abstract-hop

Syntax

```
abstract-hop abstract-hop-name {
    constituent-list constituent-list-name (include-any-list | include-all-list | exclude-all-list | exclude-any-list);
    operators (AND | OR);
}
```

Hierarchy Level

```
[edit logical systems logical-systems-name protocols mpls]
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 17.1 for all platforms.

Description

Define router clusters or groups, similar to the sequence of real-hop constraints (strict or loose), as a sequence of abstract hops for setting up a label-switched path (LSP).

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes. A path can use a combination of real and abstract hops as constraints.

Options

abstract-hop-name—Name of the abstract hop that is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops.

constituent-list constituent-list-name—Name of the predefined constituent list to be included in defining the abstract hop. A constituent list enables you to define a set of constituent attributes that is identified with a user-defined name.

include-any-list—Satisfy any one of the attributes specified in the constituent list.

include-all-list—Satisfy all of the attributes specified in the constituent list.

exclude-all-list—Satisfy none of the attributes specified in the constituent list.

exclude-any-list—Fail to satisfy any one of the attributes specified in the constituent list.

operators—Specify the operation between constituent lists when more than one constituent list is included in the abstract hop definition.

AND—Satisfy all the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

OR—Satisfy at least one of the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

adjust-threshold

Syntax

```
adjust-threshold percent;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],  
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify in percentage how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in bandwidth utilization.

To specify the changes in the automatic bandwidth adjustment for a LSP in absolute value, use the [adjust-threshold-absolute](#) statement instead.

Options

percent—Bandwidth demand for the current bandwidth adjustment interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the percentage specified by this statement, the LSP's bandwidth is adjusted to the current bandwidth demand.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

adjust-threshold-absolute

Syntax

```
adjust-threshold-absolute bps;
```

Hierarchy Level

```
[edit logical-systems name protocols mpls label-switched-path name auto-bandwidth ],
[edit logical-systems name routing-instances name protocols mpls label-switched-path name auto-bandwidth ],
[edit protocols mpls label-switched-path name auto-bandwidth ],
[edit routing-instances name protocols mpls label-switched-path name auto-bandwidth ]
```

Release Information

Statement introduced before Junos OS Release 17.4R1 on all platforms.

Description

Specify in bits per second how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in the average LSP utilization.

The **adjust-threshold-absolute** statement works in conjunction with the **adjust-threshold** statement, which specifies the change in automatic bandwidth adjustment for an LSP as a percentage.

By triggering automatic bandwidth LSP resignaling based on absolute change in bandwidth instead of percentage bandwidth change, LSP resignaling can be optimized for both big and small LSPs at the same time.

Options

bps—Change in average LSP utilization to trigger automatic bandwidth adjustment in bits per second.

Default: 0 bps

Required Privilege Level

routing

adjust-threshold-activate-bandwidth

Syntax

```
adjust-threshold-activate-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],  
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 14.1.

Description

Specify an absolute value to prevent automatic adjustment of signaled bandwidth and aggressive re-signaling of a label-switched path (LSP) when the actual bandwidth over the LSP is below the configured threshold, although the adjust-threshold percentage condition is satisfied.

Options

bps—Amount of bandwidth that is compared with the maximum of all traffic samples during an adjustment interval. If the maximum average bandwidth is less than this configured value, automatic bandwidth adjustment or re-signaling does not happen, even if the adjust-threshold percentage condition is satisfied.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

  path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced in Junos OS Release 11.1.

Description

Specifies the group name and group identifier for an administrative group. The group identifier must be within the range of values specified by the **admin-groups-extended-range** statement. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

apply-groups—Apply the specified administrative groups for the LSP or for the primary and secondary paths.

apply-groups-except—Exclude the specified administrative groups from the LSP or from the primary and secondary paths.

exclude—Define the administrative groups to exclude from an LSP or from the primary and secondary paths.

include-all—Require the LSP to traverse links that include all of the defined administrative groups.

include-any—Define the administrative groups to include for an LSP for the primary and secondary paths.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 11.1.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Enables you to configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in IGPs (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. By default, Juniper Networks routers interpret this 32-bit value as a bit mask with each bit representing a group. This normally limits each network to a total of 32 distinct administrative groups (value range 0 through 31).

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

maximum *maximum-number*—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

minimum *minimum-number*—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

advertise-mode (MPLS)

Syntax

```
advertise-mode (stub-alias | stub-proxy);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls egress-protection context-identifier context-id],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name egress-protection
 context-identifier context-id],
[edit protocols mpls egress-protection context-identifier context-id],
[edit protocols mpls label-switched-path lsp-name egress-protection context-identifier context-id]
```

Release Information

Statement introduced in Junos OS Release 13.3.

Description

Configure the method for the interior gateway protocol (IGP) to advertise egress protection availability.

Egress protection availability is advertised in the IGP. Label protocols along with CSPF use this information to do egress protection.

Options

stub-alias—Context identifier has an alias.

In the alias method, the LSP end-point address has an explicit backup egress node where the backup node can be learned or configured on the penultimate hop node (PHN) of a protected LSP. With this model, the PHN of a protected LSP sets up the bypass LSP tunnel to back up the egress node by avoiding the primary egress node. This model requires a Junos OS upgrade in core nodes, but is flexible enough to support all traffic engineering constraints.

stub-proxy—Context-identifier has a stub proxy node.

A stub node is one that only appears at the end of an AS path, which means it does not provide transit service. In this mode, known as the virtual or proxy mode, the LSP end-point address is represented as a node with bidirectional links, with the LSP's primary egress node and backup egress node. With this representation, the penultimate hop of the LSP primary egress point can behave like a PLR in setting up a bypass tunnel to back up the egress by avoiding the primary egress node. This model has the advantage that you do not need to upgrade Junos OS on core nodes and thereby helps operators to deploy this technology.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

advertisement-hold-time

Syntax

```
advertisement-hold-time seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Do not advertise when the LSP goes from up to down, for a certain period of time known as the hold time.

Options

seconds—Hold time, in seconds.

Range: 0 through 65,535 seconds

Default: 5 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

always-mark-connection-protection-tlv

Syntax

```
always-mark-connection-protection-tlv;
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols mpls interface interface-name],  
[edit protocols mpls interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 10.2.

Description

(MX Series routers only) Enable you to switch an LSP away from a network node using a bypass LSP. This feature could be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.

This statement marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, you then need to configure the **switch-away-lsps** statement.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

| [Switching LSPs Away from a Network Node](#) | 846

associate-backup-pe-groups

Syntax

```
associate-backup-pe-groups;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],  
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 9.0.

Description

Enable an LSP to monitor the status of its destination PE router. You can configure multiple backup PE router groups using the same router's address. Backup PE router groups provide ingress PE router redundancy when point-to-multipoint LSPs are configured for multicast distribution. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. This statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to the destination address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

associate-lsp

Syntax

```
associate-lsp lsp-name {  
    from from-ip-address;  
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name oam]
```

Release Information

Statement introduced in Junos OS Release 12.1.

Description

Configure associated bidirectional label-switched paths (LSPs) on the two ends of an LSP for sending and receiving GAL and G-Ach OAM messages.

Options

from *from-ip-address*—(Optional) Source address for the associated LSP configuration.

If omitted, this is derived from the **to** address of the ingress LSP configuration.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

  minimum-bandwidth-adjust-threshold-value
  monitor-bandwidth;
  resignal-minimum-bandwidth
  sync-active-path-bandwidth
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for QFX Series switches.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Allow an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel.

NOTE: In calculating the value for **Max AvgBW** (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

Options

adjust-threshold-absolute *adjust-threshold-absolute-value*—Configure an absolute value based threshold along with the percentage based threshold that helps avoid the bandwidth getting triggered for LSPs of both small and large bandwidth reservations.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for QFX10000 Series switches in release 15.1X53-D40.

Description

Enable the automatic policing of all the MPLS LSPs on the router or logical system.

Options

class all—Apply the same policer action to all the class types (**ct0**, **ct1**, **ct2**, and **ct3**).

class ctnumber—Specific class type (**ct0**, **ct1**, **ct2**, or **ct3**) to which to apply a policer action.

Policer actions—You can specify the following policer actions:

Default: no action

- **drop**—Drop all packets.
- **loss-priority-high**—Set the packet loss priority (PLP) to high.
- **loss-priority-low**—Set the PLP to low.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name fast-reroute],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

When configuring an LSP, specify the traffic rate associated with the LSP.

When configuring fast reroute, allocate bandwidth for the reroute path. By default, no bandwidth is reserved for the rerouted path. The fast reroute bandwidth does not need to be identical to that allocated for the LSP itself.

When configuring a multiclass LSP, use the **ctnumber bandwidth** statements to specify the bandwidth to be allocated for each class type.

Options

bps—Bandwidth, in bits per second. You can specify this as an integer value. You can also use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

NOTE: On the ACX Series, *bps* is the only supported option.

ctnumber bps—Bandwidth for the specified class type, in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion [also called a thousand million]).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

bandwidth-model

Syntax

```
bandwidth-model {  
    extended-mam;  
    mam;  
    rdm;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls diffserv-te],  
[edit protocols mpls diffserv-te]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the bandwidth model for differentiated services. Note that you cannot configure both bandwidth models at the same time.

Options

extended-mam—The extended maximum allocation model (MAM) is a bandwidth model based on MAM.

mam—The MAM is defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

rdm—The Russian dolls bandwidth allocation model (RDM) is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*. RDM makes efficient use of bandwidth by allowing the class types to share bandwidth.

Release Information

Statement introduced in Junos OS Release 19.2R1-S1 on MX Series Routers.

Description

Configure the compute profile for dynamically computed paths. You can use a compute profile to logically group the computation constraints. These compute profiles are referenced by the segment routing paths for computing the primary and secondary segment routing LSPs.

Options

name—Name of the computation-profile.

protected—Choose protected labels if available.

Values:

- **mandatory**—Mandatorily choose protected labels.

unprotected—Choose unprotected labels if available.

Values:

- **mandatory**—Mandatorily choose unprotected labels.

compute-segment-list—Name of the compute type segment list.

maximum-computed-segment-lists—Maximum number of segment-lists (ECMP paths) to be computed.

Range: 1 through 128

maximum-segment-list-depth—Maximum depth of computed path.

Range: 1 through 16

metric-type—Specify the metric type used for computation.

Values:

- **igp**—Interior gateway protocol metric.
- **te**—Traffic-engineering metric.

no-label-stack-compression—Provide fully expanded path, using adjacency segment identifiers.

```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.1R1 on QFX Series and QFX10000 switches.

Description

Configure preference values for entries from BGP-TE to the traffic engineering database. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value.

The credibility order for the BGP-TE protocols is as follows:

- **Unknown**—80
- **OSPF**—81
- **ISIS Level 1**—82
- **ISIS Level 2**—83
- **Static**—84
- **Direct**—85

Options

direct— Entries sourced from directly connected links.

dual-transport

Syntax

```
dual-transport {  
    inet-lsr-id inet-lsr-id;  
    inet6-lsr-id inet6-lsr-id;  
}
```

Hierarchy Level

[edit protocols ldp]

Release Information

Statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description

Configure to allow Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. **inet-lsr-id** and **inet6-lsr-id** are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Options

inet-lsr-id *inet-lsr-id*— Configure the LSR ID to establish an LDP session over IPv4 TCP transport.

inet6-lsr-id *inet6-lsr-id*— Configure the LSR ID to establish an LDP session over IPv6 TCP transport.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

dynamic (Source Packet Routing)

Syntax

```
dynamic {
  protected {
    mandatory;
  }
  unprotected {
    mandatory;
  }
}
```

Hierarchy Level

[edit protocols source-packet-routing [segment-list](#)]

Release Information

Statement introduced in Junos OS Release 19.2R1 on all platforms.

Description

Enable dynamic computation of segment routing label-switched paths (LSPs) based on tunnel destination and translation service to fetch the corresponding segment identifiers (SIDs).

NOTE:

When the dynamic statement is enabled, all the next hops must have an IP address assigned as a minimum configuration. In the case of segment-lists, if a next hop has both IP address and label configured, then the configured label is retained.

NOTE:

- Because translation service use IGP instance of traffic-engineered database (TED), you must include the **igp-topology** statement at the **[edit protocols isis traffic-engineering]** hierarchy level for successful translation.
- The **auto-translation** and **dynamic** statements are mutually exclusive, and only either of them can be configured under a segment-list.

Options

protected—(Optional) Ensures a protected adjacency SID is used for the links of the LSP.

unprotected—(Optional) Ensures an unprotected adjacency SID is used for the links of the LSP.

mandatory—(Optional) Enabled translation to fail if the specified type of adjacency SID cannot be found for a link. This option does not have effect on node SIDs.

Required Privilege Level

[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Configure a dynamic tunnel between two PE routers.

NOTE: ACX Series routers do not support the **gre** statement.

Configure dynamic IPv4-over-IPv6 tunnels and define their attributes to forward IPv4 traffic over an IPv6-only network. IPv4 traffic is tunneled from customer premises equipment to IPv4-over-IPv6 gateways. You must also configure **extended-nexthop** option at **[edit protocols bgp family inet unicast]** hierarchy level to allow BGP to route IPv4 address families over an IPv6 session.

Options

gre—Enable dynamic generic routing encapsulation type tunnel mode for IPv4

Values:

- **next-hop-based-tunnel**—Enable next hop base dynamic-tunnel for steering IPv4 traffic with IPv6 next hop address.

source-address—Specify the source address of the tunnel.

tunnel-name—Name of the dynamic tunnel.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 10.4.

Options **primary**, **protector**, and **metric** introduced in Junos OS Release 11.4R3.

Option **advertise-mode** introduced in Junos OS Release 13.3.

Description

Enables an Edge Protection Virtual Circuit (EPVC) for the MPLS protocol.

Options

context-identifier *context-id-ip-address*—(Optional) The context identifier IPv4 address.

metric *igp-metric-value*—(Optional) The IGP metric value ranging from **2** through **16777215**.

(primary | protector)—On the primary PE router, configure as type **primary**. On the protector PE router, configure as type **protector**.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

entropy-label

Syntax

```
entropy-label {  
    ingress-policy ingress-policy-name;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Assists the transit router in load-balancing MPLS traffic across ECMP paths or Link Aggregation groups by introducing the entropy label to the MPLS label stack. The entropy label allows routers to load balance MPLS traffic by using a hash-input without the need to perform deep packet inspection. Deep packet inspection requires more of the router's processing power and is not a capability shared by all routers.

Options

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit protocols bgp family inet labeled-unicast],  
[edit protocols bgp group group-name family inet labeled-unicast],  
[edit protocols bgp group group-name neighbor address labeled-unicast]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Insert the entropy label into the BGP labeled unicast LSP packets, which assists the transit router in load-balancing BGP traffic across equal-cost multipaths or link aggregation groups. The ingress label edge router inspects the flow information of a packet and maps it to an entropy label, which is inserted into the BGP label stack. LSRs in the core use this entropy label as the key to hash the packet and direct it to the correct path.

Options

import *policy-name*— (Optional) Specify a policy that lists the routes that allow the use of entropy labels.

no-next-hop-validation—(Optional) Do not validate the next-hop field in the entropy label capability attribute against the route next hop.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name link-protection bypass destination],  
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass destination]
```

Release Information

Statement introduced in Junos OS Release 11.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Exclude Shared Risk Link Group (SRLG) links for the secondary path for critical links where it is imperative to keep the secondary and primary label-switched paths completely disjoint from any common SRLG.

When specified, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. When not specified and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

  [edit class-of-service code-point-aliases],
  [edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules],
  [edit class-of-service rewrite-rules]
```

Release Information

Statement introduced in Junos OS Release 10.1 for EX Series switches.

Description

Define the experimental bits (EXP) code point mapping that is applied to MPLS packets. You can define an **exp** classifier only on EX3200 switches, EX4200 and EX8200 standalone switches, and EX8200 Virtual Chassis. You can bind an **exp** rewrite rule on EX8200 standalone switches and EX8200 Virtual Chassis.

EX Series switches support only one EXP code mapping on the switch (either default or custom). It is applied globally and implicitly to all the MPLS-enabled interfaces on the switch. You cannot bind it or disable it on individual interfaces.

Options

classifier-name—Name of the classifier.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

Point-to-multipoint LSP support introduced in Junos OS Release 11.2.

Description

Allow an LSP to traverse multiple OSPF areas within a service provider's network.

Allows a point-to-multipoint LSP to span multiple domains in a network. Effectively, this allows you to configure one or more sub-LSPs (branches) in separate network domains. Examples of such domains include OSPF areas and autonomous systems (ASs). A sub-LSP of an inter-domain point-to-multipoint LSP can be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source). Only OSPF areas are supported for inter-domain point-to-multipoint LSPs. IS-IS levels are not supported.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

explicit-null (Protocols MPLS)

Syntax

```
explicit-null;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Advertise label 0 to the egress router of an LSP.

Default

If you do not include the **explicit-null** statement in the MPLS configuration, label 3 (implicit null) is advertised.

