

Table 57: Diameter Messages and Diameter Applications (continued)

| Diameter Message                     | Code    | Application | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------|---------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Juniper-Session-Event-Request (JSER) | 8388628 | Gx-Plus     | Request from router to PCRF regarding events that take place on the router. Notifies the PCRF of certain events on the router by including the Juniper-Event-Type AVP (AVP code 2103). Events reported include cold or warm boots, explicit discovery requests, substantial configuration changes, non-response or error response from PCRF, and exhaustion of fault-tolerant resources.              |
| Juniper-Session-Event-Answer (JSEA)  | 8388628 | Gx-Plus     | Reply from PCRF to a JSER message.                                                                                                                                                                                                                                                                                                                                                                    |
| Push-Profile-Request (PPR)           | 288     | JSRC, PTSP  | Request from the SAE to the router to activate or deactivate services for a subscriber.                                                                                                                                                                                                                                                                                                               |
| Push-Profile-Answer (PPA)            | 288     | JSRC, PTSP  | Response from the router to the SAE's PPR message. Includes success or failure notification for each of the service activation or deactivation commands in the request.                                                                                                                                                                                                                               |
| Re-Auth-Request (RAR)                | 258     | Gx-Plus     | <p>Audit request from the PCRF to router to determine whether a specific subscriber is still present.</p> <p>The router updates the monitoring key and threshold values when they are received in the RAR.</p>                                                                                                                                                                                        |
| Re-Auth-Answer (RAA)                 | 258     | Gx-Plus     | <p>Reply from router to a RAR message; indicates whether the subscriber is active. The Result-Code AVP includes one of the following values:</p> <ul style="list-style-type: none"> <li>2001—DIAMETER_SUCCESS; subscriber entry was found.</li> <li>5002—DIAMETER_UNKNOWN_SESSION_ID; subscriber entry was not found.</li> <li>3002—DIAMETER_UNABLE_TO_DELIVER; Gx-Plus is not configured.</li> </ul> |
| Session-Resource-Query (SRQ)         | 277     | JSRC, PTSP  | Request from the router to the SAE or from the SAE to the router to initiate synchronization between router and the SAE.                                                                                                                                                                                                                                                                              |
| Session-Resource-Reply (SRR)         | 277     | JSRC, PTSP  | Response to the SRQ message to begin synchronization.                                                                                                                                                                                                                                                                                                                                                 |

**Table 57: Diameter Messages and Diameter Applications (continued)**

| Diameter Message                  | Code | Application        | Description                                                                                  |
|-----------------------------------|------|--------------------|----------------------------------------------------------------------------------------------|
| Session-Termination-Request (STR) | 275  | JSRC, NASREQ, PTSP | Notification from the router to the SAE that a provisioned subscriber has logged out.        |
| Session-Termination-Answer (STA)  | 275  | JSRC, NASREQ, PTSP | Response from the SAE to the router's STR message. Includes success or failure notification. |

## Diameter AVPs and Diameter Applications

Diameter conveys information by including various attribute-value pairs (AVPs) in Diameter messages, in the same way that RADIUS conveys information in both standard IETF RADIUS attributes and vendor-specific attributes (VSAs). [Table 58 on page 681](#) lists the standard Diameter AVPs used in interactions with the supported Diameter applications. Diameter reserves AVP attribute numbers 0 through 255 for RADIUS attributes that are implemented in Diameter; the Diameter attribute numbers are the same as for the corresponding standard RADIUS attributes. Attributes numbered higher than 255 have no corresponding standard RADIUS attribute. Starting in Junos OS Release 13.1R1, the packet-triggered subscribers and policy control (PTSP) feature is no longer supported.

**Table 58: Standard Diameter AVPs**

| Attribute Number | Diameter AVP      | Application                 | Description                                                                                                                                                                                                                                       | Type        |
|------------------|-------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 1                | User-Name         | Gx-Plus, JSRC, NASREQ       | Specifies the username. For a subscriber managed by AAA, the value is the subscriber's login name. For a static interface, the value is the interface name, which is used as the subscriber's login name.                                         | UTF8String  |
| 2                | User-Password     | NASREQ                      | Specifies the password of the user to be authenticated or the user's input in a multi-round authentication exchange.                                                                                                                              | OctetString |
| 4                | NAS-IP-Address    | NASREQ                      | Specifies the IP address of the NAS that is authenticating the user.                                                                                                                                                                              | IPAddress   |
| 6                | Service-Type      | NASREQ                      | Specifies the type of service the user has requested or the type of service to be provided. One such AVP may be present in an authentication or authorization request or response. A NAS is not required to implement all of these service types. | Enumerated  |
| 8                | Framed-IP-Address | Gx-Plus, JSRC, NASREQ, PTSP | Identifies the IPv4 address configured for the subscriber. This is the same value as for RADIUS Framed-IP-Address attribute [8].                                                                                                                  | OctetString |

Table 58: Standard Diameter AVPs (continued)

| Attribute Number | Diameter AVP          | Application         | Description                                                                                                                                                        | Type        |
|------------------|-----------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 9                | Framed-IP-Netmask     | NASREQ              | Identifies the four octets of the IPv4 netmask.                                                                                                                    | OctetString |
| 11               | Filter-ID             | NASREQ              | Specifies the name of the filter list for a user. It is intended to be human readable. Zero or more Filter-Id AVPs may be sent in an authorization answer message. | UTF8String  |
| 12               | Framed-MTU            | NASREQ              | Specifies the maximum transmission unit (MTU) to be configured for the user, when it is not negotiated by some other means (such as PPP).                          | Unsigned32  |
| 22               | Framed-Route          | NASREQ              | Specifies the 7-bit US-ASCII routing information.                                                                                                                  | UTF8String  |
| 25               | Class                 | NASREQ              | Returns state information from a Diameter server to the access device.                                                                                             | OctetString |
| 27               | Session-Timeout       | NASREQ              | Specifies the maximum number of seconds of service provided to the user before termination of the session.                                                         | Unsigned32  |
| 28               | Idle-Timeout          | NASREQ              | Specifies the maximum number of consecutive seconds of idle connection allowable to the user before termination of the session or before a prompt is issued.       | Unsigned32  |
| 32               | NAS-Identifier        | NASREQ              | Specifies the identity of the NAS that provides service to the user.                                                                                               | DiamIdent   |
| 44               | Acct-Session-ID       | NASREQ              | Specifies the contents of the RADIUS Acct-Session-Id attribute.                                                                                                    | OctetString |
| 50               | Acct-Multi-Session-ID | NASREQ              | Links multiple related accounting sessions, where each session has a unique Session-Id but the same Acct-Multi-Session-Id AVP.                                     | UTF8String  |
| 55               | Event-Timestamp       | Gx-Plus, JSRC, PTSP | Specifies the time of the event that triggered the message in which this AVP is included. Time is indicated in seconds since January 1, 1900, 00:00 UTC.           | Time        |
| 60               | CHAP-Challenge        | NASREQ              | Specifies the PPP Challenge-Handshake Authentication Protocol (CHAP) challenge sent by the NAS to the CHAP peer.                                                   | OctetString |
| 61               | NAS-Port-Type         | NASREQ              | Specifies the type of the port on which the NAS is authenticating the user.                                                                                        | Enumerated  |

Table 58: Standard Diameter AVPs (continued)

| Attribute Number | Diameter AVP          | Application                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Type        |
|------------------|-----------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 62               | Port-Limit            | NASREQ                      | Specifies the maximum number of ports the NAS provides to the user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Unsigned32  |
| 78               | Configuration-Token   | NASREQ                      | Indicates the type of user profile used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | OctetString |
| 85               | Acct-Interim-Interval | JSRC, PTSP                  | <p>Specifies the number of seconds between each interim accounting update for this session.</p> <p>The router uses the following guidelines for interim accounting:</p> <ul style="list-style-type: none"> <li>Attribute value is within the acceptable range (600 through 86,400 seconds)—Accounting is updated at the specified interval.</li> <li>Attribute value is less than the minimum acceptable value—Accounting is updated at the minimum interval (600 seconds).</li> <li>Attribute value is greater than the maximum acceptable value—Accounting is updated at the maximum interval (86,400 seconds).</li> </ul> | Unsigned32  |
| 87               | NAS-Port-Id           | Gx-Plus, JSRC, NASREQ, PTSP | Identifies the port of the NAS that authenticates the user. This is the same value as for RADIUS NAS-Port-Id attribute [87].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | UTF8String  |
| 88               | Framed-Pool           | NASREQ                      | Specifies the name of an assigned address pool to use to assign an address for the user. If a NAS does not support multiple address pools, the NAS disregards this AVP. Address pools are usually used for IP addresses but can be used for other protocols if the NAS supports pools for those protocols.                                                                                                                                                                                                                                                                                                                   | OctetString |
| 97               | Framed-IPv6-Prefix    | NASREQ                      | Specifies the IPv6 prefix configured for the user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | OctetString |
| 99               | Framed-IPv6-Route     | NASREQ                      | Specifies the US-ASCII routing information configured for the user on the NAS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | UTF8String  |
| 100              | Framed-IPv6-Pool      | NASREQ                      | Specifies the name of an assigned pool to use to assign an IPv6 prefix for the user. If the access device does not support multiple prefix pools, it must disregard this AVP.                                                                                                                                                                                                                                                                                                                                                                                                                                                | OctetString |

*Table 58: Standard Diameter AVPs (continued)*

| Attribute Number | Diameter AVP        | Application                 | Description                                                                                                          | Type       |
|------------------|---------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------|------------|
| 258              | Auth-Application-ID | NASREQ                      | Specifies support of the Authentication and Authorization portion of an application.                                 | Unsigned32 |
| 263              | Session-ID          | Gx-Plus, JSRC, NASREQ, PTSP | Specifies the subscriber session identifier. The router assigns the value to uniquely identify a subscriber session. | UTF8String |
| 264              | Origin-Host         | NASREQ                      | Specifies the host that originates a Diameter message.                                                               | DiamIdent  |

Table 58: Standard Diameter AVPs (continued)

| Attribute Number | Diameter AVP | Application                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Type       |
|------------------|--------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 268              | Result-Code  | Gx-Plus, JSRC, NASREQ, PTSP | <p>Indicates whether a request completed successfully. Provides an error code if the request failed.</p> <p>The following classes are recognized by Diameter:</p> <ul style="list-style-type: none"> <li>• 1xxx—Informational</li> <li>• 2xxx—Success</li> <li>• 3xxx—Protocol errors</li> <li>• 4xxx—Transient errors</li> <li>• 5xxx—Permanent failures</li> </ul> <p>Unrecognized classes, which begin with numerals 6–9 or 0, are handled as permanent failures.</p> <p>JSRC and PTSP support the following values; all non-success values are treated as permanent failures:</p> <ul style="list-style-type: none"> <li>• 1001—DIAMETER MULTI ROUND AUTH</li> <li>• 2001—DIAMETER SUCCESS</li> <li>• 5002—DIAMETER UNKNOWN SESSION ID</li> <li>• 5012—DIAMETER UNABLE TO COMPLY</li> </ul> <p>JSRC also supports the following value, which is treated as a permanent failure:</p> <ul style="list-style-type: none"> <li>• 3004—DIAMETER TOO BUSY; this is a transient condition, typically when the router already has a request in process for a specified subscriber.</li> </ul> <p>Gx-Plus supports the following values for errors in a PCRF response; when these values are received or the response is malformed or unrecognizable, the request is retried.</p> <ul style="list-style-type: none"> <li>• 3001—DIAMETER COMMAND NOT SUPPORTED; the application is not running or the command is not recognized.</li> <li>• 3004—DIAMETER TOO BUSY; the received message is above either the quota of downstream transactions or the outstanding message memory limit for messages from the network.</li> <li>• 5012—DIAMETER UNABLE TO COMPLY; the received message is greater than the local limit.</li> </ul> | Unsigned32 |

Table 58: Standard Diameter AVPs (continued)

| Attribute Number | Diameter AVP       | Application        | Description                                                                                                                                                                                                                                                                                                                                                                                                                              | Type       |
|------------------|--------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 269              | Product-Name       | Gx-Plus            | <p>Specifies the value for the Product-Name field in Capability Exchange Request (CER) and Capability Exchange Answer (CEA) messages. The value is always JUNOS unless a different name is configured with the <b>product-name</b> option at the <b>[edit diameter]</b> hierarchy level.</p> <p>If you change the product name, the router disconnects all existing connections to Diameter peers and reconnects using the new name.</p> | UTF8String |
| 277              | Auth-Session-State | JSRC, NASREQ, PTSP | <p>Indicates whether AAA session state is maintained.</p> <ul style="list-style-type: none"> <li>0—STATE MAINTAINED</li> <li>1—NO STATE MAINTAINED</li> </ul>                                                                                                                                                                                                                                                                            | Enumerated |
| 279              | Failed-AVP         | NASREQ             | Specifies debugging information in cases where a request is rejected or not fully processed due to erroneous information in a specific AVP. The value of the Result-Code AVP provides information on the reason for the Failed-AVP AVP.                                                                                                                                                                                                  | Grouped    |
| 281              | Error-Message      | NASREQ             | Specifies a human-readable error message that may accompany a Result-Code AVP. The Error-Message AVP is not intended to be useful in real-time; do not expect network entities to parse the message.                                                                                                                                                                                                                                     | UTF8String |
| 283              | Destination-Realm  | NASREQ             | Specifies the Diameter realm to which the Diameter message is routed.                                                                                                                                                                                                                                                                                                                                                                    | DiamIdent  |
| 293              | Destination-Host   | NASREQ             | Specifies the host to which a Diameter message is routed.                                                                                                                                                                                                                                                                                                                                                                                | DiamIdent  |
| 295              | Termination-Cause  | JSRC, NASREQ, PTSP | <p>Indicates the reason why a session was terminated on the access device.</p> <ul style="list-style-type: none"> <li>1—DIAMETER LOGOUT</li> <li>2—DIAMETER SERVICE NOT PROVIDED</li> <li>3—DIAMETER BAD ANSWER</li> <li>4—DIAMETER ADMINISTRATIVE</li> <li>5—DIAMETER LINK BROKEN</li> <li>6—DIAMETER AUTH EXPIRED</li> <li>7—DIAMETER USER MOVED</li> <li>8—DIAMETER SESSION TIMEOUT</li> </ul>                                        | Enumerated |

Table 58: Standard Diameter AVPs (continued)

| Attribute Number | Diameter AVP         | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Type       |
|------------------|----------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 296              | Origin-Realm         | NASREQ      | Identifies the Diameter realm of the originator of a Diameter message.                                                                                                                                                                                                                                                                                                                                                                                                               | DiamIdent  |
| 402              | CHAP-Auth            | NASREQ      | Specifies the information necessary to authenticate a user using CHAP.                                                                                                                                                                                                                                                                                                                                                                                                               | Grouped    |
| 415              | CC-Request-Number    | Gx-Plus     | Identifies a request within a session. The combination of Session-Id and CC-Request-Type is globally unique. The number is incremented for each request during the course of a session. The number is reset when a router high availability event takes place.                                                                                                                                                                                                                       | Unsigned32 |
| 416              | CC-Request-Type      | Gx-Plus     | Specifies the type of credit control request: <ul style="list-style-type: none"> <li>INITIAL REQUEST (1)</li> <li>UPDATE REQUEST (2)</li> <li>TERMINATION_REQUEST (3)</li> <li>EVENT REQUEST (4)</li> </ul>                                                                                                                                                                                                                                                                          | Enumerated |
| 431              | Granted-Service-Unit | Gx-Plus     | Contains the amount that can be provided of one or more of the following requested units specified by the client: CC-Input-Octets, CC-Output-Octets, CC-Time, or CC-Total-Octets. Included in CCA-I messages, and may be included in CCA-U messages.                                                                                                                                                                                                                                 | Grouped    |
| 443              | Subscription-Id      | Gx-Plus     | Contains the following sub-attributes that do not appear alone: <ul style="list-style-type: none"> <li>Subscription-Id-Type—(450) This subattribute has one of the following integer values: <ul style="list-style-type: none"> <li>0 = END_USER_E164</li> <li>1 = END_USER_IMSI</li> <li>2 = END_USER_SIP_URI</li> <li>3 = END_USER_NAI</li> <li>4 = END_USER_PRIVATE</li> </ul> </li> <li>Subscription-Id-Data—(444) This sub-attribute has a value of <b>reserved</b>.</li> </ul> | Grouped    |

Table 58: Standard Diameter AVPs (continued)

| Attribute Number | Diameter AVP           | Application     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Type        |
|------------------|------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 446              | Used-Service-Unit      | Gx-Plus         | Contains the amount of the requested units that have been actually used; measured from 4 when the service is activated. The units are one or more of the following requested units specified by the client: CC-Input-Octets, CC-Output-Octets, CC-Time, or CC-Total-Octets. Included in CCR-U messages.                                                                                                                                                                                                                                                                                                                                                                                                         | Grouped     |
| 480              | Accounting-Record-Type | JSRC, PTSP      | Specifies the type of account record for service accounting: <ul style="list-style-type: none"> <li>• INTERIM_RECORD—Accounting record sent between the start and stop records, at intervals specified by the Acct-Interim-Interval AVP (AVP code 85). It contains cumulative accounting data for the existing accounting session.</li> <li>• START_RECORD—Accounting record sent when the service is activated to initiate the accounting session. It contains accounting data relevant to the initiation of that session.</li> <li>• STOP_RECORD—Accounting record sent when the service is deactivated to terminate the accounting session. It contains cumulative data relevant to that session.</li> </ul> | Enumerated  |
| 1001             | Charging-Rule-Install  | Gx-Plus, NASREQ | Requests the installation of the rule (activation of the service) designated by the included Charging-Rule-Name AVP (1005). This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Grouped     |
| 1002             | Charging-Rule-Remove   | Gx-Plus         | Requests the removal of the rule (deactivation of the service) designated by the included Charging-Rule-Name AVP (1005). This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Grouped     |
| 1005             | Charging-Rule-Name     | Gx-Plus, NASREQ | Specifies the name of a specific rule that has been installed, modified, or removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | OctetString |
| 1066             | Monitoring-Key         | Gx-Plus         | Specifies which of the monitoring structures to use. Included in Charging-Rule-Install AVP (1001). The MX router does not support aggregation of statistics across services, so the value of this AVP must be different for each service. This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                             | OctetString |

**Table 58: Standard Diameter AVPs (continued)**

| Attribute Number | Diameter AVP                 | Application | Description                                                                                                                                                                                                                                                                                             | Type    |
|------------------|------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 1067             | Usage-Monitoring-Information | Gx-Plus     | Sets monitoring thresholds. When service statistics match at least one of the granted service values, the router sends a CCR-U report with the current statistics to the PCRF. Includes the Monitoring-Key AVP (1066) and the Granted-Service-Unit AVP (431). This AVP has a vendor ID of 10415 (3GPP). | Grouped |

Juniper Networks AVPs are used in addition to the standard Diameter AVPs. These AVPs have a vendor ID (enterprise number) of 2636 or 4874, and are similar in concept to RADIUS vendor-specific attributes (VSAs). [Table 59 on page 689](#) lists the Juniper Networks AVPs that the supported Diameter applications use.

**Table 59: Juniper Networks Diameter AVPs**

| Attribute Number | Diameter AVP                   | Vendor ID | Application | Description                                                                                                                                                                                                                                                                                                 | Type        |
|------------------|--------------------------------|-----------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 213              | Interface-Set-Targeting-Weight | 4874      | NASREQ      | Specify a weight for an interface set to associate it and its member links with an aggregated Ethernet member link for targeted distribution.                                                                                                                                                               | Unsigned32  |
| 214              | Interface-Targeting-Weight     | 4874      | NASREQ      | Specify a weight for an interface to associate it with an interface set and thus with the set's aggregated Ethernet member link for targeted distribution. When an interface set does not have a weight, then the interface weight value for the first authorized subscriber interface is used for the set. | Unsigned32  |
| 2004             | Juniper-Service-Bundle         | 2636      | JSRC        | Specifies the name of the service bundle.                                                                                                                                                                                                                                                                   | OctetString |
| 2010             | Juniper-DHCP-Options           | 2636      | JSRC        | Specifies the client's DHCP options.                                                                                                                                                                                                                                                                        | OctetString |
| 2011             | Juniper-DHCP-GI-Address        | 2636      | JSRC        | Specifies the DHCP relay agent's IP address.                                                                                                                                                                                                                                                                | OctetString |
| 2020             | Juniper-Policy-Install         | 2636      | JSRC, PTSP  | Specifies policies to be activated for the subscriber. Includes Juniper-Policy-Name and Juniper-Policy-Definition                                                                                                                                                                                           | Grouped     |
| 2021             | Juniper-Policy-Name            | 2636      | JSRC, PTSP  | Defines the name of a policy decision.                                                                                                                                                                                                                                                                      | OctetString |

Table 59: Juniper Networks Diameter AVPs (continued)

| Attribute Number | Diameter AVP               | Vendor ID | Application | Description                                                                                                                                                                                                                                                               | Type        |
|------------------|----------------------------|-----------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 2022             | Juniper-Policy-Definition  | 2636      | JSRC, PTSP  | Defines a policy decision. Includes Juniper-Policy-Name, Juniper-Template-Name, and Juniper-Substitution.                                                                                                                                                                 | Grouped     |
| 2023             | Juniper-Template-Name      | 2636      | JSRC, PTSP  | Specifies the profile name defined by the router. PTSP supports only the <code>__svc_rule__</code> policy template.                                                                                                                                                       | UTF8String  |
| 2024             | Juniper-Substitution       | 2636      | JSRC, PTSP  | Defines the substitution attributes. Includes Juniper-Substitution-Name and Juniper-Substitution-Value.                                                                                                                                                                   | OctetString |
| 2025             | Juniper-Substitution-Name  | 2636      | JSRC, PTSP  | Defines the name of the variable to be replaced.                                                                                                                                                                                                                          | OctetString |
| 2026             | Juniper-Substitution-Value | 2636      | JSRC, PTSP  | Defines the value of the variable to be replaced.                                                                                                                                                                                                                         | OctetString |
| 2027             | Juniper-Policy-Remove      | 2636      | JSRC, PTSP  | Specifies policies to be deactivated for the subscriber. Includes Juniper-Policy-Name.                                                                                                                                                                                    | Grouped     |
| 2035             | Juniper-Policy-Failed      | 2636      | JSRC, PTSP  | Specifies the name of the policy activation or deactivation that failed.                                                                                                                                                                                                  | OctetString |
| 2038             | Juniper-Policy-Success     | 2636      | JSRC, PTSP  | Specifies the name of the policy activation or deactivation that succeeded.                                                                                                                                                                                               | OctetString |
| 2046             | Juniper-Logical-System     | 2636      | JSRC, PTSP  | Specifies the logical system.                                                                                                                                                                                                                                             | UTF8String  |
| 2047             | Juniper-Routing-Instance   | 2636      | JSRC, PTSP  | Specifies the routing instance.                                                                                                                                                                                                                                           | UTF8String  |
| 2048             | Juniper-Jsrc-Partition     | 2636      | JSRC, PTSP  | Specifies the logical system and routing instance for the subscriber or request. Includes Juniper-Logical-System and Juniper-Routing-Instance                                                                                                                             | Grouped     |
| 2050             | Juniper-Request-Type       | 2636      | JSRC, PTSP  | Describes the type of request: <ul style="list-style-type: none"> <li>1—ADDRESS_AUTHORIZATION</li> <li>2—PROVISIONING_REQUEST</li> <li>3—SYNCHRONIZATION</li> <li>4—NETWORK_FAMILY_ACTIVATE<br/>JSRC only.</li> <li>5—NETWORK_FAMILY_DEACTIVATE<br/>JSRC only.</li> </ul> | Enumerated  |

Table 59: Juniper Networks Diameter AVPs (continued)

| Attribute Number | Diameter AVP                 | Vendor ID | Application   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Type       |
|------------------|------------------------------|-----------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 2051             | Juniper-Synchronization-Type | 2636      | JSRC, PTSP    | Describes the type of synchronization: <ul style="list-style-type: none"> <li>1—FULL-SYNC</li> <li>2—FAST-SYNC</li> <li>3—NO-STATE-TO-SYNC</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Enumerated |
| 2052             | Juniper-Synchronization      | 2636      | JSRC, PTSP    | Describes the state of synchronization: <ul style="list-style-type: none"> <li>1—NO-SYNC; this is the default state</li> <li>2—SYNC-IN-PROGRESS</li> <li>3—SYNC-COMPLETE</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Enumerated |
| 2053             | Juniper-Acct-Record          | 2636      | JSRC, PTSP    | Specifies the statistics data for each policy installed for this subscriber. Includes Juniper-Policy-Name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Grouped    |
| 2054             | Juniper-Acct-Collect         | 2636      | JSRC, PTSP    | Specifies whether to collect accounting data for the installed policy (service) when included in the Juniper-Policy-Install AVP: <ul style="list-style-type: none"> <li>1—COLLECT_ACCT</li> <li>2—NOT_COLLECT_ACCT</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Enumerated |
| 2058             | Juniper-State-ID             | 2636      | JSRC, PTSP    | Specifies the value assigned to each synchronization cycle for the purpose of identifying which messages to discard. All solicited requests containing the same <b>Juniper-State-ID</b> belong to the same Session-Resource-Query (SRQ) synchronization cycle. Messages from a previous synchronization cycle are discarded. When a new cycle begins, the value of the <b>Juniper-State-ID</b> AVP is increased by 1.<br><br><b>NOTE:</b> For solicited synchronization requests, the SRQ message contains the incremented <b>Juniper-State-ID</b> value. For unsolicited synchronization requests, the Session-Resource-Reply (SRR) message contains the incremented <b>Juniper-State-ID</b> value. | Unsigned32 |
| 2100             | Juniper-Virtual-Router       | 2636      | Gx-Plus, JSRC | Specifies the name of the virtual router associated with the session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | UTF8String |

Table 59: Juniper Networks Diameter AVPs (continued)

| 2101             | Juniper-Provisioning-Source     | 2636      | Gx-Plus     | Specifies the provisioning source for the session in CCR-N and JSDA messages: <ul style="list-style-type: none"> <li>1—Local</li> <li>2—Remote</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Enumerated |
| 2102             | Juniper-Provisioning-Descriptor | 2636      | Gx-Plus     | Defines the group used in JSDA messages that includes the session ID, and optionally Juniper-Provisioning-Source and subscriber data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Grouped    |
| 2103             | Juniper-Event-Type              | 2636      | Gx-Plus     | Communicates the event type in JSER messages: <ul style="list-style-type: none"> <li>1—Cold boot; all sessions are lost</li> <li>2—Warm boot; sessions are preserved</li> <li>3—Discovery requested by the operator</li> <li>4—<i>Are you there?</i> (AYT); application level ping sent when the notification is due to no response or an erroneous response from the PCRF, or due to a configuration change.</li> <li>5—AWD; application-level watchdog sent by the router when there has been no other activity for 15 seconds. The watchdog is sent every 5 seconds unless preempted by higher-priority synchronization event.</li> </ul> | Enumerated |
| 2104             | Juniper-Discovery-Descriptor    | 2636      | Gx-Plus     | Defines the group used in JS DR and JSDA messages that includes parameters of a discovery request: discovery type, request string, verbosity, max results.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Grouped    |
| 2105             | Juniper-Discovery-Type          | 2636      | Gx-Plus     | Specifies the discovery subcommand for JS DR and JSDA messages: <ul style="list-style-type: none"> <li>1—Exact: look up the data for the specified session.</li> <li>2—Bulk: Provide get-bulk kinds of information after the specified string.</li> <li>3—Done: Stop retries for all sessions up to the specified session.</li> </ul>                                                                                                                                                                                                                                                                                                        | Enumerated |

Table 59: Juniper Networks Diameter AVPs (continued)

| Attribute Number | Diameter AVP                | Vendor ID | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Type        |
|------------------|-----------------------------|-----------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 2106             | Juniper-Verbosity-Level     | 2636      | Gx-Plus     | <p>Specifies the verbosity level for JS DR and JS DA messages:</p> <ul style="list-style-type: none"> <li>1—Summary; include only the Session-Id AVP.</li> <li>2—Brief; include the Session-Id, Juniper-Virtual-Router, and Framed-IP-Address AVPs.</li> <li>3—Detail; include the Session-Id, Juniper-Provisioning-Source, Juniper-Virtual-Router, Framed-IP-Address, and Event-Timestamp AVPs.</li> <li>4—Extensive; include all available session information.</li> </ul> | Enumerated  |
| 2107             | Juniper-String-A            | 2636      | Gx-Plus     | Specifies a generic string that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                                     | UTF8String  |
| 2108             | Juniper-String-B            | 2636      | Gx-Plus     | Specifies a generic string that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                                     | UTF8String  |
| 2109             | Juniper-String-C            | 2636      | Gx-Plus     | Specifies a generic string that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                                     | UTF8String  |
| 2110             | Juniper-Unsigned32-A        | 2636      | Gx-Plus     | Specifies a generic, unsigned 32-bit integer that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                   | Unsigned32  |
| 2111             | Juniper-Unsigned32-B        | 2636      | Gx-Plus     | Specifies a generic, unsigned 32-bit integer that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                   | Unsigned32  |
| 2112             | Juniper-Unsigned32-C        | 2636      | Gx-Plus     | Specifies a generic, unsigned 32-bit integer that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                   | Unsigned32  |
| 2200             | Juniper-IPv6-Ndra-Prefix    | 2636      | JSRC        | <p>If available in the subscriber's session database IPv6Prefix entry, this AVP is included in AAR provisioning request messages sent to the SAE.</p> <p>This AVP is used only when you enable JSRC dual-stack support.</p>                                                                                                                                                                                                                                                  | IPv6Prefix  |
| 2201             | Juniper-Framed-IPv6-Netmask | 2636      | JSRC        | <p>If available in the subscriber's session database IPv6Address entry, this AVP is included in AAR provisioning request messages sent to the SAE.</p> <p>This AVP is used only when you enable JSRC dual-stack support.</p>                                                                                                                                                                                                                                                 | IPv6Address |

Table 59: Juniper Networks Diameter AVPs (continued)

| Attribute Number | Diameter AVP                    | Vendor ID | Application | Description                                                                                                                                                                                                                                                                    | Type        |
|------------------|---------------------------------|-----------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 2202             | Juniper-Agent-Circuit-Id        | 2636      | JSRC        | <p>Identifies the subscriber by access node and subscriber line. If available in the subscriber's session database entry, this AVP is included in AAR provisioning request messages sent to the SAE.</p> <p>This AVP is used only when you enable JSRC dual-stack support.</p> | OctetString |
| 2203             | Juniper-Agent-Remote-Id         | 2636      | JSRC        | <p>Identifies the subscriber on the access node. Tekelec AVPs are used only for Gx-Plus. These AVPs have an enterprise number of 21274. [Table 60 on page 695](#) lists the Tekelec AVPs. These four variables are used to provide substitution values for user-defined CoS service variables.