NOTE: Junos OS does not support explicit null routes with next hops to virtual tunnel (vt-) interfaces.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

failure-action (Protocols MPLS)

Syntax

```
failure-action {  
    make-before-break teardown-timeout seconds;  
    teardown;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls oam bfd-liveness-detection],  
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name oam bfd-liveness-detection],  
[edit protocols mpls label-switched-path lsp-name oam bfd-liveness-detection],  
[edit protocols mpls oam bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Configure route and next-hop properties in the event of a Bidirectional Forwarding Detection (BFD) protocol session failure event on an RSVP label-switched path (LSP). The failure event could be an existing BFD session that has gone down or a BFD session that never came up. RSVP adds back the route or next hop when the relevant BFD session comes back up.

Options

make-before-break—When a BFD session fails for an RSVP LSP, an attempt is made to signal a new LSP path before tearing down the old LSP path.

teardown—When a BFD session fails for an RSVP LSP, the associated LSP path is taken down and resigaled immediately.

teardown-timeout *seconds*—When you configure the **make-before-break** option, you can specify a time in seconds for the **teardown-timeout** option. At the end of the time specified, the associated RSVP LSP is automatically torn down and resigaled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

family

Syntax

```
family {  
    inet;  
    inet6;  
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description

Configure the address family as inet for IPv4 or inet6 for IPv6, or both. If the address family is not configured, then the default address family is IPv4.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

        source-lsb;
        destination-msb;
        destination-lsb;
      }
    }
  }
}
```

Hierarchy Level

[edit forwarding-options hash-key]

Release Information

Statement introduced before Junos OS Release 7.4.

no-label-1-exp option introduced in Junos OS Release 8.0.

label-3 and **no-labels** options introduced in Junos OS Release 8.1.

ether-pseudowire statement introduced in Junos OS Release 9.1 (M320 and T Series routers only); support extended to M120 and MX Series routers in Junos OS Release 9.4.

all-labels and **payload ip disable** options introduced in Junos OS Release 12.1X48R2. (PTX Series Packet Transport Routers only).

zero-control-word option introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

Description

For aggregated Ethernet and SONET/SDH interfaces only, configure load balancing based on MPLS labels and payload. Only the IPv4 protocol is supported.

Options

family mpls—(Aggregated Ethernet interfaces, aggregated SONET/SDH interfaces, and multiple equal-cost MPLS next hops only) Incorporate MPLS label and payload information into the hash key for per-flow load balancing. Only the IPv4 protocol is supported.

- **all-labels**—(PTX Series Packet Transport Routers only) Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This is the default setting.
- **label-1**—(M120, M320, MX Series, and T Series routers only) Include the first MPLS label into the hash key. This is used for a one-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels.
- **label-2**—(M120, M320, MX Series, and T Series routers only) Include the second MPLS label into the hash key. This is used for a two-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels. To use the second MPLS label in the hash key, include both the **label-1** and **label-2** statements at the **[edit forwarding-options hash-key family mpls]** hierarchy level. By default, the router provides hashing on the first and second labels. If both labels are specified, the entire first label and the first 16 bits of the second label are hashed.
- **label-3**—(M120, M320, MX Series, and T Series routers only) Include the third MPLS label into the hash key. To use the third MPLS label, include the **label-1**, **label-2**, and **label-3** statements at the **[edit forwarding-options hash-key family mpls]** hierarchy level.
- **no-labels**—Include no MPLS labels into the hash key.
- **no-label-1-exp**—(M120, M320, MX Series, and T Series routers only) The EXP bit of the first label is not used in the hash calculation to avoid reordering complications.
- **payload**—Incorporate bits from the IP payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
 - **disable**—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
 - **ether-pseudowire**—(M120, M320, MX Series, and T Series routers only) Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
 - **zero-control-word**—(M Series, MX Series, and PTX Series) Precedes Ethernet packet to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.
 - **ip**—Include the IP address of the IPv4 or IPv6 payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels. For the PTX Series Packet Transport Routers, this is the default setting with both Layer 3 and Layer 4 IP information included in the hash key.
 - **disable**—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
 - **layer-3-only**—Include only Layer 3 IP information from the IP payload data into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
 - **port-data**—(M120, M320, MX Series, and T Series routers only) Include the source and destination port field information into the hash key. By default, the most significant byte and least significant byte of the source and destination port fields are hashed. To select specific bytes to be hashed,

include one or more of the **source-msb**, **source-lsb**, **destination-msb**, and **destination-lsb** options at the **[edit forwarding-options hash-key family mpls payload ip port-data]** hierarchy level. To prevent all four bytes from being hashed, include the **layer-3-only** statement at the **[edit forwarding-options hash-key family mpls payload ip]** hierarchy level.

- **destination-lsb**—Include the least-significant byte of the destination port.
- **destination-msb**—Include the most-significant byte of the destination port.
- **source-lsb**—Include the least-significant byte of the source port.
- **source-msb**—Include the most-significant byte of the source port.

Required Privilege Level

[edit routing-options],
[edit routing-instances routing-instance-name routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Specify a backup path in case the primary path becomes unusable.

You specify one or more objects with common characteristics within a group. All objects are treated as /32 host addresses. The objects can be a LAN interface, a router ID, or a point-to-point link. Sequence is insignificant.

Changing the fate-sharing database does not affect existing established LSPs until the next CSPF reoptimization. The fate-sharing database does affect fast-reroute detour path computations.

Options

cost *value*—Cost assigned to the group.

Range: 1 through 65,535

Default: 1

from *address*—Address of the router or address of the LAN/NBMA interface. For example, an Ethernet network with four hosts in the same fate-sharing group would require you to list all four of the separate **from** addresses in the group.

group *group-name*—Each fate-sharing group must have a name, which can have a maximum of 32 characters, including letters, numbers, periods (.), and hyphens (-). You can define up to 512 groups.

to *address*—(Optional) Address of egress router. For point-to-point link objects, you must specify both a **from** and a **to** address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

gre (Routing Options)

Syntax

```
gre;  
next-hop-based-tunnel;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options dynamic-tunnels tunnel-name],  
[edit routing-options dynamic-tunnels tunnel-name]
```

Release Information

Statement introduced in Junos OS Release 10.1.

next-hop-based-tunnel option introduced in Junos OS Release 16.2.

Description

Enable generic routing encapsulation (GRE) type for IPv4 to automatically establish label-switched paths (LSPs) for any new provider edge (PE) router added to a full mesh of LSPs.

Options

next-hop-based-tunnel—Create a tunnel composite next hop for every dynamic GRE tunnel configured.

The tunnel composite next hop includes the dynamic tunnel's encapsulation data and a VPN label (when chained composite next hop is not enabled). When this option is not configured, the default interface-based tunnel mode is enabled. By configuring this option, a device can scale up to 32,000 IP tunnels, which is otherwise restricted to the system limit on the number of interfaces supported.

At a given point in time, either the next-hop-based dynamic tunnel or the default interface-based dynamic GRE tunnel can exist on a device. A switchover from one tunnel mode to another deletes the existing tunnels and creates new tunnels in the new tunnel mode. As a result, a tunnel mode switchover can impact network performance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

Range: 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)

Default: 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

import (MPLS Traffic Engineering Database)

Syntax

```
import {
  bgp-ls-identifier domain-identifier;
  identifier identifier;
  policy policy-name;
  igp-topology{
    bgp-link-state;
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls traffic-engineering database],
[edit protocols mpls traffic-engineering database]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Configure the traffic engineering database import parameters.

Options

bgp-ls-identifier *domain-identifier*—BGP-TE domain identifier.

identifier *identifier*—BGP-TE identifier.

Range: 2 through 18446744073709551615

policy *policy-name*—Name of the import policy.

igp-topology—Download IGP topology information into the traffic engineering database (TED). In Junos OS, the IGP installs topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. The IGP routes are installed by the traffic engineering database on behalf of the corresponding IGP into a user-visible routing table called `Isdist.0`, subject to route policies.

bgp-link-state—Export IGP topology information into BGP-Link State (BGP-LS) from the `Isdist.0` routing table. The `Isdist.0` routing table stores the network topology information from the traffic engineering database. The BGP-LS reads IGP entries from `Isdist.0` and advertises the information to BGP peers.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ip-tunnel-rpf-check

Syntax

```
ip-tunnel-rpf-check {
    mode (strict | loose);
    fail-filter filter-name;
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
```

Release Information

Statement introduced in Junos OS Release 17.1 for MX Series Routers with MICs.

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (strict | loose)—(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

Default: If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*—(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

  }
}

```

Hierarchy Level

```
[edit firewall family mpls filter name term name from ip-version]
```

Release Information

Statement introduced in Junos OS Release 18.4R1 on MX Series routers with MPC and MIC interfaces.

Description

Define Layer 3 and Layer 4 match items to match IPv4 packets for IP-based filtering of MPLS traffic.

Options

destination-address *ip-address*—Match MPLS traffic with the specified IPv4 destination address.

destination-prefix-list *destination-prefix-list-name*—Match MPLS traffic with the specified IPv4 destination prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level.

protocol *protocol*—Specify one or a range of inner IPv4 protocols for IP-based filtering of MPLS traffic.

source-address *ip-address*—Match MPLS traffic with the specified IPv4 source address.

source-prefix-list *source-prefix-list-name*—Match MPLS traffic with the specified IPv4 source prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

```

Hierarchy Level

```
[edit firewall family mpls filter name term name from ip-version],
```

Release Information

Statement introduced in Junos OS Release 18.4R1 on MX Series routers with MPC and MIC interfaces.

Description

Define Layer 3 and Layer 4 match items to match IPv6 packets for IP-based filtering of MPLS traffic.

Options

destination-address *ip-address*—Match MPLS traffic with the specified IPv6 destination address.

destination-prefix-list *destination-prefix-list-name*—Match MPLS traffic with the specified list of IPv6 destination prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level. You must configure separate prefix-lists for IPv4 and IPv6 addresses.

protocol *protocol*—Specify one or a range of inner IPv6 next header for IP-based filtering of MPLS traffic.

source-address *ip-address*—Match MPLS traffic with the specified IPv6 source address.

source-prefix-list *source-prefix-list-name*—Match MPLS traffic with the specified IPv6 source prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level. You must configure separate prefix-lists for IPv4 and IPv6 addresses.

Required Privilege Level

firewall

ip-version (Family MPLS)

Syntax

```
ip-version {
  ipv4;
  ipv6;
}
```

Hierarchy Level

```
[edit firewall family mpls filter name term name from]
```

Release Information

Statement introduced in Junos OS Release 18.4R1 on MX Series routers with MPC and MIC interfaces.

Description

Specify inner IP version to enable IP-based filtering of MPLS family filter.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

Required Privilege Level

firewall—To view this statement in the configuration.

[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
[edit protocols source-packet-routing source-routing-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Support at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level introduced in Junos OS Release 19.1R1.

Description

Associate one or more prefixes with an LSP. When the LSP is up, all the prefixes are installed as entries into the inet.3 or inet6.3 routing table.

The support of the **install** statement at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** is applicable for both colored and non-colored segment routing LSPs.

For static colored LSPs, when the install prefix is configured, a route similar to the tunnel ingress route is installed in the **inetcolor.0** or **inet6color.0** routing table.

On the other hand, for static non-colored LSPs, when the install prefix is configured, a route similar to the tunnel **to** route is installed in **inet.3** or **inet6.3** routing table.

You can use the **show route table** command to view the **install** routes for both colored and non-colored segment routing traffic-engineered LSPs.

NOTE:

Take the following into consideration when configuring the **install *destination-prefix*** statement at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level:

- The install prefixes should be unique in a tunnel, and should not be the same as the tunnel **to** address. A commit check is done to ensure that the prefixes are unique.
- If two install prefixes are same across two different tunnels, then the gateways of the both tunnels are considered only if the segment lists are of the same resolution type. If the first hop resolution types vary, the route is not installed. In such cases, a system log message is generated to record the error.

For example:

```
[edit protocols source-packet-routing]
segment-list path-1 {
  hop-1 ip-address 172.0.12.2;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
source-routing-path lsp1 {
  to 10.10.10.1;
  install 20.20.20.2;
  install 30.30.30.3;
  primary {
    path-1;
  }
}
```

The **inet.3** routing table has two additional routes (to 20.20.20.2 and 30.30.30.3) with next hops derived from the same segment list path-1 with same attributes as the **to** address route.

Options

active—(Optional) Install the route into the inet.0 or inet6.0 routing table. This allows you to issue a **ping** or **traceroute** command on this address.

NOTE: The **install *destination-prefix* active** statement is not supported on static LSPs. When the **install *destination-prefix* active** statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

destination-prefix—IPv4 or IPv6 address to associate with the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-system logical-system-name protocols ldp oam],  
[edit protocols ldp entropy-label],  
[edit protocols ldp oam]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Statement introduced at the **[edit protocols ldp entropy-label]** hierarchy level in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Configure an LDP ingress policy for either the entropy label or Operation, Administration, and Management (OAM).

For OAM, configure the ingress policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

Options

ingress-policy-names—Specify the names of the ingress policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ip-tunnel-rpf-check

Syntax

```
ip-tunnel-rpf-check {  
    mode (strict | loose);  
    fail-filter filter-name;  
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
```

Release Information

Statement introduced in Junos OS Release 17.1 for MX Series Routers with MICs.

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (strict | loose)—(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

Default: If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*—(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

cross-credibility-cspf option introduced in Junos OS Release 14.2.

self-ping-duration and **no-self-ping** options introduced in Junos OS Release 16.1.

Description

Configure an LSP to use in dynamic MPLS. When configuring an LSP, you must specify the address of the egress router in the **to** statement. All remaining statements are optional.

Options

lsp-name—Name that identifies the LSP. The name can be up to 64 characters and can contain letters, digits, periods, and hyphens. To include other characters, enclose the name in quotation marks. The name must be unique within the ingress router.

cross-credibility-cspf—Enable path computation across credibility levels. The constraint path computation is run across multi-protocol links and nodes, instead of a credibility-by-credibility basis.

link-protection—Enable protection for LSP from link faults only.

no-self-ping—Disable self-ping for the LSP.

NOTE: Starting in Junos OS 17.4, you can override the behavior of self-ping running by default using ***no-self-ping*** statement.

self-ping-duration seconds—Specify the duration (in seconds) for which to run the self-ping mechanism unless the ping succeeds sooner.

LSP self-ping for an LSP starts at the ingress label edge router (LER), once a Resv message for that LSP has been received. The configured self-ping time indicates the duration for which the self-ping mechanism runs once the LSP instance is signaled to be **UP**.

By default, self-ping is enabled. The LSP types like CCC, P2MP, VLAN-based , and non-default instances do not support self-ping .

The self-ping mechanism runs until the self-ping probe is received back (at which point the traffic is immediately switched to it) , or until the configured self-ping duration for the LSP is over (at which point traffic is switched over).

When LSP self-ping-duration is enabled, the LSP behavior reverts back to a timer-based mechanism similar to the ***optimize-switchover-delay***, where a specific amount of time is provided for all the downstream nodes to install the forwarding path before switchover. When LSP self-ping-duration is not enabled, the default behavior is to wait for an infinite amount of time for the self-ping to succeed before switching the traffic.

Range: 1 through 65535 seconds

NOTE: Starting in Junos OS 17.4R1, the default time-out duration for which the self-ping runs on an LSP instance is reduced from 65535 (runs until success) to 1800 seconds. You can also configure the self ping duration value between 1 to 65535 (runs until success) seconds.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

link-protection;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],  
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable link protection on the specified LSP, which helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails. For point-to-multipoint LSPs, including this statement extends link protection to all of the paths used by the LSP.

To fully enable link protection, you must also include the **link-protection** statement at the **[edit protocols rsvp interface *interface-name*]** or **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]** hierarchy level.

Default

Link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[link-protection \(RSVP\) | 2861](#)

link-protection (Static LSPs)

Syntax

```
link-protection bypass-name name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name ingress],  
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name ingress],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced in Junos OS Release 10.1.

Description

Enable link protection on the specified static LSP. Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

Default

Link protection is disabled.

Options

bypass-name *name*—Bypass LSP name.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

load-balance-label-capability

Syntax

```
load-balance-label-capability;
```

Hierarchy Level

```
[edit forwarding-options]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Description

Enables the router to push and pop the load balancing label and causes LDP and RSVP to advertise the entropy label TLV to neighboring routers.

The **load-balance-label-capability** and **no-load-balance-label-capability** statements at the **[edit forwarding-options]** hierarchy level are mutually exclusive, and at a given point in time, configuring one statement overrides the other.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring the Entropy Label for LSPs | 573](#)

[no-load-balance-label-capability | 2703](#)

log-updown (Protocols MPLS)

Syntax

```
log-updown {  
  no-trap {  
    mpls-lsp-traps;  
    rfc3812-traps;  
  }  
  (syslog | no-syslog);  
  trap;  
  trap-path-down;  
  trap-path-up;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

The **mpls-lsp-traps** and **rfc-3812-traps** options added in Junos OS Release 9.0.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Log a message or send an SNMP trap whenever an LSP makes a transition from up to down, or vice versa, and whenever an LSP switches from one active path to another. Only the ingress router performs these operations.

NOTE: System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the **no-syslog** option under the **log-updown** statement.

Default

There is no default behavior for this statement. If you do not specify the options, the configuration cannot be committed.

Options

no-syslog—Do not log a message to the system log file.

no-trap—Do not send an SNMP trap.

syslog—Log a message to the system log file.

trap—Send an SNMP trap.

trap-path-down—Send an SNMP trap when an LSP path goes down.

trap-path-up—Send an SNMP trap when an LSP path comes up.

The **no-trap** statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

longest-match

Syntax

```
longest-match {  
  policy value |(expression) | [values ];  
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

Description

Enable longest match to allow LDP to learn the routes aggregated or summarized across OSPF areas or IS-IS levels in inter-domain.

Options

policy *value* |(expression) | [*values*]— Specify policy to provide per prefix granularity.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

loss (responder)

Syntax

```
loss {
  min-query-interval milliseconds;
}
```

Hierarchy Level

```
[edit protocols mpls oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name primary path-name oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name secondary path-name oam performance-monitoring responder]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure loss measurement options.

Options

min-query-interval *milliseconds*—(Optional) Specify the minimum query interval that the responder supports. If the minimum query interval of the responder is greater than the query interval configured at the querier, the effective message query rate is the minimum query interval configured for the responder.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

lsping-channel-type

Syntax

```
lsping-channle-type {
  ipv4;
  on-demand-cv;
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name oam mpls-tp-mode]
[edit protocols mpls oam mpls-tp-mode]
```

Release Information

Statement introduced in Junos OS Release 16.1.

Description

Specify the control-channel types for MPLS-TP mode. By default, LSPING (0x0008) is used, and the GACH-TLV is used along with this channel type.

As per RFC 7026, GACH-TLV is deprecated for ipv4 and on-demand-cv channel types.

Options

ipv4—Channel type 0x0021. This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

on-demand-cv—Channel type 0x0025. This is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

minimum-bandwidth

Syntax

```
minimum-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],  
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Set the minimum bandwidth in bps for an LSP with automatic bandwidth allocation enabled.

NOTE: For a label-switched path (LSP) that has both **bandwidth** and **minimum-bandwidth** for autobandwidth configured under the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the maximum bandwidth.

Options

bps—Minimum bandwidth for the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit protocols l2circuit]

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Description

Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router or switch to the local customer edge (CE) router or switch. All the Layer 2 circuits using a particular remote PE router or switch designated for remote CE routers or switches are listed under the **neighbor** statement (neighbor designates the PE router or switch). Each neighbor is identified by its IP address and is usually the end-point destination for the LSP tunnel (transporting the Layer 2 circuit).