**Table 60: Tekelec Diameter AVPs**

| Attribute Number | Diameter AVP                         | Application | Description                                                                                                                                                                                                                                             | Type        |
|------------------|--------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 5555             | Tekelec-Charging-Rule-Argument-Name  | Gx-Plus     | Defines the name of the service variable to be replaced.                                                                                                                                                                                                | OctetString |
| 5556             | Tekelec-Charging-Rule-Argument-Value | Gx-Plus     | Defines the value of the service variable to be replaced.                                                                                                                                                                                               | OctetString |
| 5557             | Tekelec-Charging-Rule-Argument       | Gx-Plus     | Defines the substitution attributes used to replace service variables. Includes Tekelec-Charging-Rule-Argument-Name AVP (5555) and Tekelec-Charging-Rule-Argument-Value AVP (5556).                                                                     | Grouped     |
| 5558             | Tekelec-Charging-Rule-With-Arguments | Gx-Plus     | Requests the installation of the rule (activation of the service) designated by the included Charging-Rule-Name AVP (1005). Requested service variable substitutions are provided by the optionally included Tekelec-Charging-Rule-Argument AVP (5557). | Grouped     |

## Configuring Diameter

You configure Diameter by specifying the endpoint origin, the remote peers, the transport layer connection, and network elements that associate routes with peers. Only the master Diameter instance is currently supported. You can configure alternative values for the master instance only in the context of the master routing instance

To configure Diameter base protocol:

1. Configure the origin realm and origin host of the Diameter master instance.  
See [“Configuring the Origin Attributes of the Diameter Instance” on page 696](#)
2. Configure the Diameter peers.  
See [“Configuring Diameter Peers” on page 696](#)
3. (Optional) Configure the Diameter transport layer elements.  
See [“Configuring the Diameter Transport” on page 698](#)
4. (Optional) Configure the Diameter network elements.

See “Configuring Diameter Network Elements” on page 699

5. (Optional) Configure trace options for troubleshooting the configuration.

See *Tracing Diameter Base Protocol Processes for Subscriber Access*.

## Configuring the Origin Attributes of the Diameter Instance

You can configure the identifying characteristics of the endpoint node that originates Diameter messages for the Diameter instance. The hostname is supplied as the value for the Origin-Host AVP by the Diameter instance. The realm is supplied as the value for the Origin-Realm AVP by the Diameter instance.

To configure the origin attributes for a Diameter instance:

1. Specify the name of the host that originates the Diameter message.

```
[edit diameter origin]
user@host# set host host14
```

2. Specify the realm of the host that originates the Diameter message.

```
[edit diameter origin]
user@host# set realm example.com
```

## Configuring Diameter Peers

You can configure the peers to which Diameter sends messages. By default, logical system *default* and routing instance *master* are used. Port 3868 is used for active connections to peers by default.

To configure a remote peer for a Diameter instance:

1. Specify the name of the Diameter peer.

```
[edit diameter]
user@host# edit peer peer-name
```

2. Specify the IP address of the Diameter peer. Starting in Junos OS Release 17.3R1, both IPv4 and IPv6 addresses are supported.

**NOTE:** You must configure the same address family type for the peer and the corresponding local Diameter transport connection.

```
[edit diameter peer peer-name]
user@host# set address ip-address
```

- (Optional) Specify a routing instance, a logical system, or a logical system and routing instance for the Diameter peer.

```
[edit diameter peer peer-name]
user@host# set routing-instance routing-instance-name
```

```
[edit diameter peer peer-name]
user@host# set logical-system logical-system-name
```

```
[edit diameter peer peer-name]
user@host# set logical-system logical-system-name routing-instance
routing-instance-name
```

- (Optional) Specify the port that Diameter uses for active connections to the peer.

```
[edit diameter peer peer-name]
user@host# set connect-actively port port-number
```

- (Optional) Specify the transport that Diameter uses for active connections to the peer.

```
[edit diameter peer peer-name]
user@host# set connect-actively transport transport-name
```

- (Optional) Specify the name of the peer host and the name of the peer realm.

**NOTE:** You must specify both the host and realm for the peer origin.

```
[edit diameter peer peer-name]
user@host# set peer-origin host hostname realm realm-name
```

- (Optional) Include the Origin-State attribute-value pair (AVP) for the Diameter peer in Diameter base protocol-level messages to enable monitoring of changes in the AVP value.

```
[edit diameter peer peer-name]
user@host# set send-origin-state-id
```

For example, the following configuration for peer p3 specifies an IPv4 address, the routing instance ri8, destination port 49152, transport t6, an origin of host 1 in example.com, and includes the Origin-State AVP in messages.

```
[edit diameter]
user@host# edit peer p3
[edit diameter peer p3]
```

```

user@host# set address 192.168.23.10
user@host# set routing-instance ri8
user@host# set connect-actively port 49152
user@host# set connect-actively transport t6
user@host# set peer-origin host host1 realm example.com
user@host# set send-origin-state-id

```

## Configuring the Diameter Transport

You can configure one or more transports for a Diameter instance to set the IPv4 or IPv6 address for the local connection, and optionally configure a logical system or routing instance context. By default, the logical system *default* and the routing instance *master* are used. The logical system and routing instance for the transport connection must match that for the peer, or a configuration error is reported. Multiple peers can share the same transport.

To configure a transport for a Diameter instance:

1. Configure the transport name.

```

[edit diameter]
user@host# edit transport transport-name

```

2. Configure the local IP address for the Diameter local transport connection. Starting in Junos OS Release 17.3R1, both IPv4 and IPv6 addresses are supported.

**NOTE:** The address family must match that for the remote Diameter peer.

```

[edit diameter transport t1]
user@host# set address ip-address

```

3. (Optional) Configure a logical system and optionally a routing instance for the transport.

```

[edit diameter transport t1]
user@host# set logical-system logical-system-name

```

4. (Optional) Configure a routing instance for the transport.

```

[edit diameter transport t1]
user@host# set routing-instance routing-instance-name

```

For example, the following configuration for transport t1 specifies an IPv6 address, logical system ls5, and routing instance ri10.

```

[edit diameter]

```

```

user@host# edit transport t1
[edit diameter transport t1]
user@host# set address 2001:db8::113:200
user@host# set logical-system ls5
user@host# set routing-instance ri10

```

## Configuring Diameter Network Elements

A Diameter network element (DNE) consists of associated applications (called functions in the CLI), a list of prioritized peers, and a set of forwarding rules. The forwarding rules define individual routes through a set of associated destinations, applications, and metrics. At least one DNE must be configured per chassis to start the Diameter process (jdiameterd).

Before you configure Diameter network elements, perform the following task:

- Define the Diameter peers. See [“Configuring Diameter Peers” on page 696](#).

To configure a Diameter network element:

1. Specify the name of the network element.

```

[edit diameter]
user@host# set network-element dne25

```

2. (Optional) Associate one or more applications with the network element. All applications are associated by default.

```

[edit diameter network-element dne25]
user@host# set function jsrsc

```

3. Associate a Diameter peer with the network element and set the priority for the peer.

```

[edit diameter network-element dne25]
user@host# set peer peer1 priority 1

```

4. Specify a route that is reachable through the network element based on the forwarding rules that you define.

```

[edit diameter network-element dne25]
user@host# set forwarding route dne-route2

```

5. Specify a metric for the route.

```

[edit diameter network-element dne25 forwarding route dne-route2]
user@host# set metric 15

```

6. (Optional) Associate the route with a destination host and realm.

```
[edit diameter network-element dne25 forwarding route dne-route2]
user@host# set destination host host5 realm example.com
```

7. (Optional) Specify an application associated with the route.

```
[edit diameter network-element dne25 forwarding route dne-route2]
user@host# set function jsrc
```

8. (Optional) Specify the realm of the network element origin and optionally also specify the name of the element host.

**NOTE:** Only the realm name is required.

```
[edit diameter peer p3]
user@host# set dne-origin realm realm-name <host hostname>
```

Release History Table

| Release | Description                                                                                                                     |
|---------|---------------------------------------------------------------------------------------------------------------------------------|
| 17.3R1  | Starting in Junos OS Release 17.3R1, both IPv4 and IPv6 addresses are supported.                                                |
| 17.3R1  | Starting in Junos OS Release 17.3R1, both IPv4 and IPv6 addresses are supported.                                                |
| 13.1R1  | Starting in Junos OS Release 13.1R1, the packet-triggered subscribers and policy control (PTSP) feature is no longer supported. |
| 13.1R1  | Starting in Junos OS Release 13.1R1, the packet-triggered subscribers and policy control (PTSP) feature is no longer supported. |
| 13.1R1  | Starting in Junos OS Release 13.1R1, the packet-triggered subscribers and policy control (PTSP) feature is no longer supported. |

Gx-Plus for Provisioning Subscribers Overview

Gx-Plus is a Diameter-based application that extends the capability of the Gx interface. The 3rd Generation Partnership Project (3GPP) defined Gx as the online policy interface between the Policy Control and Charging Rules Function (PCRF) and the Policy and Charging Enforcement Function (PCEF), to provide control over policy and flow-based charges for subscribers. The PCRF is a centralized policy decision point that deploys business policy rules to allocate broadband network resources and manages flow-based charges for subscribers and services. The router functions as the PCEF in this environment.

Gx-Plus provides provisioning, activation, and deactivation of services; threshold triggers for service statistics processing; service accounting; subscriber session termination; fault recovery; and event (subscriber login and logout) notifications. The terminology typically used for PCRFs varies slightly from standard Junos OS terminology. The terms listed in [Table 61 on page 701](#) are interchangeable.

Table 61: Differences Between Gx-Plus and Junos OS Terminology

| Gx-Plus                      | Junos OS                            |
|------------------------------|-------------------------------------|
| policy                       | service                             |
| rule                         | service                             |
| rule install or installation | service activation or instantiation |
| rule uninstall               | service deactivation                |
| usage monitoring             | service accounting                  |

Gx-Plus enables the router acting as a PCEF to exchange Diameter Credit-Control Application (DCCA) messages with a PCRF residing on a server to request credit authorization and service provisioning for authenticated subscribers. When an application requests AAA to activate a subscriber’s session, the router sends a Credit-Control-Request (CCR) message to determine whether the subscriber has credit for the desired services and to request provisioning of those services from the PCRF policy manager.

The PCRF responds with a Credit-Control-Answer (CCA) message that indicates success or failure for credit authorization. If the subscriber has sufficient credit for the requested services, credit is authorized. If the subscriber has insufficient credit for the services, credit authorization fails.

The CCA can include services to be activated for the subscriber. If the response times out, the subscriber is logged in but only default services—if present—are activated for

the subscriber. The router interprets the omission of the Result-Code AVP from the CCA as a provisioning authorization failure and does not allow the subscriber to log in.

When a subscriber client application, such as DHCP, sends a subscriber logout notice to AAA, the router in turn sends a CCR message to the PCRF to request subscriber termination. The PCRF acknowledges the logout with a CCA message.

Different Diameter message types exchanged by the router and the PCRF contain different sets of attribute-value pairs (AVPs). If data for an AVP is not available for a request to the PCRF, that AVP is omitted from the message. If the PCRF subsequently has insufficient information to decide on the request, it may deny the request.

Gx-Plus establishes sessions that correspond to IPv4 DHCP sessions on dual-stack IPv6/IPv4 or IPv4-only subscriber interfaces, depending on the access profile. By default, IPv6 information is not communicated to the PCRF. You must explicitly configure Gx-Plus to include IPv6 information. When you do so, Gx-Plus can establish sessions that correspond to DHCPv6 sessions on IPv6-enabled subscriber interfaces and on dual-stack IPv6/IPv4-enabled interfaces.

For dual-stack DHCP subscribers (DHCPv4 and DHCPv6 on the same VLAN), each DHCP session is treated as a separate Gx-Plus session. However, only a single Gx-Plus session exists for dual-stack PPP sessions.

Gx-Plus includes the following fault tolerance and recovery capabilities:

- Unlimited retries of unacknowledged provisioning requests
- Unlimited retries of logout requests
- Router event notification
- Router discovery

**NOTE:** More than one Diameter-based application (function), such as Gx-Plus or JSRC, can run on a router simultaneously.

---

## Understanding Gx-Plus Interactions Between the Router and the PCRF

This topic describes the sequences of Diameter messages exchanged by means of Gx-Plus between the Policy Control and Rules Charging Function (PCRF) and the router acting as a Policy and Charging Enforcement Function (PCEF) as they interact to perform the following tasks for subscriber access:

- Subscriber login
- Fault tolerance and event notification
- Subscriber usage thresholds and monitoring
- Subscriber audit
- Subscriber logout

## Subscriber Login

Gx-Plus provisioning is enabled for subscribers when you include the **provisioning-order gx-plus** statement at the **[edit access profile *profile-name*]** hierarchy level. When an application requests AAA to activate the subscriber's session, the router sends a CCR-I message to the PCRF to request provisioning for the subscriber session. The CCR-I message must include the Juniper-Virtual-Router, Framed-IP-Address, and NAS-Port-ID AVPs. The request is not generated when no IPv4 address has been assigned to the subscriber, when IPv6 is enabled and an IPv6 address has been assigned, or when the NAS-Port-ID is unknown. Starting in Junos OS Release 17.4R1, the CCR-I message includes the Subscription-Id AVP (AVP code 443) with the Subscription-Id-Type AVP set to 4 and Subscription-Id-Data AVP set to **reserved**.

The PCRF returns a CCA-I message that includes the Result-Code AVP (AVP code 268). The router considers a CCA-I that does not include the Result-Code AVP as a failed response. The CCA-I can return the Charging-Rule-Install AVP (AVP code 1001), which identifies services to be activated.

If the Result-Code value is DIAMETER\_SUCCESS (2001), the router communicates to AAA that the requested service is activated. If the Result-Code value is DIAMETER\_AUTHORIZATION\_REJECTED, the router communicates to AAA that the service activation is not permitted. If the Result-Code AVP has any other value, or is missing, the request is retried. A total of three CCR-I messages can be sent.

If the PCRF does not indicate success or failure, then by default the router continues to send requests, but the retry requests are CCR-N messages (no-response notifications) that include the Juniper-Provisioning-Source AVP (AVP code 2101). This AVP indicates that the router has local decision-making authority to provision services in the absence of a PCRF response to the CCR-I. This AVP is not present in the CCR-I message.

A subscriber login initiates the following sequence of events:

1. A client application—such as DHCP, PPP, or static subscriber sessions—requests AAA to authenticate the subscriber.
2. Authentication begins if the subscriber access profile specifies RADIUS authentication. Login continues when the authentication is successful. Login fails when the **authentication-order** statement in the profile does not specify RADIUS authentication or no authentication. Login also fails when authentication fails.
3. Default services are activated for the subscriber. Any services that the authentication server includes in the authentication grant are activated. Additionally, a default service may have been configured for the client application.
4. If the subscriber access profile specifies Gx-Plus provisioning, the router initiates the Gx-Plus message exchange by sending a CCR-I message to the PCRF. The router waits for the PCRF to respond with a CCA-I message within a non-configurable timeout period.

When the PCRF responds within the timeout period and includes the Charging-Rule-Install AVP in the CCA-I message, subscriber login is delayed while the router deactivates any default services and attempts to activate the specified services.

- If all the specified services are activated, then the login completes.
- If any of the services cannot be activated, the router sends the PCRF a CCR-U message with the status of the services (a rule report). The PCRF responds to this message with a CCA-U that can contain a new set of services for activation.
- The router ignores any default services, even if the CCA-I message does not include any services. In this circumstance, no services are activated.

If the PCRF does not return a CCA-I within the timeout period, subscriber login completes.

- The router searches first for services returned from the authentication server and activates any it finds. If no such services are found, then the router activates any locally configured default services. Subscriber login completes when default service activation is successful, but fails when any default service fails to activate. Because default services are not required to be present, login also completes when no default services are found.
  - If login completes (with or without a default service), the router periodically resends the CCR-I message to the PCRF. If the PCRF subsequently returns a CCA-I, the router deactivates the default service, if any, and then activates any services included in the CCA-I. If the message does not include any services, then no service is activated, not even a default service.
  - If any of the services contained in the CCA-I cannot be activated, the router sends the PCRF a CCR-U message with the status of the services (a rule report). The PCRF responds to this message with a CCA-U that can contain a new set of services for activation.
5. The router begins to monitor session accounting statistics if the CCA-I message includes any threshold triggers for usage monitoring. The Usage-Monitoring-Information AVP (AVP code 1067) contains the threshold triggers in the Granted-Service-Unit AVP (AVP code 431). The triggers are the values granted by the PCRF for the following statistics: duration of the session, input octets count, output octets count, and total octets count.
- a. If the service statistics meet or exceed any of these trigger thresholds during the session, the router sends a CCR-U message to the PCRF with accounting information in the Usage-Monitoring-Information AVP (AVP code 1067). The AVP now contains the Used-Service-Unit AVP (AVP code 446) to report the current values for all four statistics.
  - b. In response, the PCRF may return a CCA-U message with the Usage-Monitoring-Information AVP, which can include any of the following: the Granted-Service-Unit AVP with new threshold triggers (absolute values rather than increments to the previous thresholds), the Charging-Rule-Install AVP (AVP code 1001) for service activations, or the Charging-Rule-Remove AVP (AVP code 1002) for service deactivations.

**NOTE:** The router does not aggregate statistics across services.

6. When the subscriber logs out, the router sends a CCR-T message (termination notice) to the PCRF, which responds with a CCA-T message.

**Fault Tolerance and Event Notification**

Although the probability is low, the PCRF and the router can have different values for the number of subscribers. This error can arise from the following scenarios:

- CCA-I loss: if no CCA-I is delivered to the router, then the PCRF considers a subscriber as provisioned whereas the router considers it not provisioned.
- CCR-T loss: if no CCR-T is delivered to the PCRF, then the PCRF considers a subscriber to be provisioned whereas the router considers the subscriber not provisioned (logged out).

Loss of messages can be greater during cold boots and high availability events. Unacknowledged CCR-I and CCR-T requests are retransmitted forever until a satisfactory response is received to reduce the incidence of failure, and significant events are reported to Gx-Plus. By default, the number of outstanding requests is limited to 40 to avoid overloading the PCRF. This limit reduces the possibility of losing requests. You can modify this number by including the **max-outstanding-requests** statement at the **[edit access-gx-plus global]** hierarchy level.

Gx-Plus does not rely on the connection state between devices to detect router or PCRF outages, because some events do not affect the connection state and others are not detected when there is a Diameter relay or proxy between the devices. Event notifications (JSE messages) are sent when certain events take place on the router. The Juniper-Event-Type AVP (AVP code 2103) in the message describes the event.

Event notifications are retried until Gx-Plus returns a JSEA message with a Result-Code value of DIAMETER\_SUCCESS (2001) to acknowledge receipt of the event notification. When retrying notifications, one notification is sent for each outstanding event. No other request are sent as long as there is any outstanding event other than an application watch dog (AWD).

Table 62 on page 705 lists router events and the subsequent router and PCRF actions.

Table 62: Router Events, Router Actions, and PCRF Actions

| Router Event                                                                                                                                                                                    | Router Action            | PCRF Action                                          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|------------------------------------------------------|
| The router receives no response from the PCRF or an error response.                                                                                                                             | Send event notification. | Respond to event notification.                       |
| The configuration changes.<br><br>Significant changes such as the origin host or realm and the Gx-Plus partition destination host or realm also increment the value of the Origin-State-Id AVP. | Send event notification. | Respond to event notification and perform discovery. |

*Table 62: Router Events, Router Actions, and PCRF Actions (continued)*

| Router Event                                                                                                                                                                    | Router Action            | PCRF Action                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|-------------------------------------------------------|
| The router receives an explicit discovery request from the PCRF.                                                                                                                | Send event notification. | Respond to event notification.                        |
| The router undergoes a cold boot and all sessions are lost. This can result from a catastrophic failure or power cycle.                                                         | Send event notification. | Respond to event notification and clear the database. |
| The router undergoes a warm boot.                                                                                                                                               | Send event notification. | Respond to event notification and clear the database. |
| Recovery resources that are needed to continuously retry unacknowledged requests (CCR-N and CCR-T messages) are exhausted. The value of the Origin-State-Id AVP is incremented. | Send event notification. | Respond to event notification and perform discovery.  |
| This event is unlikely to occur.                                                                                                                                                |                          |                                                       |

An important aspect of Gx-Plus fault tolerance is that subscriber login and termination requests are retried (replayed) forever until a satisfactory response is received from the PCRF. In rare circumstances, this can result in a stack of pending requests being replayed over and over.

You can issue the **clear network-access gx-plus replay** command to clear all pending requests. This command causes Gx-Plus to send a JSER message to PCRF that includes the Juniper-Event-Type AVP (AVP code 2103) with a value of 3 indicating a discovery request. The PCRF then returns a JDER message to initiate discovery of all subscribers. When this discovery completes, all pending subscriber requests are cleared.

### PCRF-Generated Discovery

The PCRF runs a discovery process in response to data loss, exhaustion of router resources, operator request, or router request. The JSER message specifies the level of verbosity desired in the reply from Gx-Plus. The message also specifies whether the request is for data about a particular session or information similar to an SNMP Get-Bulk for all sessions. Gx-Plus returns a JSDA message that indicates complete success, limited success, or an error. In the event of success, the requested data is also returned.

### Subscriber Accounting

When the PCRF returns a CCA-I message to the router, the message may contain thresholds for any of several usage statistics for a subscriber session or service session: Duration, input data, output data, or total data for the session. Upon receipt of a threshold, the router begins monitoring the subscriber's service session activity for that statistic. When the usage statistic reaches the threshold, it triggers the router to send a Gx-Plus usage notification message (CCR-U) to the PCRF. In response, the PCRF may send a CCA-U message to specify a new threshold, activate new services, or deactivate current services.

The PCRF can also send a CCR-U message that explicitly requests usage monitoring for statistics at different levels. The router can monitor usage at the subscriber level or at the service level. The Granted-Service-Unit AVP in the message specifies one or more of the following the statistics:

- CC-Input-Octets
- CC-Output-Octets
- CC-Total-Octets
- CC-Time

If any other statistics are specified, the router sends the PCRF a CCA message indicating that incorrect statistics were requested. When the specified threshold for a monitored statistic is reached, the router sends a CCR-U that contains the usage report for the statistics. In response, the PCRF sends another CCA-R with new thresholds or a request to activate or deactivate services.

### Subscriber Usage Thresholds

Gx-Plus threshold monitoring enables the tracking of session statistics including the duration of session and the number of input bytes, output bytes, and total bytes allowed (granted) and used. Threshold monitoring involves the use of numerous AVPs.

- Rule-Install AVP—a grouped AVP that can consist of the following two AVPs:
  - Rule-Install-Name AVP—The name of the dynamic-profile to activate, corresponding to a service.
  - Monitoring-Key AVP—(Optional) The name of the monitoring definition, which is part of the CCR/RAR messages, and indicates that Gx-Plus thresholds are enabled. The Monitoring-Key AVP must be unique within the context of the subscriber, but more than one of these keys can be included in the Rule-Install AVP, one per subscriber. For every Monitoring-Key AVP referenced in the Rule-Install AVP, there must be a corresponding Monitoring AVP.
- Monitoring AVP—The monitoring definition, consisting of the Monitoring-Key AVP and either the Granted-Service-Unit AVP or the Used-Service-Unit AVP:
  - Monitoring-Key AVP—The name of the monitoring definition.
  - Granted-Service-Unit AVP—A grouped AVP that includes the following session threshold values:
    - Duration AVP—Period of time in seconds allotted to the subscriber before having to ask for an extension.
    - Input-Bytes AVP—Number of input bytes allotted to the subscriber before having to ask for an extension. A value of zero indicates the threshold is turned off.
    - Output-Bytes AVP—Number of output bytes allotted to the subscriber before having to ask for an extension. A value of zero indicates the threshold is turned off.
    - Total-Bytes AVP—Number of input and output bytes in total allotted to the subscriber before having to ask for an extension.

The Granted-Service-Unit threshold values are somewhat analogous to a lease. In this case, if no threshold values are supplied, then the granted values or “lease” is effectively infinite. The absence of thresholds means no limits are placed on the values.

- Used-Service-Unit AVP—A grouped AVP that includes the following session threshold values, which are analogous to a kind of lease:
  - Duration AVP—Period of time in seconds that the service has been used.
  - Input-Bytes AVP—Number of input bytes used by the subscriber in this session.
  - Output-Bytes AVP—Number of output bytes used by the subscriber in this session.
  - Total-Bytes AVP—Number of input and output bytes in total used by the subscriber in this session.

No thresholds are enabled if the router acting as a PCEF receives a CCA or RAR message that contains one or more Rule-Install-AVPs, but no Monitoring-Key AVPs.

Consider the following example. The PCEF receives the listed AVPs in a CCA-I message. When the PCEF activates the svc-21-g service, the set of monitored thresholds, thresh-459 becomes active for the service. The instantiated service is granted 600 seconds, 1 billion input bytes, 1 billion output bytes, and a total of 2 billion bytes combined.

- Rule-Install AVP
  - Rule-Install-Name AVP = svc-21-g
  - Monitoring-Key AVP = thresh-459
- Monitoring AVP
  - Monitoring-Key AVP = thresh-459
  - Granted-Service-Unit AVP
    - Duration AVP = 600s
    - Input-Bytes AVP = 1,000,000,000
    - Output-Bytes AVP = 1,000,000,000
    - Total-Bytes AVP = 2,000,000,000

If the CCA-I includes the following AVPs and values, everything is the same as above except that no limits are placed on either input bytes or output bytes, just a limit on the total number of bytes. Omitting the Input-Bytes and Output-Bytes AVPs from the Granted-Service-Unit AVP has the same effect.

- Rule-Install AVP
  - Rule-Install-Name AVP = svc-21-g
  - Monitoring-Key AVP = thresh-459
- Monitoring AVP

- Monitoring-Key AVP = thresh-459
- Granted-Service-Unit AVP
  - Duration AVP = 600s
  - Input-Bytes AVP = 0
  - Output-Bytes AVP = 0
  - Total-Bytes AVP = 2,000,000,000

It does not matter which threshold is met first; the PCEF behaves the same.

1. It disables the complete set of monitored thresholds for the service. In the examples above, thresh-459 is disabled for service svc-21-g.
2. Authd sends a threshold report (CCR-U) to the PCRF that includes the Monitoring AVP with the current values for the thresholds; these make up the Used-Service-Unit AVP:
  - Monitoring AVP
    - Monitoring-Key AVP = thresh-459
    - Used-Service-Unit AVP
      - Duration AVP = 600s
      - Input-Bytes AVP = 22,110,000
      - Output-Bytes AVP = 21,161,004
      - Total-Bytes AVP = 43,271,004
3. authd expects the PCRF to respond to the CCR-U with the Monitoring AVP, supplying new values for the thresholds. To use the lease analogy, the reply should extend the “lease” for the session; for example:
  - Monitoring AVP
    - Monitoring-Key AVP = thresh-459
    - Granted-Service-Unit AVP
      - Duration AVP = 3600s
      - Input-Bytes AVP = 1,500,000,000
      - Output-Bytes AVP = 2,000,000,000
      - Total-Bytes AVP = 3,500,000,000

If the new Duration AVP supplied by the PCRF is low, it could result in a tight cycle of threshold hits, reports, and updates. Consequently the PCEF ensures that the threshold is of a reasonable duration by adding the new value from the PCRF to the current reported value; this becomes the new duration grant. Using the example above, the (current value + new value) = 600 + 3600 = 4200 seconds.

What happens if the PCRF fails to respond to the CCR-U? Rather than leave the thresholds disabled, the PCEF supplies the Monitoring AVP with a single new value, the duration:

- Monitoring AVP
  - Monitoring-Key AVP = thresh-459
  - Granted-Service-Unit AVP
    - Duration AVP = *current value + minimum-duration*

The router has default minimum values for all the threshold AVPs:

- Input-Bytes minimum - 1,000,000
- Output-Bytes minimum - 1,000,000
- Total-Bytes minimum - 1,000,000
- Duration minimum - 600

Using the example of 600 seconds for the current duration value, if the PCRF does not respond to the CCR-U, the new duration value becomes 600 + 600 = 1200 seconds. There are no thresholds for the byte counts. When the new duration threshold is met, the PCEF generates another CCR-U threshold report for the PCRF.

---

### Subscriber Audit

The PCRF can send a reauthorization request (RAR message) to Gx-Plus at any time to determine whether a particular subscriber is still logged in. You can also manually trigger the PCRF to do so by issuing the **clear network-access aaa gx-plus replay** command.

The Session-Id AVP identifies the subscriber session. Gx-Plus returns an RAA message to provide status on the subscriber session. When the session is still up (found in the session database) the Result-Code AVP value in the RAA message is DIAMETER\_SUCCESS (2001). When the session is not found, the Result-Code value is DIAMETER\_UNKNOWN\_SESSION\_ID (5002). A Result-Code value of DIAMETER\_UNABLE\_TO\_DELIVER (3002) indicates that Gx-Plus is not configured.

Starting in Junos OS Release 17.4R1, the router updates monitored statistics when they are received in the RAR from the PCRF. When Gx-Plus sends an RAA message after receiving an RAR message requesting service activation or deactivation, it also sends a CCR-U message to the PCRF with updated statistics.

---

### Subscriber Logout

When the client application sends a subscriber logout notice to AAA, Gx-Plus sends a CCR-T message to notify the PCRF that the provisioned subscriber session is being terminated. The PCRF returns a CCA-T message that includes the Result-Code AVP. If the Result-Code value is DIAMETER\_SUCCESS, Gx-Plus notifies AAA, and AAA notifies the application that the logout is complete. If Gx-Plus does not receive a CCA-T message, or if the Result-Code AVP has any other value or is missing, then the termination request is retried until the CCA-T message is returned with DIAMETER\_SUCCESS.

## Configuring Gx-Plus

You can configure the Gx-Plus client application to work with a PCRF policy manager residing on a server. The PCRF is a centralized policy decision point that deploys business rules to allocate broadband network resources and manage subscribers and services. AAA on the router (acting as the PCEF) uses Gx-Plus to request service provisioning from the PCRF.

**NOTE:** Contact the Juniper Networks Technical Assistance Center (JTAC) for information on supported PCRFs.

To configure Gx-Plus:

1. Configure the Gx-Plus partition.  
See [“Configuring the Gx-Plus Partition” on page 712](#).
2. Configure Gx-Plus global attributes: the number of outstanding requests permitted and the inclusion of IPv6 subscribers.  
See [“Configuring Gx-Plus Global Attributes” on page 713](#).
3. Configure Gx-Plus provisioning for subscribers.  
See [“Provisioning Subscribers with Gx-Plus” on page 714](#).
4. (Optional) Override PCRF control of a subscriber session to correct services or troubleshoot a problem.  
See [“Disabling PCRF Control of a Subscriber Session” on page 714](#).
5. (Optional) Configure Gx-Plus event tracing as part of general authentication service tracing operations.  
See [Tracing General Authentication Service Processes](#).

## Configuring the Gx-Plus Partition

Gx-Plus works within a specific logical system:routing instance context, called a partition.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system:routing instance context.

Before you configure the Gx-Plus partition, perform the following task:

- Configure the Diameter instance at the **[edit diameter]** hierarchy level. See [“Configuring Diameter” on page 695](#).

Configuration for the Gx-Plus partition consists of naming the partition and then associating a Diameter instance, the PCRF hostname, and the PCRF realm with the partition.

To configure the Gx-Plus partition:

1. Create the partition or specify the name of an existing partition.

```
[edit access gx-plus]
user@host# set partition partition-name
```

2. Specify the Diameter instance for the Gx-Plus partition.

**NOTE:** Currently, only the default Diameter instance, *master*, is supported.

```
[edit access gx-plus partition partition-name]
user@host# set diameter-instance instance-name
```

3. (Optional) Configure the destination host for the Gx-Plus partition.

```
[edit access gx-plus partition partition-name]
user@host# set destination-host hostname
```

4. Configure the destination realm for the Gx-Plus partition.

```
[edit access gx-plus partition partition-name]
user@host# set destination-realm realm
```

The following example shows a Gx-Plus partition configuration.

```
gx-plus {
  partition partition1 {
    diameter-instance master;
```

```

destination-host pcrf1;
destination-realm generic.example.com;
}
}

```

## Configuring Gx-Plus Global Attributes

You can configure attributes that apply to all Gx-Plus partitions globally.

When a request from Gx-Plus to the PCRF is not answered or is improperly answered, Gx-Plus keeps retrying the request until it receives an appropriate answer. If the number of requests grows too large, the PCRF can become overloaded and messages can be lost. To reduce this risk, you can set a limit on the number of outstanding requests to the PCRF that Gx-Plus can retry.

By default, Gx-Plus does not include IPv6 subscribers in Gx-Plus provisioning requests to the PCRF. Instead, Gx-Plus only establishes sessions that correspond to IPv4 DHCP sessions on dual-stack IPv6/IPv4 or IPv4-only subscriber interfaces. You must explicitly configure Gx-Plus to include IPv6 information. When you do so, Gx-Plus can establish sessions that correspond to DHCPv6 sessions on IPv6-enabled subscriber interfaces and on dual-stack IPv6/IPv4-enabled interfaces.

To configure Gx-Plus global attributes:

1. (Optional) Set a limit on the number of outstanding requests.

```

[edit access gx-plus global]
user@host# set max-outstanding-requests number

```

2. (Optional) Include IPv6 subscribers in provisioning requests.

```

[edit access gx-plus global]
user@host# set include-ipv6

```

For example to limit the number of outstanding requests to 30 and to include IPv6 subscribers:

```

[edit access gx-plus global]
user@host# set max-outstanding-requests 30
user@host# set include-ipv6

```

## Provisioning Subscribers with Gx-Plus

You can configure AAA to use Gx-Plus to request provisioning from a PCRF to instantiate services for an authenticated subscriber.

Before you configure Gx-Plus provisioning for subscribers, perform the following task:

- Create the subscriber access profile at the **[edit access profile]** hierarchy level. See [“Configuring an Access Profile for Subscriber Management” on page 60](#).

To configure Gx-Plus provisioning:

- Specify **gx-plus** as the provisioning method in the profile.

```
[edit access profile profile-name]  
user@host# set provisioning-order gx-plus
```

## Disabling PCRF Control of a Subscriber Session

When a subscriber has been provisioned with Gx-Plus, services for that subscriber can be activated and deactivated only by the PCRF. Accordingly, AAA rejects any RADIUS CoA requests for subscribers provisioned by Gx-Plus. Similarly, CLI-based service activation and deactivation do not work while a subscriber is remotely provisioned.

Network administrators without PCRF access or authority may need to override PCRF control on a particular subscriber session to troubleshoot the session or correct the subscriber services. You can disable PCRF control by issuing the **request network-access aaa subscriber set session-id** command. In response, the router sends a termination notice to the PCRF, but does not actually log out the subscriber.

When you have confirmed that provisioning is disabled, you can then activate or deactivate subscriber services for that session with the **request network-access aaa subscriber add session-id** and **request network-access aaa subscriber delete session-id** commands, respectively. These commands fail if provisioning is still enabled.

Another consequence of disabling provisioning for a subscriber session is that RADIUS change of authorization (CoA) messages can modify the session.

Before you begin, determine or verify the ID for the session by displaying the session IDs of all current subscribers with the **show subscribers detail** or **show network-access aaa subscribers** command.

To disable control by the PCRF over a subscriber session:

1. Disable provisioning for the specified subscriber session ID.

```
user@host> request network-access aaa subscriber set session-id subscriber-session-id  
provisioning-state none
```

2. (Optional) Verify that provisioning is disabled for the session.

```
user@host> show network-access aaa subscribers session-id subscriber-session-id
detail
```

For example, to disable provisioning for subscriber larry:

```
user@host> show network-access aaa subscribers

Username      Logical system/Routing instance  Client type  Session-ID
...
larry         default:default                  dhcp         55
...

user@host> request network-access aaa subscriber set session-id 55 provisioning-state none
user@host> show network-access aaa subscribers session-id 55 detail

Type: dhcp
Username: user23@example.net
Stripped username: user23
AAA Logical system/Routing instance: default:default
Target Logical system/Routing instance: default:retail-onlinecompany-ca
Access-profile:retailer-onlinecompany-sjc
Session ID: 55
Accounting Session ID: 55
Multi Accounting Session ID: 0
IP Address: 192.168.44.104
Authentication State: AuthStateActive
Accounting State: Acc-Start-Send
Provisioning-type: none
Service name: basic-service
Service State: SvcActive
Session ID: 56
Session uptime: 00:01:45
```

## 3GPP Policy and Charging Control Overview for Wireline Provisioning and Accounting

The 3rd Generation Partnership Project (3GPP) Policy and Charging Control (PCC) provides the unification of wireline provisioning and accounting for customers. [Figure 30 on page 716](#) shows the components of an overall 3GPP PCC architecture.

*Figure 30: 3GPP PCC Architecture Overview*

The four major components of the PCC architecture are:

- Policy and Charging Rules Function (PCRF)—A centralized policy decision point that deploys business policy and charging rules to allocate broadband network resources and manages flow-based charges for subscribers and services. PCRF pushes the rules down to the Policy and Charging Enforcement Function (PCEF) using the 3GPP Gx protocol and online policy interface.
- Policy and Charging Enforcement Function (PCEF)—A function that provides user traffic handling and QoS at the gateway, provides service data flow detection, and applies the rules received from the PCRF. PCEF optionally interacts with the Online Charging Function (OCF) within the Online Charging System (OCS) using the 3GPP Gy protocol to retrieve policy and charging authorization for quotas and credit control.
- Online Charging System (OCS)—The component responsible for interacting with the PCEF. The PCEF optionally reports usage and receives additional authorizations from the OCS using the 3GPP Gy protocol. Broadband PCEF (BPCEF) interactions with the OCS use online session charging with centralized unit determination and centralized rating.
- Offline Charging System (OFCS)—A process where charging information for network resource usage is collected concurrently with that resource usage. If credit-based authorization is not required, the PCEF applies policies and report usage to the OFCS using the 3GPP Gz protocol. You can also use the OCS as the primary accounting destination and use the OFCS as a backup.

Table 63 on page 717 lists the functionality differences between PCRF and PCEF.

**Table 63: Functionality Comparison Between PCRF and PCEF**

| Functionality                            | PCRF                                                                                                                            | PCEF                                                           |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Charging policing implementation         | Involved at different levels; aggregates information inside the hosting network and is considered part of the PCC architecture. | Involved at different levels; located at the gateway.          |
| Functions included                       | Includes mainly policy control decision and flow-based control functions.                                                       | Includes policy enforcement and flow-based charging functions. |
| Predefined PCC rules                     | Activation or deactivation of predefined PCC rules can only be done by the PCRF.                                                | Preconfigured by the PCEF.                                     |
| Online and offline charging interactions | Not supported                                                                                                                   | Supported                                                      |

The three other components that make up the PCC architecture in Figure 30 on page 716 are:

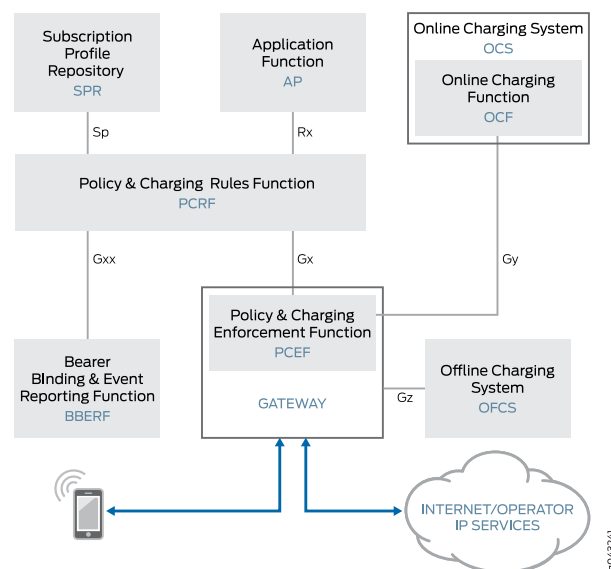

- Application Function (AF)—The Application Function interacts with applications or services that require dynamic PCC. The Application Function extracts session information from the application signalling and provides application session-related information to the PCRF using the Rx protocol.

- **Subscription Profile Repository (SPR)**—SPR contains subscriber and subscription information on a per-packet data network (PDN) basis. The Sp protocol enables the PCRF to request subscription information related to a subscriber's service or session.
- **Bearer Binding and Event Reporting Function (BBERF)**—The PCC rule needs to be mapped to a particular IP bearer to ensure the packets receive the appropriate QoS treatment. The association between a PCC rule and a bearer is referred to as *bearer binding*. The BBERF location depends on the access technology. For 3GPP, the BBERF is located in the serving gateway and uses the Gxx protocol.

## Policy and Charging Enforcement Function Overview for Broadband Wireline Subscribers

The Policy and Charging Enforcement Function (PCEF) is one of four major components of the 3rd Generation Partnership Project (3GPP) Policy and Charging Control (PCC) architecture in [Figure 31 on page 718](#).

**Figure 31: 3GPP PCC Architecture Overview**

PCEF provides user traffic handling and quality of service (QoS) at the gateway, provides service data flow detection, and applies the rules received from the Policy Control and Charging Rules Function (PCRF). 3GPP defines Gx as the online policy protocol between the PCRF and the PCEF to provide control over policy and flow-based charges for subscribers. The PCRF is a centralized policy decision point that deploys business policy rules to allocate broadband network resources and manages flow-based charges for subscribers and services. Optionally, the PCEF interacts with the Online Charging System (OCS) using the 3GPP Gy protocol to retrieve policy and charging authorization for quotas and credit control.

PCEF provides support for the following environments:

- [Wireline Access Environment on page 719](#)
- [Junos OS Environment on page 720](#)

### Wireline Access Environment

For mobile subscribers, the user equipment requests services; for broadband wireline subscribers, the PCRF requests services. In the wireline environment, PCRF functions as the service requester, and the PCEF functions as the service receiver and enforcer.

Adapting the PCC model in a wireline environment provides these benefits:

- Convenience
- Advanced technology
- Already implemented by the wireless branch of the carrier that often provides a much bigger business than the wireline branch

The PCRF controls the PCEF by pushing charging rules. Charging rules are reused as service (policy) rules to push policies. Charging rules may also have an associated rating group, or charging key. As a result, the PCEF configuration must define charging rules and mapping between credit control services (cc-services) and rating groups.

In many instances, both OCS and Offline Charging System (OFCS) 3GPP accounting services require Mobile Station International Subscriber Directory Number (MSISDN) be used for subscriber identification. The MSISDN is passed as the subscription ID. While each mobile user equipment device has an associated MSISDN, this information is not available for wireline subscribers. To enable the PCRF to dynamically pass subscription-ID parameters, and support a variety of authentication, authorization, and provisioning configuration, the Juniper attribute-value pairs (AVPs) in [Table 64 on page 719](#) have been allocated from the Juniper Vendor-ID space (2636) vendor-specific attribute (VSA).

**NOTE:** If no dynamic-subscription ID is received, then neither OCS or OFCS communications are initiated.

**Table 64: Allocated Juniper AVPs**

| AVP Name                           | Vendor-ID | AVP Type | Diameter Type | Diameter Flag |
|------------------------------------|-----------|----------|---------------|---------------|
| Juniper-Dyn-Subscription-Indicator | 2636      | 10001    | Enum          | V             |
| Juniper-Dyn-Subscription-Id        | 2636      | 10002    | Grouped       | VM            |
| Juniper-Dyn-Subscription-Id-Type   | 2636      | 10003    | Integer32     | VM            |
| Juniper-Dyn-Subscription-Id-Data   | 2636      | 10004    | UTF8String    | VM            |

The client system (router) sends the Juniper-Dyn-Subscription-Id-Indicator AVP to indicate support of the dynamic assignment of the subscription ID. The Juniper-Dyn-Subscription-Id-Indicator attribute has two values:

- DYN\_SUBSCRIPTION\_NOT\_SUPPORTED (0)
- DYN\_SUBSCRIPTION\_SUPPORTED (1)

The server then sends the Juniper-Dyn-Subscription-Id AVP to the client that indicated support. This is a grouped AVP that contains the values to be sent as Subscription-Id-Type and Subscription-Id-Data.

**NOTE:**

- The PCRF server may use standard Subscription-Id AVP to communicate the dynamic-subscription ID to the router.
- If both Juniper-Dyn-Subscription-Id and Subscription-Id are sent by the PCRF, the Subscription-Id value is used.

In many cases, wireline subscribers support only one IP family, which is required information for both AAA service and PCRF. To indicate this information, the Juniper-Network-Family-Indicator AVP has been allocated from the Juniper Vendor-ID space (2636) VSA in [Table 65 on page 720](#).

**Table 65: Family Indicator AVP**

| AVP Name                         | Vendor-ID | AVP Type | Diameter Type | Diameter Flag |
|----------------------------------|-----------|----------|---------------|---------------|
| Juniper-Network-Family-Indicator | 2636      | 10010    | Enum          | V             |

The client system (router) sends the Juniper-Network-Family-Indicator AVP to indicate which network families are associated with the service request and supported by the subscriber. When you configure the Juniper-Network-Family-Indicator AVP to indicate the associated network family, the system sends the information to the PCRF. The Juniper-Network-Family-Indicator attribute has four values:

- UNSPECIFIED (0)
- IPV4\_FAMILY (1)
- IPV6\_FAMILY (2)
- IPV4\_IPV6\_FAMILY (3)

Wireline customers often control user services solely through the PCRF and use the OCS as a convenient real-time usage monitoring mechanism rather than as an enforcement unit. To decrease the number of possible erroneous OCS configurations, include the [force-continue](#) statement at the `[edit access ocs partition partition-name]` hierarchy level to force the broadband PCEF (BPCEF) to limit the impact of negative responses from the OCS and quota expirations, and to prevent sending OCS notifications for affected rating-groups. Whenever the PCEF receives a negative response to any reported group, it stops reporting this group to the OCS.

### Junos OS Environment

There are three categories of dynamic-profiles within the Junos OS environment:

- client-dynamic-profiles
- cos-service-dynamic-profiles

- firewall-service-dynamic-profiles

Client-dynamic-profiles and cos-service-dynamic-profiles define bandwidth and other characteristics of the services provided to a subscriber; the firewall-service-profiles perform filtering and usage counting. For all of the dynamic-profiles' categories, the service-dynamic-profile name is used as the value of a Charging-Rule-Name AVP.

When the service-dynamic-profile has no variables, or when defaults provided in service-dynamic-profile definition are requested, no additional elements are required. To provide custom values for a service-dynamic-profile, use the Charging-Rule-Definition AVP with additional VSAs.

The PCRF uses existing Juniper-Substitution VSAs (Vendor-ID 2636 and Type 2024) to supply attributes as a name-value pairs. The PCRF may also include parameters as positional notation for part of the rule name. The Redirect-Information AVP (Vendor-ID 10415 and Type 1085) supplies a value for the Redirect-URL parameter.

For every possible service-dynamic-profile parameter name requested by customers, a new Juniper-Parameter VSA is defined. [Table 66 on page 721](#) describes the initial set of fixed Juniper-Parameter VSAs.

**Table 66: Initial Set of Fixed Juniper-Parameter VSAs**

| Parameter                 | VSA Name                                | Vendor-ID | Type  | Diameter Type |
|---------------------------|-----------------------------------------|-----------|-------|---------------|
| Cos-Tcp                   | Juniper-Param-Cos-Tcp                   | 2636      | 10005 | UTF8String    |
| V4-Firewall-Input-Filter  | Juniper-Param-V4-Firewall-Input-Filter  | 2636      | 10006 | UTF8String    |
| V4-Firewall-Output-Filter | Juniper-Param-V4-Firewall-Output-Filter | 2636      | 10007 | UTF8String    |
| V6-Firewall-Input-Filter  | Juniper-Param-V6-Firewall-Input-Filter  | 2636      | 10008 | UTF8String    |
| V6-Firewall-Output-Filter | Juniper-Param-V6-Firewall-Output-Filter | 2636      | 10009 | UTF8String    |

If parameters or the Service-Identifier and Rating-Group are required to be indicated by the PCRF, the Charging-Rule-Definition AVP is used; otherwise, the Charging-Rule-Name AVP is used.

```
Charging-Rule-Definition ::= < AVP Header: 1003 >
{ Charging-Rule-Name }
[ Service-Identifier ]
[ Rating-Group ]
[ Online ]
[ Precedence ]
[ Juniper-Param-VSA ]
[ AVPs ] - standard AVPs used as parameters
```

For instances when there is a Service-Identifier and Rating-Group combination, or when only the Service-Identifier or only the Rating-Group is specified, the combination must

be unique among the rules installed for a subscriber. You configure the service-context-id on the router.

## Understanding Gx Interactions Between the Router and the PCRF

The sequences of Diameter messages are exchanged by means of the 3rd Generation Partnership Project (3GPP) Gx protocol between the Policy Control and Rules Charging Function (PCRF) and the router acting as a Policy and Charging Enforcement Function (PCEF).

Starting in Junos OS Release 17.3R1, support for additional OCS and PCRF features are added using Gy and Gx protocols. The new statements:

- **accept-sdr** is added for PCRF partition at the hierarchy level **[edit access pcrf partition *partition-name*]**.
- **alternative-partition-name** is added for OCS partition at the hierarchy level **[edit access ocs partition *partition-name*]**.

They interact to perform the following subscriber access tasks:

- [Subscriber Login on page 722](#)
- [Subscriber Update on page 726](#)
- [Subscriber Logout on page 727](#)
- [Subscriber Disconnect on page 728](#)
- [Connectivity Fault Recovery on page 729](#)

---

### Subscriber Login

The router sends a Diameter CCR request containing a fixed set of required information to a policy manager (PCRF) and receives a CCA response containing policies and other information. Gx provisioning is enabled for subscribers when you include the **provisioning-order pcrf** statement at the **[edit access profile *profile-name*]** hierarchy level. When an application requests AAA to activate the subscriber's session, the router sends a CCR-GX-I (where I represents INITIAL\_REQUEST) message to the PCRF to request a fix set of provisioning information for the subscriber session, and receives a CCA-GX-I response message containing policies and other information, including the Result-Code AVP (AVP code 268).

When you configure the **provisioning-order** statement in the access profile, the broadband PCEF (BPCEF) module sends a provisioning request to the PCRF during the client activation. The following examples show a CCR-GX-I and CCA-GX-I packet exchange:

### CCR-GX-I Packet Example

```
CCR-GX-I ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <configurable-string> }
{ Origin-Realm: <configurable-string> }
{ Destination-Realm: <configurable-string> }
{ CC-Request-Type: INITIAL_REQUEST(1) }
```

```

{ CC-Request-Number: 0 }
{ Subscription-Id:
  { Subscription-Id-Type: <configurable-integer> }
  { Subscription-Id-Data: <configurable-string> }
}
}
[ Destination-Host: <configurable-string> ] -- if configured
[ Origin-State-Id: <u32> ] -- if configured to send
[ Framed-IP-Address: <ipv4-address-in-radius-encoding> ] -- if available
[ Framed-IPv6-Prefix: <ipv6-prefix-in-radius-encoding> ] -- if available
{ IP-CAN-Type: <configurable-integer> }
{ Online: ENABLE_ONLINE (1) }
[ User-Name: <string> ]
[ NAS-Port-Id: <string> ] -- if included by config
[ Juniper-Virtual-Router: <virtual-router-name> ] -- if included by config
[ Event-Timestamp: <timestamp> ] -- login timestamp, if included by config
{ Juniper-Dyn-Subscription-Indicator: DYN_SUBSCRIPTION_SUPPORTED(1) }
{ Juniper-Network-Family-Indicator: <subscriber-family> }

```

**NOTE:** The T (potentially retransmitted message) bit recalculates when the CCR-GX-I is resent. This flag is set after a link failover procedure to remove duplicate requests.

### CCA-GX-I Packet Example

```

CCA-GX-I ::= <Diameter Header: 272, PXY, 16777238>
{ <Session-Id> }
{ Result-Code: <integer> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <string> } -- should match destination-host if configured
{ Origin-Realm: <string> } -- should match destination-realm
{ Result-Code: <integer> }
{ CC-Request-Type: INITIAL_REQUEST(1) }
{ CC-Request-Number: 0 }
[ Juniper-Dyn-Subscription-Id:
  {Juniper-Dyn-Subscription-Id-Type: <value-to-be-used-for-ocs-interactions>
  }
  {Juniper-Dyn-Subscription-Id-Data: <value-to-be-used-for-ocs-interactions>
  }
]
*[ Supported-Features ] -- ignored
[ Origin-State-Id: <u32> ] -- Indicates restart PCRF side
*[ Downstream data units ]

```

**NOTE:** If no rule-install AVP is defined in the CCA-GX-I, then the default rule is installed.

All event triggers, including those not yet defined, are acceptable. However, only a few event triggers actually generate events when implemented.

The PCRF returns a CCA-GX-I message that includes the Result-Code AVP (AVP code 268) that maps to the result categories listed in [Table 67 on page 724](#).

**Table 67: Result-Code-AVP Categories**

| Result-Code-AVP Value                                                                                                                                                                    | Result Category   |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| SUCCESS(2001), LIMITED_SUCCSS(2002), and valid message                                                                                                                                   | Grant             |
| AUTHENTICATION_REJECTED(4001), UNKNOWN_SESSION_ID(5002), AUTHORIZATION_REJECTED(5003), and USER_UNKNOWN(5030)                                                                            | Deny              |
| UNABLE_TO_DELIVER(3002), REALM_NOT_SERVED(3003), TOO_BUSY(3004), LOOP_DETECTED(3005), and REDIRECT_INDICATION(3006)                                                                      | Failure           |
| All other Diameter Permanent-failure Result-Code AVPs greater than and equal to 5000, and all Diameter protocol error Result-Code AVPs greater than and equal to 3000 and less than 4000 | Permanent-failure |
| Other Result-Code AVPs for invalid message or no-response                                                                                                                                | Failure           |

As shown in [Table 68 on page 724](#), the CCA-GX-I response processing depends on three factors:

- Whether the local decision timeout has expired
- The setting of the local decision
- The result category

[Table 68 on page 724](#) also contains PCRF local decision timeout expiration actions.