Options

address—IP address of a neighboring router or switch.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-bfd-triggered-local-repair

Syntax

```
no-bfd-triggered-local-repair;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],  
[edit routing-options]
```

Release Information

Statement introduced in Junos OS Release 12.2.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Disable Bidirectional Forwarding Detection (BFD) sessions to trigger fast reroute (FRR) using MPLS-FRR and loop-free alternates (LFAs). When this statement is configured, no BFD-triggered local repair is supported. However, logical interface down-based local repair is in force.

When using this statement to disable local repair, you also must restart routing to ensure proper behavior. To restart routing, include the **graceful-restart** command for the interior gateway protocol (IGP) used in your configuration. For example, if your IGP is OSPF, include the **graceful-restart** statement at the [edit protocols ospf] hierarchy level.

Default

BFD-triggered local repair is the default behavior. The loss of a neighbor results in BFD local repair for all next hops that derive themselves from the base next hop with which the BFD session is established.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable constrained-path LSP computation.

An explicit-path LSP is completely configured through operator action. Once configured, it is initiated only along the explicitly specified path.

A constrained-path LSP relies on an ingress router to compute the complete path. The ingress router takes into account the following information during the computation:

- Interior gateway protocol (IGP) topology database
- Link utilization information from extensions in the IGP link-state database
- Administrative group information from extensions in the IGP link-state database
- LSP requirements, including bandwidth, hop count, and administrative group

Constrained-path LSPs can generally avoid link failures and congested links. They also permit recomputation (therefore, a new path) during topology changes or unsuccessful setup.

Default

Constrained-path LSP computation enabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable normal time-to-live (TTL) decrementing, which decrements the TTL field in the IP header by 1. This statement decrements the IP TTL by 1 before encapsulating the IP packet within an MPLS packet. When the penultimate router pops off the top label, it does not use the standard write-back procedure of writing the MPLS TTL into the IP TTL field. Therefore, the IP packet is decremented by 1. The ultimate router then decrements the packet by one more for a total cloud appearance of 2, thus hiding the network topology.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit routing-options],  
[edit routing-instances routing-instance-name routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.1 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

You configure the graceful restart routing option globally to enable the feature, but not to enable graceful restart for all routing protocols in a routing instance. To enable graceful restart globally, include the graceful-restart statement under the **[edit routing options]** hierarchy level. This enables graceful restart globally for all routing protocols. You can, optionally, modify the global settings at the individual protocol level.

NOTE:

- For VPNs, the **graceful-restart** statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.
- For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.
- LDP sessions flap when **graceful-restart** configurations change.

Default

Graceful restart is disabled by default.

Options

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-mcast-replication

Syntax

```
no-mcast-replication;
```

Hierarchy Level

```
[edit chassis fpc slot-number pic pic-number],  
[edit chassis lcc number fpc slot-number pic pic-number]
```

Release Information

Statement introduced in Junos OS Release 11.3.

Description

For point-to-multipoint LSPs configured on T Series routers, protect the Packet Forwarding Engine (PFE) from bandwidth saturation. When a PFE does not need to replicate traffic, the PFE's bandwidth is less likely to become saturated. When you include the **no-mcast-replication** statement, the PFE is forced to be a leaf node in the binary tree. Leaf nodes, unlike branch nodes, do not replicate traffic in the process of forwarding traffic. Because leaf nodes have no children, they do not need to replicate traffic, and thus are less likely to become saturated with traffic.

Default

If you omit the **no-mcast-replication** statement, the PFE can become a branch node or a leaf node. When the PFE becomes a branch node, the PFE must replicate traffic.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

RELATED DOCUMENTATION

no-propagate-ttl

Syntax

```
no-propagate-ttl;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable normal time-to-live (TTL) decrementing. You configure this statement once per router, and it affects all RSVP-signaled or LDP-signaled LSPs. When this router acts as an ingress router for an LSP, it pushes an MPLS header with a TTL value of 255, regardless of the IP packet TTL. When the router acts as the penultimate router, it pops the MPLS header without writing the MPLS TTL into the IP packet.

When you add the **no-propagate-ttl** statement to the configuration or delete it from the configuration, the effect takes place immediately. There is no need to clear existing RSVP LSPs or LDP sessions.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

normalization

Syntax

```
normalization {
    failover-normalization;
    no-incremental-normalize;
    normalization-retry-duration seconds;
    normalization-retry-limits number;
    normalize-interval seconds;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.2R1 for QFX Series switches.

Description

Perform normalization.

Options

failover-normalization—Enable the ingress router to pro-actively normalize or re-distribute traffic when a link or node failure happens on a member LSP. A member LSP can go down between two scheduled normalization events because of a link-failure or pre-emption.

Default: Disabled

no-incremental-normalize—Disables automatic switchover by the ingress router to a new instance of the container LSP until the desired demand is satisfied, although the given number of LSPs can be successfully signaled such that the new aggregate bandwidth value exceeds the old aggregate bandwidth value.

Default: False (disabled)

normalization-retry-duration *seconds*—Specifies the duration before which the ingress router performs a normalization reattempt when the previous normalization has not been successful. Normalization is done until a sufficient number of LSPs come up with an aggregate bandwidth that is more than the current aggregate or desired bandwidth.

Default: 30 seconds

normalization-retry-limits *number*—Specifies the maximum number of times the ingress router performs normalization reattempts until a sufficient number of LSPs come up successfully with new bandwidth values.

Default: 1

normalize-interval *seconds*—Specifies the duration between two normalization events.

Range: 21600 seconds through 6 hours

Default: 21600 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-adaptive-teardown

Syntax

```
optimize-adaptive-teardown {  
  p2p:  
    delay value (3..65535 seconds)  
}
```

Hierarchy Level

```
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 15.1R1.

Description

Make use of a new feedback mechanism from TAG library which relies on RPD infrastructure to decide when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover. When this statement is configured, the **optimize-hold-dead-delay** statement, which delays the teardown of the old LSP instance after MBB switchover, is ignored.

Options

p2p—Only point-to-point LSPs configured in the system will be affected.

delay—Delays the tearing down of old optimized LSP paths based on the configured value. The value configured is in the range of 3..65535 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-aggressive

Syntax

```
optimize-aggressive;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

If enabled, the LSP reoptimization is based solely on the IGP metric. The reoptimization process ignores the available bandwidth ratio calculations, the least-fill 10 percent congestion improvement rule, and the hop-counts rule. This statement makes reoptimization more aggressive than the default.

Default

Aggressive optimization is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-hold-dead-delay

Syntax

```
optimized-hold-dead-delay seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switch-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switch-path lsp-name]
```

Description

Allows you to specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths. This delay timer starts when the timer specified by the **optimize-switchover-delay** statement has elapsed, which is typically 30 seconds, and at the start of the next retry sequence (in other words, the delay is not an absolute countdown of the seconds configured here).

You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The specified delay helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths.

Options

seconds—Configure the time in seconds to wait before tearing down the old paths that were in use prior to the last LSP optimization.

Default: 60 to 90 seconds

Range: 0 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 11.1R1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Delays the switch over of LSPs to newly optimized paths. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The specified delay helps to ensure that the new optimized paths have been established before traffic is switched over from the old paths.

Options

seconds—Configure the time in seconds to wait before switching LSPs to newly optimized paths.

Default: 1 second

Range: 1 through 900 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Enable periodic reoptimization of an LSP that is already set up. If topology changes occur, an existing path might become suboptimal, and a subsequent recomputation might be able to determine a better path. This feature is useful only on LSPs for which constrained-path computation is enabled; that is, for which the **no-cspf** statement is not configured. Also, you only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers).

To avoid extensive resource consumption that might result because of frequent path recomputations, or to avoid destabilizing the network as a result of constantly changing LSPs, we recommend that you either leave the timer value sufficiently large or disable the timer value.

Default

The optimize timer is disabled.

Options

seconds—Length of the optimize timer, in seconds.

Range: 0 through 65,535 seconds

Default: 0 seconds (the optimize timer is disabled)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

path (Protocols MPLS)

Syntax

```
path path-name {
    abstract-hop-name (abstract | loose | loose-link | strict);
    (address | hostname) <strict | loose>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

abstract-hop-name option introduced in Junos OS Release 17.1 for all platforms.

Description

Create a named path and optionally specify the sequence of explicit routers that form the path.

You must include this statement when configuring explicit LSPs.

Options

abstract-hop-name—Name of the predefined abstract hop. The abstract hop can be used in combination with real IP next hops. An abstract hop is traversed by traversing the member nodes. This traversal can be done by either links that satisfy the logical combination of defined constituent attributes, or by any kind of link. This choice is controlled by the use of abstract hop qualifiers – abstract, loose, loose-link, and strict.

abstract—Indicate that the next hop configured in the **path** statement is an abstract hop..

loose-link—Indicate that the next hop in the **path** statement is a loose-link abstract hop. This means that the LSP cannot traverse other routers before reaching this router. In other words, the abstract hop of type loose-link is processed only if any of the viable routers is reached in constraint through a link of associated abstract hop membership.

loose—Indicate that the next hop in the **path** statement is a loose abstract hop. The path can traverse any real nodes that do not have abstract hop membership, before reaching a node with abstract hop membership, which is a feasible starting point for processing the next abstract hop.

strict—Indicate that the next hop in the **path** statement is a strict abstract hop. After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership, before reaching a node with abstract hop membership, which is a feasible starting point for processing the next abstract hop.

address—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.

hostname—See **address**.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.

loose—(Optional) Indicate that the next address in the **path** statement is a loose link. This means that the LSP can traverse through other routers before reaching this router.

Default: **strict**

path-name—Name that identifies the sequence of nodes that form an LSP. The name can contain up to 32 characters and can include letters, digits, periods, and hyphens. To include other characters or use a longer name, enclose the name in quotation marks. The name must be unique within the ingress router.

strict—(Optional) Indicate that the LSP must go to the next address specified in the **path** statement without traversing other nodes. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Configure path protection on your MPLS network.

Options

destination —Name of a label switched path (LSP). In addition to specifying the name of the configured LSP, you can include some other designation such as **primary-path**.

address —(Optional) IP address of each transit switch (or the IP address of the loopback interface on the switch) in the LSP. If you want to control exactly which switches are selected for the LSP, specify the address or hostname of each transit switch. Specify the addresses in order, starting with the first provider (transit) switch, and continuing sequentially along the path until reaching the egress provider edge switch.

Default: If you do not specify the addresses or hostnames of any switches, the LSP is calculated by the switch.

hostname —(Optional) See **address** .

Default: If you do not specify the addresses or hostnames of any switches, the LSP is calculated by the switch.

loose—(Optional) Indicates that the next address in the **path** statement is a loose link. This means that the LSP can traverse through other switches before reaching this switch.

Default: **strict**

strict—(Optional) Indicates that the LSP must go to the next address specified in the **path** statement without traversing other switches. This is the default.

```

Release Information

Statement introduced in Junos OS Release 12.1x48 for PTX Series Packet Transport Routers.

Statement introduced in Junos OS Release 12.3 for M Series, T Series, and MX Series routers.

Description

Allocate a unique label for each prefix. The **per-prefix-label** statement helps minimize packet loss in most deployments.

Although allocating a label for each prefix is not generally ideal for scaling, it is assumed that a small number of labels are used for BGP labeled-unicast. When labeled BGP is used to set up transport label-switched paths (LSPs), the common case is that each prefix has a unique next hop. Thus, the use of per-prefix labels does not have an adverse scaling impact. On the contrary, the use of per-prefix labels reduces churn in the network when multipath load balancing is enabled for IPv4 labeled-unicast, and a subset of the paths are withdrawn for some reason.

The advantage of per-prefix labeling is that the advertised upstream label is more stable during network changes. That is, if the downstream label changes, the advertised upstream label remains the same under most scenarios. This way, the upstream router is isolated from the downstream network change, and the overall network is more stable. The greater stability of the advertised upstream label helps to reduce traffic loss during many different network change scenarios.

Default

By default, label allocation is per next-hop router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit tenants name routing-instances name routing-options rib]
```

Release Information

Statement introduced in Junos OS Release 19.1R1 for all platforms.

Description

Create policy-based multipath route using a combination of segment routing traffic-engineered (SR-TE) LDP or RSVP routes and SR-TE IP routes. You can resolve BGP service routes over the multipath route, and apply export policies to steer traffic differently for different prefixes. The policy-based multipath feature is supported for both IP and IPv6 protocols.

Options

policy—Import policy to create policy-based multipath.

NOTE: This statement is supported only at the **[edit routing-option policy-multipath]** hierarchy level.

Any action commands configured in the policy, such as apply, is evaluated using the active route. For non-active routes, the policy is applied to check if the routes can participate in the multipath route or not. Multipath routes inherit all attributes of the active route. These attributes can be modified using the multipath policy configuration.

The remaining statements are explained separately. See [CLI Explorer](#).

Description

Define a routing policy, including subroutine policies.

A *term* is a named structure in which match conditions and actions are defined. Routing policies are made up of one or more terms. Each routing policy term is identified by a term name. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in double quotation marks.

Each term contains a set of match conditions and a set of actions:

- Match conditions are criteria that a route must match before the actions can be applied. If a route matches all criteria, one or more actions are applied to the route.
- Actions specify whether to accept or reject the route, control how a series of policies are evaluated, and manipulate the characteristics associated with a route.

Generally, a router compares a route against the match conditions of each term in a routing policy, starting with the first and moving through the terms in the order in which they are defined, until a match is made and an explicitly configured or default action of **accept** or **reject** is taken. If none of the terms in the policy match the route, the router compares the route against the next policy, and so on, until either an action is taken or the default policy is evaluated.

If none of the match conditions of each term evaluates to true, the final action is executed. The final action is defined in an unnamed term. Additionally, you can define a default action (either **accept** or **reject**) that overrides any action intrinsic to the protocol.

The order of match conditions in a term is not relevant, because a route must match all match conditions in a term for an action to be taken.

To list the routing policies under the **[edit policy-options]** hierarchy level by **policy-statement** *policy-name* in alphabetical order, enter the **show policy-options** configuration command.

The statements are explained separately.

Options

actions—(Optional) One or more actions to take if the conditions match. The actions are described in *Configuring Flow Control Actions*.

family *family-name*—(Optional) Specify an address family protocol. Specify **inet** for IPv4. Specify **inet6** for 128-bit IPv6, and to enable interpretation of IPv6 router filter addresses. For IS-IS traffic, specify **iso**. For IPv4 multicast VPN traffic, specify **inet-mvpn**. For IPv6 multicast VPN traffic, specify **inet6-mvpn**. For multicast-distribution-tree (MDT) IPv4 traffic, specify **inet-mdt**. For BGP route target VPN traffic, specify **route-target**. For traffic engineering, specify **traffic-engineering**.

NOTE: When **family** is not specified, the routing device or routing instance uses the address family or families carried by BGP. If multiprotocol BGP (MP-BGP) is enabled, the policy defaults to the protocol family or families carried in the network layer reachability information (NLRI) as configured in the *family* statement for BGP. If MP-BGP is not enabled, the policy uses the default BGP address family unicast IPv4.

from—(Optional) Match a route based on its source address.

as-path-unique-count *count* (*equal* | *orhigher* | *orlower*)—(Optional) Specify a number from 0 through 1024 to filter routes based on the number of unique autonomous systems (ASs) in the AS path. Specify the match condition for the unique AS path count.

aggregate-bandwidth—(Optional) Enable BGP to advertise aggregate outbound link bandwidth for load balancing.

dynamic-tunnel-attributes *dynamic-tunnel-attributes*—(Optional) Choose a set of defined dynamic tunnel attributes for forwarding traffic over V4oV6 tunnels.

match-conditions—(Optional in **from** statement; required in **to** statement) One or more conditions to use to make a match. The qualifiers are described in *Routing Policy Match Conditions*.

multipath-resolve *multipath-resolve*—(Optional) Enable the use of all paths for resolution over the specified prefix.

limit-bandwidth *limit-bandwidth*—(Optional) Specify the limit for advertised aggregate outbound link bandwidth for load balancing.

Range: 0 through 4,294,967,295 bytes

no-entropy-label-capability—(Optional) Disable the entropy label capability advertisement at egress or transit routes specified in the policy.

priority (*high* | *medium* | *low*)—(Optional) Configure the priority for an IS-IS route to change the default order in which the routes are installed in the routing table, in the event of a network topology change.

policy subroutine-policy-name—Use another policy as a match condition within this policy. The name identifying the subroutine policy can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" "). Policy names cannot take the form `__.*-internal__`, as this form is reserved. For information about how to configure subroutines, see *Understanding Policy Subroutines in Routing Policy Match Conditions*.

policy-name—Name that identifies the policy. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" ").

prefix-list prefix-list-name—Name of a list of IPv4 or IPv6 prefixes.

prefix-list-filter prefix-list-name—Name of a prefix list to evaluate using qualifiers; **match-type** is the type of match, and **actions** is the action to take if the prefixes match.

protocol protocol-name—Name of the protocol used to control traffic engineering database import at the originating point.

Starting in Junos OS Release 19.1R1, you can specify options to match label IS-IS and label OSPF routes using the **l-isis** and **l-ospf** options, respectively. The **isis** options matches all IS-IS routes, excluding labelled IS-IS routes. The **ospf** option matches all OSPF routes, including OSPFv2, OSPFv3 and labelled OSPF routes.

resolution-map—(Optional) Set resolution map modes. A given resolution-map can be shared across multiple policy-statements.

route-filter destination-prefix match-type <actions>—(Optional) List of routes on which to perform an immediate match; **destination-prefix** is the IPv4 or IPv6 route prefix to match, **match-type** is the type of match (see *Configuring Route Lists*), and **actions** is the action to take if the **destination-prefix** matches.

source-address-filter source-prefix match-type <actions>—(Optional) Unicast source addresses in multiprotocol BGP (MBGP) and Multicast Source Discovery Protocol (MSDP) environments on which to perform an immediate match. **source-prefix** is the IPv4 or IPv6 route prefix to match, **match-type** is the type of match (see *Configuring Route Lists*), and **actions** is the action to take if the **source-prefix** matches.

tag value—(Optional) A numeric value that identifies a route. You can tag certain routes to prioritize them over other routes. In the event of a network topology change, Junos OS updates these routes in the routing table before updating other routes with lower priority. You can also tag some routes to identify and reject them based on your requirement.

term term-name—Name that identifies the term. The term name must be unique in the policy. It can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" "). A policy statement can include multiple terms. We recommend that you name all terms. However, you do have the option to include an unnamed term which must be the final term in the policy. To configure an unnamed term, omit the **term** statement when defining match conditions and actions.

to—(Optional) Match a route based on its destination address or the protocols into which the route is being advertised.

then—(Optional) Actions to take on matching routes. The actions are described in *Configuring Flow Control Actions* and *Configuring Actions That Manipulate Route Characteristics*.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Understanding Source Packet Routing in Networking (SPRING)

pop

Syntax

```
pop;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Remove the label from the top of the label stack. If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Preference for the route.