**Table 68: CCA-GX-I Response Processing**

| PCRF Local Decision Timeout | PCRF Local Decision | Result Category   | Action                                                                                                                                              |
|-----------------------------|---------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Not-expired                 | –                   | Grant             | Clear the local decision timer, apply rules from the CCA-GX-I, notify the Online Charging System (OCS), and then acknowledge subscriber activation. |
| Not-expired                 | –                   | Deny              | Clear the local decision timer and fail subscriber activation.                                                                                      |
| Not-expired                 | –                   | Failure           | Retry the CCA-GX-I until the local decision time outs.                                                                                              |
| Not-expired                 | Grant               | Permanent-failure | Clear the local decision timer, apply the default rule, acknowledge subscriber activation, and then keep retrying the CCA-GX-I.                     |
| Not-expired                 | Deny                | Permanent-failure | Fail the subscriber activation and initiate the subscriber logout process.                                                                          |

Table 68: CCA-GX-I Response Processing (continued)

| PCRF Local Decision Timeout | PCRF Local Decision | Result Category   | Action                                                                                                                                                  |
|-----------------------------|---------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| On-expiration               | Grant               | –                 | Apply the default rule, keep retrying the CCA-GX-I indefinitely, and acknowledge subscriber activation.                                                 |
| On-expiration               | Deny                | –                 | Fail the subscriber activation and initiate the subscriber logout process.                                                                              |
| Expired                     | Grant               | Grant             | If the CCA-GX-I contains rules, remove the default rules and install the received rules, and then notify the OCS and acknowledge subscriber activation. |
| Expired                     | Grant               | Deny              | Log out the client.                                                                                                                                     |
| Expired                     | Grant               | Failure           | Keep retrying the CCA-GX-I indefinitely.                                                                                                                |
| Expired                     | Grant               | Permanent-failure | Take a long pause and then restart retrying the CCA-GX-I.                                                                                               |
| Expired                     | Deny                | Deny              | If subscriber still logging out, ignore subscriber; otherwise, no action required.                                                                      |

A subscriber login initiates the following sequence of events:

1. A client application—such as DHCP, PPP, or static subscriber sessions—requests AAA to authenticate the subscriber.
2. Authentication begins if the subscriber access profile specifies RADIUS authentication. Login continues when the authentication is successful. Login fails when the **authentication-order** statement in the profile does not specify RADIUS authentication or no authentication. Login also fails when authentication fails.
3. Default services are activated for the subscriber. Any services that the authentication server includes in the authentication grant are activated. Additionally, a default service may have been configured for the client application.
4. If the subscriber access profile specifies Gx provisioning, the router initiates the Gx message exchange by sending a CCR-GX-I message to the PCRF. The router waits for the PCRF to respond with a CCA-GX-I message within a non-configurable timeout period.

When the PCRF responds within the timeout period and includes the Charging-Rule-Install AVP in the CCA-GX-I message, subscriber login is delayed while the router deactivates any default services and attempts to activate the specified services.

- If all the specified services are activated, then the login completes.
- If any of the services cannot be activated, the router sends the PCRF a CCR-GX-U (where U represents UPDATE\_REQUEST) message with the status of the services

(a rule report). The PCRF responds to this message with a CCA-GX-U that can contain a new set of services for activation.

- The router ignores any default services, even if the CCA-GX-I message does not include any services. In this circumstance, no services are activated.

If the PCRF does not return a CCA-GX-I within the timeout period, subscriber login completes.

- The router searches first for services returned from the authentication server and activates any it finds. If no such services are found, then the router activates any locally configured default services. Subscriber login completes when default service activation is successful, but fails when any default service fails to activate. Because default services are not required to be present, login also completes when no default services are found.
- If login completes (with or without a default service), the router periodically resends the CCR-GX-I message to the PCRF. If the PCRF subsequently returns a CCA-GX-I, the router deactivates the default service, if any, and then activates any services included in the CCA-GX-I. If the message does not include any services, then no services are activated, not even a default service.
- If any of the services contained in the CCA-GX-I cannot be activated, the router sends the PCRF a CCR-GX-U message with the status of the services (a rule report). The PCRF responds to this message with a CCA-GX-U that can contain a new set of services for activation.

### Subscriber Update

Whenever a trigger event occurs on the router, an update request is sent to the PCRF. The following examples show a CCR-GX-U (where U represents UPDATE\_REQUEST) and CCA-GX-U packet exchange:

#### CCR-GX-U Packet Example

```
CCR-GX-U ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <configurable-string> }
{ Origin-Realm: <configurable-string> }
{ Destination-Realm: <configurable-string> }
{ CC-Request-Type: UPDATE_REQUEST(2) }
{ CC-Request-Number: <u32> }
[ Destination-Host: <configurable-string> ] -- if configured
[ Origin-State-Id: <u32> ] -- if configured to send
*[ Upstream data units ]
```

**NOTE:** The T bit recalculates when the CCR-GX-U is resent.

CCA-GX-U Packet Example

```
CCA-GX-U ::= <Diameter Header: 272, PXY, 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <string> } -- should match destination-host if configured
{ Origin-Realm: <string> } -- should match destination-realm
{ Result-Code: <integer> }
{ CC-Request-Type: UPDATE_REQUEST(2) }
{ CC-Request-Number: <u32> }
[ Origin-State-Id: <u32> ] -- Indicates PCRF restart
*[ Downstream data units ]
```

The PCRF returns a CCA-GX-U message that includes the Result-Code AVP (AVP code 268) that maps to the result categories listed in [Table 69 on page 727](#).

Table 69: Result-Code-AVP Categories

| Result-Code-AVP Value                                                                                                                                                                    | Result Category |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| SUCCESS(2001), LIMITED_SUCCSS(2002), and valid message                                                                                                                                   | Success         |
| UNABLE_TO_DELIVER(3002), REALM_NOT_SERVED(3003), TOO_BUSY(3004), LOOP_DETECTED(3005), and REDIRECT_INDICATION(3006)                                                                      | Failure         |
| All other Diameter Permanent-failure Result-Code AVPs greater than and equal to 5000, and all Diameter protocol error Result-Code AVPs greater than and equal to 3000 and less than 4000 | Success         |
| Other Result-Code AVPs for invalid message or no-response                                                                                                                                | Failure         |

Subscriber Logout

When the client application sends a subscriber logout notice to AAA, Gx sends a CCR-GX-T (where T represents TERMINATION\_REQUEST) message to notify the PCRF that the provisioned subscriber session is being terminated.

Whenever a trigger event occurs on the router, a terminate request is sent to the PCRF. The following examples show a CCR-GX-T and CCA-GX-T packet exchange:

CCR-GX-T Packet Example

```
CCR-GX-T ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <configurable-string> }
{ Origin-Realm: <configurable-string> }
{ Destination-Realm: <configurable-string> }
{ CC-Request-Type: TERMINATION_REQUEST(3) }
{ CC-Request-Number: <u32> }
[ Destination-Host: <configurable-string> ] -- if configured
{ Termination-Cause: DIAMETER_LOGOUT(1) }
[ Origin-State-Id: <u32> ] -- if configured to send
*[ Upstream data units ]
```

**NOTE:** The T bit recalculates when the CCR-GX-T is resent.

### CCA-GX-T Packet Example

```
CCA-GX-T ::= <Diameter Header: 272, PXY, 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <string> } -- should match destination-host if configured
{ Origin-Realm: <string> } -- should match destination-realm
{ Result-Code: <integer> }
{ CC-Request-Type: TERMINATION_REQUEST(3) }
{ CC-Request-Number: <u32> }
[ Origin-State-Id: <u32> ] -- Indicates PCRF restart
*[ Downstream data units ]
```

The PCRF returns a CCA-GX-T message that includes the Result-Code AVP (AVP code 268) that maps to the result categories listed in [Table 70 on page 728](#).

**Table 70: Result-Code-AVP Categories**

| Result-Code-AVP Value                                                                                                                                                                    | Result Category |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| SUCCESS(2001), LIMITED_SUCCSS(2002), and valid message                                                                                                                                   | Success         |
| UNABLE_TO_DELIVER(3002), REALM_NOT_SERVED(3003), TOO_BUSY(3004), LOOP_DETECTED(3005), and REDIRECT_INDICATION(3006)                                                                      | Failure         |
| All other Diameter Permanent-failure Result-Code AVPs greater than and equal to 5000, and all Diameter protocol error Result-Code AVPs greater than and equal to 3000 and less than 4000 | Success         |
| Other Result-Code AVPs for invalid message or no-response                                                                                                                                | Failure         |

If the Result-Code value is Success, Gx notifies AAA, and AAA notifies the application that the logout is complete. If Gx does not receive a CCA-GX-T message, or if the Result-Code AVP has any other value or is missing, then the termination request is retried until the CCA-GX-T message is returned with Success. The router notifies the PCRF about subscriber logouts by sending another CCR request to be acknowledged by a CCA response. The PCRF may also use RAR requests to force subscriber logout or to change applied services.

If the Result-Code value is Failure, then the request is retried.

### Subscriber Disconnect

To perform subscriber disconnects, the PCRF sends a RAR-GX-D (where D represents DISCONNECT) and the BPCEF responds with a RAA-GX-D message.

The following examples show a RAR-GX-D and RAA-GX-D packet exchange:

RAR-GX-D Packet Example

```
RAR-GX-D ::= <Diameter Header: 258, PXY, 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <string> } -- should match destination-host if configured
{ Origin-Realm: <string> } -- should match destination-realm
{ Destination-Realm: <string> } -- should match origin-realm
{ Destination-Host: <string> } -- should match origin-host
{ Re-Auth-Request-Type: AUTHORIZE_ONLY(0) }
[ Origin-State-Id: <u32> ] -- Indicates PCRF restart
{ Session-Release-Cause: <enum> }
*[ Downstream data units ] -- ignored
```

RAA-GX-D Packet Example

```
RAA-GX-D ::= <Diameter Header: 272, REQ, PXY, 16777238>
{ <Session-Id> }
{ Auth-Application-Id: 16777238 }
{ Origin-Host: <configurable-string> }
{ Origin-Realm: <configurable-string> }
{ Result-Code: <integer> }
[ Origin-State-Id: <u32> ]
*[ Upstream data units ]
```

The PCRF returns a RAA-GX-T message that includes the Result-Code AVP (AVP code 268) that maps to the result categories listed in [Table 71 on page 729](#).

Table 71: Result-Code-AVP Categories

| Result-Code-AVP Value           | Result Category                                                     |
|---------------------------------|---------------------------------------------------------------------|
| DIAMETER_SUCCESS(2001)          | Subscriber disconnect is in progress or the subscriber is not found |
| DIAMETER_UNABLE_TO_COMPLY(5012) | Subscriber is not removable                                         |
| DIAMETER_TOO_BUSY(3004)         | Too many outstanding disconnect requests                            |

**NOTE:** The BPCEF contains buffering space for at least 512 RAR-GX-D or RAA-GX-D messages.

Connectivity Fault Recovery

Gx does not rely on the connection state between devices to detect router or PCRF outages, because some events do not affect the connection state and others are not detected when there is a Diameter relay or proxy between the devices.

To mitigate connectivity faults with the PCRF, the router uses the following fault recovery procedures:

- If the PCRF is not available, and if you installed and configured a default service, the subscriber login proceeds accordingly.
- Unacknowledged provisioning requests replay indefinitely or until the subscriber logs out.
- Logout requests wait for the final OCS interrogation to complete, and then any unacknowledged logout requests replay for 24 hours.
- The router uses standard Diameter transport redundancy to communicate with redundant PCRFs.

An important aspect of Gx fault tolerance is that subscriber login and termination requests are retried (replayed) 24 hours until a satisfactory response is received from the PCRF. You can issue the **clear network-access pcrf subscribers** command to clear all PCRF subscribers.

## Understanding Gy Interactions Between the Router and the OCS

Information or interrogations are exchanged by means of the 3rd Generation Partnership Project (3GPP) Gy protocol between the Online Charging System (OCS), and the router acting as a Policy and Charging Enforcement Function (PCEF). Broadband PCEF (BPCEF) interactions with the OCS use online session charging with centralized unit determination and centralized rating. PCEF optionally reports usage and receives additional authorizations from the OCS using the Gy protocol.

Starting in Junos OS Release 17.3R1, support for additional OCS and PCRF features are added using Gy and Gx protocols. The new statements:

- **accept-sdr** is added for PCRF partition at the hierarchy level **[edit access pcrf partition *partition-name*]**.
- **alternative-partition-name** is added for OCS partition at the hierarchy level **[edit access ocs partition *partition-name*]**.

Starting in Junos OS Release 18.1R1, broadband PCEF provides the file backup for OCS data when both primary and alternative paths to the OCS are not available. The CCR-GY-T frames are stored in the files on remote location. The backup is supported at the hierarchy **[edit access ocs partition *partition-name*]**.

After subscriber provisioning has been completed between the Policy Control and Rules Charging Function (PCRF) and PCEF, the router begins sending the following interrogations between the OCS and PCEF:

- [First Interrogation to the OCS on page 731](#)
- [Intermediate Interrogation to the OCS on page 732](#)
- [Final Interrogation to the OCS on page 734](#)
- [Connectivity Fault Recovery on page 735](#)
- [Abort Session Requests on page 735](#)

### First Interrogation to the OCS

During the first interrogation, the router sends a Diameter CCR request containing a fixed set of required information to the OCS charging server. The OCS charging server then replies with validity-time, rating groups, and usage-quotas.

**NOTE:** For this implementation phase, the router allows subscriber access without waiting for the OCS to respond, and the OCS always grants necessary quotas.

To configure a list of charging services to communicate information with the OCS over the Gy protocol, configure the **charging-service-list ocs** statement at the **[edit access profile profile-name]** hierarchy level. The following examples show a CCR-GY-I and CCA-GY-I packet exchange:

**NOTE:** The T (potentially retransmitted message) bit recalculates when the CCR-GY-I is resent. This flag is set after a link failover procedure to aid the removal of duplicate requests.

### CCR-GY-I Packet Example

```
CCR-GY-I ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Origin-Host:    <configurable-string> }
{ Origin-Realm:   <configurable-string> }
{ Destination-Realm: <configurable-string> }
{ Auth-Application-Id: 4 }
{ Service-Context-Id: 98924@customer.com }
{ CC-Request-Type:  INITIAL_REQUEST(1) }
{ CC-Request-Number: 0 }
[ Destination-Host: <configurable-string> ] -- if configured
[ User-Name:        <string> ]
[ Origin-State-Id:  <u32> ] -- if configured to send
[ Event-Timestamp:  <timestamp> ] -- login timestamp, if included by config
{ Subscription-Id:
  { Subscription-Id-Type: <received-from-pcrf> }
  { Subscription-Id-Data: <received-from-pcrf> }
}
{ Multiple-Services-Indicator:  MULTIPLE_SERVICES_SUPPORTED(1) }
  { Multiple-Services-CC:
    { Service-Identifier: 7 }
    { Rating-group: 292 }
  }
  { Multiple-Services-CC:
    { Service-Identifier: 7 }
    { Rating-group: 293 }
  }
  { Multiple-Services-CC:
    { Service-Identifier: 7 }
    { Rating-group: 292 }
  }
  { Multiple-Services-CC:
```

```

    { Service-Identifier: 1 }
    { Rating-group: 17 }
}

```

### CCA-GY-I Packet Example

```

CCA-GY-I ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Result-Code:    DIAMETER_SUCCESS(2001) }
{ Origin-Host:    <string> } -- should match dest-host if configured
{ Origin-Realm:    <string> } -- should match dest-realm
{ Auth-Application-Id: 4 }
{ CC-Request-Type:  INITIAL_REQUEST(1) }
{ CC-Request-Number: 0 }
{ CC-Session-Failover:  FAILOVER_NOT_SUPPORTED(0) } -- ignored
}
{ Multiple-Services-CC:
  { Granted-Service-Unit:
    { CC-Time: 123456 }
    { CC-Total-Octets: 123455999000 }
  }
  { Service-Identifier: 7 }
  { Rating-group: 292 }
  { Validity-Time: 7200 }
  { Result-Code:  DIAMETER_SUCCESS(2001) }
}
{ Multiple-Services-CC:
  { Service-Identifier: 7 }
  { Rating-group: 293 }
  { Result-Code:  DIAMETER_CREDIT_CONTROL_NOT_APPLICABLE(4011) }
}
{ Multiple-Services-CC:
  { Service-Identifier: 7 }
  { Rating-group: 292 }
  { Result-Code:  DIAMETER_CREDIT_CONTROL_NOT_APPLICABLE(4011) }
}
{ Multiple-Services-CC:
  { Granted-Service-Unit:
    { CC-Time: 123456 }
    { CC-Total-Octets: 123455999000 }
  }
  { Service-Identifier: 1 }
  { Rating-group: 17 }
  { Result-Code:  DIAMETER_SUCCESS(2001) }
}
{ CC-Failure-Handling:  TERMINATE(0) }

```

### Intermediate Interrogation to the OCS

After the router has sent a fixed set of required information to the OCS charging server, the OCS charging server replies with validity-time, rating groups, and usage-quotas. Validity-time and quota expirations trigger intermediate interrogation events.

Whenever a trigger event occurs on the router, an update request is sent to the OCS. The following examples show a CCR-GY-U (where U represents UPDATE\_REQUEST) and CCA-GY-U packet exchange:

## CCR-GY-U Packet Example

```

CCR-GY-U ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Origin-Host:    <configurable-string> }
{ Origin-Realm:   <configurable-string> }
{ Destination-Realm: <configurable-string> }
{ Auth-Application-Id: 4 }
{ Service-Context-Id: 98924@customer.com }
{ CC-Request-Type:  UPDATE_REQUEST(2) }
{ CC-Request-Number: <integer> }
[ Destination-Host: <configurable-string> ] -- if configured
[ User-Name:        <string> ]
[ Origin-State-Id:  <u32> ] -- if configured to send
[ Event-Timestamp:  <timestamp> ] -- change timestamp, if included by config
{ Multiple-Services-Indicator:  MULTIPLE_SERVICES_SUPPORTED(1) }
{ Multiple-Services-CC:
  { Used-Service-Unit:
    { Reporting-Reason:  VALIDITY_TIME(4) }
    { CC-Time:          7200 }
    { CC-Total-Octets:  12345 }
    { CC-Input-Octets:  10000 }
    { CC-Output-Octets: 2345 }
  }
  { Service-Identifier: 7 }
  { Rating-group:      292 }
}
{ Multiple-Services-CC:
  { Used-Service-Unit:
    { Reporting-Reason:  FINAL(2) }
    { CC-Time:          334556 }
    { CC-Total-Octets:  12345 }
    { CC-Input-Octets:  10000 }
    { CC-Output-Octets: 2345 }
  }
  { Service-Identifier: 1 }
  { Rating-group:      17 }
}
*[ More Multiple-Services-CC]

```

## CCA-GY-U Packet Example

```

CCA-GY-U ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Result-Code:    DIAMETER_SUCCESS(2001) }
{ Origin-Host:    <string> } -- should match dest-host if configured
{ Origin-Realm:   <string> } -- should match dest-realm
{ Auth-Application-Id: 4 }
{ CC-Request-Type:  UPDATE_REQUEST(1) }
{ CC-Request-Number: <integer> }
{ Multiple-Services-CC:
  { Granted-Service-Unit:
    { CC-Time: 123456 }
    { CC-Total-Octets: 123455999000 }
  }
  { Service-Identifier: 7 }
  { Rating-group:      292 }
  { Validity-Time:     7200 }
}

```

```
{ Result-Code:    DIAMETER_SUCCESS(2001) }
}
*[ More Multiple-Services-CC]
```

### Final Interrogation to the OCS

When the client application sends a subscriber logout notice to AAA, Gy sends a CCR-GY-T (where T represents TERMINATION\_REQUEST) message to notify the OCS that the provisioned subscriber is being terminated.

Whenever a trigger event occurs on the router, a terminate request is sent to the OCS. The following examples show a CCR-GY-T and CCA-GY-T packet exchange:

#### CCR-GY-T Packet Example

```
CCR-GY-T ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Origin-Host:    <configurable-string> }
{ Origin-Realm:   <configurable-string> }
{ Destination-Realm: <configurable-string> }
{ Auth-Application-Id: 4 }
{ Service-Context-Id: 98924@customer.com }
{ CC-Request-Type:  TERMINATE_REQUEST(2) }
{ CC-Request-Number: <integer> }
[ Destination-Host: <configurable-string> ] -- if configured
[ User-Name:        <string> ]
[ Origin-State-Id:  <u32> ] -- if configured to send
[ Event-Timestamp: <timestamp> ] -- logout timestamp, if included by config
{ Termination-Cause: DIAMETER_LOGOUT(1) }
{ Multiple-Services-CC:
  { Used-Service-Unit:
    { Reporting-Reason: FINAL(2) }
    { CC-Total-Octets: 12345 }
    { CC-Input-Octets: 10000 }
    { CC-Output-Octets: 2345 }
  }
  { Service-Identifier: 7 }
  { Rating-group: 292 }
}
*[ More Multiple-Services-CC]
```

#### CCA-GY-T Packet Example

```
CCA-GY-T ::= <Diameter Header: 272, REQ, PXY 16777238>
{ <Session-Id> }
{ Result-Code:    DIAMETER_SUCCESS(2001) }
{ Origin-Host:    <string> } -- should match dest-host if configured
{ Origin-Realm:   <string> } -- should match dest-realm
{ Auth-Application-Id: 4 }
{ CC-Request-Type:  TERMINATE_REQUEST(1) }
{ CC-Request-Number: <integer> }
```

### Connectivity Fault Recovery

Gy does not rely on the connection state between devices to detect router or OCS outages, because some events do not affect the connection state and others are not detected when there is a Diameter relay or proxy between the devices.

To mitigate connectivity faults with the OCS, the router uses the following fault recovery procedures:

- If the OCS is not available, you can configure to allow subscriber traffic by setting the **force-continue** statement at the **[edit access ocs partition *partition-name*]** hierarchy level.

**NOTE:** The **force-continue** statement is a required configuration statement.

- Unacknowledged first and intermediate interrogations replay indefinitely or until the subscriber logs out.
- Unacknowledged final interrogations replay for up to 24 hours.
- The router uses standard Diameter transport redundancy to communicate with redundant OCSs.
- You can configure transport redundancy events to trigger failures in application traffic.

An important aspect of Gy fault tolerance is that subscriber login and termination requests are retried (replayed) 24 hours until a satisfactory response is received from the OCS. You can issue the **clear network-access ocs statistics** command to clear all OCS statistics.

### Abort Session Requests

The OCS may issue an ASR (Abort-Session-Request) when the receiving MX Series router collects final data and posts the final interrogation. After the MX Series router receives the response, it stops updating the OCS for the session involved.

## Gy File Backup Overview

The Gy protocol, also known as OCS, is based on incremental usage reporting while retaining the intermediate data. Therefore, the OCS server includes multiple failure protection mechanisms such as diameter transport redundancy, alternative path to OCS, and file backup. Starting in Junos OS Release 18.1R1, broadband PCEF provides the file backup when neither primary nor alternative paths are available. The CCR-GY-T frames are stored in the files on remote location.

The OCS backup comes into effect when the OCS final-response-timeout expires. The data is queued for backup process and subscriber logout proceeds to pcrf session termination. In all cases, the backup operations are controlled by the following configuration parameters:

- **backup-limit**—limit on the total number of backup entries. After the limit is reached, new subscriber's login fails or oldest backup entries are dropped depending upon backup-overflow settings.

- **backup-timeout**— timeout for backup operation.
- **backup-overflow**—controls action when number of backup entries exceeds backup-limit.

### OCS SFTP-Backup

---

The stfp-backup is the first backup mechanism implemented. The operations are controlled by the following parameters:

- accumulation-timeout – The files are written after the file accumulation time of the first CCR-GY-T submission.
- accumulation-count – The files are written after the number of requests are fulfilled for the file-account-count.
- accumulation-size – The files are written after its size is reaches the accumulation size limit.
- retry-interval – Every failed write operation is retried after this interval until backup-timeout is accumulated.
- response-timeout – The timeout on individual sftp command response.

**NOTE:** The OCS SFTP-Backup server is configured by its address, login, password, directory and file-prefix. A target directory exists by default, if not, the directory is created. If a target file with the same name already exists it will be overwritten.

---

### Benefits of Gy File Backup:

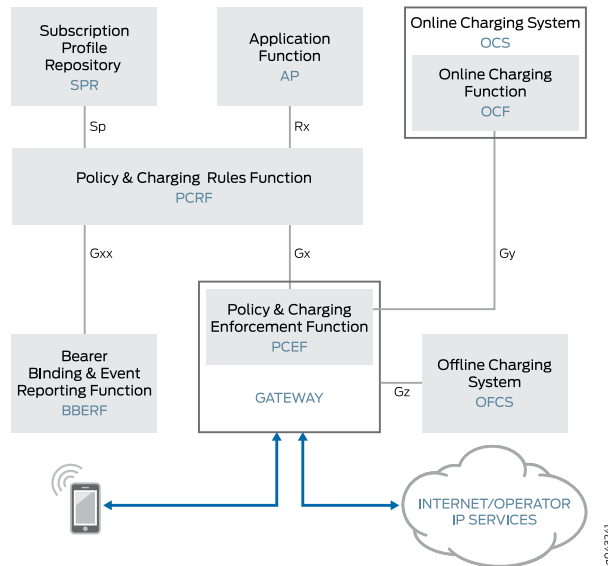

---

- Provides yet another way to deal with instability of internal network.

## Understanding Rule Interactions Between the PCRF, PCEF, and OCS

Figure 32 on page 737 shows the components of an overall 3rd Generation Partnership Project (3GPP) Policy and Charging Control (PCC) architecture.

Figure 32: 3GPP PCC Architecture Overview

The Policy and Charging Rules Function (PCRF) pushes the rules down to the Policy and Charging Enforcement Function (PCEF) on the MX Series router using the 3GPP Gx protocol and online policy interface. The PCEF provides service data flow detection, and applies the rules received from the PCRF. Optionally, the PCEF interacts with the Online Charging System (OCS) using the 3GPP Gy protocol to retrieve policy and charging authorization for quotas and credit control. Broadband PCEF (BPCEF) interactions with the OCS use online session charging with centralized unit determination and centralized rating.

The behavior and rule interactions among the PCRF, PCEF, and OCS prohibit you from adding or modifying rules with a rating group, and require you to set the **force-continue** statement at the **[edit access ocs partition partition-name] hierarchy level**. Two loosely coupled finite state machines (FSMs), one for PCRF/Gx interactions and the other for OCS/Gy interactions, control the functionality.

**NOTE:** Gx is implemented by the PCRF. Gy is implemented by the OCS.

The PCRF, PCEF, and OCS provide the following interactions:

- [Login Interactions on page 738](#)
- [Update Interactions on page 738](#)
- [Quota Expiration and Validity-Time Interactions on page 739](#)
- [Connection and Monitoring Interactions on page 739](#)
- [Logout Interactions on page 740](#)

### Login Interactions

---

This login sequence of events is triggered by a CCA-GX-I message received by the PCEF from the PCRF.

1. The PCEF installs the requested services.
2. The PCEF acknowledges subscriber activation and allows subscriber traffic to flow.
3. The PCEF sends a notification to the OCS.
4. The PCEF sends the first interrogation to the OCS using a CCR-GY-I message, and the OCS sends applicable reports to the PCRF using a CCR-GX-U message.
  - The rule is reported to the PCRF as inactive when both of the following are true:
    - The service-dynamic-profile instantiation fails.
    - Resource-Allocation-Notification (ENABLE\_NOTIFICATION) is set for the charging rule.

When the rule is reported as inactive, it does not affect subscriber login or other rules.

- The rule is reported to the PCRF as active when all of the following are true:
  - The service-dynamic-profile instantiation succeeds.
  - Resource-Allocation-Notification (ENABLE\_NOTIFICATION) is set for the charging rule.
  - The SUCCESSFUL\_RESOURCE\_ALLOCATION event trigger is set in the request.
- The report is not sent when there are no rules to report.

### Update Interactions

---

This update sequence of events is triggered by an RAR-GX-U message received by the PCEF from the PCRF.

1. If the update request contains any installation or modification of rules with rating groups, then the PCRF rejects the message request; otherwise, it acknowledges the message request.
2. The PCEF starts the service removal and installation process.
3. The PCEF waits for the service removal and installation process to complete, and if applicable, the OCS starts the final data collection process. When the final statistics are collected, the service sends a CCR-GY-U request to notify the OCS that is part of the existing service removal process in each of the following cases:
  - When the service being removed has a rating group.