You can optionally configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for LSPs is lower (more preferred) than all learned routes except direct interface routes.

Options

preference—Preference to assign to the route. A route with a lower preference value is preferred.

Range: 1 through 255

Default: 5 for static MPLS LSPs, 7 for RSVP MPLS LSPs, 9 for LDP MPLS LSPs

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the setup priority and reservation priority for an LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. Sessions with lower hold priorities are preempted.

Options

reservation-priority—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 0 (Once the session is set up, no other session can preempt it.)

setup-priority—Setup priority.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 7 (The session cannot preempt any existing sessions.)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols connections \(MPLS\)]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Configure MPLS LSP tunnel cross-connects. This makes an association between a CCC interface and two LSPs, one for transmitting MPLS packets from the local provider edge switch to the remote provider edge switch and the other for receiving MPLS packets on the local provider edge switch from the remote provider edge switch.

Options

connection-name—Connection name.

interface interface-name.unit-number—Interface name. Include the logical portion of the name, which corresponds to the logical unit number of the CCC interface.

receive-lsp label-switched-path—Name of the LSP from the connection's source. This LSP name was specified by the **label-switched-path** statement on the remote provider edge switch in the **protocols mpls** stanza.

transmit-lsp label-switched-path—Name of the LSP to the connection's destination. This LSP name was specified by the **label-switched-path** statement on the local provider edge switch in the **protocols mpls** stanza.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations. The more time you configure, the more time a source node (ingress of an RSVP LSP) can have to learn about the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes.

Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the database and the network.

Options

seconds—Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations.

Range: 0 through 240 seconds

Default: 25 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Statement introduced in Junos OS Release 17.2R1 for the QFX Series switches.

Description

Configure traffic sampling. By default, sampling mode is set to **Max Aggregate** which means the system will compare each new sample with the previous sample. If the new sample is higher than the old sample, then the newer sample is considered **Sampled Aggregate bandwidth**

Max Aggregate Example

If normalization happens every 20min (T0, T20, T40..) then if at time T0 the traffic rate is 185Gbps, and subsequently drops to 7.5Gbps at time T3, the max-aggregate sample for the current normalization window T0-T20 will be 185Gbps. When the current normalization window expires at time T20, we use the previous sampled max-aggregate of 185Gbps to calculate the split/merge activities of the next (or now current) normalization window between T20 – T40. If traffic remains at 7.5Gbps for this second normalization period, then at time T40 the max-aggregate sample of 7.5Gbps would then be used for split/merge activities. Even though traffic volumes dropped at time T3, LSP split/merge activities would not occur until time T40 which might be unexpected. This default behavior can be modified with use-average-aggregate or use-percentile to achieve alternative normalization behavior if desired.

Options

cut-off-threshold *percentile*—Specify the percentile value to be used as a cut-off threshold in removing outlier bandwidth samples. All the aggregate bandwidth samples determined as outliers are used for computing aggregate bandwidth used at the time of normalization.

Default: 0 percentile (the ingress considers all aggregate bandwidth samples for normalization.)

Range: 0 through 100

use-average-aggregate—Specify the ingress router to take average of the aggregate samples for normalization.

This option is mutually exclusive with the **use-percentile** configuration option.

use-percentile *percentile*—Specify the ingress router to compute and use the **pth** percentile from all the bandwidth samples, and use that for normalization.

This option is mutually exclusive with the **use-average-aggregate** configuration option.

Range: 0 through 100

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify one or more secondary paths to use for the LSP. You can configure more than one secondary path. All secondary paths are equal, and the first one that is available is chosen.

You can specify secondary paths even if you have not specified any primary paths.

Optionally, you can specify preference, CoS, and bandwidth values for the secondary path, which override any equivalent values that you configure for the LSP (at the **[edit mpls label-switched-path]** hierarchy level).

Options

path-name—Name of a path that you created with the **path** statement.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

```

Release Information

Statement introduced in Junos OS Release OS 18.1R1 for MX Series, PTX Series, and QFX Series.

Description

Static segment for segment routing. A static segment is identified by a unique name. This segment type is assigned a segment identifier (SID) which falls under a default range of 100000 through 1048575. The segment has label operation such as pop-and-forward for adjacency segment and swap-and-forward for prefix or node segment. For both types of label operation, the segment is assigned a next hop that specifies the remote IP address if the outgoing interface is a multi-access interface, or the name of the outgoing interface if the interface is a point-to-point interface. Static segment configuration is used to statically configure or provision the adjacency SIDs, node SIDs, and prefix SIDs on transit routers.

Options

pop—Pop the SID label

swap—Swap the SID label to this label

description—Text description of label-switched path

next-hop—IPv4 address or interface of next-hop router

sid-label—Segment identifier (SID) label

The remaining statements are explained separately. See [CLI Explorer](#).

Release Information

Statement introduced in Junos OS Release 17.4R1 for MX Series and PTX Series with FPC-PTX-P1-A.

ip-address statement introduced in Junos OS Release 18.1R1 on MX Series routers.

inherit-label-nexthops, **node-type**, and **auto-translate** statements introduced in Junos OS Release 19.1R1 on MX Series routers.

dynamic statement introduced in Junos OS Release 19.2R1 on all platforms.

compute, **loose**, and **strict** statements introduced in Junos OS Release 19.1R1-S1 on MX Series routers.

Description

Specify an name to identify the segment routing list (used in traffic engineering policy) and the explicit path for source routing label switched path (LSPs) to traverse through traffic engineering segments. The segment list is essentially a stack of segment identifiers.

Starting in Junos OS release 19.1R1 for MX and PTX Series routers, you can enable a translation service to translate next-hop IP addresses into the corresponding segment identifier (SID) labels. The translation service keeps track of the node reached at each hop.

When configured, the **segment-list** of a segment routing traffic engineering (SR-TE) LSP accepts IP addresses for all the hops along the path. These IP addresses can be either the loopback address of a node, or the

IP address of a link, as identified by the **node-type**. When **auto-translation** is enabled, next hop IP addresses are automatically translated to corresponding SIDs using the translation service. A retry rate can be set for the retry timer at the **source-packet-routing** hierarchy level.

NOTE: The segment list enables BGP and static segment routing LSP to steer traffic based on segment routing policies. When a segment list is used by the protocol BGP, the BGP protocol validates these segment identifiers and selects valid segments for traffic engineering.

Options

<hop-name>—Indicates the next hop in the segment routing traffic engineering policy (SR-TE).

- **ip-address**—Specify the IP address of the hop. For a segment-list to be used by a non-colored segment routing LSP, the first hop must specify an IP address.
- **label**—Specify the SID label of the hop in a segment routing traffic engineering segment list. In static segment routing LSPs, the source routing path uses the segment list only if the second to Nth hop specifies segment identifiers (SID) labels.

NOTE: The range is from 0 to 1,048,576 and is applies to BGP and static segment routing LSPs.

- **label-type**—Use with the option below to indicate that the specified address is the IP address of the node, for example, its loopback address, as opposed to that of a link.
- **node**—Hops that have been specified as **node** are translated to a prefix SID, which can be either a node SID or an anycast SID depending on the type of hop IP address. IP addresses not identified as **node** are consider to be a link.

NOTE: If the first hop is a **node**, for LSP resolution to work correctly, **inherit-label-nexthops** must be enabled at either **source-packet-routing** hierarchy level, or at the relevant **segment-list** hierarchy level.

- **loose | strict**—IP hops specified using router IDs in the sequence can be strict or loose hops. A strict hop must be directly connected to the previous node in the sequence. A loose hop is not necessarily directly connected to the previous node.

NOTE: You can specify only router IDs as loose or strict hop constraints. Labels and other IP addresses are not supported as loose or strict hop constraints in Junos OS Release 19.2R1-S1.

auto-translate— This option must be enabled before a given segment list can use IP addresses instead of SIDs for any hop other than the first hop. In addition, all hops in the segment list must have IP addresses. If any hops on the list have both an IP address and a label configured, the label will be retained. Link addresses are only translated into labels if the preceding node advertises an adjacency SID for the address (otherwise translation fails).

NOTE: In Junos OS Release 19.1R1, for auto-translate to work for OSPF, RSVP for segment routing must be enabled on all participating interfaces.

- **protected**—(Optional) Enable this option to ensure the adjacency SID is eligible to have a backup path, and that a B-flag is set in adjacency SID advertisements. Note that unless **mandatory** is also selected, the choice succeeds regardless.
- **mandatory**—(Optional) Enable this option to have translation fail if any *unprotected* links are found in the hop-list.
- **unprotected**—(Optional) Enable this option to ensure that no backup path is calculated for a specific adjacency SID, and that a B-flag is not set in adjacency SID advertisements. Note that unless **mandatory** is also selected, the choice succeeds regardless.
- **mandatory**—(Optional) Enable this option to have translation fail if any *protected* links are found in the hop-list.

compute—(Optional) Enable use of explicit paths specified in segment list for path computation.

inherit-label-nexthops—Inherit label next hops for first hop in this segment list that have both IP address and label configured in the first hop.

You can configure the **inherit-label-nexthops** statement globally or individually for each segment list.

The **inherit-label-nexthops** statement takes effect only when the segment list first hop has both IP address and SID label present.

If the **inherit-label-nexthops** is not configured at the **[edit protocols source-packet-routing segment-list]** hierarchy, and the first hop in the segment list has both IP address and label specified, the default behavior is to use the IP address.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

smart-optimize-timer

Syntax

```
smart-optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable the smart optimization timer. When you enable the smart optimization timer on a router, the Junos OS operates on the assumption that the original LSP path is preferable to any alternate or secondary path. When you enable the smart optimization timer and an LSP fails and its traffic is switched to an alternate path, the smart optimization timer starts and waits 3 minutes (this time is configurable). After 3 minutes have passed, the LSP is switched back to the original path. If the original path fails again and the LSP is switched to an alternate path again, the router waits 1 hour before attempting to switch the LSP back to its original path.

If you want to disable the smart optimizer, you can set it to zero. The **smart-optimize-timer** value in seconds indicates the time before which the LSP is switched back to its primary path in case the primary path becomes available. Otherwise, the time to wait is controlled by the **optimize-timer**, which is usually set to a high value. Some ISPs have the **optimize-timer** set to once a day. Sometimes after the smart optimizer causes the LSP to be placed back on its primary path, the primary path goes down again within 60 minutes. When this happens, the **smart-optimize-timer** is disabled automatically, and the **optimize-timer** (regular path optimization) goes into effect. This is to protect against a flapping link being used.

Default

The smart optimization timer is enabled by default.

Options

seconds—(Optional) Specify the number of seconds to wait before switching an LSP back to its original path. If you do not specify the number of seconds, the default value is used.

Range: 0 through 65,535 seconds

Default: 180 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

source-routing-path

Syntax

```
source-routing-path name {
  binding-sid binding-sid;
  color color;
  metric value;
  no-ingress;
  preference preference;
  primary name {
    weight weight;
  }
  secondary name {
    weight weight;
  }
  sr-preference sr-preference;
  to to;
}
```

Hierarchy Level

```
[edit logical-systems name protocols source-packet-routing],
[edit protocols source-packet-routing]
```

Release Information

Statement introduced in Junos OS Release 17.4R1 for MX Series and PTX Series with FPC-PTX-P1-A. The **metric**, **no-ingress**, and **secondary** statements are introduced in Junos OS Release 18.1R1 for MX Series.

Description

Configure a source routing label switched path (LSP) for steering traffic at an ingress router. Specify a binding segment identifier from the static label range. Configure other parameters such as color, weight, preference, and segment routing (SR) preference for traffic engineering.

Starting with Junos OS Release 18.1R1, static non-colored SR label switched paths (LSPs) for protocol SPRING-TE in an MPLS network. Configure parameters such as destination address, binding SIDs, primary segment, secondary segment, metric, and preference. These SR LSPs do not have a color associated with them. If an ingress route is not required for a non-colored SR LSP then the ingress route installation in inet.3 table can be disabled.

Options

name—Specify a name to identify a source routing path.

binding-sid—Specify the binding label to enable transit functionality for this tunnel. For a non-colored static SR LSP, the binding SID label of protocol SPRING-TE have , by default, a preference of 8 and a metric of 1.

NOTE: This is optional for MPLS networks.

Range: 16 through 1,048,576

color—Specify a color identifier for the tunnel end point.

NOTE: This is only for colored SR LSPs. For non-colored SR LSPs, you do not have to configure the color parameter.

metric—Specify metric for routes downloaded for the non-colored static SR tunnel.

Default:

NOTE: This is the default label range for static LSPs in MPLS networks. You can configure the label range at **[edit protocols mpls label-range static label-range]** hierarchy level.

1000000 through 1048575

Range:

NOTE: This range is for protocol BGP.

1 through 16777215

no-ingress—Disable ingress route that is not required for the non-colored static SR tunnel

preference—Specify the preference for routes downloaded for this tunnel.

primary—Specify a primary segment list for the configured source routing path.

The non-colored static SR LSP can have a maximum of 8 primary paths. incase of multiple operational primary paths, the PFE distributes the traffic over the paths based on the weight configured on the paths. If none of the paths have weights configured then the weights default to 1 making it an ECMP path. the paths become weighted ECMP if the at least one of the paths have a non-zero weight. In both cases , when one or some of the paths fail, the PFE automatically re-balances the traffic over the remaining paths resulting in path protection.

weight *weight_value*—Specify a percentage of the bandwidth with respect to the sum of weights of all paths for the primary segment list. If forwarding interfaces are also configured with weighted ECMP, then Junos OS applies hierarchical weighted ECMP. If the weight percentage is not configured, then only IGP weights are applied on the forwarding interfaces.

secondary—Specify a secondary segment list for the configured non-colored static SR LSP.

sr-preference—Configure a preference for segment routing routes for traffic engineering. BGP chooses a higher preference over a lower preference value.

Range: 0 through 4,294,967,295

to—Specify the IP address of the tunnel end-point

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details..

source-routing-path-template

Syntax

```
source-routing-path-template name {
  bfd-liveness-detection;
  ldp-tunneling;
  metric metric;
  no-ingress;
  primary name {
    weight weight;
  }
  secondary name;
  sr-preference sr-preference;
}
```

Hierarchy Level

```
[edit protocols source-packet-routing]
```

Release Information

Statement introduced in Junos OS Release 19.2R1 on all platforms.

bfd-liveness-detection and **ldp-tunneling** options introduced in Junos OS Release 19.4R1 on all platforms.

Description

Configure a source-routing-path-template for dynamic creation of segment routing label-switched paths (LSPs).

Options

name—Name of the source routing path.

ldp-tunneling—Allow LDP to use this LSP for tunneling. This configuration can be applied to PCE-initiated segment routing LSPs only.

metric—Metric for routes downloaded for this tunnel.

Range: 1 through 16777215

no-ingress—Disable ingress functionality for this tunnel.

primary *name*—Configure a named identifier for the segment-list that describes the primary segment routing path along which the packet is to be routed. This segment list must have the **dynamic** statement enabled for dynamic creation of segment routing LSPs.

weight *weight*—(Optional) Specify the balance factor for this segment list in SR-TE tunnel.

If the forwarding interfaces have weights assigned by IGP, then hierarchical weighted ECMP is applied. When weight is not specified, only the IGP weights are applied on the forwarding interfaces.

secondary name—Configure a named identifier for the segment-list that describes the secondary segment routing path along which the packet is to be routed. This segment list must have the **dynamic** statement enabled for dynamic creation of segment routing LSPs.

sr-preference—Segment routing preference for the segment routing traffic engineered (SPRING-TE) routes. A greater value indicates higher preference.

The preference value of the routes programmed for the segment routing LSP is inherited from the **preference value** statement at the **[edit protocols source-packet-routing]** hierarchy level. When this value is not configured, the default preference value of 8 is used.

Range: 0 through 4294967295

The remaining statements are explained separately. See [CLI Explorer](#).

[edit protocols mpls container-label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced for QFX Series switches in Junos OS Release 15.1X53-D30.

Description

Perform splitting and merging.

Options

maximum-member-lsps *number*—Number of label-switched paths (LSPs) that a container LSP can have as member LSPs at maximum.

Default: 1

maximum-signaling-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at maximum after normalization. When **maximum-signaling-bandwidth** is not configured, the value is derived from the **splitting-bandwidth**.

When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the **splitting-bandwidth**.

Default: 1 bps

merging-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that is used for merging during normalization.

Default: 1 bps

minimum-member-lsps *number*—Number of LSPd that a container LSP can have as member LSPs at minimum.

Default: 64

minimum-signaling-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at minimum after normalization. When **minimum-signaling-bandwidth** is not configured, the value is derived from the **merging-bandwidth**.

When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the **merging-bandwidth**.

Default: 1 bps

splitting-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be used for splitting during normalization.

Default: 1 bps

splitting-merging-threshold *percent*—Percentage changes in aggregate bandwidth relevant for splitting and merging.

Default: 0%

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

spring-te (Dynamic Tunnels)

Syntax

```
spring-te {
  destination-networks name;
  source-routing-path-template name {
    (color [ color ... ] | color-any);
  }
}
```

Hierarchy Level

```
[edit routing-options dynamic-tunnels],
```

Release Information

Statement introduced in Junos OS Release 19.2R1 on all platforms.

Description

Enable next hop-base dynamic tunnel mode.

Options

source-routing-path-template *template-name*—Configure template color mapping for segment routing traffic-engineered (SPRING-TE) dynamic LSP parameters.

color—Specify set of color list to be mapped to corresponding SPRING-TE template.

- When enabled, all templates should have color objects defined.
- All destinations are assumed to be colored as well.
- A color can be mapped to only one template at a given point in time.
- Both the **color** and **color-any** statements can coexist. When the two statements are enabled together, preference is given to a specific color template than color-any.
- A colored and non-colored destination cannot co-exist in the same SR-TE configuration.

color-any—Enables mapping of any color to corresponding SPRING-TE template. Only one color-any template can be configured for one SR-TE LSP.

Required Privilege Level

srgb-label-range

Syntax

```
srgb-label-range <range-start> <range-end>
```

Hierarchy Level

```
[edit protocols mpls label-range],  
[edit protocols ospf source-packet-routing srgb]
```

Release Information

Statement introduced in Junos OS Release 19.1 for MX Series routers.

Description

SRGB configured under **mpls label-range** is termed as global SRGB. The MPLS label range is based on the start range and the end range. The value of the start range indicates the start of the label range, and the value of the end range along with the value of the start range indicate the end of the label range.

Options

<range-start> <range-end>—Start range and end range of the global SRGB label block.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

statistics (Protocols MPLS)

Syntax

```
statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
  traffic-class-statistics;
  transit-statistics-polling;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

traffic-class-statistics option introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Enable MPLS statistics collection and reporting.

Options

file *filename*—(Optional) Name of the file to receive the output. We recommend that you place MPLS tracing output in the file `mpls-stat` in the `/var/log` directory.

files *number*—(Optional) Maximum number of trace files. When a trace file named *file* reaches its maximum size, it is renamed *file.0*, then *file.1*, and so on, until the maximum number of files is reached. Then, the oldest file is overwritten.

Range: 2 or more

Default: 2 files

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option.

interval *seconds*—Interval at which to periodically collect statistics.

Range: 1 through 65,535

Default: 300 seconds

no-world-readable—(Optional) Prevent users from reading the log file.

size *size*—(Optional) Maximum size of each file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a file named *file* reaches this size, it is renamed *file.0*. When the *file* again reaches its maximum size, *file.0* is renamed *file.1* and *file* is renamed *file.0*. This renaming scheme continues until the maximum number of files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of files with the **files** option.

world-readable—(Optional) Enable users to read the log file.

Syntax: Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

traffic-class-statistics—(Optional) Create counters that maintain data traffic statistics per traffic class at the ingress of all types of LSPs and egress of ultimate hop popping (UHP) point-to-point LSPs. These counters are not created by default and are required to be configured to perform traffic-class-scoped loss measurement.

transit-statistics-polling—(Optional) Enable the polling and display of MPLS statistics for LSPs transiting the router. By default, RSVP does not periodically poll for transit LSP statistics. You cannot configure this statement and the **no-transit-statistics** statement at the same time.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

swap

Syntax

```
swap out-label;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Remove the label at the top of the label stack and replace it with the specified label. Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. This statement is used to configure static LSPs at transit routers.

Options

out-label—Manually assigned outgoing label value.

Range: 0 through 1,048,575

Default: If you do not define the **out-label** option, the original label value remains unchanged.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

switch-away-lsps

Syntax

```
switch-away-lsps;
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols mpls interface interface-name],  
[edit protocols mpls interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 10.2.

Description

(MX Series routers only) Enable you to switch an LSP away from a network node using a bypass LSP. This feature could be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic. Configure this statement only after you have configured and committed the **always-mark-connection-protection-tlv** statement.

The **always-mark-connection-protection-tlv** statement marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. When you configure the **switch-away-lsps** statement, traffic is switched to the bypass LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the switching method for the LSP. The switching method can be one of the following values:

- **fiber**—Fiber switching
- **lambda**—Lambda switching
- **psc-1**—Packet switching
- **tdm**—Time-division multiplexing (TDM) switching

Default

psc-1

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

sync-active-path-bandwidth

Syntax

```
sync-active-path-bandwidth;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced in Junos OS Release 13.2.

Description

When you have a primary and a secondary path configuration, specify that a path needs to be signaled with the active-path bandwidth when the auto-bandwidth adjustment happens and that the secondary path synchronizes the bandwidth reservations to that of the primary path.

When a primary path fails, bandwidth reservations are made by the secondary path on the links that it uses. If you include the **sync-active-path-bandwidth** statement, the secondary path releases the bandwidth it has reserved and adjusts its bandwidth after the primary path begins carrying traffic.

For example, suppose the active path is a secondary path with a reserved bandwidth of 10 GB as a result of the automatic bandwidth adjustment. Then suppose there is a switchover from the secondary path to the primary path. After some time the primary path reserves 5 GB as a result of a new automatic adjustment. Without the **sync-active-path-bandwidth** statement, the secondary path does not release the 10 GB after a switchover occurs. That bandwidth is wasted. If the **sync-active-path-bandwidth** is included in the configuration, the secondary path adjusts its bandwidth to 5 GB along with the primary path.

Default

When you have a primary and a secondary path configuration, and the primary path fails, bandwidth reservations are made by the secondary path on the links that it uses. When the primary path comes back and the traffic switches over, the secondary path does not release its bandwidth reservations.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

    priority priority;
    traffic-class {
      ctnumber priority priority;
    }
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls diffserv-te],
[edit protocols mpls diffserv-te]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the traffic engineering class matrix for a multiclass LSP or a DiffServ-aware traffic engineering LSP.

Default

The default traffic engineering class matrix is:

```
te-class-matrix {
  te0 traffic-class ct0 priority 7;
  te1 traffic-class ct1 priority 7;
  te2 traffic-class ct2 priority 7;
  te3 traffic-class ct3 priority 7;
  te4 traffic-class ct0 priority 0;
  te5 traffic-class ct1 priority 0;
  te6 traffic-class ct2 priority 0;
  te7 traffic-class ct3 priority 0;
}
```

If you define any of the traffic engineering classes, all the default values are dropped.

Options

ctnumber—Specify the number of the class type. It can be one of four values: **ct0**, **ct1**, **ct2**, or **ct3**.

priority *priority*—Specify the priority of the class type. It can be one of eight values from 0 through 7.

tenumber—Specify the number of the traffic engineering class. It can be one of eight values: **te0**, **te1**, **te2**, **te3**, **te4**, **te5**, **te6**, or **te7**. You must configure the traffic engineering classes in order, starting with **te0**.

traffic-class—Specify the traffic class for the traffic engineering class.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

ted-export option introduced in Junos OS Release 14.2.

ted-import option introduced in Junos OS Release 14.2.

lsp-history option added in Junos OS Release 15.1.

Description

Configure MPLS tracing options at the protocol level or for a label-switched path.

To specify more than one tracing operation, include multiple **flag** statements.

Default

The default MPLS protocol-level tracing options are inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MPLS Tracing Flags

- **all**—Trace all operations
- **autobw-state**—Automatic bandwidth events.
- **connection**—All circuit cross-connect (CCC) activity
- **connection-detail**—Detailed CCC activity
- **cspf**—CSPF computations
- **cspf-link**—Links visited during CSPF computations
- **cspf-node**—Nodes visited during CSPF computations
- **error**—MPLS error packets
- **graceful-restart**—Trace MPLS graceful restart events
- **lsp-history**—Trace LSP history events
- **lsping**—Trace lsping packets and return codes
- **nsr-synchronization**—Trace NSR synchronization events
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail
- **state**—All LSP state transitions
- **static**—Trace static label-switched path
- **ted-export**—Trace leaking of entries from **lsdist.0** table into the traffic engineering database
- **ted-import**—Trace leaking traffic engineering database entries into the **lsdist.0** table
- **timer**—Timer usage

no-world-readable—(Optional) Allow only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

traffic-class (delay)

Syntax

```
traffic-class tc-value {
  average-sample-size sample size;
  padding-size size;
  query-interval milliseconds;
  rtt-delay-threshold rtt threshold value;
  twcd-delay-threshold twcd threshold value;
}
```

Hierarchy Level

```
[edit protocols mpls oam performance-monitoring querier delay],
[edit protocols mpls label-switched-path lsp-name oam performance-monitoring querier delay],
[edit protocols mpls label-switched-path lsp-name primary path-name oam performance-monitoring querier delay],
[edit protocols mpls label-switched-path lsp-name secondary path-name oam performance-monitoring querier delay]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure traffic class specific options.

Specify the traffic classes for which loss measurement has to be performed. This parameter takes one of the *tc-all|tc-0|tc-1|tc-2|tc-3|tc-4|tc-5|tc-6|tc-7|tc-none* traffic-class values. For each traffic class, you can configure the respective parameters.

To enable traffic-class parameters, configure the **traffic-class-statistics** configuration statement under the **[edit protocol mpls statistic]** hierarchy level.

Options

average-sample-size *sample size*—(Optional) Specify the number of samples used for calculating the average of various metrics.

Default: 5

Range: 1 through 30

padding-size *size*—(Optional) Specify the delay-measurement message length, which is used to calculate the delay experienced by messages of different sizes.

Default: 0

Range: 1 through 1500

query-interval *milliseconds*—Specify the minimum transmit interval, which signifies how often the loss measurement message is generated from the querier.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

rtt-delay-threshold *rtt threshold value*—Specify the round-trip delay threshold value.

Range: 1 through 4294967295 microseconds

twcd-delay-threshold *twcd threshold value*—Specify the two-way channel delay threshold value.

Range: 1 through 4294967295 microseconds

Required Privilege Level

[edit protocols mpls label-switched-path lsp-name primary path-name oam performance-monitoring querier loss],
[edit protocols mpls label-switched-path lsp-name secondary path-name oam performance-monitoring querier loss]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure traffic class specific options.

Specify the traffic classes for which loss measurement has to be performed. This parameter takes one of the *tc-all|tc-0|tc-1|tc-2|tc-3|tc-4|tc-5|tc-6|tc-7|tc-none* traffic-class values. For each traffic class, you can configure the respective parameters.

To enable traffic-class parameters, configure the **traffic-class-statistics** configuration statement under the **[edit protocol mpls statistic]** hierarchy level.

Options

average-sample-size *sample size*—(Optional) Specify the number of samples used for calculating the average of various metrics.

Default: 5

Range: 1 through 30

loss-threshold *loss threshold value*—Specify the threshold value that will be used with **loss-threshold-window** to calculate the loss within specified window size.

Range: 1 through 4294967295

loss-threshold-window *number of samples for loss threshold*—Specify the number of samples used for loss threshold calculation.

Range: 1 through 30

measurement-quantity *bytes|packets*—(Optional) Specify whether packet or byte loss is being measured at the querier.

Default: packets

query-interval *milliseconds*—Specify the minimum transmit interval, which signifies how often the loss measurement message is generated from the querier.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure traffic class specific options.

Specify the traffic classes for which loss measurement has to be performed. This parameter takes one of the *tc-all|tc-0|tc-1|tc-2|tc-3|tc-4|tc-5|tc-6|tc-7|tc-none* traffic-class values. For each traffic class, you can configure the respective parameters.

To enable traffic-class parameters, configure the **traffic-class-statistics** configuration statement under the **[edit protocol mpls statistic]** hierarchy level.

Options

average-sample-size *sample size*—(Optional) Specify the number of samples used for calculating the average of various metrics.

Default: 5

Range: 1 through 30

loss-threshold *loss threshold value*—Specify the threshold value that will be used with **loss-threshold-window** to calculate loss within specified window size.

Range: 1 through 4294967295

loss-threshold-window *number of samples for loss threshold*—Specify the number of samples used for loss threshold calculation.

Range: 1 through 30

measurement-quantity *bytes|packets*—(Optional) Specify whether packet or byte loss is being measured at the querier.

Default: packets

padding-size *size*—(Optional) Specify the delay-measurement message length, which is used to calculate the delay experienced by messages of different sizes.

Default: 0

Range: 1 through 1500

query-interval *milliseconds*—Specify the minimum transmit interval, which signifies how often the loss measurement message is generated from the querier.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

rtt-delay-threshold *rtt threshold value*—Specify the round-trip delay threshold value.

Range: 1 through 4294967295 microseconds

twcd-delay-threshold *twcd threshold value*—Specify the two-way channel delay threshold value.

Range: 1 through 4294967295 microseconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traffic-engineering (Protocols MPLS)

Syntax

```
traffic-engineering (bgp | bgp-igp | bgp-igp-both-ribs | mpls-forwarding);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Select whether MPLS performs traffic engineering on BGP destinations only or on both BGP and IGP destinations. Affects only LSPs originating from this routing device, not transit or egress LSPs.

Default

bgp

Options

bgp—On BGP destinations only. Ingress routes are installed in the inet.3 routing table.

bgp-igp—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 routing table. If IGP shortcuts are enabled, the shortcut routes are automatically installed in the inet.0 routing table.

bgp-igp-both-ribs—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 and inet.3 routing tables. This option is used to support VPNs.

mpls-forwarding—On both BGP and IGP destinations. Use ingress routes for forwarding only, not for routing.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

traffic-engineering

Syntax

```
traffic-engineering {
  disable;
}
```

Hierarchy Level

```
[edit protocols ospf | isis]
```

Release Information

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Enable the traffic engineering features of the specified routing protocol.

Default

Traffic engineering is disabled.

Starting in Junos OS release 15.1, traffic engineering is enabled by default whenever the IS-IS protocol is enabled. You can disable it by including the **disable** statement at the **[edit protocols isis traffic-engineering]** hierarchy level. For the EX3300, EX4200, EX4500, EX4550, EX8200 and XRE200, you can disable traffic engineering starting in Junos OS release 15.1R7.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced on QFX5100 switches in Junos OS Release 15.1

Statement introduced on QFX10000 switches in Junos OS Release 17.1.

Description

Enable traffic engineering address family. This generates a multiprotocol address family indicator (AFI) and a subsequent address family identifier (SAFI) to be negotiated with the BGP peers.

The BGP network layer reachability information (NLRI) information is exchanged between the peers only when the traffic engineering AFI and SAFI are shared between them. If the peers do not agree on the use of the AFI and SAFI, the connection between the peers is terminated.

Options

unicast—Include BGP-TE NLRI.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ultimate-hop-popping

Syntax

```
ultimate-hop-popping;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path label-switched-path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

Description

Enable ultimate-hop popping on LSPs. Configure this statement on the device at the LSP ingress. In ultimate-hop popping, the MPLS label is popped from the IP packet at the PE router. The IP address is checked in a second address lookup (also at the PE router), and then the packet is forwarded to its destination.

Be aware of the following platform requirements and restrictions:

- UHP LSPs using VT interfaces—Supported on all M Series, MX Series, T Series, and TX Matrix routers.
- UHP LSPs using LSI interfaces—Supported on MX 3D Series routers only.
- UHP LSP requirements for the egress PE device—For M Series and T Series routers, a VT interface is needed.
- UHP LSPs and Layer 3 VPNs—UHP LSPs are supported for Layer 3 VPNs configured on MX 3D Series routers only.
- UHP LSPs and VPLS—UHP LSPs are supported for VPLS configured on MX 3D Series routers only. You must configure the *no-tunnel-services* statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

Default

Ultimate-hop popping is disabled by default on LSPs. Penultimate-hop popping is the default behavior. In penultimate-hop popping, the final MPLS label is popped from the IP packet at the last provider router in the network before being forwarded to the PE router. The PE router receives the packet and checks the IP address, and then the packet is forwarded to its destination.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

vrf-table-label

Syntax

```
vrf-table-label {  
    source-class-usage;  
    static;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name],  
[edit routing-instances routing-instance-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for the **source-class-usage** statement added in Junos OS Release 9.3.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Statement introduced in Junos OS Release 15.1F5 and 16.1R2 for PTX5000 routers with third-generation FPCs installed.

Statement introduced in Junos OS Release 15.1F6 and 16.1R2 for PTX3000 routers with third-generation FPCs.

Statement introduced in Junos OS Release 16.1X65 and 17.2R1 for PTX1000 routers.

Statement introduced in cRPD Release 19.4R1.

Support for the **static** statement added in Junos OS Release 17.2.

Description

Map the inner label of a packet to a specific VPN routing and forwarding (VRF) instance. This allows the examination of the encapsulated IP header. The first lookup is done on the VPN label to determine which VRF instance to refer to, and the second lookup is done on the IP header to determine how to forward packets to the correct end hosts.

When you include the **vrf-table-label** statement in the configuration of a VRF routing instance, a label-switched interface (LSI) logical interface label is created and mapped to the VRF routing table. Any routes in the VRF routing table are advertised with the LSI logical interface label allocated for the VRF routing table. When packets destined for the VRF routing instance arrive on a core-facing interface, they are treated as if the enclosed IP packet arrived on the LSI interface and are then forwarded and filtered based on the correct table.

All routes in a VRF routing instance configured with this option are advertised with one label allocated per VRF.

NOTE:

- The **vrf-table-label** statement is supported on PTX5000 and PTX3000 routers only when third-generation FPCs are installed on the router and **enhanced-ip** command is configured on the chassis.
- Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability. The **vrf-table-label** space is increased to at least 16,000, if the platform can support the scale.

Options

The remaining statements are explained separately.

Range: 16 through 1,048,575 for static label value.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

admin-group

Syntax

```
admin-group {
  exclude [ group-names ];
  include-all [ group-names ];
  include-any [ group-names ];
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced in Junos OS Release 9.2.

Description

Enable you to configure administrative groups for bypass label-switched paths (LSPs). You can configure administrative groups either globally for all bypass LSPs traversing an interface or for just a specific bypass LSP.

Options

exclude *group-names*—Specify the administrative groups to exclude for a bypass LSP.

include-all *group-names*—Specify the administrative groups whose links the bypass LSP must traverse.

include-any *group-names*—Specify the administrative groups whose links the bypass LSP can traverse.

Required Privilege Level

aggregate (Protocols RSVP)

Syntax

```
(aggregate | no-aggregate);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp peer-interface peer-interface-name],  
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the use of RSVP aggregate messages on an interface or peer interface, as described below.

NOTE: Starting in Junos OS Release 15.2, the **aggregate** statement is deprecated at the **[edit protocols rsvp interface *interface-name*]** and **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]** hierarchy levels, as RSVP message aggregation is enabled by default.

- **aggregate**—Use RSVP aggregate messages.
- **no-aggregate**—Do not use RSVP aggregate messages.

Aggregate messages can pack multiple RSVP messages into a single transmission, thereby reducing network overhead and enhancing efficiency. The number of supportable sessions and processing overhead are significantly improved when aggregation is enabled.

Not all routers connected to a subnet need to support aggregation simultaneously. Each RSVP router negotiates its intention to use aggregate messages on a per-neighbor basis. Only when both routers agree are aggregate messages sent.

To have refresh reduction and reliable delivery, you must include the **aggregate** and **reliable** statements.