- When a new rule with a rating group was added.
  - When rules with a rating group were both removed and added.
4. The PCEF sends applicable reports to the PCRF using a CCR-GX-U message.
- The rule is reported to the PCRF as inactive when both of the following are true:
    - The service-dynamic-profile instantiation fails.
    - Resource-Allocation-Notification (ENABLE\_NOTIFICATION) is set for the charging rule.
- When the rule is reported as inactive, it does not affect the update or other rules.
- The rule is reported to the PCRF as active when all of the following are true:
    - The service-dynamic-profile instantiation succeeds.
    - Resource-Allocation-Notification (ENABLE\_NOTIFICATION) is set for the charging rule.
    - The SUCCESSFUL\_RESOURCE\_ALLOCATION event trigger is set in the request.
  - The report is not sent when there are no rules to report.

### Quota Expiration and Validity-Time Interactions

For quota expirations and validity-time interactions, the router sends an intermediate interrogation to the OCS using a CCR-GY-U message and processes the OCS response.

### Connection and Monitoring Interactions

When establishing a connection with the PCRF, OCS, or Diameter Relay/Proxy server, the Diameter daemon performs a standard Capability Exchange Request (CER)/Capability Exchange Answer (CEA) transaction. You use existing Junos OS Diameter infrastructure to configure an appropriate topology with the necessary redundancy features. Additionally, you can use the same Diameter connection for both PCRF and OCS communications, and other applications.

The following examples show two different communication connection scenarios:

#### CER Example with a Dedicated Connection Used to Communicate with the PCRF

```
CER ::= <Diameter Header: 257, REQ>
{ Origin-Realm:   CSim.PCRF.net }
{ Origin-Host:    MX-GWR3 }
{ Host-IP-Address: 10.8.52.91 }
{ Vendor-Id:      2636 }
{ Product-Name:   JUNOS }
[ Origin-State-Id: 7777 ] -- if configured
{ Supported-Vendor-Id: 10415 }
{ Supported-Vendor-Id: 2636 } -- have Juniper VSAs
{ Auth-Application-Id: 16777238 }
{ Vendor-Specific-Application-Id {
  { Vendor-Id:      10415 }
  { Auth-Application-Id: 16777238 }
```

```
{ Acct-Application-Id: 16777238 }
}
```

**NOTE:** If you set the [send-origin-state-id](#) statement for the router at either the `[edit access pcrf partition partition-name]` or `[edit access ocs partition partition-name]` hierarchy level, then the Origin-State-Id is included in Diameter level messages such as: CER, Device Watchdog Request (DWR)/Device Watchdog Answer (DWA), and Disconnect Peer Request (DPR)/Disconnect Peer Answer (DPA).

### CER Example with a Dedicated Connection Used to Communicate with Both PCRF and OCS

```
CER ::= <Diameter Header: 257, REQ>
{ Origin-Realm:   CSim.PCRF.net }
{ Origin-Host:    MX-GWR3 }
{ Host-IP-Address: 10.8.52.91 }
{ Vendor-Id:      2636 }
{ Product-Name:   JUNOS }
[ Origin-State-Id: 7777 ] -- if configured
{ Supported-Vendor-Id: 10415 }
{ Supported-Vendor-Id: 2636 } -- have Juniper VSAs
{ Auth-Application-Id: 4 }      -- this is the difference with previous
{ Auth-Application-Id: 16777238 }
{ Vendor-Specific-Application-Id {
  { Vendor-Id:      10415 }
  { Auth-Application-Id: 16777238 }
  { Acct-Application-Id: 16777238 }
}
```

**NOTE:** The Auth-Application-Id: 4 field and value is the authentication application ID for the OCS. This is the difference between the first and second examples.

You monitor and manage connections using standard DWR/DWA and DPR/DPA messages.

### Logout Interactions

This logout sequence of events is triggered by a CCR-GX-T message from the PCRF to the PCEF.

1. The system infrastructure notifies the OCS that the subscriber logout has started.
2. If applicable, the OCS starts the final data collection process.
  - If the service being removed has a rating group, final data for this service is required to be reported. The OCS starts final data collection as necessary.
3. Both the PCRF and the PCEF wait for the final interrogation process to complete.

4. The PCEF starts a termination request, and then waits for the termination request to complete.
5. The PCEF allows the subscriber logout process to proceed.

## Understanding Upstream and Downstream Messages for the PCRF

The MX Series router implements a number of measures to protect against data overload for both downstream and upstream transactions. Downstream transactions are protected by throttling input from the network under overload conditions. The upstream transactions are protected by limiting both the number of outstanding requests and using slow retries of the first unacknowledged message for a reliable recovery.

Built-in features of the Policy and Charging Enforcement Function (PCEF) environment provide protection from overload resulting from an excessive subscriber login rate. If there are too many rule changes and disconnect operations due to Reauthorization Request (RAR-GX) messages, the router sends a Reauthorization Answer (RAA-GX) response with the result-code: DIAMETER\_TOO\_BUSY (3004).

Within the router's AAA component, a session represents a subscriber (client) session entry in the Session Database (SDB).

**NOTE:** This is a representation of subscriber session only; it is not a connection-independent permanent identifier similar to a phone number. A subscriber can disconnect and reconnect, and it receives a different Session-Id.

There is a one-to-one correspondence between a session and the Session-Id. The Session-Id is globally and eternally unique because it is bound to the unique router identity and used to identify a user session without any reference to other information. The same subscriber could be mapped to several sessions, such as one from a disconnect and reconnect event. However, the session is always associated with a single subscriber.

The Session-Id (AVP Code 263) is of type UTF8String.

```
Session-Id AVP ::= <DiameterIdentity>;  
                <upper 32 bits of the AAA COMPONENT session-id>;  
                <lower 32 bits of the AAA COMPONENT session-id>;
```

The *DiameterIdentity* field is the value you configure for the Diameter origin-host. Internal Session-Ids are 64-bit integers assigned in ascending order. Both numeric parts of the Session-Id string are generated using %010u format, which guarantees that Session-Id AVP values are in the same order lexicographically as internal 64-bit sessions.

The Policy and Charging Rules Function (PCRF) pushes rules and messages down to the PCEF using the 3GPP Gx protocol and online policy interface. The PCRF and Gx protocol include the following messages:

- [Common Upstream Messages on page 743](#)
- [Common Downstream Messages on page 744](#)

Common Upstream Messages

The upstream messages for Credit Control Response for Initiation, Update, and Termination (CCR-GX-I, CCR-GX-U, and CCR-GX-T) and RAA-GX may include the following rules, parameters and data:

- [Event-Timestamp AVP on page 743](#)
- [Charging Rules Installation Notifications on page 743](#)
- [Event Trigger Commands on page 744](#)

Event-Timestamp AVP

The following shows an AVP for CCR-GX-I, CCR-GX-U, and CCR-GX-T, and RAA-GX messages between the PCRF and Gx:

```
{ Event-Timestamp: <timestamp> }
```

If you configure the Event-Timestamp AVP, it is included in the downstream message. The message definition in [Table 72 on page 743](#) varies depending on the transaction.

Table 72: Event-Timestamp AVP Message Definition

| Message  | Definition                 |
|----------|----------------------------|
| CCR-GX-I | Subscriber login timestamp |

Charging Rules Installation Notifications

The following notifications show a failed installation example and a successful installation example of charging rules installation for CCR-GX-U messages between the PCRF and Gx:

**NOTE:** If unacknowledged reports are still pending at the time of the client logout, these charging rules are included in CCR-GX-T messages.

Notification Reporting a Rule Installation Failure

```
{ Charging-Rule-Report
{ Charging-Rule-Name: <string> }
{ Charging-Rule-Name: <string> }
{ PCC-Rule-Status: INACTIVE(1) }
{ Rule-Failure-Code: UNKNOWN_RULE_NAME(1) }
}
```

Notification Reporting a Rule Installation Success

```
{ Charging-Rule-Report
{ Charging-Rule-Name: <string> }
{ Charging-Rule-Name: <string> }
```

```
{ PCC-Rule-Status:  ACTIVE(0) }
}
```

### Event Trigger Commands

The following shows a predefined event trigger command for CCR-GX and RAA-GX messages between the PCRF and Gx:

```
{ Event-Trigger:  SUCCESSFUL_RESOURCE_ALLOCATION(22) }
```

### Common Downstream Messages

The downstream messages for Credit Control Answer for Initiation and Update (CCA-GX-I and CCA-GX-U) and RAR-GX may include the following predefined rules with parameters and data:

**NOTE:** The CCA-GX-T (Termination) message is not included as a downstream message.

- [Charging Rule Installation Commands on page 744](#)
- [Charging Rule Removal Commands on page 745](#)
- [Event Trigger Commands on page 745](#)

### Charging Rule Installation Commands

The following example shows predefined rule installation commands for CCA-GX and RAR-GX messages between the PCRF and Gx:

```
{ Charging-Rule-Install
  { Charging-Rule-Name:  "fixed-cos" }
  { Charging-Rule-Definition:
    { Charging-Rule-Name:  "firewall" }
    { Service-Identifier:  10 }
    { Rating-Group:       292 }
    { Juniper-Param-V4-Input-Filter: "my_input_filter" }
    { Juniper-Param-V4-Output-Filter: "my_output_filter" }
  }
  [ Resource-Allocation-Notification:  ENABLE_NOTIFICATION(0) ]
}
```

**NOTE:** Some PCRFs may be unable to generate a Resource-Allocation-Notification AVP. As a result, the [report-resource-allocation](#) statement at the [edit access pcrf partition *partition-name*] hierarchy level provides generated reports by default.

### Charging Rule Removal Commands

The following example shows predefined rule removal commands for CCA-GX and RAR-GX messages between the PCRF and Gx:

```
{ Charging-Rule-Remove
  { Charging-Rule-Name: "predefined-ftp" }
  { Charging-Rule-Name: "firewall" }
}
```

The router processes all rule removal operations before any rule installation operations enabling you to simultaneously request both removal of an existing rule and installation of a rule having the same base name in a single transaction.

### Event Trigger Commands

The following shows a predefined event trigger command for CCA-GX and RAR-GX messages between the PCRF and Gx:

```
{ Event-Trigger: SUCCESSFUL_RESOURCE_ALLOCATION(22) }
```

If the SUCCESSFUL\_RESOURCE\_ALLOCATION (22) trigger value exists in the downstream data, the Broadband PCEF reports successful installations of rules marked with Resource-Allocation-Notification AVP in the Charging-Rule-Install AVP.

**NOTE:** Some PCRFs may be unable to generate this event trigger. As a result, the [report-successful-resource-allocation](#) statement at the `[edit access pcrf partition partition-name]` hierarchy level provides generated reports by default.

## Configuring the OCS Partition

The Online Charging System (OCS) works within a specific logical system: routing instance context, called a partition.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system: routing instance context.

Before you configure the OCS partition, perform the following task:

- Configure the Diameter instance at the `[edit diameter]` hierarchy level. See [“Configuring Diameter” on page 695](#).

Configuration for the OCS partition consists of naming the partition and then defining or associating a numerous parameters to define the characteristics of the partition.

To configure the OCS partition:

1. Create the partition or specify the name of an existing partition.

```
[edit access ocs]  
user@host# set partition partition-name
```

2. Specify the Diameter instance for the OCS partition.

**NOTE:** Currently, only the default Diameter instance, *master*, is supported.

```
[edit access ocs partition partition-name]  
user@host# set diameter-instance instance-name
```

3. (Optional) Configure the Called-Station-ID AVP used in all CCR-Gy packets for the partition.

```
[edit access ocs partition partition-name]  
user@host# set called-station-id station-name
```

4. (Optional) Configure the 3GPP-Charging-Id AVP used in all CCR-Gy packets for the partition.

```
[edit access ocs partition partition-name]  
user@host# set charging-id number
```

5. (Optional) Configure the Destination-Host AVP value used in the CCR-GY-I message.

```
[edit access ocs partition partition-name]  
user@host# set destination-host ocs-hostname
```

6. (Optional) Configure the Destination-Realm AVP value used in all CCR-GY messages

```
[edit access ocs partition partition-name]  
user@host# set destination-realm ocs-realm-name
```

7. (Optional) Configure the OCS partition to the draining state to make substantial configuration changes quickly.

```
[edit access ocs partition partition-name]  
user@host# set draining
```

8. (Optional) Configure the amount of time in seconds before the OCS partition responds and begins to drain after it has been placed in the draining state.

```
[edit access ocs partition partition-name]
user@host# set draining-response-timeout seconds
```

9. (Optional) Configure the amount of time in seconds before the OCS partition stops attempting to send the final interrogation during the subscriber logout process.

```
[edit access ocs partition partition-name]
user@host# set final-response-timeout seconds
```

10. Configure the OCS partition so that subscriber traffic is allowed before the first OCS interrogation and services are not removed by the PCEF when it receives negative responses from the OCS.

```
[edit access ocs partition partition-name]
user@host# set force-continue
```

11. (Optional) Configure the GGSN-Address AVP value used in all CCR-GY messages.

```
[edit access ocs partition partition-name]
user@host# set ggsn-address address
```

12. (Optional) Configure the 3GPP-GGSN-MCC-MNC AVP value used in all CCR-GY messages.

```
[edit access ocs partition partition-name]
user@host# set ggsn-mcc-mnc ggsn-mcc-mnc
```

13. (Optional) Configure the number of outstanding requests from the OCS to the OCS server that can be retried when the requests are improperly answered.

```
[edit access ocs partition partition-name]
user@host# set max-outstanding-requests number
```

14. (Optional) Specify that the Origin-State-ID AVP is included in Diameter base protocol level messages for the partition, and synchronized with the latest value sent to aid in monitoring changes in value.

```
[edit access ocs partition partition-name]
user@host# set send-origin-state-id
```

15. (Optional) Configure the information concatenated as a string in usernames that the OCS partition sends to the PCEF to identify the subscribers.

- a. (Optional) Include the underlying or physical interface name.

```
[edit access ocs partition partition-name]
```

```
user@host# set user-name-include base-interface-name
```

- b. (Optional) Use the specified character to separate the components of the username.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include delimiter delimiter-character
```

- c. (Optional) Include the specified domain name.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include domain-name domain-name
```

- d. (Optional) Include the interface name.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include interface-name
```

- e. (Optional) Include the client hardware MAC address from the incoming packet.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include mac-address
```

- f. (Optional) Include the NAS-Port-ID (RADIUS attribute 87) that identifies the physical interface that subscriber is using.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include nas-port-id
```

- g. (Optional) Include the name of the host that originates the Diameter message.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include origin-host
```

- h. (Optional) Include the name of the realm that originates the Diameter message.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include origin-realm
```

- i. Include the username.

```
[edit access ocs partition partition-name]  
user@host# set user-name-include user-name
```

- j. (Optional) Include the specified prefix.

```
[edit access ocs partition partition-name]
user@host# set user-name-include user-prefix prefix
```

16. (Optional) Configure the information required for providing file backup for OCS data.

- a. (Optional) Include the limit on the total number of backup entries for the OCS data.

```
[edit access ocs partition partition-name]
user@host# set backup limit
```

- b. (Optional) Include the timeout for backup operation.

```
[edit access ocs partition partition-name]
user@host# set backup timeout
```

- c. (Optional) Include the action on the number of backup entries over limit.

```
[edit access ocs partition partition-name]
user@host# set backup overflow
```

17. (Optional) Configure the information required for providing the sftp-backup mechanism implemented for OCS data.

- a. (Optional) Configure the length of time to write the file after the first CCR-GY-T was submitted.

```
[edit access ocs partition partition-name]
user@host# set sftp-backup accumulation-timeout
```

- b. (Optional) Configure the accumulation-count statement to set a specific value.

```
[edit access ocs partition partition-name]
user@host# set sftp-backup accumulation-count
```

- c. (Optional) Configure the accumulation-size statement to set a specific value.

```
[edit access ocs partition partition-name]
user@host# set sftp-backup accumulation-size
```

- d. (Optional) Configure the retry-interval statement to set a specific value.

```
[edit access ocs partition partition-name]
user@host# set sftp-backup retry-interval
```

- e. (Optional) Configure the response-timeout statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup response-timeout
```

- f. (Optional) Configure the routing-instance statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup routing-instance
```

- g. (Optional) Configure the address statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup address
```

- h. (Optional) Configure the port statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup port
```

- i. (Optional) Configure the directoryl statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup directory
```

- j. (Optional) Configure the file-prefix statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup file-prefix
```

- k. (Optional) Configure the node-ipv4-address statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup node-ipv4-address
```

- l. (Optional) Configure the ssh-login statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup ssh-login
```

- m. (Optional) Configure the ssh-connection-linger statement to set a specific value.

```
[edit access ocs partition partition-name]  
user@host# set sftp-backup ssh-connection-linger
```

- n. (Optional) Configure the ssh-log-verbose statement to set a specific value.

```
[edit access ocs partition partition-name]
user@host# set sftp-backup ssh-log-verbose
```

- o. (Optional) Configure the ssh-passphrase statement to set a specific value.

```
[edit access ocs partition partition-name]
user@host# set sftp-backup ssh-passphrase
```

## Configuring the PCRF Partition

The Policy Control and Rules Charging Function (PCRF) works within a specific logical system:routing instance context, called a partition.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system:routing instance context.

Before you configure the PCRF partition, perform the following task:

- Configure the Diameter instance at the **[edit diameter]** hierarchy level. See “[Configuring Diameter](#)” on page 695.

Configuration for the PCRF partition consists of naming the partition and then defining or associating numerous parameters to define the characteristics of the partition.

To configure the PCRF partition:

1. Create the partition or specify the name of an existing partition.

```
[edit access pcrf]
user@host# set partition partition-name
```

2. Specify the Diameter instance for the PCRF partition.

**NOTE:** Currently, only the default Diameter instance, *master*, is supported.

```
[edit access pcrf partition partition-name]
user@host# set diameter-instance instance-name
```

3. (Optional) Configure the Destination-Host AVP value used in the CCR-GX-I message.

```
[edit access pcrf partition partition-name]
user@host# set destination-host pcrf-hostname
```

4. (Optional) Configure the Destination-Realm AVP value used in all CCR-GX messages

```
[edit access pcrf partition partition-name]  
user@host# set destination-realm pcrf-realm-name
```

5. (Optional) Configure the PCRF to the draining state to make substantial configuration changes quickly.

```
[edit access pcrf partition partition-name]  
user@host# set draining
```

6. (Optional) Configure the amount of time in seconds before the PCRF responds and begins to drain after it has been placed in the draining state.

```
[edit access pcrf partition partition-name]  
user@host# set draining-response-timeout seconds
```

7. Configure the an IP connectivity access network (IP-CAN) that best fits your operating environment and access network.

```
[edit access pcrf partition partition-name]  
user@host# set ip-can-type number seconds
```

8. Configure the PCRF partition so that the subscriber login proceeds even if the PCRF is unavailable or the PCRF does not respond within the corresponding logout response timeout period.

```
[edit access pcrf partition partition-name]  
user@host# set local-decision
```

9. (Optional) Configure the amount of time in seconds before the PCRF stops attempting to send a subscriber logout message.

```
[edit access pcrf partition partition-name]  
user@host# set logout-response-timeout seconds
```

10. (Optional) Configure the number of outstanding requests from the PCRF to the PCRF server that can be retried when the requests are improperly answered..

```
[edit access pcrf partition partition-name]  
user@host# set max-outstanding-requests number
```

11. (Optional) Specify that the PCRF sends local report downstream messages by default.

```
[edit access pcrf partition partition-name]  
user@host# set report-local-rule
```

12. (Optional) Specify that the PCRF reports by default when installation fails for rules marked with the Resource-Allocation-Notification AVP in the Charging-Rule.

```
[edit access pcrf partition partition-name]
user@host# set report-resource-allocation
```

13. (Optional) Specify that the PCRF reports by default when installation either fails or succeeds for rules marked with the Resource-Allocation-Notification AVP in the Charging-Rule.

```
[edit access pcrf partition partition-name]
user@host# set report-successful-resource-allocation
```

14. (Optional) Specify that the Juniper-Dyn-Subscription-Id-Indicator AVP is included to indicate support for dynamic assignment of the subscription ID.

```
[edit access pcrf partition partition-name]
user@host# set send-dyn-subscription-indicator
```

15. (Optional) Specify that the Juniper-Network-Family-Indicator AVP is included to indicate the network families that are associated with the service request and supported by the subscriber.

```
[edit access pcrf partition partition-name]
user@host# set send-network-family-indicator
```

16. (Optional) Specify that the

```
[edit access pcrf partition partition-name]
user@host# set send-origin-state-id
```

17. (Optional) Specify that the Origin-State-ID AVP is included in Diameter base protocol level messages for the partition, and synchronized with the latest value sent to aid in monitoring changes in value.

```
[edit access pcrf partition partition-name]
user@host# set send-origin-state-id
```

18. (Optional) Configure the subscriber data to use in the PCRF partition messages to identify subscribers.

- a. (Optional) Include the underlying or physical interface name.

```
[edit access pcrf partition partition-name]
user@host# set subscription-id-data-include base-interface-name
```

- b. (Optional) Use the specified character to separate the components of the subscription identifier.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include delimiter delimiter-character
```

- c. (Optional) Include the specified domain name.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include domain-name domain-name
```

- d. (Optional) Include the interface name.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include interface-name
```

- e. (Optional) Include the client hardware MAC address from the incoming packet.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include mac-address
```

- f. (Optional) Include the NAS-Port-ID (RADIUS attribute 87) that identifies the physical interface that subscriber is using.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include nas-port-id
```

- g. (Optional) Include the name of the host that originates the Diameter message.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include origin-host
```

- h. (Optional) Include the name of the realm that originates the Diameter message.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include origin-realm
```

- i. Include the username.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include user-name
```

- j. (Optional) Include the specified prefix.

```
[edit access pcrf partition partition-name]  
user@host# set subscription-id-data-include user-prefix prefix
```

- k. (Optional) Include the subscriber VLAN tags. You can use this instead of the **interface-name** option when the outer VLAN tag is unique across the system, which is dependent on your network topology and use case.

```
[edit access pcrf partition partition-name]
user@host# set subscription-id-data-include vlan-tags
```

19. (Optional) Identify the subscriber with a custom or predefined type value during the login session in CCR-GX-I and CCA-GX-I messages.

```
[edit access pcrf partition partition-name]
user@host# set subscription-id-type number
```

20. (Optional) Configure the amount of time in seconds before a PCRF partition stops attempting to send an updated rule report response using a CCR-GX-U message.

```
[edit access pcrf partition partition-name]
user@host# set update-response-timeout seconds
```

## Configuring OCS Global Parameters

You can configure global attributes of the 3rd Generation Partnership Project (3GPP) Diameter credit control service charging system for the Online Charging System (OCS), which interacts with the Policy and Charging Enforcement Function (PCEF).

Currently, the only configurable global attribute is the service context identifier allocated by the service provider or operator. This value corresponds to the Service-Context-Id AVP, which together with the Service-Identifier-AVP uniquely and globally identifies the Diameter credit control service.

To configure the OCS global parameters:

- Configure the service context identifier.

```
[edit access ocs global]
user@host# set service-context-id service-context
```

## Diameter Network Access Server Application (NASREQ)

The Diameter Network Access Server Requirements (NASREQ) protocol is a Diameter-based authentication, authorization, and accounting protocol defined in RFC 7155, *Diameter Network Access Server Application*. It is an alternative to using RADIUS AAA in a Diameter environment. Junos OS supports the authentication and authorization functions, but not accounting. Authentication is used for the initial subscriber login to verify the subscriber identity. Similarly, authorization is used at login to set up the initial conditions or services or both that may be needed for the subscriber. The NASREQ protocol is not used for re-authentication or re-authorization of subscribers.

Junos OS supports the following NASREQ protocol exchanges:

- AA-Request/Answer—The authentication/authorization request at login.
- Session-Termination-Request/Answer—Notification that the subscriber's session has been terminated.
- Abort-Session-Request/Answer—Request to terminate the subscriber's session from a NASREQ server.

**NOTE:** The Auth-Application-Id AVP must be set to a value of 1 in AA-Request, Session-Termination-Request, and Abort-Session-Request messages.

---

The NASREQ client has two queues, the transmit queue and response queue. The transmit queue stores outbound packets until they are sent to Diameter, and includes requests and responses. The response queue stores packets until Diameter responds to the request, and includes only requests waiting for a response.

The following configuration variables control transmission flow and use of the queues:

- *outstanding-requests*—The maximum number of requests (includes AAR and STR) that are sent to Diameter for wireline transmissions—effectively this is the maximum count of requests on the response-queue (the maximum number of in-flight requests for which there has not been a response or timeout); it does not include sent responses.
- *request-retry*—The number of times to re-send a given request to Diameter after it times out for its initial request. This value applies only to requests in the response queue.
- *timeout*—The number of seconds that an outbound packet remains in the transmit queue before it is declared timed out. Packets that exceed the timeout value are not transmitted. Diameter manages packets that time out after transmission. The timeout value applies to all packets in the transmit queue, including both requests and responses to be sent.

The exchange flow takes place as follows:

1. A subscriber attempts to log in and authd, acting as the NASREQ client, sends the NASREQ server a Diameter AA-Request (AAR) message that includes information about the subscriber and authentication information.

- If the number of outstanding requests is less than the configured maximum outstanding request value, then authd sends the request to the NASREQ server for transmission and places the request on the response queue.
  - If the number of outstanding requests is greater than or equal to the configured maximum outstanding request value, then authd stores the request on the transmit queue.
2. When a response is received from the NASREQ server in the form of a Diameter AA-Answer (AAA) message, authd checks the response queue for a matching request (AAR).
    - If a matching request is found, the request is pulled from the queue and used to process the response.
    - If no matching request is found, the response is ignored and dropped.

When Diameter notifies the NASREQ client that a request has timed out, one of the following actions occurs:

- If the request is not on the response queue, the timeout is ignored.
- If the retry counter for this request is less than the configured **request-retry** value, authd sends the request again and increments the retry counter for that request.
- If the retry counter for this request is greater than or equal to the configured value, authd processes the request timeout and sends the next request that is on the transmit queue to the NASREQ server.

When the configured timeout period expires, authd removes any expired outbound packets from the transmit queue and processes them as having timed out.

### Benefits of Using the Diameter NASREQ Protocol

Enables the use of an external NASREQ server to provide authentication and authorization for subscribers, rather than using a RADIUS server. Some customer models might not employ a RADIUS server, or want to stop using a RADIUS server when they move to a Diameter subscriber provisioning model.

## Configuring the Diameter Network Access Server Application (NASREQ)

You configure the NASREQ client as an alternative to RADIUS for subscriber authentication and authorization when the subscribers log in.

To configure NASREQ for authentication and authorization:

1. Specify NASREQ as a Diameter application (function) associated with a network element.

```
[edit diameter network-element network-element-name]
user@host# set function nasreq
```

2. Specify NASREQ as the Diameter network element forwarding function and partition.

```
[edit diameter network-element network-element-name forwarding route route]
user@host# set function nasreq
```

3. Specify NASREQ for subscriber authentication and authorization.

```
[edit access profile profile-name]
user@host# set authentication-order nasreq
```

4. Specify NASREQ for subscriber authorization only (no authentication).

```
[edit access profile profile-name]
user@host# set authorization-order nasreq
```

**NOTE:** When you configure both `authentication-order` and `authorization-order`, the behavior depends on the subscriber type. For DHCP subscribers, `authorization-order` has precedence over `authentication-order`. For all other subscriber types, `authentication-order` has precedence over `authorization-order`.

5. Specify the destination identity of the NASREQ partition.

```
[edit access nasreq partition partition-name]
user@host# set diameter-instance master destination-realm realm-name
destination-host hostname
```

6. Specify the maximum number of requests to send to the Diameter engine for transmission. This is also the maximum number of requests in the response queue.

```
[edit access nasreq]
user@host# set max-outstanding-requests number
```

7. Specify the number of times to retry sending a request to the Diameter engine if a timeout is received from Diameter for the request.

```
[edit access [edit access nasreq]]
user@host# set request-retry retries
```

8. Specify the number of seconds an outbound packet remains in the transmit queue before it is declared timed out.