Default

Aggregation is enabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

authentication-key (Protocols RSVP)

Syntax

```
authentication-key key;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],
[edit logical-systems logical-system-name protocols rsvp peer-interface peer-interface-name],
[edit protocols rsvp],
[edit protocols rsvp interface interface-name],
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Authentication key (password). Neighboring routers use the password to verify the authenticity of packets sent from this interface or peer interface. To authenticate node hellos or remote messages between the Point of Local Repair (PLR) to the Merge Point (MP), enable **authentication-key** at the **[edit protocols rsvp]** hierarchy level.

RSVP uses HMAC-MD5 authentication, which is defined in RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*.

All routers that are connected to the same IP subnet must use the same authentication scheme and password.

Options

key—Authentication password. It can be 1 through 16 contiguous digits or letters. Separate decimal digits with periods. Separate hexadecimal digits with periods and precede the string with 0x. If you include spaces in the password, enclose the entire password in quotation marks (" ").

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

For certain logical interfaces (such as Asynchronous Transfer Mode [ATM], Permanent Virtual Circuit [PVC], or Frame Relay), you cannot determine the correct bandwidth from the hardware. This statement enables you to specify the actual available bandwidth.

This statement also enables you to specify the bandwidth for a bypass label switched path (LSP). If you have configured multiple bypasses, this statement is mandatory and is applied to all of the bypass LSPs.

Default

The hardware raw bandwidth is used.

Options

bps—Bandwidth in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion [also called a thousand million]).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

bypass (Signaled LSP)

Syntax

```
bypass bypass-name {
  bandwidth bps;
  description text;
  hop-limit number;
  no-cspf;
  path address <strict | loose>;
  priority setup-priority reservation-priority;
  subscription subscription-percentage;
  to address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.

description option was added in Junos OS Release 10.4.

subscription *subscription-percentage* option introduced in Junos OS Release 19.2R1 on all platforms.

Description

Enables you to configure specific bandwidth and path constraints for a bypass LSP. It is possible to individually configure multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.

If you specify the **bandwidth**, **hop-limit**, and **path** statements for the bypass LSP, these values take precedence over the values configured at the **[edit protocols rsvp interface *interface-name* link-protection]** hierarchy level. The other attributes (**subscription**, **no-node-protection**, and **optimize-timer**) are inherited from the general constraints.

Options

bypass-name—(Required) Specify a name for the bypass LSP. The name can be up to 64 characters.

description—Provides a textual description of the bypass LSP. Enclose any descriptive text that includes spaces in quotation marks (" "). Any descriptive text you include is displayed in the output of the **show mpls lsp bypass detail** command and has no effect on the operation of the bypass LSP. The description text can be no more than 80 characters in length.

subscription *subscription-percentage*—(Optional) Specify the subscription percentage per manual bypass LSP. The subscription percentage configured under a particular manual bypass LSP overrides the subscription percentage configured commonly for all manual bypass LSPs under an interface.

Range: 0 through 65000

to *address*—(Required) Specify the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

chained-composite-next-hop

Syntax

```
chained-composite-next-hop {  
    ingress;  
    transit;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table],  
[edit routing-options forwarding-table]
```

NOTE: The [edit logical-systems] hierarchy level is not supported on the QFX10000 switches.

Release Information

Statement introduced in Junos OS Release 12.1.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Statement introduced in Junos OS Release 15.1 for QFX10000 Series switches.

Description

Allows you to configure the chained composite next hops for devices handling ingress or transit traffic in the network.

Chained composite next hops help to facilitate the handling of large volumes of transit traffic in the core of large networks by allowing the router to process much larger volumes of routes. A chained composite next hop allows the router to direct sets of routes sharing the same destination to a common forwarding next hop, rather than having each route also include the destination. In the event that a network destination is changed, rather than having to update all of the routes sharing that destination with the new information, just the shared forwarding next hop is updated with the new information. The chained composite next hops continue to point to this forwarding next hop which now contains the new destination.

On platforms containing only MPCs, such as PTX Series Packet Transport Routers, the MX80 router, the MX2020 router, and the QFX10000 switches, chained composite next hops are enabled by default. On MX Series 5G Universal Routing Platforms containing both DPC and MPC FPCs and on T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default and need to be explicitly configured.

To explicitly configure chained composite next hops, include the **enhanced-ip** statement at the **[edit chassis network-services]** hierarchy level. However, take the following into consideration when enabling the **enhanced-ip** mode:

- Non-service DPCs do not work with enhanced network services mode options. Only MPCs, MS-DPCs, and MS-MPCs provide support for the **enhanced-ip** configuration.
- If you configure chained composite next hops on MX Series routers with both MPCs, and DPCs or DPCEs, the network services mode must be changed from **enhanced-ip** to **ethernet** for the DPC or DPCE to come online.

You can verify the FPC status in such cases, using the **show chassis fpc** command output, where the DPCs and DPCEs are marked as **FPC misconfiguration**.

NOTE:

- When chained composite next hops are enabled on a device, the BGP connections are reset.
- On MX Series routers with DPCs or DPCEs, only the *l3vpn* option is supported under the *ingress* configuration statement; all other configuration options and functionality are not supported.
- The **transit** statement and the associated functionality is supported only on PTX Packet Transport Routers and QFX10000 switches.
- On MX Series routers, removing the **chained-composite-next-hop** statement from a PE device configuration causes all IBGP sessions to be torn down and triggers the BGP session to flap as well. A similar change on a router configured as a route reflector does not have any effect, however.

The following is a sample system log message that is generated to record such an event:

```
Nov  6 15:16:21.670 host PE1: rpd[6947]: bgp_peer_mgmt_clear:5995:
NOTIFICATION sent to 10.0.100.2 (External AS 100): code 6 (Cease) subcode
  4 (Administratively Reset), Reason: Management session cleared BGP
neighbor
```

- Starting with Junos OS Release 17.2, you cannot configure **chained-composite-next-hop ingress l3vpn extended-space** on a logical system.

The remaining statements are explained separately. See [CLI Explorer](#).

Default

This statement is disabled by default.

Options

ingress—Enable or disable composite chained next hop for ingress traffic.

transit—(PTX and QFX10000) Enable or disable composite chained next hop for transit traffic. Starting in Junos OS Release 14.1, the **transit l3vpn** statement is enabled by default on PTX Series Packet Transport Routers only.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

class-of-service (Protocols RSVP)

Syntax

```
class-of-service cos-value;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Class-of-service (CoS) value given to all packets in the bypass LSP. You can specify a single CoS value for all the bypass LSPs traversing an interface. You can also configure CoS values for specific bypass LSPs traversing an interface.

The CoS value might affect the scheduling or queuing algorithm of traffic traveling along an LSP.

Options

cos-value—CoS value. A higher value typically corresponds to a higher level of service.

Range: 0 through 7

Default: If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

devices

Syntax

```
devices device-names;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 8.1.

Description

Specifies one of the virtual tunnel (VT) interfaces to de-encapsulate the egress traffic for ultimate-hop popping on point-to-multipoint LSPs. If no device is specified, the selection process is performed automatically.

Default

The device selection process is performed automatically if no device is configured. Junos OS selects one of the available VT interfaces to de-encapsulate the egress traffic.

Options

device-names—Specify which VT interfaces are used to handle the RSVP traffic.

Range: 0 to 8 devices

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable RSVP or RSVP graceful restart. Explicitly disable link protection on the specified interface.

Default

RSVP is enabled on interfaces and peer interfaces configured with the RSVP **interface** statement. RSVP graceful restart is enabled on the router. Link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

dynamic-bidirectional-transport

Syntax

```
dynamic-bidirectional-transport {  
    template template;  
}
```

Hierarchy Level

```
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Enable the dynamic setup of associated bidirectional packet LSP for transporting non-packet Generalized Multiprotocol Label Switching (GMPLS) label-switched path (LSP).

Options

template *template*—Name of the template for the dynamic bidirectional packet LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

fast-reroute (Protocols RSVP)

Syntax

```
fast-reroute optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement added in Junos OS Release 7.5.

Statement introduced in Junos OS Release 14.1 for the QFX Series.

Description

Configure the optimize timer for fast reroute. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

Options

seconds—Specify the number of seconds between fast reroute detour LSP optimizations.

Range: 0 through 65,535 seconds

Default: 0 (disabled)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

graceful-restart (Protocols RSVP)

Syntax

```
graceful-restart {
  disable;
  helper-disable;
  maximum-helper-recovery-time seconds;
  maximum-helper-restart-time seconds;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit protocols rsvp],
[edit routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure graceful restart on the router. You must configure the **graceful-restart** statement at the **[edit routing-options]** hierarchy level to enable graceful restart on the router.

Options

disable—Disable graceful restart on the router or for RSVP.

helper-disable—Disable RSVP graceful restart helper mode (this option is only available at the **[edit protocols rsvp]** hierarchy level).

Default: Helper mode is enabled by default.

maximum-helper-recovery-time *seconds*—The maximum length of time the router stores the state of neighboring routers when they undergo a graceful restart. The value applies to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

Default: 180 seconds

Range: 1 through 3600 seconds

maximum-helper-restart-time *seconds*—The maximum length of time the router waits between when it discovers that a neighboring router has gone down and when it declares the neighbor down. This value is applied to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

Default: 20 seconds

Range: 1 through 1800 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

hello-acknowledgements

Syntax

```
hello-acknowledgements;
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable hello messages from nonsession neighbors to be acknowledged with a hello acknowledgment message. Once hello acknowledgments are enabled, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or the configuration is changed by an administrator.

Default

Hello acknowledgments are disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

Range: 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)

Default: 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

keep-multiplier

Syntax

```
keep-multiplier number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify a value used by RSVP to calculate timer values for network outages, and declare that a reservation or a neighbor is down. It indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

Starting in Junos OS Release 16.1, for MX Series routers and PTX Series routers, the default RSVP message refresh time, to which this multiplier is applied, has increased from 30 seconds to 20 minutes. The higher message refresh time provides support for RSVP Refresh Reduction Extensions, and improved scaling for MPLS traffic-engineered LSPs, as defined in RFC 2961. The changes are backward compatible so if any nodes in the two-hop neighborhood do not support the higher refresh time, the updated node will automatically fall back to the previous default refresh time to prevent error or tear down messages.

Options

number—Multiplier value.

Range: 1 through 255

Default: 3

NOTE: For MX Series routers and PTX Series routers (running Junos OS release 16.1 or later), this multiplier is applied to a default refresh time of 20 minutes. In earlier Junos OS releases, and for other platforms, the default refresh time remains 30 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

Statement introduced in Junos OS Release 18.2. under the heirarchy level [edit routing-instances *instance-name* provider-tunnel]

Description

Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs. This feature can be used for a number of applications, including point-to-multipoint LSPs, flooding VPLS traffic, configuring ingress replication for IP multicast using MBGP MVPNs, and to enable RSVP automatic mesh. There is no default setting for the **label-switched-path-template** statement, so you must configure either the default-template using the **default-template** option, or you must specify the name of your preconfigured LSP template.

Options

default-template—Specify that the default LSP template be used for the dynamically generated LSPs.

lsp-template-name—Specify the name of an LSP to be used as a template for the dynamically generated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable link protection on the specified interface. Using link protection, you can configure a network to reroute traffic quickly around broken links. To fully enable link protection, you also need to configure the **link-protection** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level. You can configure single or multiple bypasses for protected interface.

Default

Link protection is disabled.

Options

no-node-protection—Disable node-link protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

max-bypasses

Syntax

```
max-bypasses number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],  
[edit protocols rsvp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Range modified in Junos OS Release 9.3.

Description

Specify the maximum number of dynamic bypass LSPs permitted for protecting this interface. When this option is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled. The limit on bypasses configured applies only to dynamically generated bypass LSPs. By default, this option is disabled and only one dynamic bypass LSP is enabled for each interface. If you configure **max-bypasses**, you must also configure the **bandwidth** statement.

Options

number—Configure the maximum number of bypass LSPs. If you configure a value of 0, no dynamic bypass LSPs are allowed to be established for the interface. Only static bypass LSPs can be configured.

Range: 0 through 99

Default: 1

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 10.4.

Description

Disable RSVP local revertive mode as specified in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, **no-local-reversion** is enabled by default, that is, local reversion is not running, and the statement has been deprecated. To enable local reversion, use the **local-reversion** statement.

RSVP local revertive mode is supported on all Juniper Networks routers running Junos OS. It is the default behavior. If you include this statement, the Juniper Networks router uses global revertive mode instead. You might need to disable RSVP local revertive mode on Juniper Networks routers if your network includes equipment that does not support this mode.

The following information can also be found in RFC 4090. Refer to the RFC for additional information. When an LSP fails, the connection can be repaired locally using a traffic protection mechanism such as fast reroute. To restore the LSP to a full working path, RFC 4090 specifies the following strategies:

- Local revertive mode—Upon detecting that the path is restored, the point of local repair (PLR) resignals each of the LSPs that were formerly routed over the restored path. Every LSP successfully resignaled along the restored path is switched back.
- Global revertive mode—The ingress router of each tunnel is responsible for reoptimizing the LSPs that used the failed path. There are several potential reoptimization triggers: RSVP error messages, inspection of OSPF LSAs or IS-IS LSPs, and timers. This re-optimization process can proceed as soon as the failure is detected. It is not tied to the restoration of the failed path.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

node-hello

Syntax

```
(node-hello | no-node-hello);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable node-ID based RSVP hellos globally on all of the RSVP interfaces on the router to allow Juniper Networks routers to interoperate with the equipment of other vendors. By default, the Junos OS uses interface-based RSVP hellos; node-ID based RSVP hellos are disabled. If you have not enabled RSVP node IDs on the router, Junos OS does not accept any node-ID hello packets.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, when using enhanced FRR, node-ID based hellos are enabled by default. Disabling the enhanced fast reroute (FRR) profile by using the **no-enhanced-frr-bypass** command also disables the **node-hello** command. To re-enable node hellos after the enhanced FRR profile has been disabled, use the **node-hello** command.

NOTE: If **link-protection** is enabled, remote node hellos that are initiated by the Point of Local Repair (PLR) to Node Protecting Merge Point (NP-MP) are enabled automatically. Similarly, if **no-enhanced-frr-profile** is enabled (that is, enhanced FRR is off), remote node hellos are automatically disabled. There is no command to explicitly enable or disable remote-node hellos.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-adjacency-down-notification (Protocols IS-IS)

Syntax

```
no-adjacency-down-notification;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols isis interface interface-name],  
[edit protocols isis interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Description

Disable adjacency down notification for IS-IS to allow for migration from IS-IS to OSPF without disruption of the RSVP neighbors and associated RSVP-signaled label-switched paths (LSPs).

Whenever IS-IS is deactivated, the IS-IS adjacencies are brought down. IS-IS signals to RSVP to bring down any RSVP neighbors associated with the IS-IS adjacencies, and this further causes the associated LSPs signaled by RSVP to go down as well.

A similar process occurs whenever OSPF is deactivated. The OSPF neighbors are brought down. OSPF signals to RSVP to bring down any of the RSVP neighbors associated with the OSPF neighbors, and this further causes the associated LSPs signaled by RSVP to go down as well.

If you need to migrate from IS-IS to OSPF or from OSPF to IS-IS, the internal gateway protocol (IGP) notification to RSVP for an adjacency or neighbor down event needs to be ignored. Using the **no-adjacency-down-notification** or **no-neighbor-down-notification** statements, you can disable IS-IS adjacency down notification or OSPF neighbor down notification, respectively, until the migration is complete. The network administrator is responsible for configuring the statements before the migration, and then removing them from the configuration afterward, so that IGP notification can function normally.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-interface-hello

Syntax

```
no-interface-hello;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable RSVP interface hellos globally on the router.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, the behavior of this statement has changed. On these platforms, rather than disabling RSVP interface hellos globally, the **no-interface-hello** command triggers a switch back to the previous profile for all label-switched paths (LSPs.)

This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the [hello-interval](#) statement. This configuration disables RSVP interface hellos globally but enables RSVP interface hellos on the specified interface. This configuration might be necessary in a heterogeneous network where some devices support RSVP node-ID hellos and other devices support RSVP interface hellos.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols ospf area area-id interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Description

Disable neighbor down notification for OSPF to allow for migration from OSPF to IS-IS without disruption of the RSVP neighbors and associated RSVP-signaled LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-node-id-subobject

Syntax

```
no-node-id-subobject;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable the record route object (RRO) node-ID subobject for compatibility with earlier versions of Junos OS.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, the behavior of this statement has changed. On these platforms, rather than disabling the record route object (RRO) node ID sub-object, the **no-node-id-subobject** command triggers a switch back to the previous profile for all label-switched paths (LSPs).

To interoperate with other vendors' equipment, Junos OS supports the RRO node-ID subobject for use in inter-AS link and node protection configurations.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-p2mp-sublsp

Syntax

```
no-p2mp-sublsp;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 9.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Reject Resv messages that include the S2L_SUB_LSP object. By default, Resv messages that include the S2L_SUB_LSP object are accepted. However, in a network which includes Juniper Networks devices running both Junos OS Release 9.2 and later and Junos OS Release 9.1 and earlier, it is necessary to configure the **no-p2mp-sublsp** statement on devices running Junos OS Release 9.2 and later to ensure that point-to-multipoint LSPs function properly.

Default

Resv messages that include the S2L_SUB_LSP object are accepted.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-timer (Protocols RSVP)

Syntax

```
optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],  
[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure an optimize timer for a bypass LSP. The optimize timer initiates a periodic optimization process that reshuffles data LSPs among bypass LSPs to achieve the most efficient use of network resources. The optimization process attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all bypasses, or both.

Options

seconds—Specify the number of seconds between optimizations.

Range: 0 through 65,535 seconds

Default: 0 (disabled)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

path (Protocols RSVP)

Syntax

```
path address <strict | loose>;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure an explicit path (a sequence of strict or loose routes) to control where and how a bypass LSP is established. If multiple bypasses are configured, they all will use the same explicit path.

Default

No path is configured. CSPF automatically calculates the path the bypass LSP takes.

Options

address—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the bypass LSP.

loose—(Optional) The next address in the **path** statement is loose. The LSP can traverse other routers before reaching this router.

Default: **strict**

strict—(Optional) The LSP must go to the next address specified in the **path** statement without traversing other nodes. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

priority (Protocols RSVP)

Syntax

```
priority setup-priority reservation-priority;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],  
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],  
[edit protocols rsvp interface interface-name link-protection],  
[edit protocols rsvp interface interface-name link-protection bypass bypass-name],
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the setup priority and reservation priority for a bypass LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. The session with the lower-hold priority is preempted.

Options

reservation-priority—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 0 (Once the session is set up, no other session can preempt it.)

setup-priority—Setup priority.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 7 (The session cannot preempt any existing sessions.)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable RSVP-level trace options.

Default

The default RSVP-level trace options are those inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

enhanced-frr—(Optional) Enable this option to trace internal events and state changes related to the FRR facility protection enhancements associated with the increased RSVP scaling introduced in Junos OS Release 16.1.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**.

files number—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **all**—All tracing operations
- **error**—All detected error conditions
- **event**—RSVP-related events
- **io-event [detail] [disable]** —Enable tracing of events that occur within the RSVP I/O task; can only be configured for the master routing instance. The trace output is generally independent of routing instance.
- **io-packets [detail] [disable] [receive] [send]** —Enable tracing of messages as they are received from the network or as they are sent out. This flag can be configured independently for each routing instance. Both bundled and individual messages are identified. Use *detail* to show all objects contained in the message. Use *send* and *receive* to limit tracing to outgoing or incoming packets.
- **lmp**—RSVP-LMP interactions
- **packets**—All RSVP packets
- **path**—All path messages
- **pathtear**—PathTear messages
- **resv**—Resv messages
- **resvtear**—ResvTear messages
- **route**—Routing information
- **state**—Session state transitions, including when RSVP-signaled LSPs come up and go down.

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-world-readable—(Optional) Enable only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

[edit routing-instances name protocols mpls static-label-switched-path name],
[edit tenants name routing-instances name protocols mpls static-label-switched-path name]
```

Release Information

Statement introduced in Junos OS Release 10.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

switch option introduced in Junos OS Release 14.1X53-D25.

member-interface option introduced in Junos OS Release 17.4R1 for the MX Series and PTX 5000.

Description

Configure a transit static LSP.

NOTE: When configuring transit static LSPs with label operation as **stitch**, the configured next-hop can only be a valid IP address and not an interface name.

Options

incoming-label—Incoming label value.

Range: 1000000 through 1048575

member-interface—Aggregated Ethernet (AE) member interface name.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

tunnel-services (RSVP)

Syntax

```
tunnel-services {  
    devices device-names;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 8.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable ultimate-hop popping on point-to-multipoint LSPs. The Junos OS selects one of the available virtual tunnel (VT) interfaces to de-encapsulate the egress traffic. By default, the selection process is performed automatically.

Default

Ultimate-hop popping is disabled.

Options

devices *device-names*—Specify which VT interfaces are used to handle the RSVP traffic.

Range: 0 to 8 devices

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ultimate-hop-popping

Syntax

```
ultimate-hop-popping;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path label-switched-path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

Description

Enable ultimate-hop popping on LSPs. Configure this statement on the device at the LSP ingress. In ultimate-hop popping, the MPLS label is popped from the IP packet at the PE router. The IP address is checked in a second address lookup (also at the PE router), and then the packet is forwarded to its destination.

Be aware of the following platform requirements and restrictions:

- UHP LSPs using VT interfaces—Supported on all M Series, MX Series, T Series, and TX Matrix routers.
- UHP LSPs using LSI interfaces—Supported on MX 3D Series routers only.
- UHP LSP requirements for the egress PE device—For M Series and T Series routers, a VT interface is needed.
- UHP LSPs and Layer 3 VPNs—UHP LSPs are supported for Layer 3 VPNs configured on MX 3D Series routers only.
- UHP LSPs and VPLS—UHP LSPs are supported for VPLS configured on MX 3D Series routers only. You must configure the *no-tunnel-services* statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

Default

Ultimate-hop popping is disabled by default on LSPs. Penultimate-hop popping is the default behavior. In penultimate-hop popping, the final MPLS label is popped from the IP packet at the last provider router in the network before being forwarded to the PE router. The PE router receives the packet and checks the IP address, and then the packet is forwarded to its destination.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[explicit-null | 2611](#)

update-threshold

Syntax

```
update-threshold {  
    threshold-percent;  
    threshold-value threshold-value;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],  
[edit protocols rsvp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

threshold-value option introduced in Junos OS Release 19.4R1 on all platforms.

Description

Adjust the threshold at which a change in bandwidth triggers an interior gateway protocol (IGP) update.

Options

threshold-percent—Specify the percentage change in reserved bandwidth to trigger IGP update.

Default: 10 percent

Range: 0.001 through 20 percent

threshold-value *threshold-value*—Specify the change in reserved bandwidth to trigger IGP update. (is capped at 20% of link bandwidth).

If the threshold-value is configured to greater than 20% of bandwidth on that link, the threshold-value is capped at 20% of bandwidth.

For instance, if bandwidth on an interface is 1Gbps, and the **threshold-value** is configured greater than 200Mbps, the **threshold-value** is capped at 200Mbps. The *threshold-percent* is displayed as 20.000% and the **threshold-value** as 200Mbps.

NOTE: The two options, *threshold-percent* and **threshold-value**, are mutually exclusive. You can configure only one option at a given point in time to generate an IGP update for lower bandwidth reservations. As a result, when one option is configured, the other option is calculated and displayed on the CLI.

For instance, on a link of 1Gbps, if the *threshold-percent* is configured to 5%, the **threshold-value** is calculated and displayed as 50Mbps. Similarly, if the **threshold-value** is configured to 50m, then the *threshold-percent* is calculated and displayed as 5%.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

Statement introduced for BGP in Junos OS Release 8.0.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Statement introduced for BMP in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced for BMP in Junos OS Release 13.3.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Configure an authentication algorithm type.

NOTE: Keep the following points in mind when you configure the authentication algorithm in an IPsec proposal:

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, an error occurs and the tunnel is not established in this scenario. For example, if one end of the tunnel contains router 1 configured with the authentication algorithm as hmac-sha-256-128 and the other end of the tunnel contains router 2 configured with the authentication algorithm as hmac-md5-96, the VPN tunnel is not established.
- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, and when one end of the tunnel contains two IPsec proposals to check whether a less secure algorithm is selected or not, an error occurs and the tunnel is not established. For example, if you configure two authentication algorithms for an IPsec proposal as hmac-sha-256-128 and hmac-md5-96 on one end of the tunnel, router 1, and if you configure the algorithm for an IPsec proposal as hmac-md5-96 on the other end of the tunnel, router 2, the tunnel is not established and the number of proposals mismatch.
- When you configure two IPsec proposals at both ends of a tunnel, such as the **authentication-algorithm hmac-sha-256-128** and **authentication-algorithm hmac-md5-96** statements at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level on one of the tunnel, router 1 (with the algorithms in two successive statements to specify the order), and the **authentication-algorithm hmac-md5-96** and **authentication-algorithm hmac-sha-256-128** statements at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level on one of the tunnel, router 2 (with the algorithms in two successive statements to specify the order, which is the reverse order of router 1), the tunnel is established in this combination as expected because the number of proposals is the same on both ends and they contain the same set of algorithms. However, the authentication algorithm selected is hmac-md5-96 and not the stronger algorithm of hmac-sha-256-128. This method of selection of the algorithm occurs because the first matching proposal is selected. Also, for a default proposal, regardless of whether the router supports the Advanced Encryption Standard (AES) encryption algorithm, the 3des-cbc algorithm is chosen and not the aes-cfb algorithm, which is because of the first algorithm in the default proposal being selected. In the sample scenario described here, on router 2, if you reverse the order of the algorithm configuration in the proposal so that it is the same order as the one specified on router 1, hmac-sha-256-128 is selected as the authentication method.
- You must be aware of the order of proposals in an IPsec policy at the time of configuration if you want the matching of proposals to happen in a certain order of preference, such as the strongest algorithm to be considered first when a match is made when both policies from the two peers have a proposal.

Options

algorithm—Specify one of the following types of authentication algorithms:

- **aes-128-cmac-96**—Cipher-based message authentication code (AES128, 96 bits).
- **hmac-sha-1-96**—Hash-based message authentication code (SHA1, 96 bits).
- **md5**—Message digest 5.

Default: **hmac-sha-1-96**

NOTE: The default is not displayed in the output of the **show bgp bmp** command unless a key or key-chain is also configured.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 8.0.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Apply and enable an authentication keychain to the routing device. Note that the referenced key chain must be defined. When configuring the authentication key update mechanism for LDP, you cannot commit the **0.0.0.0/allow** statement with authentication keys or key chains. The CLI issues a warning and fails to commit such configurations.

NOTE: You must also configure an authentication algorithm using the **authentication-algorithm** statement.

Options

key-chain—Authentication keychain name. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Configure session parameters for LDP sessions established with the remote LFA node that are automatically targeted using the loopback addresses. Configure parameters of automatically targeted sessions for remote LFA only.

Options

maximum-sessions *seconds* —Specify the maximum number of auto-targeted LDP sessions allowed. Include this statement to optimize the use of router memory.

Default: 100

Range: 1 through 1000

teardown-delay *seconds* —Specify the minimum time period for which the auto-targeted session must be alive before tearing down the auto-targeted LDP sessions to the remote LFA node. Include this statement to prevent rapid route-resolution in case of temporary change in IGP topology.

Default: 90 seconds

Range: 1 through 300 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable LDP on an interface, or explicitly disable LDP graceful restart.

Default

LDP is enabled on interfaces configured with the LDP **interface** statement. LDP graceful restart is automatically enabled when graceful restart is enabled under the **[edit routing-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

dod-request-policy

Syntax

```
dod-request-policy dod-request-policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 12.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the name of the LDP downstream on demand request policy. The **dod-request-policy** statement performs exact match, as a result, LDP sends label request messages only for those FECs matching in the downstream on demand request policy.

Options

dod-request-policy-name—Specify the name of the downstream on demand request policy.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

downstream-on-demand

Syntax

```
downstream-on-demand;
```

Hierarchy Level

```
[edit logical systems logical-system-name protocols ldp session session-address],  
[edit protocols ldp session session-address]
```

Release Information

Statement introduced in Junos OS Release 12.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable LDP downstream on demand on the LDP session. LDP is widely deployed in downstream unsolicited advertisement mode. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between access and aggregation networks to minimize the workload for the access node (AN) control plane and to avoid the storage of tens of thousands of label bindings from upstream aggregation nodes.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ecmp

Syntax

```
ecmp;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-liveness-detection],  
[edit logical-systems logical-system-name protocols ldp oam fec address bfd-liveness-detection],  
[edit protocols ldp oam bfd-liveness-detection],  
[edit protocols ldp oam fec address bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 8.5.

Statement introduced in Junos OS Release 15.1X53-D30 for QFX Series switches.

Description

Allows LDP to establish BFD sessions for all ECMP paths configured for the specified FEC. If you configure the **ecmp** statement, you must also configure the **periodic-traceroute** statement for the specified FEC. If you do not do so, the commit operation fails. You can configure the **periodic-traceroute** statement at the global hierarchy level ([**edit protocols ldp oam**]) while only configuring the **ecmp** statement for a specific FEC ([**edit protocols ldp oam fec *address* bfd-liveness-detection**]).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

egress-policy

Syntax

```
egress-policy [ policy-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the prefixes advertised into LDP.

Default

Only the loopback address is advertised.

Options

policy-names—Name of one or more routing policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

| [Configuring the Prefixes Advertised into LDP from the Routing Table](#) | 971

explicit-null (Protocols LDP)

Syntax

```
explicit-null;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Advertise label 0 to the egress router of a label-switched path (LSP).

Default

If you do not include the **explicit-null** statement in the MPLS configuration, label 3 (implicit null) is advertised.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

failure-action (Protocols LDP)

Syntax

```
failure-action {  
    remove-nexthop;  
    remove-route;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-livenesss-detection],  
[edit logical-systems logical-system-name protocols ldp oam fec address bfd-livenesss-detection],  
[edit protocols ldp oam bfd-livenesss-detection],  
[edit protocols ldp oam fec address bfd-livenesss-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Configure route and next-hop properties in the event of a BFD session failure event on an LDP LSP. The failure event could be an existing BFD session that has gone down or could be a BFD session that never came up. LDP adds back the route or next hop when the relevant BFD session comes back up.

Options

remove-nexthop—Remove a route corresponding to a next hop of the LSP's route at the ingress node when a BFD session failure event is detected.

remove-route—Remove the route corresponding to an LSP from the appropriate routing tables when a BFD session failure event is detected. If the LSP is configured with ECMP and a BFD session corresponding to any path goes down, the route is removed.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

    exp exp-value;
    fanout fanout-value;
    frequency minutes;
    paths number-of-paths;
    retries retry-attempts;
    source address;
    ttl ttl-value;
    wait seconds;
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols ldp oam],
[edit protocols ldp oam]
```

Release Information

Statement introduced in Junos OS Release 8.5.

Statement introduced in Junos OS Release 12.2 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Allows you to configure BFD for a specific LDP forwarding equivalence class (FEC).

Options

fec-address—Specify the FEC address.

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

graceful-restart (Protocols LDP)

Syntax

```
graceful-restart {  
    disable;  
    helper-disable;  
    maximum-neighbor-recovery-time value;  
    reconnect-time seconds;  
    recovery-time value;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure LDP graceful restart on the LDP master protocol instance or for a specific routing instance.

NOTE: When you alter the graceful restart configuration at either the **[edit routing-options graceful-restart]** or **[edit protocols ldp graceful-restart]** hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp interface
  interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp targeted-hello],
[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for LDP targeted hellos added in Junos OS Release 9.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the LDP timer that regulates how often hello messages are sent. You can control the rate both link hello messages and targeted hello messages are sent depending on the hierarchy level at which you configure the **hello-interval** statement.

Options

seconds—Length of time between transmission of hello packets.

Range: 1 through 65,535 seconds

Default: 5 seconds for link hello messages, 15 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring the LDP Timer for Hello Messages](#) | 934

helper-disable (LDP)

Syntax

```
helper-disable;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp graceful-restart],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp graceful-restart],  
[edit protocols ldp graceful-restart],  
[edit routing-instances routing-instance-name protocols ldp graceful-restart]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable helper mode for LDP graceful restart. When helper mode is disabled, a router cannot help a neighboring router that is attempting to restart LDP.

Default

Helper mode is enabled by default on all routing protocols (including LDP) that support graceful restart.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit protocols ldp oam bfd-livenesss-detection],  
[edit protocols ldp oam fec address bfd-livenesss-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Specify how long the BFD session should be up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

Options

holddown-interval—Number of seconds the BFD session should remain up before adding the route or next hop.

Default: 0 seconds

Range: 0 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for LDP targeted hellos added in Junos OS Release 9.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. You can specify times for both link hello messages and targeted hello messages depending on the hierarchy level at which you configure the **hold-time** statement.

Options

seconds—Hold-time value.

Range: 1 through 65,535 seconds

Default: 15 seconds for link hello messages, 45 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ignore-lsp-metrics

Syntax

```
ignore-lsp-metrics;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ospf traffic-engineering shortcuts],  
[edit protocols ospf traffic-engineering shortcuts]
```

Release Information

Statement introduced in Junos OS Release 7.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Cause OSPF to ignore the RSVP LSP metric.

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This can cause interoperability problems when you configure LDP tunneling over RSVP LSPs in heterogeneous networks.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 9.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

Options

holddown-interval *seconds*—Time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational.

Default: 10 seconds

Range: 10 through 60 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-system logical-system-name protocols ldp oam],  
[edit protocols ldp entropy-label],  
[edit protocols ldp oam]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Statement introduced at the **[edit protocols ldp entropy-label]** hierarchy level in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Configure an LDP ingress policy for either the entropy label or Operation, Administration, and Management (OAM).

For OAM, configure the ingress policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

Options

ingress-policy-names—Specify the names of the ingress policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols]

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

dual-transport statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

family statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

transport-preference option introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description

Enable LDP routing on the router or switch.

You must include the **ldp** statement in the configuration to enable LDP on the router or switch.

Default

LDP is disabled on the router.

Options

transport-preference ipv4 | ipv6— Select the preferred transport for TCP connection when both IPv4 and IPv6 are enabled. If **transport-preference ipv4** is configured, LDP will attempt to establish the TCP connection using IPv4. If **transport-preference ipv6** is configured, LDP will attempt to establish the TCP connection using IPv6.

Default: ipv6

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable LDP traps on the router, logical system, or routing instance.

Options

trap disable—Disable LDP traps.

Default: LDP traps are enabled on the router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

make-before-break (LDP)

Syntax

```
make-before-break {
    timeout seconds;
    switchover-delay seconds;
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Description

Configures make before break (MBB) for multicast LDP (MLDP) link protection to ensure minimum packet loss when attempting to signal a new label-switched path (LSP) before tearing down the old LSP path.

Options

timeout *seconds*—Specify a value to change a make -before-break timeout for point-to-multipoint LSPs.

Even if an MBB acknowledgment is not received for a point-to-multipoint LSP before the specified timeout period expires, the label-switching router (LSR) performs an MBB switchover from the old LSR to the new upstream LSR.

Range: 1 through 300 seconds

Default: 30 seconds

switchover-delay *seconds*—Specify a value to change switchover delay for a point-to-multipoint LSP from the old LSR to the new upstream LSR. If an MBB acknowledgment is received on a point of local repair (PLR) router, the PLR waits for the specified seconds to switch its upstream LSR from the old LSR to the new LSR.

Range: 1 through 300 seconds

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

mapping-server-entry

Syntax

```
mapping-server-entry mapping-server-name {  
    prefix-segment prefix;  
    prefix-segment-range prefix-segment-range-name;  
}
```

Hierarchy Level

```

[edit logical-systems name routing-options source-packet-routing],  
[edit routing-instances name routing-options source-packet-routing],  
[edit routing-options source-packet-routing]
```

Release Information

Statement introduced in Junos OS Release 18.2R1.

Description

Configure an LDP mapping server to enable interoperability between islands of devices supporting only segment routing and only LDP in an LDP network domain.

The mapping server configuration can be included on any device in the segment routing network.

Options

mapping-server-entry-name—Name of the LDP mapping server.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing

maximum-neighbor-recovery-time

Syntax

```
maximum-neighbor-recovery-time seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp graceful-restart],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp graceful-restart],
[edit protocols ldp graceful-restart],

```

Release Information

Statement introduced before Junos OS Release 7.4. Statement changed from **maximum-recovery-time** to **maximum-neighbor-recovery-time** in Junos OS Release 9.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum amount of time to wait before giving up an attempt to gracefully restart.

Options

seconds—Configure the maximum recovery time, in seconds.

Range: 120 through 1800 seconds

Default: 140 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

mldp-inband-signalling (Protocols Multipoint LDP)

Syntax

```
mldp-inband-signalling {
  policy policy-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim],
[edit protocols pim],
```

Release Information

Statement introduced in Junos OS Release 13.2.

Support added in Junos OS Release 18.2R1 for using this command in conjunction with distributed MLD or distributed IGMP.

Description

Multipoint LDP (mLDP) in-band signalling lets you carry multicast traffic across an existing IP/MPLS backbone, while avoiding the use of PIM in the provider core.

On the label-edge router (LER), enable PIM to use mLDP in-band signaling for the upstream neighbors when the LER does not detect a PIM upstream neighbor. On the egress nodes, configure the MPLS LSP root in the PIM configuration, using the **policy** statement.

When used in conjunction with distributed MLD or distributed IGMP, mLDP inband signalling supports interconnecting separate PIM domains via a MPLS-based core. To enable the inter-working, **chassis network-services enhanced-ip** must be enabled and you need to set the **dynamic-profiles profile-name protocols igmp|mld interface interface-name** to **distributed**. Enabling this command, **mldp-inband-signalling**, has PIM act as a multipoint LDP inband edge router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

mofrr-asm-starg (Multicast-Only Fast Reroute in a PIM Domain)

Syntax

```
mofrr-asm-starg;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-options multicast
  stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

Enable **mofrr-asm-starg** to include any-source multicast (ASM) for (*,G) joins in the Multicast-only fast reroute (MoFRR).