```
[edit access [edit access nasreq]]
user@host# set timeout seconds
```

## Juniper Networks Session and Resource Control (SRC) and JSRC Overview

The Juniper Networks Session and Resource Control (SRC) environment provides a central administrative point for managing subscribers and their services. The SRC software runs on Juniper Networks C Series Controllers. The SRC software uses the Diameter protocol for communications between the local SRC peer on a Juniper Networks routing platform and the remote SRC peer on a C Series Controller. The local SRC peer is known as JSRC and is part of the AAA application. The remote SRC peer is the service activation engine (SAE); the SAE acts as the controlling agent in the SRC environment. JSRC and the SAE jointly provide the remote control enforcement functionality (RCEF).

JSRC has the following responsibilities:

- Request address authorization from the SAE.
- Request service activations from the SAE.
- Activate and deactivate services as specified by the SAE. JSRC can activate multiple policies with the same service (dynamic profile) name.
- Optionally report volume statistics for service accounting.
- Log out subscribers as specified by the SAE.
- Update the SAE with status of new service activations and deactivations.

- Synchronize subscriber state and service information with the SAE.
- Notify the SAE when subscribers log out.

The SRC software enables the SAE to activate and deactivate subscriber services (described by SRC policies) and log out subscribers. The SAE can control only those resources that have been provisioned through SAE. Therefore, the SAE receives information about only those subscribers for whom JSRC has requested provisioning from the SAE. For example, when a subscriber logs in, but the configuration did not require the session activation path to include SAE provisioning, the SAE does not receive information about this subscriber and cannot control the subscriber session.

Similarly, the SAE can control only the subscriber services that it has activated. When a service is not activated from the SAE—a RADIUS-activated service, for example—the SAE receives no information about the service and has no control over it.

The SAE can also direct JSRC to collect accounting statistics per service session.

**NOTE:** More than one Diameter-based application (function) can run on a router simultaneously.

---

### Benefits of Using JSRC

---

- Enables the use of MX Series routers to act as the local peer in a Juniper Networks Session and Resource Control (SRC) environment for centralized management of subscribers and their services.

### Hardware Requirements for JSRC for Subscriber Access

---

JSRC is supported on Juniper Networks MX Series 5G Universal Routing Platforms. JSRC currently supports subscriber sessions on static and dynamic interfaces.

## Understanding JSRC-SAE Interactions

This topic describes the sequences of Diameter messages exchanged between JSRC (the local SRC peer) and the SAE (the remote SRC peer) as they interact to perform the following tasks for subscriber access:

- Subscriber login
- Service activation
- Service deactivation
- Resynchronization
- SAE-initiated subscriber logout
- Statistics collection and reporting
- Subscriber-initiated logout

---

### Subscriber Login

JSRC authorization works as follows for different subscriber types:

- When you configure both **authorization-order jsrc** and **authentication-order** in the access profile, the authorization order applies only to DHCP subscribers affected by the profile and the authentication order applies only to non-DHCP subscribers.
- When you configure only **authorization-order jsrc** in the access profile, the authorization order applies to all subscribers affected by the profile.

When a subscriber attempts to log in, the protocol daemon sends an authentication request to AAA. In turn, JSRC sends a Diameter AA-Request message to the SAE. SAE returns a Diameter AA-Answer message that can include the Framed-IP-Address attribute and the Juniper-DHCP-Options AVP (AVP code 2010). JSRC ignores any other optional AVPs included in this AA-Answer message.

JSRC provisioning is enabled for DHCP (and SSC) subscribers when you include the **provisioning-order** statement at the **[edit access profile *profile-name*]** hierarchy level. When the application requests AAA to activate the subscriber's session, JSRC sends an AA-Request message that includes the Juniper-Request-Type AVP (AVP code 2050) with a value that indicates service provisioning is requested from the SAE.

The SAE returns a AA-Answer message that contains an ACK if the request is accepted or a NAK if the request is denied. If the request is accepted, the AA-Answer message includes the Juniper-Policy-Install AVP (AVP code 2020), which is used to specify the service to attach to the subscriber's interface. When this AVP is included, the SAE sets the Result-Code AVP to 1001 (DIAMETER\_MULTI\_ROUND\_AUTH). This code means that the JSRC must send another AA-Request message to the SAE to report the success or failure of the policy instantiation (service activation) by AAA. JSRC ignores any other optional AVPs included in this AA-Answer message. The SAE returns an AA-Answer message to acknowledge this second AA-Request message.

### Subscriber Service Activation and Deactivation

---

SAE policies provision subscriber services. After a subscriber is logged in, the SAE can send a PPR message to JSRC to activate or deactivate services. A given PPR can include the Juniper-Policy-Install AVP (AVP code 2020) to activate a service, the Juniper-Policy-Remove AVP (AVP code 2027) to deactivate a service, or both (for different services). A PPR can include no more than three of these AVPs (install, remove, or mixed).

JSRC sends a PPA message to the SAE when it has completed the tasks requested in the PPR. The PPA indicates the success or failure of the actions requested in the PPR.

**NOTE:** If you use RADIUS or the CLI to deactivate a service that the SAE, the SAE becomes unsynchronized with the state of subscribers on the routing engine.

---

### Subscriber Resynchronization

---

During resynchronization, JSRC informs the SAE about the services that are active for the provisioned subscribers. Either JSRC or the SAE initiates the resynchronization.

- The SAE initiates resynchronization at startup or when a backup SAE takes over session control due to resource limits or conditions on the primary SAE. The SAE clears its database of all entries in preparation for the synchronization.
- JSRC initiates resynchronization at JSRC startup, such as when AAA starts or restarts.

JSRC can also initiate resynchronization in another circumstance. When an SAE in a multi-SAE environment becomes active, it must send an SRQ to JSRC as its first message. JSRC then locks the Origin-Host AVP of the active SAE. JSRC subsequently triggers resynchronization if it receives a message from any other SAE as indicated by the Origin-Host AVP. Such an incident can occur if communication between the active SAE and a standby SAE is interrupted.

Both entities initiate a resynchronization by sending an SRQ message. The recipient responds with an SRR message. After the SRR is sent, regardless of whether the SAE or JSRC initiates the synchronization, JSRC sends an AA-Request message to the SAE for each provisioned subscriber present in the session database. The AA-Request message includes a Juniper-Policy-Install AVP for the active services. The SAE returns an AA-Answer message with an ACK to acknowledge receipt.

### Subscriber Session Terminated by the SAE

---

When the SAE terminates a subscriber session, it sends an ASR message to JSRC. JSRC causes AAA to send a logout request to the DHCP (or SSC) client application. When the DHCP client application accepts the logout request, JSRC includes an ACK in the ASR message it sends to the SAE to signify success. If the DHCP client application does not accept the request, then JSRC includes a NAK in the ASR to signify failure. The DHCP client application is responsible for initiating the actual logout sequence with AAA.

Statistics Collection and Reporting per Service Rule

Statistics information can be sent from the router to the SAE or from the SAE to the router. Both the Diameter Accounting-Request (ACR) and Accounting-Answer (ACA) messages include the Juniper-Acct-Record AVP (AVP code 2053), which identifies the policy (service) for which accounting information is requested.

Subscriber Logout

When the DHCP (or SSC) client application sends a subscriber logout notice to AAA, JSRC sends an STR message to notify the SAE that the provisioned subscriber session is being terminated. The SAE returns an STA message to JSRC, and JSRC notifies DHCP that the logout is complete.

JSRC Provisioning for Dual-Stack Subscribers

Starting in Junos OS Release 18.1R1, you can include the **dualstack-support** statement at the **[edit jsrc]** hierarchy level to configure JSRC provisioning for dual-stack subscribers so that it reports information about the separate stacks for a given subscriber, using a single JSRC session. In earlier releases, the DHCPv4 and DHCPv6 stacks are treated as a single subscriber; the remote SRC peer (SAE) is not informed about whether only one family or both families are active. The statistics are reported as an aggregate of both families rather than separated by family. The default behavior starting in Junos OS Release 18.1R1 is the same as the behavior in earlier releases.

This dual-stack provisioning behavior is not backward compatible with other releases. [Table 73 on page 763](#) on page 2 lists some of the differences in behavior when dual-stack support is configured and when it is not configured (the default).

Table 73: Differences Between JSRC Dual-Stack Behavior by Release

| Dual-Stack Support Configured                                                                                                                                        | Dual-Stack Support Not Configured                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| When the first network family is activated, sends the addresses for only that family in the initial request to the provisioning server.                              | When the first network family is activated, requests provisioning from the provisioning server (SAE; remote SRC peer). |
| When the second network family is activated, sends a special family-activate packet to inform the provisioning server that the family is active.                     | When the second network family is activated, reports nothing to the provisioning server.                               |
| When the next-to-last network family is deactivated, sends a special family-deactivate packet to inform the provisioning server that the family is no longer active. | When the next-to-last network family is deactivated, reports nothing to the provisioning server.                       |
| Reports IPv4 and IPv6 statistics separately.                                                                                                                         | Reports subscriber and services statistics as an aggregate of statistics for both IPv4 and IPv6 statistics.            |

Benefits of JSRC Dual-Stack Provisioning

- Enables SAE to be aware of which network families are currently active for a subscriber.

- Enables collection of accurate accounting statistics per address family, rather than an aggregated count that includes statistics for both families without distinction.

### AA-Request Messages When Dual-Stack Support Configured

When **dualstack-support** is configured, Diameter AA-Request (AAR) provisioning messages sent to the SAE include the following:

- IPv4 or IPv6 addresses of the currently active network families as well as the families that are in the process of being activated. When either address type is not included in the AAR message, it means that the corresponding network family is not active and is not being activated when the request is sent.
- For IPv4 addressing, the following Diameter AVPs when they are available in the subscriber's session database entry:
  - Framed-IP-Address (AVP 8)
  - Framed-IP-Netmask (AVP 9)
- For IPv6 addressing, the following Diameter AVPs and Juniper Networks Diameter AVPs when they are available in the subscriber's session database entry:
  - Framed-IPv6-Address (AVP 168)
  - Framed-IPv6-Prefix (AVP 97)
  - Delegated-IPv6-Prefix (AVP 123)
  - Juniper-IPv6-Ndra-Prefix (AVP 2200)
  - Juniper-Framed-IPv6-Netmask (AVP 2201)
- The following Juniper Networks Diameter AVPs when they are available in the subscriber's session database entry:
  - Juniper-Agent-Circuit-Id (AVP 2202)
  - Juniper-Remote-Circuit-Id (AVP 2203)
- One of the following new values in the Juniper-Request-Type AVP (2636:2050) to notify the SAE when an inactive network family activates or an existing network family deactivates:
  - 4—NETWORK\_FAMILY\_ACTIVATE
  - 5—NETWORK\_FAMILY\_DEACTIVATE

Only the addressing of the family being activated or deactivated is included in the notification.

**NOTE:** An activation notification is not sent for the first network family that activates. A deactivation notice is not sent for the last family that deactivates.

- When the AAR message is used for synchronization and recovery, only the addressing for the currently active address families for that subscriber. The AAR message does not include addressing for deactivated families.

### Accounting-Request Messages When Dual-Stack Support Configured

When **dualstack-support** is configured, the Diameter Accounting-Request (ACR) messages always include both IPv4 and IPv6 statistics, even when the value is zero.

Statistics are reported for the life of the subscriber session and not merely for the life of the network family session. When one of the network families is inactive, JSRC continues to report the last statistics value for the inactive family with the current statistics of the active network family. If the deactivated family becomes active again, the new family statistics are added to the existing values.

The following Juniper Networks Diameter AVPs (IANA enterprise number 2636) are used to report IPv6 statistics:

- Accounting-IPv6-Input-Octets attribute (2204)
- Accounting-IPv6-Output-Octets attribute (2205)
- Accounting-IPv6-Input-Pkts attribute (2206)
- Accounting-IPv6-Output-Pkts attribute (2207)

These IPv6 AVPs are not used when **dualstack-support** is not configured. In that case the IPv6 statistics are aggregated with the IPv4 statistics in the corresponding IPv4 AVPs.

### Network Family Activation and Deactivation Notification When Dual-Stack Support Configured

The following sequence describes client and authd process (daemon) behavior when a network family is activated:

1. A subscriber initiates login.
2. The client application on the router, such as PPP or DHCP, sends an authentication and authorization (AA) request to authd.
3. The authd process sends the AA request as configured and returns the response to the client application, which then returns a response to the subscriber.
4. The client application builds and configures the subscriber's interface on the router with information from the client dynamic profile.
5. The client application sends the first network family activation request to authd.
6. The authd process sends a provisioning request to the SAE that contains the addresses of the family that is being activated. Because authd sends a provisioning request for

the first family activation, there is no reason to also send a family-activation notification.

7. The SAE returns policies (services) for authd to activate for the subscriber.
8. The authd process activates those services and sends a family-activation ACK response to the client application.
9. The client application might send a family activation request for the other network family.
  - a. The authd process activates any services for that specific network family and then sends a family-activation ACK response to the client application.
  - b. The authd process then sends a family-activation notification to the SAE with the addresses of the second family. The AAR message includes the Juniper-Request-Type AVP (2636:2050) with a value of 4 (NETWORK\_FAMILY\_ACTIVATE). The notification includes only addresses for this family.

For deactivations, the client application sends a family deactivation request only when both network families are active. The authd process deactivates the network family (and any associated services) as requested and sends the SAE a family deactivation notification with the addresses for that family. The AAR message includes the Juniper-Request-Type AVP (2636:2050) with a value of 5 (NETWORK\_FAMILY\_DEACTIVATE). The notification includes only addresses for this family.

However, when the last network family deactivates, the client sends a termination request, which causes authd to send the JSRC-Acct-Stop message to the SAE. Consequently there is no need for authd to send a family deactivation notification.

## JSRC Configuration Overview

You can configure the JSRC client application to work with Session and Resource Control (SRC) to centrally manage subscribers and services. JSRC requests address and service authorizations from the remote SRC peer (the SAE), activates and deactivates services as specified by the SAE, logs out subscribers as specified by the SAE, and synchronizes subscriber state and service information with the SAE.

To configure JSRC:

1. Configure the JSRC partition.  
See [“Configuring the JSRC Partition” on page 767](#).
2. Assign the JSRC partition.  
See [“Assigning a Partition to JSRC” on page 768](#).
3. Configure JSRC authorization for subscribers.  
See [“Authorizing Subscribers with JSRC” on page 768](#).

4. Configure JSRC provisioning for subscribers.  
See [“Provisioning Subscribers with JSRC” on page 769](#).
5. (Optional) Configure JSRC to exclude an AVP from Messages Sent to SAE.  
See [“Excluding AVPs from Diameter Messages for JSRC” on page 771](#).
6. Configure service accounting by JSRC.  
See [“Configuring Service Accounting with JSRC” on page 772](#).
7. Configure JSRC support for dual-stack subscribers.  
See [“Configuring JSRC for Dual-Stack Subscribers” on page 770](#).
8. Configure JSRC event tracing as part of general authentication service tracing operations.  
See *Tracing General Authentication Service Processes*.

## Configuring the JSRC Partition

JSRC works within a specific logical system: routing instance context, called a partition.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system: routing instance context.

Before you configure the JSRC partition, perform the following task:

- Configure the Diameter instance at the **[edit diameter]** hierarchy level. See [“Configuring Diameter” on page 695](#).

Configuration for the JSRC partition consists of naming the partition and then associating a Diameter instance, the SAE hostname, and the SAE realm with the partition.

To configure the JSRC partition:

1. Create the partition.

```
[edit jsrc]
user@host# set partition partition1
```

2. Specify the Diameter instance for the JSRC partition.

**NOTE:** Currently, only the default Diameter instance, *master*, is supported.

```
[edit jsrc partition partition1]
```

```
user@host# set diameter-instance master
```

3. Configure the destination host for the JSRC partition.

```
[edit jsrc partition partition1]  
user@host# set destination-host sae1
```

4. Configure the destination realm for the JSRC partition.

```
[edit jsrc partition partition1]  
user@host# set destination-realm generic.example.com
```

## Assigning a Partition to JSRC

You must associate a configured JSRC partition with the JSRC instance that you are configuring.

Before you assign a partition to JSRC, perform the following task:

- Configure the JSRC partition. See [“Configuring the JSRC Partition” on page 767](#)

To assign the JSRC partition:

- Specify the partition name.

```
[edit jsrc]  
user@host# set jsrc-partition partition1
```

## Authorizing Subscribers with JSRC

You can configure AAA to use JSRC in an SRC environment to request authorization from the SAE when AAA is verifying whether a DHCP subscriber can access the router. When JSRC authorization is configured, AAA ignores any configured authentication order settings.

Before you configure JSRC authorization, perform the following tasks:

- Create the subscriber access profile at the **[edit access profile]** hierarchy level.
- Define the subscriber username with the **username-include** statement in the authentication configuration for DHCP local server or DHCP relay.

To configure JSRC authorization:

- Specify **jsrc** as the authorization method in the profile.

```
[edit access profile dhcpsub1]  
user@host# set authorization-order jsrc
```

## Provisioning Subscribers with JSRC

You can configure AAA to use JSRC in an SRC environment to request provisioning from the SAE to instantiate services for an authenticated subscriber.

Before you configure JSRC provisioning for subscribers, perform the following task:

- Create the subscriber access profile at the **[edit access profile]** hierarchy level.

To configure JSRC provisioning:

- Specify **jsrc** as the provisioning method in the profile.

```
[edit access profile dhcpsub1]  
user@host# set provisioning-order jsrc
```

## Configuring JSRC for Dual-Stack Subscribers

By default, JSRC provisioning for dual-stack subscribers treats the DHCPv4 and DHCPv6 stacks as a single subscriber. The remote SRC peer (SAE) is not informed about whether only one family or both families are active. The statistics are reported as an aggregate of both families rather than separated by family.

Starting in Junos OS Release 18.1R1, you can configure dual-stack support so that JSRC reports information about the separate stacks for a given subscriber, using a single JSRC session.

When you configure dual-stack support for JSRC, Diameter AA-Request (AAR) provisioning messages sent to the SAE include Diameter AVPs (IANA enterprise number 2636) to convey the IPv4 and IPv6 addressing information that is available in the session database.

For IPv4, that includes the following AVPs:

- Framed-IP-Address (AVP 8)
- Framed-IP-Netmask (AVP 9)

For IPv6, that includes the following AVPs:

- Framed-IPv6-Address (AVP 168)
- Framed-IPv6-Prefix (AVP 97)
- Delegated-IPv6-Prefix (AVP 123)
- Juniper-IPv6-Ndra-Prefix (AVP 2200)
- Juniper-Framed-IPv6-Netmask (AVP 2201)

JSRC also includes information about the access line if it is available in the session database, by means of Juniper-Agent-Circuit-Id (AVP 2202) and Juniper-Remote-Circuit-Id (AVP 2203).

When the first network family is activated, JSRC sends the addresses for only that family in the initial request to the provisioning server. When the second network family is activated, the AAR message includes the Juniper-Request-Type AVP (2050) with a value of 4 to signify family activation. When the next-to-last family is deactivated, the same AVP is sent with a value of 5 to signify the deactivation.

To configure JSRC provisioning to report dual-stack subscriber information by family:

- Enable dual-stack support.

```
[edit jsrc]
user@host# set dualstack-support
```

## Excluding AVPs from Diameter Messages for JSRC

Starting in Junos OS Release 14.2, you can configure the router to exclude AVPs from Diameter messages that are sent to the SAE from JSRC.

**NOTE:** Currently, only the user-name (1) AVP is supported.

To configure JSRC to exclude an AVP in Diameter messages:

1. Specify that you want to configure JSRC settings in the access profile.

```
[edit access profile profilewestern55]
user@host# edit jsrc
```

2. Specify that you want to configure Diameter attribute usage.

```
[edit access profile profilewestern55 jsrc]
user@host# edit attributes
```

3. Configure the router to exclude the specified AVP from the specified messages. The following example excludes the user-name AVP from authorization and provisioning AAR messages.

```
[edit access profile profilewestern55 jsrc attributes]
user@host# set exclude user-name authorization-request
user@host# set exclude user-name provisioning-request
```

## Service Accounting with JSRC

A service session represents a service for a specific subscriber. Service sessions exist in the context of a subscriber session. JSRC activates and deactivates services as specified by the SAE (remote SRC peer). JSRC can collect and report service accounting data by volume. JSRC accounting requires that either classic firewall filters or fast update firewall filters be configured to count service packets—the service packet information provides the volume statistics.

**NOTE:** JSRC supports only volume statistics accounting for service sessions. Time statistics and subscriber accounting are not supported.

JSRC service accounting supports both accounting based on service activation/deactivation and interim accounting.

- Service activation/deactivation accounting—When accounting is enabled, JSRC sends an accounting start message to the SAE when it activates a service and an accounting stop message when it deactivates the service. The start message initiates the accounting session and provides initial information about the service session. The stop

message terminates the accounting session and reports the final (cumulative) accounting data.

- Interim accounting—When interim accounting is enabled for a service session, JSRC sends interim accounting messages to the SAE at a specified interval to report the cumulative accounting information available at that time. Interim accounting is ignored when accounting is not enabled for the corresponding service session.

JSRC accounting for a service begins when the service is activated, and remains in effect while the service is active. The SAE specifies the service (policy) to be activated for the subscriber with the Juniper-Policy-Install AVP (AVP code 2020). When this AVP includes the Juniper-Acct-Collect AVP (AVP code 2054), JSRC initiates service activation/deactivation accounting for the service.

JSRC initiates interim accounting when the Juniper-Policy-Install AVP includes the Acct-Interim-Interval AVP (AVP code 85). In this case, JSRC updates the accounting values at the interval specified in the AVP— in the range 600 through 86,400 seconds. Aggregate counters are reported for the dual stack case.

JSRC and the SAE exchange Diameter Accounting-Request (ACR) and Accounting-Answer (ACA) messages to communicate accounting data. Both messages include the Juniper-Acct-Record AVP (AVP code 2053) to identify the service for which accounting information is requested.

JSRC sends ACR messages to report accounting data to the SAE. The ACR message includes the Accounting-Record-Type AVP (AVP code 480) to specify the kind of accounting record that it is sending. When a service is activated, this AVP has a value of START\_RECORD. When a service is deactivated, it has a value of STOP\_RECORD. For interim accounting, ACR messages are sent at the specified accounting interval and the AVP has a value of INTERIM\_RECORD.

In addition to specifying the accounting record type, the ACR messages include standard RADIUS attributes to specify the desired statistics: Acct-Input-Octets [42], Acct-Output-Octets [43], Acct-Input-Packets [47], Acct-Output-Packets [48], and Acct-Session-Time [46].

The SAE returns ACA messages to the JSRC to acknowledge receipt of the ACR messages.

An access profile specifies subscriber access authentication and accounting parameters. When a service is activated through JSRC, the accounting reports can be sent either to the SAE or to RADIUS. The default configuration sends the reports to the SAE; you can also configure this by including the **service accounting-order activation-protocol** statement in the access profile. To send the reports instead to the RADIUS server, include the **service accounting-order radius** statement in the access profile.

When a service is activated through RADIUS rather than through JSRC, the accounting reports of the service session are sent to the RADIUS server.

## Configuring Service Accounting with JSRC

You can configure JSRC to report accounting statistics for service sessions.

In addition to the configuration shown here, the network context for JSRC service accounting includes the configuration of firewall filters to count the statistics, Diameter, JSRC, the subscriber services, RADIUS, and the SRC.

To configure service accounting by JSRC:

1. Configure JSRC to provision subscriber services.

```
[edit access profile profile-name]
user@host# set provisioning-order jsrc
```

2. Configure service accounting to be provided by the application that provisions the service—JSRC.

```
[edit access profile profile-name service]
user@host# set accounting-order activation-protocol
```

#### Release History Table

| Release | Description                                                                                                                                                                                                                                                                                                   |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18.1R1  | Starting in Junos OS Release 18.1R1, you can include the <b>dualstack-support</b> statement at the <b>[edit jsrc]</b> hierarchy level to configure JSRC provisioning for dual-stack subscribers so that it reports information about the separate stacks for a given subscriber, using a single JSRC session. |
| 14.2    | Starting in Junos OS Release 14.2, you can configure the router to exclude AVPs from Diameter messages that are sent to the SAE from JSRC.                                                                                                                                                                    |

## Subscribers on Static Interfaces Overview

You can associate subscribers with statically configured interfaces and provide dynamic service activation and deactivation for these subscribers. When the static interface comes up, the event is treated as a subscriber login. When the interface goes down, it is treated as a subscriber logout.

You can configure the static subscribers to be authenticated and authorized by means of RADIUS. In this case, RADIUS can then activate and deactivate services with change of authorization (CoA) messages. However, this configuration does not prevent the interface from coming up and forwarding traffic. Further, authorization parameters are not imposed on the subscriber interface.

Alternatively, you can use JSRC for dynamic service activation and deactivation for these subscribers. After the subscribers are present in the session database (SDB), JSRC can report the subscribers to the SAE so that the SRC software can subsequently manage the subscribers.

The following guidelines apply to static subscribers:

- Static subscribers are supported only on Ethernet interfaces, static demux interfaces, and pseudowire interfaces over logical tunnels (PS/LT). PS/LT support, introduced in Junos OS Release 18.3R1, enables full subscriber management (equivalent to dynamic subscribers) for statically provisioned subscribers whose traffic is transported over IP/MPLS access models.
- Only one static subscriber can exist over a given interface.
- An interface cannot appear in more than one group.
- Static subscribers cannot be created over dynamic interfaces.

Static subscribers are intended to work with JSRC. Include the **provisioning-order jsrc** statement at the **[edit access profile *profile-name*]** hierarchy level to enable JSRC to handle the subscribers at the direction of the SRC software.

If the authentication request fails for a static subscriber, a 60-minute, nonconfigurable timer begins counting down. The request is reissued when the timer expires. This action repeats for as long as the interface is operationally up.

You can force a logout of the static subscriber by issuing the **request services static-subscribers logout interface *interface-name*** command. A static subscriber can also be logged out by AAA or an external policy manager. In both cases, no subsequent logins can take place on the underlying interface until you reset the state by issuing the **request services static-subscribers login interface *interface-name*** command or the router or process reboots.

You can log out an interface group by issuing the **request services static-subscriber logout group *group-name*** command. You can subsequently log in a group of interfaces by issuing the **request services static-subscriber login group *group-name*** command.

No new CLI statements are required to configure the dynamic profile for static subscribers. The dynamic profile can be very simple; it is activated at login and deactivated at logout. If you do not configure a profile, then the *junos-default-profile* is automatically activated.

During a graceful Routing Engine switchover (GRES) event, active static subscribers are recovered, inactive subscribers are cleaned up, and logout continues for subscribers that were in the process of logging out.

Include the **static-subscribers** statement at the **[edit system services]** hierarchy level to configure static subscribers. Include the **traceoptions** statement at the **[edit system processes static-subscribers]** hierarchy level to configure tracing operations for static subscribers.

You can configure the access profile, dynamic profile, service profile, and authentication parameters for all static subscribers or for a particular group of static subscribers:

- To configure the access profile that triggers AAA services for the static subscriber for all static subscribers, include the **access-profile** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level to apply the profile to a specific group and override a top-level configuration.
- To configure the dynamic profile that is instantiated when the static subscriber logs in for all static subscribers, include the **dynamic-profile** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level to apply the profile to a specific group and override a top-level configuration. Do not specify a dynamic profile that creates a dynamic interface.
- To configure the service profile for all static subscribers at the global level and at the group level, include the **service-profile** statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level.
- To configure the authentication parameters that trigger an Access-Request message to AAA for all static subscribers, include the **authentication** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include the statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level to configure authentication for a specific group and override a top-level configuration. If you do not configure authentication, then by default the interface name is modified and used as the default username for the subscriber session and the authentication request.

The configurable authentication parameters include the password and details of how the username is formed. Include the **password** statement at the **[edit system services static-subscribers authentication]** hierarchy level to configure the authentication password for all static subscribers. Alternatively, include the statement at the **[edit system services static-subscribers group *group-name* authentication]** hierarchy level to configure authentication for a specific group and override a top-level configuration.

The username that is sent to AAA for authentication must include at least one of the following attributes:

- Domain name
- User prefix
- Interface name
- Logical system name
- Routing instance name

To configure how the username is formed for all static subscribers, include the desired statements at the **[edit system services static-subscribers authentication]** hierarchy level: **domain-name**, **user-prefix**, **logical-system-name**, or **routing-instance-name**. Alternatively, include the desired statements at the **[edit system services static-subscribers group *group-name* authentication]** hierarchy level to configure the username for a specific group and override a top-level configuration.

If you change the authentication configuration for an existing group or for static subscribers globally, the change has no effect on existing static subscribers. The changes are applied only to any new logins that are attempted after you commit the changes.

A group configuration must specify all the interfaces that you expect to support static subscribers. Include the **interface** statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level to specify the interfaces. This statement enables you to specify a single interface or a range of interfaces.

You must also statically configure these interfaces before any static subscribers can be supported on them. You must configure the static interfaces in the same logical system and routing instance as the group that includes the interfaces.

If you change the interfaces that are included in an existing interface group, existing static subscribers are automatically logged out and then back in when you commit the changes. However, changes made to the configuration of the interface itself have no effect on the login or logout state of the static subscriber associated with that interface.

By default, multiple subscribers are not supported on top of the same VLAN logical interface. If you want to support this behavior, then you can manage multiple subscribers on a single logical interface in one of two ways. You can either merge attributes such as firewall filters and CoS attributes for the multiple subscribers, or you can replace the current attributes with those of a new subscriber whenever a new subscriber logs into the underlying VLAN logical interface.

- To enable attribute merging for all static interfaces, include the **aggregate-clients merge** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group group-name]** hierarchy level to enable attribute merging for a specific group of static interfaces and override a top-level configuration.
- To enable attribute replacement for all static interfaces, include the **aggregate-clients replace** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group group-name]** hierarchy level to enable attribute replacement for a specific group of static interfaces and override a top-level configuration.

### Benefits of subscribers on static interfaces

---

Subscribers on Static Interfaces provides the following benefits:

- Offers static-subscribers the ability to configure service-profile.
- Provides dynamic service activation for the associated subscribers with statically configured interfaces.
- Provides competitive advantage with RFC compliancy.

## Subscribers over Static Interfaces Configuration Overview

This topic describes the procedure for configuring subscribers over static interfaces (static subscribers).

Before you configure subscribers over static interfaces, perform the following tasks:

- Configure the static interfaces on which you want to create and manage subscribers.
- Create an access profile to trigger AAA services for static subscribers.
- Create a dynamic profile that is instantiated when static subscribers log in.

To configure static subscribers:

1. Specify the global access profile that triggers AAA services for static subscribers.  
See [“Specifying the Static Subscriber Global Access Profile” on page 780](#).
2. Specify the global dynamic profile that is instantiated when static subscribers log in.  
See [“Specifying the Static Subscriber Global Dynamic Profile” on page 781](#).
3. Configure global method to handle multiple subscribers on a VLAN Logical Interface.  
See [“Enabling Multiple Subscribers on a VLAN Logical Interface for All Static Subscribers” on page 781](#).
4. Configure the global authentication password for static subscribers.  
See [“Configuring the Static Subscriber Global Authentication Password” on page 782](#).

5. Configure the global username for static subscribers.  
See [“Configuring the Static Subscriber Global Username” on page 782.](#)
6. Configure a group of subscribers to share values different from the global configuration.  
See [“Creating a Static Subscriber Group” on page 784.](#)
7. Specify the access profile for the static subscriber group.  
See [“Specifying the Static Subscriber Group Access Profile” on page 785.](#)
8. Specify the dynamic profile for the static subscriber group.  
See [“Specifying the Static Subscriber Group Dynamic Profile” on page 785.](#)
9. Specify the service profile for the static subscriber group.  
See [“Specifying the Static Subscriber Group Service Profile” on page 785.](#)
10. Configure method to handle multiple subscribers on a VLAN Logical Interface for a static subscriber group.  
See [“Enabling Multiple Subscribers on a VLAN Logical Interface for a Static Subscriber Group” on page 786.](#)
11. Configure the authentication password for the static subscriber group.  
See [“Configuring the Static Subscriber Group Authentication Password” on page 786.](#)
12. Configure the username for the static subscriber group.  
See [“Configuring the Static Subscriber Group Username” on page 787.](#)
13. (Optional) Force a static subscriber to be logged out from an interface.  
See [“Forcing a Static Subscriber to Be Logged Out” on page 797.](#)
14. (Optional) Enable an interface to accept static subscriber logins.  
See [“Resetting the State of an Interface for Static Subscriber Login” on page 797.](#)
15. (Optional) Force static subscribers to be logged out from a group of interfaces.  
See [“Forcing a Group of Static Subscribers to Be Logged Out” on page 797.](#)
16. (Optional) Enable a group of interfaces to accept static subscriber logins.  
See [“Resetting the State of an Interface Group for Static Subscriber Login” on page 797.](#)
17. Configure trace options for troubleshooting the configuration.

See *Tracing Static Subscriber Operations*.

## Example: Configuring Static Subscribers for Subscriber Access

This example shows a static subscriber configuration.

1. Configure the access profile to be used for static subscribers.

```
access {
  profile access5 {
    provisioning-order jsr;
    accounting {
      order radius;
    }
    authentication {
      order radius;
    }
  }
}
```

2. Configure the dynamic profile to be used for static subscribers.

If you do not configure this profile, the default profile, junos-default-profile, is used.

3. Configure the static interfaces on which to layer the static subscribers.
4. Configure the parameters that apply globally to all static subscribers in the configuration context.

```
static-subscribers {
  access-profile access5;
  dynamic-profile dyn-profile-1;
  authentication {
    password $ABC123;
    username-include {
      user-prefix Building5;
      interface;
      logical-system-name;
      routing-instance-name;
      domain-name example.com;
    }
  }
}
```

5. If you want to override the global parameters for certain static subscribers, create a group of static interfaces for those subscribers and configure parameters to apply to that group. Repeat this step for as many groups as you need.

```
static-subscribers {
```

```
group boston {  
  interface ge-1/0/1.1 upto ge-1/0/1.102  
  interface ge-1/0/1.6 exclude  
  interface ge-1/0/1.70 upto ge-1/0/1.80 exclude  
  access-profile boston-acs;  
  dynamic-profile dyn-profile-2;  
  authentication {  
    password $ABC123;  
    username-include {  
      user-prefix 2ndFloor;  
      interface;  
      logical-system-name;  
      routing-instance-name;  
      domain-name example.net;  
    }  
  }  
}
```

6. Configure tracing options for static subscriber events.

```
static-subscribers {  
  traceoptions {  
    file filename <files number> <match regular-expression> <size maximum-file-size>  
      <world-readable | no-world-readable>;  
    flag flag;  
    level (all | error | info | notice | verbose | warning);  
    no-remote-trace;  
  }  
}
```

## Specifying the Static Subscriber Global Access Profile

You specify a previously created access profile that triggers AAA services for all static subscribers. This value can be overridden for a group of static subscribers when a different profile is configured for that group.

To specify the access profile used for all static subscribers:

- Specify the profile name.

```
[edit system services static-subscribers]  
user@host# set access-profile access5
```

## Specifying the Static Subscriber Global Dynamic Profile

You specify a previously created dynamic profile that is instantiated when a static subscriber logs in. This profile is used for all static subscribers. This value can be overridden for a group of static subscribers when a different profile is configured for that group.

To specify the dynamic profile used for all static subscribers:

- Specify the profile name.

```
[edit system services static-subscribers]
user@host# set dynamic-profile dyn-profile-1
```

## Enabling Multiple Subscribers on a VLAN Logical Interface for All Static Subscribers

For a given interface, only a single static subscriber (or group) is logged in. Although we do not recommend this practice, you might have other kinds of subscribers configured on the same interface, such as a DHCP subscriber managed by the DHCP application. You can use the **aggregate-clients** statement to extend the dynamic profile for all static subscribers to enable multiple subscribers to share the same VLAN logical interface.

You can specify that attributes (such as CoS or firewall) for the multiple subscribers are merged for the logical interface. That is, the profiles for multiple subscribers of different types are instantiated on the interface, but the profile attributes of each are merged together. Alternatively, you can specify that the instantiated profile for the current subscriber is replaced by the profile of a new subscriber that logs in using the same logical interface. This configuration can be overridden for a group of static subscribers when a different configuration is applied for that group.

**NOTE:** The **aggregate-clients** statement is not supported for enhanced subscriber management.

To enable multiple subscribers to share the same VLAN logical interface for all static subscribers, do one of the following:

- Specify that the multiple subscriber attributes are merged for the logical interface.

```
[edit system services static-subscribers dynamic-profile dyn-profile-1]
user@host# set aggregate-clients merge
```

- Specify that the entire logical interface is replaced when a new subscriber logs into the network using the same VLAN logical interface.

```
[edit system services static-subscribers dynamic-profile dyn-profile-3]
user@host# set aggregate-clients replace
```

## Configuring the Static Subscriber Global Authentication Password

You configure a password that is included in the Access-Request message sent to AAA to authenticate all static subscribers. This value can be overridden for a group of static subscribers when a different password is configured for that group.

To specify the authentication password used for all static subscribers:

- Specify the password.

```
[edit system services static-subscribers authentication]  
user@host# set password $ABC123
```

## Configuring the Static Subscriber Global Username

You configure how the username is formed. The username serves as the username for all static subscribers that are created and is included in the Access-Request message sent to AAA to authenticate all static subscribers. This value can be overridden for a group of static subscribers when a different username is configured for that group.

The username must include at least one of the possible elements. The value of each element is concatenated in a specific order; the resulting string is the username. If you specify their inclusion, the interface name, logical system name, routing instance name, and VLAN tags are derived from the configuration context. The elements are ordered as follows (shown with the default delimiter):

```
user-prefix.interface.outer-tag-inner-tag.logical-system-name.  
routing-instance-name@domain-name
```

To configure the username for all static subscribers:

1. (Optional) Specify a prefix for the username.

```
[edit system services static-subscribers authentication username-include]  
user@host# set user-prefix user-prefix-string
```

2. (Optional) Specify that the interface name is included in the username.

```
[edit system services static-subscribers authentication username-include]  
user@host# set interface
```

3. (Optional) Specify that the VLAN tags (VLAN IDs) associated with the static interface are included in the username. For single-tagged VLANs, the component is the **outer-tag**. For dual-tagged (stacked) VLANs, the component is **outer-tag-inner-tag**. For IP demux interfaces configured for static subscribers, the VLAN tags configured on the underlying interface are used.

```
[edit system services static-subscribers authentication username-include]  
user@host# set vlan-tags
```

4. (Optional) Specify that the logical system name is included in the username.

```
[edit system services static-subscribers authentication username-include]
user@host# set logical-system-name
```

5. (Optional) Specify that the routing instance name is included in the username.

```
[edit system services static-subscribers authentication username-include]
user@host# set routing-instance-name
```

6. (Optional) Specify a domain name to include in the username.

```
[edit system services static-subscribers authentication username-include]
user@host# set domain-name domain-name
```

7. (Optional) Specify a delimiter character to separate the username elements except for the domain name. The domain name is always preceded by the @ character. The default delimiter is a period (.).

```
[edit system services static-subscribers authentication username-include]
user@host# set delimiter delimiter-character
```

Consider the following configuration:

```
[edit system services static-subscribers authentication username-include]
user@host# set user-prefix Building5
user@host# set interface
user@host# set logical-system-name
user@host# set routing-instance-name
user@host# set domain-name campus.example.com
```

Configured in the default logical system and master routing instance for interface ge-0/1/1.100, this sample configuration generates the following username:

**Building5.ge-0-1-1-100.default.master@campus.example.com**

Now consider a different configuration, where the static interface has a dual-tagged VLAN, with an outer VLAN ID of 4040 and an inner VLAN ID of 3000:

```
[edit system services static-subscribers authentication username-include]
user@host# set user-prefix Floor12
user@host# set domain-name Bldg5.example.com
user@host# set vlan-tags
user@host# set delimiter $
```

This sample configuration generates the following username:

**Floor12\$4040-3000@Bldg5.example.com**

Even though a delimiter of \$ is configured, outer and inner VLAN IDs are always separated by - and the domain name is always separated from preceding elements by @.

## Creating a Static Subscriber Group

You can override the configuration that is applied globally to static subscribers by creating a static subscriber group that consists of a set of statically configured interfaces. You can then apply a common configuration for the group with values different from the global values for access and dynamic profiles, password, and username.

To configure an interface group for static subscribers:

1. Access the **[edit system services static-subscribers]** hierarchy level.
2. Create the group and assign the name.

```
[edit system services static-subscribers]
user@host# edit group boston
```

3. Specify the names of one or more interfaces on which static subscribers can be created. You can repeat the **interface interface-name** statement to specify multiple interfaces within the group, but you cannot use the same interface in more than one group.

```
[edit system services static-subscribers group boston]
user@host# set interface ge-1/0/1.1
user@host# set interface ge-1/0/1.2
```

4. (Optional) You can use the **upto upto-interface-name** option to specify a range of interfaces for a group.

```
[edit system services static-subscribers group boston]
user@host# set interface ge-1/0/1.3 upto ge-1/0/1.9
```

5. (Optional) You can use the **exclude** option to exclude a specific interface or a specified range of interfaces from the group. For example:

```
[edit system services static-subscribers group boston]
user@host# set interface ge-1/0/1.1 upto ge-1/0/1.102
user@host# set interface ge-1/0/1.6 exclude
user@host# set interface ge-1/0/1.70 upto ge-1/0/1.80 exclude
```

## Specifying the Static Subscriber Group Access Profile

You can override the configured global access profile by specifying a different profile for a group of static subscribers. The access profile triggers AAA services for that group of static subscribers.

To specify the access profile used for a group of static subscribers:

- Specify the profile name.

```
[edit system services static-subscribers group boston]  
user@host# set access-profile boston-acs
```

## Specifying the Static Subscriber Group Dynamic Profile

You can override the configured global dynamic profile by specifying a different profile for a group of static subscribers. The dynamic profile is instantiated when any static subscriber in the group logs in.

To specify the dynamic profile used for a group of static subscribers:

- Specify the profile name.

```
[edit system services static-subscribers group boston]  
user@host# set dynamic-profile dyn-profile-2
```

## Specifying the Static Subscriber Group Service Profile

When external policy server is unavailable, you can assign a default dynamic service profile to be applied to a static subscriber session by specifying the service profile from Junos OS Release 17.4R1 onwards. The service profile can be specified at the group level and at the global level. Specify **service-profile** statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level

To specify the service profile used for a group of static subscribers:

- Specify the dynamic service profile name.

```
[edit system services static-subscribers group group-name]  
user@host# set service-profile service-profile-name
```

## Enabling Multiple Subscribers on a VLAN Logical Interface for a Static Subscriber Group

For a given interface, only a single static subscriber group (or static subscriber) is logged in. Although we do not recommend this practice, you might have other kinds of subscribers configured on the same interface, such as a DHCP subscriber managed by the DHCP application. You can use the **aggregate-clients** statement to extend the dynamic profile for a static subscriber group to enable multiple subscribers to share the same VLAN logical interface.

You can specify that attributes (such as CoS or firewall) for the multiple subscribers are merged for the logical interface. That is, the profiles for multiple subscribers of different types are instantiated on the interface, but the profile attributes of each are merged together. Alternatively, you can specify that the instantiated profile for the current subscriber group is replaced by the profile of a new subscriber that logs in using the same logical interface. This configuration overrides the configuration applied to all static subscribers that are not members of the group.

To enable multiple subscribers to share the same VLAN logical interface for a static subscriber group, do one of the following:

- Specify that the multiple subscriber attributes are merged for the logical interface.

```
[edit system services static-subscribers group boston dynamic-profile dyn-profile-2]  
user@host# set aggregate-clients merge
```

- Specify that the entire logical interface is replaced when a new subscriber logs into the network using the same VLAN logical interface.

```
[edit system services static-subscribers group boston dynamic-profile dyn-profile-4]  
user@host# set aggregate-clients replace
```

## Configuring the Static Subscriber Group Authentication Password

You can override the configured global authentication password by specifying a different password for a group of static subscribers. This password is included in the Access-Request message sent to AAA to authenticate all static subscribers in the group.

To specify the authentication password used for a group of static subscribers:

- Specify the password.

```
[edit system services static-subscribers group boston authentication]  
user@host# set password $ABC123
```

## Configuring the Static Subscriber Group Username

You can override the configured global username by specifying a different username for a group of static subscribers. The username serves as the username for a group of static subscribers that is created and is included in the Access-Request message sent to AAA to authenticate that group.

The username must include at least one of the possible elements. The value of each element is concatenated in a specific order; the resulting string is the username. If you specify their inclusion, the interface name, logical system name, routing instance name, and VLAN tags are derived from the configuration context. The elements are ordered as follows (shown with the default delimiter):

*user-prefix.interface.outer-tag-inner-tag.logical-system-name.  
routing-instance-name@domain-name*

To configure the username for a group of static subscribers:

1. (Optional) Specify a prefix for the username.

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set user-prefix user-prefix-string
```

2. (Optional) Specify that the interface name is included in the username.

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set interface
```

3. (Optional) Specify that the VLAN tags (VLAN IDs) associated with the static interface are included in the username. For single-tagged VLANs, the component is the **outer-tag**. For dual-tag (stacked) VLANs, the component is the **outer-tag-inner-tag**. For IP demux interfaces configured for static subscribers, the VLAN tags configured on the underlying interface are used.

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set vlan-tags
```

4. (Optional) Specify that the logical system name is included in the username.

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set logical-system-name
```

5. Specify that the routing instance name is included in the username.

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set routing-instance-name
```

6. Specify a domain name to include in the username.

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set domain-name domain-name
```

7. (Optional) Specify a delimiter character to separate the username elements except for the domain name. The domain name is always preceded by the @ character. The default delimiter is a period (.).

```
[edit system services static-subscribers group group-name authentication
username-include]
user@host# set delimiter delimiter-character
```

Consider the following configuration for the subscriber group, **shipping**:

```
[edit system services static-subscribers group shipping authentication username-include]
user@host# set user-prefix warehouse3
user@host# set interface
user@host# set logical-system-name
user@host# set routing-instance-name
user@host# set domain-name campus.example.com
```

Configured in the default logical system and routing instance R5 for interface ge-0/1/2.50, this sample configuration generates the following username:

**warehouse3.ge-0-1-2-50.default.R5@campus.example.com**

Now consider a different configuration for the same subscriber group, where the static interface has a single-tagged VLAN with an outer VLAN ID of 2101:

```
[edit system services static-subscribers group shipping authentication username-include]
user@host# set user-prefix warehouse3
user@host# set domain-name Bldg5.example.com
user@host# set vlan-tags
user@host# set delimiter %
```

This sample configuration generates the following username:

**warehouse3%2101@Bldg5.example.com**

Even though a delimiter of % is configured, the domain name is always separated from preceding elements by @.

**Release History Table**

| Release | Description                                                                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18.3R1  | PS/LT support, introduced in Junos OS Release 18.3R1, enables full subscriber management (equivalent to dynamic subscribers) for statically provisioned subscribers whose traffic is transported over IP/MPLS access models. |

**Verifying Diameter Node, Instance, and Route Information**

**Purpose** View Diameter node information:

**Action** • To display summary information about all Diameter nodes:

```
user@host> show diameter
```

- To display summary information about all Diameter nodes and add information about Diameter applications (functions), instances, network elements, and peers:

```
user@host> show diameter brief
```

- To display brief information about all Diameter nodes and add information about Diameter routes:

```
user@host> show diameter detail
```

- To display summary information about all Diameter instances:

```
user@host> show diameter instance
```

- To display detailed information about all Diameter instances:

```
user@host> show diameter instance detail
```

- To display information about a specific Diameter instance, add the instance name to the command:

```
user@host> show diameter instance master
```

```
user@host> show diameter instance detail master
```

- To display summary information about all Diameter routes:

```
user@host> show diameter route
```

- To display detailed information about all Diameter routes:

```
user@host> show diameter route detail
```

- To display information about a specific Diameter route, add the route name to the command:

```
user@host> show diameter route dne-route2
```

```
user@host> show diameter route detail dne-route2
```

## Verifying and Managing Diameter Application Information

**Purpose** View or clear Diameter application (function) information:

- Action**
- To display summary information about all applications associated with Diameter:

```
user@host> show diameter function
```

- To display detailed information about all applications associated with Diameter:

```
user@host> show diameter function detail
```

- To display information about a specific application associated with Diameter, add the application name to the command:

```
user@host> show diameter function jsrc
```

```
user@host> show diameter function detail gx-plus
```

- To display summary statistics about all applications associated with Diameter:

```
user@host> show diameter function statistics
```

- To display detailed statistics about all applications associated with Diameter:

```
user@host> show diameter function statistics detail
```

- To display statistics about a specific application associated with Diameter, add the application name to the command:

```
user@host> show diameter function statistics gx-plus
```

```
user@host> show diameter function statistics detail jsrc
```

- To delete current statistics for all applications associated with Diameter:

```
user@host>clear diameter function statistics
```

- To delete current statistics for a specific application associated with Diameter:

```
user@host>clear diameter function gx-plus statistics
```

## Verifying and Managing Diameter Peer Information

**Purpose** View or clear Diameter peer information:

- Action**
- To display summary information about all Diameter peers:

```
user@host> show diameter peer
```

- To display detailed information about all Diameter peers:

```
user@host> show diameter peer detail
```

- To display information about a specific Diameter peer, add the peer name to the command:

```
user@host> show diameter peer peer235
```

```
user@host> show diameter peer detail peer235
```

- To display summary information about Diameter peer-to-network-element mapping for all peers:

```
user@host> show diameter peer map
```

- To display detailed information about Diameter peer-to-network-element mapping for all peers:

```
user@host> show diameter peer map detail
```

- To display information about Diameter peer-to-network-element mapping for a specified peer, add the peer name to the command:

```
user@host> show diameter peer map peer235
```

```
user@host> show diameter peer map detail peer235
```

- To display summary statistics about all Diameter peers:

```
user@host> show diameter peer statistics
```

- To display detailed statistics about all Diameter peers:

```
user@host> show diameter peer statistics detail
```

- To display summary statistics about a specified Diameter peer:

```
user@host> show diameter peer statistics peer235
```

- To display detailed statistics about a specified Diameter peer:

```
user@host> show diameter peer statistics detail peer235
```

- To delete the specified Diameter peer and all of its statistics.

```
user@host> clear diameter peer peer5 connection
```

- To delete the specified Diameter peer and its current statistics:

```
user@host> clear diameter peer peer5 statistics
```

## Verifying Diameter Network Element Information

**Purpose** View Diameter network element information:

- Action**
- To display summary information about Diameter network elements:

```
user@host> show diameter network-element
```

- To display detailed information about Diameter network elements:

```
user@host> show diameter network-element detail
```

- To display information about Diameter network elements for a specified network element, include the element name in the command:

```
user@host> show diameter network-element dne-1
```

```
user@host> show diameter network-element detail dne-1
```

- To display summary information about Diameter network-element-to-peer mapping for all network elements:

```
user@host> show diameter network-element map
```

- To display detailed information about Diameter network-element-to-peer mapping for all network elements:

```
user@host> show diameter network-element map detail
```

## Tracing Diameter Base Protocol Events for Troubleshooting

The Junos OS trace feature tracks Diameter base protocol operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `jdiameterd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). For more information about how log files are created, see the [System Log Explorer](#).

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

The following topics describe how to configure all aspects of tracing Diameter base protocol operations:

- [Configuring the Diameter Base Protocol Trace Log Filename on page 793](#)
- [Configuring the Number and Size of Diameter Base Protocol Log Files on page 794](#)
- [Configuring Access to the Diameter Base Protocol Log File on page 794](#)
- [Configuring a Regular Expression for Diameter Base Protocol Messages to Be Logged on page 795](#)
- [Configuring the Diameter Base Protocol Tracing Flags on page 795](#)
- [Configuring the Severity Level to Filter Which Diameter Base Protocol Messages Are Logged on page 795](#)

### Configuring the Diameter Base Protocol Trace Log Filename

By default, the name of the file that records trace output for Diameter base protocol is `jdiameterd`. You can specify a different name with the `file` option.

To configure the filename for Diameter base protocol tracing operations:

- Specify the name of the file used for the trace output.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_logfile_1
```

## Configuring the Number and Size of Diameter Base Protocol Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output. (Diameter base protocol supports the **files** and **size** options for the **traceoptions** statement.)

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1_logfile_1 files 20 size 2097152
```

## Configuring Access to the Diameter Base Protocol Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1_logfile_1 no-world-readable
```

## Configuring a Regular Expression for Diameter Base Protocol Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1 _logfile_1 match regex
```

## Configuring the Diameter Base Protocol Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system processes diameter-service traceoptions]
user@host# set flag dne
```

## Configuring the Severity Level to Filter Which Diameter Base Protocol Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

```
[edit system processes diameter-service traceoptions]
user@host# set level severity
```

## Troubleshooting Diameter Networks

---

- [Troubleshooting Diameter Network Configuration on page 796](#)
- [Troubleshooting Diameter Network Connectivity on page 796](#)

### Troubleshooting Diameter Network Configuration

**Problem**    **Description:** A misconfiguration of the network can prevent Diameter from functioning properly. Configuration options for the Diameter base protocol are simplifying the discovery of a misconfiguration.

**Symptoms:** The output of the **show diameter peer** command indicates a peer is in the no-activation state. In this case issue the **show diameter peer map** and **show diameter network-element map** commands to determine which network elements use the peer. The output of these commands can indicate why the peer is not activated. For example, all the associated network elements might have higher-priority peers in the open state. The failed-to-forward counters are increasing in the output of the **show diameter function statistics detail** command. this can indicate that the routes to the peer are incorrectly configured. Check the network connectivity, then use the **show diameter routes** command to determine whether application traffic is being correctly forwarded.

**Cause**    Typical misconfigurations appear in the routes, peers, and network element configurations.

**Solution**    Use the appropriate statements to correct the misconfiguration.

### Troubleshooting Diameter Network Connectivity

**Problem**    **Description:** In some circumstances, problems can arise with network connectivity to Diameter peers. The problem may originate with the peer or the peer host.

**Symptoms:** The output of the **show diameter peer** command indicates a peer is in the suspended, rejected, or bad-peer state.

**Cause**    The suspended state indicates that the peer is not responding or has some other malfunction, or the network path to the peer does not exist.

The rejected state indicates that the network connection has been rejected by the peer.

The bad-peer state indicates that the network connection has been rejected by the router on which the peer resides.

**Solution**    Determine how persistent the problem is by issuing the **show diameter peer statistics peer-name brief** command to check the connectivity statistics.

## Monitoring and Managing Static Subscriber Information

- [Forcing a Static Subscriber to Be Logged Out on page 797](#)
- [Resetting the State of an Interface for Static Subscriber Login on page 797](#)
- [Forcing a Group of Static Subscribers to Be Logged Out on page 797](#)
- [Resetting the State of an Interface Group for Static Subscriber Login on page 797](#)
- [Verifying Information about Subscriber Sessions on Static Interfaces on page 798](#)

### Forcing a Static Subscriber to Be Logged Out

You can force a static subscriber to be logged out on an interface. After you do so, no subscriber can subsequently log in on that interface until the interface state is reset either by a router reset or by entering the **request services static-subscribers login interface** command.

- To forcibly log out a static subscriber on a static interface:

```
user@host> request services static-subscribers logout interface ge-2/0/1.5
```

### Resetting the State of an Interface for Static Subscriber Login

When a static subscriber has been forcibly logged out on an interface with the **request services static-subscribers logout interface** command, you can reset the state of the interface. This action enables a static subscriber to log in on the interface. If you do not reset the state manually, then no static subscribers can log in on the interface until the state is reset by a router reset.

- To reset the state of a static interface:

```
user@host> request services static-subscribers login interface ge-2/0/1.5
```

### Forcing a Group of Static Subscribers to Be Logged Out

You can force the static subscribers on all interfaces in a group to be logged out. After you do so, no subscriber can subsequently log in on an interface in that group until the interface state is reset either by a router reset or by entering the **request services static-subscribers login group** command.

- To forcibly log out all static subscribers on a static interface group:

```
user@host> request services static-subscribers logout group boston
```

### Resetting the State of an Interface Group for Static Subscriber Login

When static subscribers have been forcibly logged out on an interface group with the **request services static-subscribers logout group** command, you can reset the state of the

group. This action enables static subscribers to log in on the interfaces in the group. If you do not reset the state manually, then no static subscribers can log in on any interface in the group until the state is reset by a router reset.

- To reset the state of a static interface group:

```
user@host> request services static-subscribers login group boston
```

## Verifying Information about Subscriber Sessions on Static Interfaces

**Purpose** View information about subscriber sessions on static interfaces:

- Action**
- To display information about all static subscriber sessions:

```
user@host> show static-subscribers sessions
```

- To display information about the subscriber sessions for the specified group of static interfaces:

```
user@host> show static-subscribers sessions group boston
```

- To display information about the subscriber session for the specified interface:

```
user@host> show static-subscribers sessions interface ge-0/0/1.1
```

## Tracing Static Subscriber Events for Troubleshooting

The Junos OS trace feature tracks static subscriber operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the **/var/log** directory. By default, the router uses the filename **jsscd**. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file **filename** reaches 128 kilobytes (KB), it is compressed and renamed **filename.0.gz**. Subsequent events are logged in a new file called **filename**, until it reaches capacity again. At this point, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the [System Log Explorer](#).)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

The following topics describe how to configure all aspects of tracing static subscriber operations:

- [Configuring the Static Subscribers Trace Log Filename on page 799](#)
- [Configuring the Number and Size of Static Subscribers Log Files on page 799](#)
- [Configuring Access to the Static Subscribers Log File on page 800](#)
- [Configuring a Regular Expression for Static Subscriber Messages to Be Logged on page 800](#)
- [Configuring the Static Subscribers Tracing Flags on page 800](#)
- [Configuring the Severity Level to Filter Which Static Subscriber Messages Are Logged on page 801](#)

## Configuring the Static Subscribers Trace Log Filename

By default, the name of the file that records trace output for static subscribers is `jsscd`. You can specify a different name with the `file` option.

To configure the filename for static subscribers tracing operations:

- Specify the name of the file used for the trace output.

```
[edit system processes static-subscribers traceoptions]
user@host# set file stat-subs_1
```

## Configuring the Number and Size of Static Subscribers Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format `.number.gz`. The newest archived file is `.0.gz` and the oldest archived file is `.(maximum number)-1.gz`. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.

```
[edit system processes static-subscribers traceoptions]  
user@host# set file stat-subs_1_logfile_1 files 20 size 2097152
```

## Configuring Access to the Static Subscribers Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system processes static-subscribers traceoptions]  
user@host# set file stat-subs_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit system processes static-subscribers traceoptions]  
user@host# set file stat-subs_1_logfile_1 no-world-readable
```

## Configuring a Regular Expression for Static Subscriber Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit system processes static-subscribers traceoptions]  
user@host# set file stat-subs_1_logfile match regex
```

## Configuring the Static Subscribers Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system processes static-subscribers traceoptions]
```

```
user@host# set flag authentication
```

## Configuring the Severity Level to Filter Which Static Subscriber Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

```
[edit system processes static-subscribers traceoptions]  
user@host# set level severity
```

## aaa-logical-system (Domain Map)

**Syntax** `aaa-logical-system logical-system-name {  
    aaa-routing-instance routing-instance-name;  
}`

**Hierarchy Level** `[edit access domain map domain-map-name]`

**Release Information** Statement introduced in Junos OS Release 10.4.

**Description** Configure a non-default logical system in which the **authd** daemon sends AAA requests for the domain map.

**NOTE:** Subscriber management is supported in the default logical system only. The `aaa-logical-system` statement is for future extensions of subscriber management and is not supported in current Junos OS releases.

**Default** Default logical system for the subscriber.

**Options** *logical-system-name*—Name of the logical system.

The remaining statement is explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

**Related Documentation** • [Specifying an AAA Logical System/Routing Instance in a Domain Map](#) on page 206

## aaa-routing-instance (Domain Map)

| Description              | Associate an access-loop circuit identifier (ACI) with the VLAN or set of VLANs that carry traffic to the subscriber using that access loop; identify a particular subscriber. This statement requires that the name of the interface or interface set is statically configured or deterministic. This means that it can be used with dynamic or static interface sets, VLAN-tagged interface sets, or static VLAN/VLAN demux interfaces. |
| Options                  | <i>identifier-string</i> —Unique identifier string for the access loop circuit; also configured on the access node.                                                                                                                                                                                                                                                                                                                       |
| Required Privilege Level | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                       |

**Hierarchy Level** [edit system]

**Release Information** Statement introduced in Junos OS Release 17.4R1.  
hierarchical-access-network-detection option added in Junos OS 18.4R1.

**Description** Configure values to adjust data rates by a percentage of the actual data rate, or adjust encapsulation overhead by adding to or subtracting from the total cell or frame bytes a specified number of bytes. Depending on the value, it may be reported to AAA, CoS, or both.

The actual (unadjusted) downstream and upstream data rates, DSL line type, and encapsulation mode are received from the access node by the ANCP agent in ANCP port messages, or by the PPPoE daemon from the PPPoE intermediate agent (PPPoE-IA) on PADI or PADO messages. The ANCP agent or PPPoE daemon subsequently adjusts rates and bytes based on the configuration.

Adjustments are applied to all subscribers using access lines of the specific DSL line type. Adjusted and unadjusted downstream and upstream rates are always reported to AAA in response to an AAA request. Adjusted and unadjusted downstream rates and overhead byte adjustments are reported to CoS, but only when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level. Overhead byte adjustments are not reported to AAA.

For bonded total adjust values, AAA reports the values to the RADIUS server in the Access-Request and Accounting-Request messages through Juniper VSAs 141 or 142 and to L2TP in the ICCN and CSUN messages as AVPs 24 and 38.

**Options** **adsl-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream cell overhead for all subscribers on an ADSL access line to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

**NOTE:** This option replaces the **adsl-bytes** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**adsl-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on an ADSL access line. The adjusted rate is reported only to AAA.

**NOTE:** This option replaces the **qos-adjust-adsl** statement at the **[edit protocols ancp]** hierarchy level.

**Range:** 0 through 100 percent

**Default:** 100 percent

**adsl2-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream cell overhead for all subscribers on an ADSL2 access line to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

**NOTE:** This option replaces the **adsl2-bytes** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**adsl2-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on an ADSL2 access line. The adjusted rate is reported only to AAA.

**NOTE:** This option replaces the **qos-adjust-adsl2** statement at the **[edit protocols ancp]** hierarchy level.

**Range:** 0 through 100 percent

**Default:** 100 percent

**adsl2-plus-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream cell overhead for all subscribers on an ADSL2+ access line to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

**NOTE:** This option replaces the **adsl2-plus-bytes** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**adsl2-plus-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on an ADSL2+ access line. The adjusted rate is reported only to AAA.

**NOTE:** This option replaces the **qos-adjust-adsl2-plus** statement at the **[edit protocols ancp]** hierarchy level.

**Range:** 0 through 100 percent

**Default:** 100 percent

**gfast-bonded-overhead-adjust *percentage***—Adjustment factor in percent that is applied to the downstream and upstream bonded data overhead rates for all subscribers on a high speed bonded DSL line connected to a PON tree infrastructure.

**Range:** 80 through 100 percent

**Default:** 100 percent

**gfast-bonded-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream cell bonded overhead for all subscribers on a high speed bonded DSL line connected to a PON tree infrastructure. Specify G.fast bonded value in bytes.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**gfast-bonded-total-adjust *percentage***—Adjustment factor in percent that is globally applied to the downstream and upstream bonded data rates for all subscribers on a high speed bonded DSL line connected to a PON tree infrastructure.

**Range:** 0 through 100 percent

**Default:** 100 percent

**gfast-overhead-adjust *percentage***—Adjustment factor in percent that is applied to the downstream and upstream data overhead rates for all subscribers on a high speed bonded DSL line connected to a PON tree infrastructure.

**Range:** 80 through 100 percent

**Default:** 100 percent

**gfast-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream cell overhead for all subscribers on a high speed bonded DSL line connected to a PON tree infrastructure.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**gfast-total-adjust *percentage***—Adjustment factor in percent that is globally applied to the downstream and upstream data rates for all subscribers on a high speed bonded DSL line connected to a PON tree infrastructure.

**Range:** 0 through 100 percent

**Default:** 100 percent

**hierarchical-access-network-detection**—Enable parsing of ANCP subscriber access loop attributes (TLVs) for backhaul line identifiers, to recognize when the access node references a logical interface set rather than an individual subscriber. If the Access-Aggregation-Circuit-ID-ASCII attribute (TLV 0x0003) string begins with a # sign, then the remainder of the string represents a logical intermediate node (DPU-C or PON tree) in the access network to which the subscriber is attached. The string is used as the name of a CoS Level 2 interface set that groups subscribers.

**NOTE:** The Access-Loop-Remote-ID (TLV (0x0002) is similarly parsed for the # character, but the resulting string is not used in the current release.

These TLVs can be parsed in ANCP messages or PPPoE IA tags in PADR messages.

**Default:** Disabled, in case some users include an initial # character for some other purpose.

**other-overhead-adjust *percentage***—Adjust the actual downstream rate for an access line of DSL type OTHER by multiplying the rate by the specified percentage. The adjusted rate is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

The router reports some access technology types—such as Gigabit passive optical network (GPON) lines—as DSL type OTHER.

**NOTE:** This option replaces the **other-overhead-adjust** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

---

**Range:** 80 through 100 percent

**Default:** 100 percent

**other-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on an access line of DSL type OTHER to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

The router reports some access technology types—such as Gigabit passive optical network (GPON) lines—as DSL type OTHER.

**NOTE:** This option replaces the **other-bytes** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

---

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**other-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on an access line of DSL type OTHER. The adjusted rate is reported only to AAA.

The router reports some access technology types—such as Gigabit passive optical network (GPON) lines—as DSL type OTHER.

**NOTE:** This option replaces the **qos-adjust-other** statement at the **[edit protocols ancp]** hierarchy level.

---

**Range:** 0 through 100 percent

**Default:** 100 percent

**sdsl-bonded-overhead-adjust *percentage***—Adjust the actual downstream rate for an SDSL bonded access line by multiplying the rate by the specified percentage.

**Range:** 80 through 100 percent

**Default:** 100 percent

**sdsl-bonded-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on an SDSL bonded access line to account for the traffic encapsulation overhead.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**sdsl-bonded-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on an SDSL bonded access line. This value is reported to AAA.

**Range:** 0 through 100 percent

**Default:** 100 percent

**sdsl-overhead-adjust *percentage***—Adjust the actual downstream rate for an SDSL access line by multiplying the rate by the specified percentage. The adjusted rate is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

**NOTE:** This option replaces the **sdsl-overhead-adjust** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

**Range:** 80 through 100 percent

**Default:** 100 percent

**sdsl-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on an SDSL access line to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

**NOTE:** This option replaces the **sdsl-bytes** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**sdsl-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on an SDSL access line. The adjusted rate is reported only to AAA.

**NOTE:** This option replaces the **qos-adjust-sdsl** statement at the [edit protocols ancp] hierarchy level.

**Range:** 0 through 100 percent

**Default:** 100 percent

**vdsl-overhead-adjust *percentage***—Adjust the actual downstream rate for a VDSL access line by multiplying the rate by the specified percentage. The adjusted rate is reported to CoS when you include the **qos-adjust** statement at the [edit protocols ancp] hierarchy level.

**NOTE:** This option replaces the **vdsl-overhead-adjust** statement at the [edit protocols ancp qos-adjust] hierarchy level.

**Range:** 80 through 100 percent

**Default:** 100 percent

**vdsl-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on a VDSL access line to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the [edit protocols ancp] hierarchy level.

**NOTE:** This option replaces the **vdsl-bytes** statement at the [edit protocols ancp qos-adjust] hierarchy level.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**vdsl-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on a VDSL access line. The adjusted rate is reported only to AAA.

**NOTE:** This option replaces the **qos-adjust-*vdsl*** statement at the [edit protocols anc] hierarchy level.

**Range:** 0 through 100 percent

**Default:** 100 percent

**vdsl2-annex-q-bonded-overhead-adjust *percentage***—Adjust the actual downstream rate for a VDSL2 annex q bonded access line by multiplying the rate by the specified percentage. The adjusted rate is reported to AAA.

**Range:** 80 through 100 percent

**Default:** 100 percent

**vdsl2-annex-q-bonded-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on a VDSL2 annex q bonded access line to account for the traffic encapsulation overhead.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**vdsl2-annex-q-bonded-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on a VDSL2 annex q bonded access line. The adjusted rate is reported to AAA.

**Range:** 0 through 100 percent

**Default:** 100 percent

**vdsl2-annex-q-overhead-adjust *percentage***—Adjust the actual downstream rate for a VDSL2 annex q access line by multiplying the rate by the specified percentage. The adjusted rate is reported to AAA.

**Range:** 80 through 100 percent

**Default:** 100 percent

**vdsl2-annex-q-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on a VDSL2 annex q access line to account for the traffic encapsulation overhead.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**vdsl2-annex-q-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on a VDSL2 annex q access line. The adjusted rate is reported to AAA.

**vdsl2-bonded-overhead-adjust *percentage***—Adjust the actual downstream rate for a VDSL2 bonded access line by multiplying the rate by the specified percentage. The adjusted rate is reported to AAA.

**Range:** 80 through 100 percent

**Default:** 100 percent

**vdsl2-bonded-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on a VDSL2 bonded access line to account for the traffic encapsulation overhead.

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**vdsl2-bonded-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on a VDSL2 bonded access line. The adjusted rate is reported to AAA.

**Range:** 0 through 100 percent

**Default:** 100 percent

**vdsl2-overhead-adjust *percentage***—Adjust the actual downstream rate for a VDSL2 access line by multiplying the rate by the specified percentage. The adjusted rate is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

**NOTE:** This option replaces the **vdsl2-overhead-adjust** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

---

**Range:** 80 through 100 percent

**Default:** 100 percent

**vdsl2-overhead-bytes *bytes***—Number of bytes added to or subtracted from the actual downstream frame overhead for all subscribers on a VDSL2 access line to account for the traffic encapsulation overhead. The adjusted value is reported to CoS when you include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

Number of bytes added to or subtracted from the actual downstream frame overhead.

**NOTE:** This option replaces the **vdsl2-bytes** statement at the **[edit protocols ancp qos-adjust]** hierarchy level.

---

**Range:** -100 through 100 bytes

**Default:** 0 bytes

**vdsl2-total-adjust *percentage***—Adjustment factor applied globally to the downstream and upstream data rates for all subscribers on a VDSL2 access line. The adjusted rate is reported only to AAA.

**NOTE:** This option replaces the [qos-adjust-\*vdsl2\*](#) statement at the [edit protocols *ancp*] hierarchy level.

**Range:** 0 through 100 percent

**Default:** 100 percent

| Description              | <p>After you have created the access profile that specifies authentication and accounting parameters, you must specify where the profile is used. Authentication and accounting will not run unless you specify the profile. You can attach access profiles globally at the <b>[edit]</b> hierarchy level, or you can apply them to DHCP clients or subscribers, VLANs, or to a routing instance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Syntax</b>              | <code>accounting-order (activation-protocol   local   radius);</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Hierarchy Level</b>     | <code>[edit access profile <i>profile-name</i> <b>service</b>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Release Information</b> | Statement introduced in Junos OS Release 11.4.<br><b>local</b> option added in Junos OS Release 17.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>         | <p>Specify the method that is used for reporting subscriber service accounting.</p> <p>When you specify the <b>activation-protocol</b> method, the service accounting statistics are reported differently depending on how the service is activated:</p> <ul style="list-style-type: none"> <li>• When the service is activated by the RADIUS server, the statistics are reported to the RADIUS server.</li> <li>• When the service is activated by JSRC, the statistics are reported to JSRC.</li> <li>• When the service is activated by the CLI configuration or a command—for example, through DHCP—the statistics are reported as determined by the flat-file profile configured at the <code>[edit access profile <i>profile-name</i> <b>local</b>]</code> hierarchy level. In this case, statistics are not reported if no flat-file profile is configured.</li> </ul>                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>             | <b>activation-protocol</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>             | <p><b>activation-protocol</b>—Send service accounting reports by means of the application that activates services, such as JSRC, RADIUS, or the CLI.</p> <p><b>local</b>—Send service accounting information to a flat file stored locally on the router. This method requires you to also configure the name of a flat-file profile at the <code>[edit access profile <i>profile-name</i> <b>local</b>]</code> hierarchy level. This profile determines which statistics and which nonstatistical parameters are collected for the service.</p> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p> <b>NOTE:</b> When you configure the <b>local</b> option, both volume and time statistics are collected for the service accounting sessions. In this case, you must not configure the <b>volume-time</b> option at the <code>[edit access profile <i>profile-name</i> <b>service</b> accounting statistics]</code> hierarchy level, or an error is generated when you commit the configuration.</p> </div> <p><b>radius</b>—Send service accounting reports to the RADIUS server by means of the RADIUS protocol.</p> |

| Release Information      | Statement introduced in Junos OS Release 14.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description              | Configure the number of times the router retransmits RADIUS accounting messages when no response is received from the server. When you do not configure this statement, the number of retry attempts is determined by the <a href="#">retry</a> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                          | <p> <b>NOTE:</b> To successfully set a retry limit for the accounting servers different from the authentication servers, you must configure both the <code>accounting-retry</code> and <code>accounting-timeout</code> statements. If you configure only one of these statements, then the value you configure is ignored in favor of the values configured with the <code>retry</code> and <code>timeout</code> statements.</p> <p> <b>NOTE:</b> The maximum retry duration (the number of retries times the length of the timeout) cannot exceed 2700 seconds. An error message is displayed if you configure a longer duration.</p> |

| Description              | <p>Configure RADIUS accounting to send an Acct-Stop message when a subscriber session has been successfully authenticated and authorized, but then fails before an Acct-Start message is sent. By default, an Acct-Stop message is sent only if an Acct-Start message has been exchanged with the accounting server.</p> <p>Consider a situation where RADIUS address pools are used to assign IP/IPv6 addresses. After a subscriber session is successfully authenticated, the RADIUS server authorizes the session by assigning an IP address from the RADIUS address pool and conveying that address in the Framed-IP-Address attribute. If a negotiation failure occurs at this point, the session is terminated before activating. The Acct-Start message is never sent because it is initiated by session activation. By default, an Acct-Stop message cannot be sent because the Acct-Start is never sent. However, if the <b>acct-stop-on-failure</b> statement is configured, the negotiation failure causes the Acct-Stop message to be sent, which explicitly notifies the RADIUS server that the session is disconnected and that it can free the allocated IP address back to the pool.</p> |

| Release Information      | Statement introduced in Junos OS Release 14.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description              | Configure how long the local router waits to receive a response from a RADIUS accounting server before retransmitting the message. When you do not configure this statement, the length of the timeout is determined by the <a href="#">timeout</a> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | <p> <b>NOTE:</b> To successfully set a timeout value for the accounting servers different from the authentication servers, you must configure both the <code>accounting-retry</code> and <code>accounting-timeout</code> statements. If you configure only one of these statements, then the value you configure is ignored in favor of the values configured with the <code>retry</code> and <code>timeout</code> statements.</p> <p> <b>NOTE:</b> The maximum retry duration (the number of retries times the length of the timeout) cannot exceed 2700 seconds. An error message is displayed if you configure a longer duration.</p> |
| Options                  | <p><b>seconds</b>—Duration of timeout period.</p> <p><b>Default:</b> 0 (disabled)</p> <p><b>Range:</b> 0 through 1000 seconds</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>              | Configure the DHCP local server to stop allocating addresses from this pool. When this is configured, the DHCP local server gracefully shifts clients from this address pool to an alternative pool for which active drain is not configured. When existing clients with an address from this pool submit a DHCPv4 request or DHCPv6 renew, they receive a NAK, forcing them to renegotiate. The server responds with a DHCPv4 offer or DHCPv6 advertise message with an address from a different pool. |

| <b>Description</b>         | <p>Apply a DHCP relay agent configuration to the named group of DHCP server addresses. The server group itself is configured with the <b>server-group</b> statement. You can apply an active server group globally or for specific groups of interfaces, configured with the <b>group</b> statement. An active server group applied to an interface group overrides a global configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Options</b>             | <p><b>allow-server-change</b>—(Optional) (DHCPv4 only) Enable the relay agent to accept and forward a DHCP request (renew or rebind) ACK message to the client from any DHCP local server in the active server group. Starting in Junos OS Release 18.4R1, this option also applies to DHCP information request (DHCPINFORM) ACK messages.</p> <p><b>Default:</b> Forward ACK messages from only the original binding server.</p> <p><b>server-group-name</b>—Name of the group of DHCP or DHCPv6 server addresses to which the DHCP or DHCPv6 relay agent configuration applies.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Release Information      | Statement introduced in Junos OS Release 15.1R3 and 17.4R1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description              | <p>Enable <b>actual-transit-statistics</b> to enable the collection and reporting of accurate accounting statistics for subscribers. The accurate statistics provide packet-level and byte-level counts for all transmit and receive traffic forwarded across the specified interface. The counts do not include overhead bytes, filtered traffic, drops, discards, or control traffic. These accurate statistics match the accounting statistics used by RADIUS. You can display these statistics with the <b>show subscribers id <i>session-id</i> accounting-statistics</b> and <b>show subscribers interface <i>interface</i> accounting-statistics</b> commands.</p> <p> <b>NOTE:</b> Starting in Junos OS Release 18.4R1, you must enable <b>actual-transit-statistics</b> to collect subscriber statistics. If you do not configure this statement, subscriber statistics are not collected; the <b>show subscribers accounting-statistics</b> command displays a value of 0 for subscriber statistics; and the subscriber statistics are reported to RADIUS with values of zero.</p> |
| Default                  | Disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## address-assignment (Address-Assignment Pools)

**Syntax**

```
address-assignment {
  abated-utilization percentage;
  abated-utilization-v6 percentage;
  high-utilization percentage;
  high-utilization-v6 percentage;
  neighbor-discovery-router-advertisement ndra-pool-name;
  pool pool-name {
    active-drain;
    family family {
      dhcp-attributes {
        protocol-specific attributes;
      }
      excluded-address ip-address;
      excluded-range name low minimum-value high maximum-value;
      host hostname {
        hardware-address mac-address;
        ip-address ip-address;
      }
      network ip-prefix /<prefix-length>;
      prefix ipv6-prefix;
      range range-name {
        high upper-limit;
        low lower-limit;
        prefix-length prefix-length;
      }
    }
    hold-down;
    link pool-name;
  }
}
```

**Hierarchy Level** [edit access]

**Release Information** Statement introduced in Junos OS Release 9.0.  
Statement introduced in Junos OS Release 12.1 for EX Series switches.

**Description** Configure address-assignment pools that can be used by different client applications.

**NOTE:** Support for subordinate statements is platform-specific. See individual statement topics for support information.

**Options** *pool-name*—Name assigned to an address-assignment pool.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

## address-change-immediate-update

---

**Syntax** address-change-immediate-update;

**Hierarchy Level** [edit access profile *profile-name* **accounting**]

**Release Information** Statement introduced in Junos OS Release 13.1.

**Description** Configure the router to send an Interim-Accounting message to the RADIUS server immediately after on-demand IPv4 allocation and de-allocation.

Changes to this setting take effect for new subscriber logins. Existing subscribers are not impacted by this change except when the AAA daemon restarts.

**Default** This functionality is disabled by default.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

| Description         | <p>Prevent IPv4 addresses and IPv6 prefixes from being assigned to more than one subscriber session when you use AAA to supply IPv4 addresses.</p> <p>For IPv4:</p> <p>If enabled, the router checks the following attributes received from external servers:</p> <ul style="list-style-type: none"><li>• <i>Framed-IP-Address</i></li><li>• <i>Framed-Pool</i></li></ul> <p>The router then takes one of the following actions:</p> <ul style="list-style-type: none"><li>• If an address matches an address in an address pool, the address is taken from the pool, provided it is available.</li><li>• If the address is already in use, it is rejected as unavailable.</li></ul> <p>For IPv6:</p> <p>If enabled, the router checks the following attributes received from external servers:</p> <ul style="list-style-type: none"><li>• <i>Framed-IPv6-Prefix</i></li><li>• <i>Framed-IPv6-Pool</i></li></ul> <p>The router then takes one of the following actions:</p> <ul style="list-style-type: none"><li>• If a prefix matches a prefix in an address pool, the prefix is taken from the pool, provided it is available.</li><li>• If the prefix is already in use, it is rejected as unavailable.</li><li>• If the prefix length requested from the external server does not exactly match the pool's prefix length, the authentication request is denied. If configured, the Acct-Stop message includes the cause for termination.</li></ul> |

**Options** **reassign-on-match**—Enable reassignment of an address from an existing subscriber to a new subscriber requesting that address. The address in use must not be part of a locally configured pool and address protection must be enabled. The request from the new subscriber is still rejected, but the existing subscriber is sent a disconnect request to begin the logout process. This enables the new subscriber to renegotiate and be assigned that IP address.

If the requested address is in a locally configured pool, the existing subscriber is not disconnected.

**NOTE:** This option is not supported for IPv6.

**Default:** Rejects the address request from the new subscriber; the existing subscriber remains intact with the IP address.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## address-range (Demux)

```
Syntax address-ranges {
    dynamic-profile <dyn-prof-name> {
        network <ip-addr> {
            range <range-name> {
                low <low-addr>;
                high <high-addr>;
            }
        }
    }
    authentication {
        password <password-string>;
        username-include {
            delimiter <delimiter-character>;
            domain-name <domain-name-string>;
            interface-name;
            auth-server-realm <auth-server-realm-string>;
            source-address;
            user-prefix <user-prefix-string>;
        }
    }
}
```

**Hierarchy Level** [edit interfaces *interface-name* unit *unit-number* demux inet auto-configure]  
[edit interfaces *interface-name* unit *unit-number* demux inet6 auto-configure]

**Release Information** Statement introduced in Junos OS Release 18.1R1.

**Description** Specify the address range for the demultiplexing (demux) interface options. The remaining statement is explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Description</b>              | Adjust the number of cell overhead bytes by the specified number of bytes in the actual downstream rate reported in the ANCP Port Up message for an ADSL access line. The ANCP agent reports the adjusted value to CoS. The adjusted value accounts for the traffic encapsulation overhead.                                                                                                                                                                                                                                                                                                                           |         |             |        |                                                                                                                                                                                                                            |
|                                 | <div>  <p><b>NOTE:</b> Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the <code>adsl-overhead-bytes</code> option of the <code>access-line</code> statement at the <code>[edit system]</code> hierarchy level. The ANCP agent ignores the <code>adsl-bytes</code> statement if it is present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing configuration, you must reconfigure your adjustment with the <code>access-line</code> statement.</p> </div> |         |             |        |                                                                                                                                                                                                                            |

| Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Adjust the number of cell overhead bytes by the specified number of bytes in the actual downstream rate reported in the ANCP Port Up message for an ADSL2 access line. The ANCP agent reports the adjusted value to CoS. The adjusted value accounts for the traffic encapsulation overhead.                           |         |             |        |                                                                                                                                                                                                                      |
| <div>  <p><b>NOTE:</b> Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the <a href="#">adsl2-overhead-bytes</a> option of the <a href="#">access-line</a> statement at the [edit system] hierarchy level. The ANCP agent ignores the <a href="#">adsl2-bytes</a> statement if it is present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing configuration, you must reconfigure your adjustment with the <a href="#">access-line</a> statement.</p> </div> |                                                                                                                                                                                                                                                                                                                        |         |             |        |                                                                                                                                                                                                                      |

| <b>Description</b>              | Adjust the number of cell overhead bytes by the specified number of bytes in the actual downstream rate reported in the ANCP Port Up message for an ADSL2+ access line. The ANCP agent reports the adjusted value to CoS. The adjusted value accounts for the traffic encapsulation overhead.                                                                                                                                                                                                                                                                                                                                     |         |             |        |                                                                                                                                                                                                                                  |
|                                 | <div>  <p><b>NOTE:</b> Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the <code>adsl2-plus-overhead-bytes</code> option of the <code>access-line</code> statement at the <code>[edit system]</code> hierarchy level. The ANCP agent ignores the <code>adsl2-plus-bytes</code> statement if it is present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing configuration, you must reconfigure your adjustment with the <code>access-line</code> statement.</p> </div> |         |             |        |                                                                                                                                                                                                                                  |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.6.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | Specify for all static subscribers or for a group of static subscribers that the router merge (chain) subscriber (client) attributes such as firewall filters and CoS attributes or replace them when multiple subscriber sessions exist on the same underlying VLAN. The group version of this statement overrides the global version.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                 | <p> <b>NOTE:</b> This statement is not supported for IP demux subscriber interfaces.</p> <p> <b>NOTE:</b> This statement is not supported for enhanced subscriber management.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default</b>                  | By default, multiple subscribers cannot be on the same logical interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Options</b>                  | <p><b>merge</b>—Aggregate the attributes of multiple subscribers for the logical interface.</p> <p><b>replace</b>—Replace the entire logical interface whenever a new client logs in to the network using the same VLAN logical interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