NOTE: **mofrr-asm-starg** applies to IP-PIM only. When enabled for group G, *,G will undergo MoFRR as long as there is no S#,G for Group G. In other words, *,G MoFRR will cease and any old states will be torn down when S#,G is created. Note too, that **mofrr-asm-starg** is not supported for mLDP (since mLDP itself does not support *,G).

In a PIM domain with MoFRR enabled, the default for **stream-protection** is S,G routes only.

Context: Multicast-only fast reroute (MoFRR) can be used to reduce traffic loss in a multicast distribution tree in the event of link down. To employ MoFRR, a downstream router is configured with an alternative path back towards the source, over which it receives a backup live stream of the same multicast traffic. That router propagates the same (S,G) join toward both upstream neighbors in order to create duplicate multicast trees. If a failure is detected on the primary tree, the router switches to the backup tree to prevent packet loss.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

When you configure multicast-only fast reroute (MoFRR) in a PIM domain, allow only a disjoint RPF (an RPF on a separate plane) to be selected as the backup RPF path.

In a multipoint LDP MoFRR domain, the same label is shared between parallel links to the same upstream neighbor. This is not the case in a PIM domain, where each link forms a neighbor. The

mofrr-disjoint-upstream-only statement does not allow a backup RPF path to be selected if the path goes to the same upstream neighbor as that of the primary RPF path. This ensures that MoFRR is triggered only on a topology that has multiple RPF upstream neighbors.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

MoFRR is supported on both equal-cost multipath (ECMP) paths and non-ECMP paths. Unicast loop-free alternate (LFA) routes need to be enabled to support MoFRR on non-ECMP paths. LFA routes are enabled with the link-protection statement in the interior gateway protocol (IGP) configuration. When you enable link protection on an OSPF or IS-IS interface, Junos OS creates a backup LFA path to the primary next hop for all destination routes that traverse the protected interface.

In the context of load balancing, MoFRR prioritizes the disjoint backup in favor of load balancing the available paths.

For Junos OS releases before 15.1R7, for both ECMP and Non-ECMP scenarios, the default MoFRR behavior was *sticky*, that is, if the Active link went down, the Active Path selection would give preference to Backup Path for the transition. The Active Path would not follow the unicast selected gateway

Starting in Junos OS Release 15.1R7 however, the default behavior for non-EMCP scenarios is to be *nonsticky*, that is, the selection of Active Path strictly follows unicast selected gateway. MoFRR no longer chooses a unicast LFA path to become the MoFRR Active path; only a unicast LFA path can be selected to become MoFRR Backup.

Default

By default, the backup path gets promoted to be the primary path when MoFRR is configured in a PIM domain.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

neighbor (Protocols LDP)

Syntax

```
neighbor neighbor-address;
```

Hierarchy Level

```
[edit protocols ldp],
```

Release Information

Statement introduced in Junos OS Release 14.2R1 on all platforms.

Description

Configure an LDP targeted neighbor.

LDP sends a targeted hello message to the configured remote neighbor with a targeted request-send-targeted hello message (T) bit set. If the remote neighbor allows receipt of asymmetric hello messages, or if it is configured with the source address as the targeted neighbor, it responds with a targeted hello message. The receipt of a targeted hello message establishes a targeted adjacency with the remote neighbor as described in RFC 5036. Subsequently, a targeted session is established to the remote neighbor.

Options

neighbor-address—IP address of the remote LDP neighbor.

Required Privilege Level

routing

p2mp (Protocols LDP)

Syntax

```
p2mp {
  no-rsvp-tunneling;
  recursive;
  root-address root-address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 11.2.

no-rsvp-tunneling option added in Junos OS Release 16.1R5.

Description

Enable point-to-multipoint MPLS LSPs in an LDP-signaled LSP.

Options

no-rsvp-tunneling—(Optional) Disable LDP point-to-multipoint LSPs from using RSVP-TE LSPs for tunneling, and use LDP paths instead.

NOTE: The **no-rsvp-tunneling** option is introduced in Junos OS Release 16.1R5, 17.3R1, 17.2R2, 16.2R3, and later releases.

Starting in Junos OS Release 12.3R1, Junos OS provides support for Multipoint LDP (M-LDP) for Targeted LDP (T-LDP) sessions with unicast replication, in addition to link sessions. As a result, the default behavior of M-LDP over RSVP tunneling is similar to unicast LDP. However, because T-LDP is chosen over LDP and link sessions to signal point-to-multipoint LSPs, the **no-rsvp-tunneling** option enables LDP natively throughout the network.

recursive—(Optional) Configure point-to-multipoint recursive parameters, including **route**.

root-address *root-address*—(Optional) Specify the root address of the point-to-multipoint LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

policy (Multicast-Only Fast Reroute)

Syntax

```
policy policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-options multicast
stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

When you configure multicast-only fast reroute (MoFRR), apply a routing policy that filters for a restricted set of multicast streams to be affected by your MoFRR configuration. You can apply filters that are based on source or group addresses.

For example:

```
routing-options {
  multicast {
    stream-protection {
      policy mofrr-select;
    }
  }
}
policy-statement mofrr-select {
  term A {
    from {
      source-address-filter 225.1.1.1/32 exact;
    }
    then {
      accept;
    }
  }
  term B {
    from {
```

```

        source-address-filter 226.0.0.0/8 orlonger;
    }
    then {
        accept;
    }
}
term C {
    from {
        source-address-filter 227.1.1.0/24 orlonger;
        source-address-filter 227.4.1.0/24 orlonger;
        source-address-filter 227.16.1.0/24 orlonger;
    }
    then {
        accept;
    }
}
term D {
    from {
        source-address-filter 227.1.1.1/32 exact;
    }
    then {
        reject; #MoFRR disabled
    }
}
term E {
    from {
        route-filter 227.1.1.0/24 orlonger;
    }
    then accept;
}
...
}

```

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

policy (Protocols Multipoint LDP)

Syntax

```
policy policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim mldp-inband-signalling],  
[edit protocols pim mldp-inband-signalling]
```

Release Information

Statement introduced in Junos OS Release 13.2.

Description

Multipoint LDP (M-LDP) in-band signaling enables you to carry multicast traffic across an existing IP/MPLS backbone, while avoiding the use of PIM in the provider core.

On the egress nodes of the point-to-multipoint LSP, specify an M-LDP join translation filter policy where PIM messages are translated into M-LDP FEC bindings. The policy statement is needed when internal BGP (IBGP) is not available in the core site or to override IBGP-based LSP root detection.

The filter policy is configured at the **[edit policy-options]** hierarchy level. The policy generally specifies one or more source-address filters and the point-to-multipoint LDP root IP address using the **p2mp-lsp-root** policy action.

Options

policy-name—Name of a policy configured at the **[edit policy-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

prefix-segment (Routing Options)

Syntax

```
prefix-segment prefix-segment {
    index index;
}
```

Hierarchy Level

```
[edit logical-systems name routing-instances name routing-options source-packet-routing mapping-server-entry],
[edit logical-systems name routing-options source-packet-routing mapping-server-entry],
[edit routing-instances name routing-options source-packet-routing mapping-server-entry],
[edit routing-options source-packet-routing mapping-server-entry]
```

Release Information

Statement introduced in Junos OS Release 18.2R1.

Description

Configure the IP address and index number of the prefix segment for the LDP mapping server.

Options

prefix-segment—IP address of the prefix segment.

index index—Prefix segment index.

Range: 0 through 199999

Required Privilege Level

routing

prefix-segment-range

Syntax

```
prefix-segment-range prefix-segment-range-name {
    attached;
    domain-wide-flooding;
    no-node-segment;
    size size;
    start-index start-index;
    start-prefix start-prefix;
}
```

Hierarchy Level

```
[edit logical-systems name routing-instances name routing-options source-packet-routing mapping-server-entry],
[edit logical-systems name routing-options source-packet-routing mapping-server-entry],
[edit routing-instances name routing-options source-packet-routing mapping-server-entry],
[edit routing-options source-packet-routing mapping-server-entry]
```

Release Information

Statement introduced in Junos OS Release 18.2R1.

attached, **domain-wide-flooding**, and **no-node-segment** options introduced in Junos OS Release 19.1R1.

Description

Configure the prefix segment range for the LDP mapping server.

Options

prefix-segment-range-name—Name of the prefix segment range.

attached—(Optional) Set the flag in IS-IS mapping server advertisement to indicate that the prefixes and SIDs advertised in the SID or Label Binding TLV are directly connected to their originators.

domain-wide-flooding—(Optional) Set an S flag in the IS-IS mapping server advertisement to indicate that the SID or Label Binding TLV is flooded across the entire routing domain.

no-node-segment—(Optional) Clear the node segment flag in the mapping server prefix segment to indicate that the prefix has originated from a single node.

size *size*—Size of prefix segment range.

Range: 1 through 1024

start-index *start-index*—Include start index.

Range: 0 through 199999

start-prefix *start-prefix*—Include start prefix.

Required Privilege Level

- routing—To view this statement in the configuration.
- routing-control—To add this statement to the configuration.

  (mtu-discovery | no-mtu-discovery);
  transport-address transport-address;
}
```

Hierarchy Level

```
[edit logical-systems name protocols ldp],
[edit logical-systems name routing-instances name protocols ldp],
[edit protocols ldp],
[edit routing-instances name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

authentication-algorithm statement introduced in Junos OS Release 7.6.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

transport-address option introduced in Junos OS Release 19.1R1 for all platforms.

Description

Configure LDP session parameters by specifying the session destination address.

Options

session-address—Session destination address.

authentication-algorithm—Authentication algorithm name.

Values:

- **aes-128-cmac-96**—Cipher-based Message Authentication Code (AES128) (96 bits).
- **hmac-sha-1-96**—Hash-based Message Authentication Code (SHA1) (96 bits).
- **md5**—Message Digest 5.

authentication-key—MD5 authentication key.

authentication-key-chain—Key chain name.

downstream-on-demand—Configure downstream on demand label distribution mode.

mtu-discovery—Enable TCP path MTU discovery.

no-mtu-discovery—Disable TCP path MTU discovery.

transport-address *transport-address*—IP address used for TCP sessions to the LDP neighbors that have targeted-LDP adjacencies.

You cannot configure this statement for LDP sessions that have discovered adjacencies.

The transport-address configuration can be rejected at the time of validation, if there is no interface with the configured IP address.

Required Privilege Level

routing

session-group

Syntax

```
session-group name {
  authentication-algorithm (aes-128-cmac-96 | hmac-sha-1-96 | md5);
  authentication-key authentication-key;
  authentication-key-chain authentication-key-chain;
  downstream-on-demand;
  (mtu-discovery | no-mtu-discovery);
  transport-address transport-address;
}
```

Hierarchy Level

```
[edit logical-systems name protocols ldp],
[edit logical-systems name routing-instances name protocols ldp],
[edit protocols ldp],
[edit routing-instances name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 16.1.

transport-address option introduced in Junos OS Release 19.1R1 for all platforms.

Description

Specify the prefix address of the aggregated group of LDP neighbors for the remote end of the LDP session.

The **session-group** statement is useful when an LDP neighbor is dynamic; for instance, in the case of remote loop free alternate (LFA), a targeted or indirect LDP neighbor is automatically picked from any of the nodes in the network.

The **session-group** statement can also be used for configuring authentication for a prefix group, as LDP authentication for all sessions or authentication at the interface level is not supported.

The remaining statements are explained separately. See [CLI Explorer](#).

Options

name—Session destination address or prefix length.

authentication-algorithm—Authentication algorithm name.

Values:

- *aes-128-cmac-96*—Cipher-based Message Authentication Code (AES128) (96 bits)
- *hmac-sha-1-96*—Hash-based Message Authentication Code (SHA1) (96 bits)

- *md5*—Message Digest 5

authentication-key—MD5 authentication key.

authentication-key-chain—Authentication key chain name.

downstream-on-demand—Configure downstream on demand label distribution mode.

mtu-discovery | **no-mtu-discovery**—Enable and disable TCP path MTU discovery, respectively.

transport-address *transport-address*—IP address used for TCP sessions to the LDP neighbors that have targeted-LDP adjacencies, and fall under the same IP subnet.

You cannot configure this statement for LDP sessions that have discovered adjacencies.

The transport-address configuration can be rejected at the time of validation, if there is no interface with the configured IP address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

| [Configuring the TCP MD5 Signature for LDP Sessions](#) | 1118

session-protection

Syntax

```
session-protection {  
    timeout seconds;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Description

Configure when an LDP session is torn down and resignaled after the router stops receiving hello messages from a neighboring router. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished. The LDP session remains up for the duration specified as long as the routers maintain IP network connectivity.

Options

timeout *seconds*—Time in seconds before the LDP session is torn down and resignaled.

Range: 1 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traceoptions (Protocols LDP)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

match-on address option for the **filter** flag modifier added in Junos OS Release 10.4.

nsr-synchronization and **p2mp-nsr-synchronization** operations for **flag** statement introduced in Junos OS Release 13.3.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify LDP protocol-level trace options.

Default

The default LDP protocol-level trace options are inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **ldp-log**. We recommend that you place LDP tracing output in the file **ldp-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **address**—Operation of address and address withdrawal messages
- **binding**—Label-binding operations
- **error**—Error conditions
- **event**—Protocol events
- **initialization**—Operation of initialization messages
- **label**—Operation of label request, label map, label withdrawal, and label release messages
- **notification**—Operation of notification messages
- **nsr-synchronization**— Nonstop active routing synchronization events
- **p2mp-nsr-synchronization**—Point-to-multipoint nonstop active routing synchronization events
- **packets**—Equivalent to setting **address**, **initialization**, **label**, **notification**, and **periodic** flags (see also the **filter** flag modifier)
- **path**—Label-switched path operations
- **periodic**—Operation of hello and keepalive messages
- **route**—Operation of route messages
- **state**—Protocol state transitions

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information.
- **disable**—Disable this trace flag.
- **filter**—Filter to apply to this flag. The **filter** flag modifier can be applied only to the **route**, **path**, and **binding** flags. This flag modifier has the following options:
 - **match-on**—Match on argument specified. The **match-on** option has the following suboptions:
 - **address**—Filter based on the source and destination addresses of packets. Available for the **packets** flag option only.
 - **fec**—Filter based on the FEC associated with the traced object.
 - **policy *policy-name***—Specify the filter policy.
- **receive**—Packets being received.
- **send**—Packets being transmitted.

no-world-readable—(Optional) Prevent all users from reading the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

LDP traffic statistics display the amount of traffic passed through a router for a particular FEC.

Options

file *filename*—Name of the file to receive the output of the LDP statistics operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.

files *number*—(Optional) Maximum number of LDP statistics files. When a statistics file named ***ldp-stat*** reaches its maximum size, it is renamed ***ldp-stat.0***, then ***ldp-stat.1***, and so on, until the maximum number of LDP statistics files is reached. Then the oldest file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you also must include the **size** statement to specify the maximum file size.

interval *seconds*—(Optional) Specify the interval at which the statistics are polled and written to the file.

Default: 300 seconds (5 minutes)

no-penultimate-hop—(Optional) Do not collect traffic statistics on the penultimate hop router.

no-world-readable—(Optional) Prevent all users from reading the log file.

size *size*—(Optional) Maximum size of each statistics file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a statistics file named *ldp-stat* reaches this size, it is renamed *ldp-stat.0*. When *ldp-stat* again reaches this size, *ldp-stat.0* is renamed *ldp-stat.1* and *ldp-stat* is renamed *ldp-stat.0*. This renaming scheme continues until the maximum number of statistics files is reached. Then the oldest statistics file is overwritten.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you also must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable log file access for all users.

[edit protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

address option introduced in Junos OS Release 19.1R1 for all platforms.

Description

Enables you to configure the IP address used to specify the TCP session for the LDP session. Routers must first establish a TCP session between one another before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

Default

router-id

Options

address—Use the specified IP address as the transport address for the LDP session.

interface—Use the first IP address on the interface as the transport address for any LDP sessions to neighbors that can be reached over that interface. You cannot specify the **interface** option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the **router-id** option.

router-id—Use router identifier as the transport address. Unless otherwise configured, the router identifier is the loopback address.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers

(**ethernet**, **vlan-ccc**, and **vlan-tcc** options only).

Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Metro Routers. Only the **atm-ccc-cell-relay** and **atm-ccc-vc-mux** options are supported on ACX Series routers.

Statement introduced in Junos OS Release 17.3R1 for QFX10000 Series switches (**ethernet-ccc** and **vlan-ccc** options only).

Description

Configure a logical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.

Options

atm-ccc-cell-relay—Use ATM cell-relay encapsulation.

atm-ccc-vc-mux—Use ATM virtual circuit (VC) multiplex encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

atm-cisco-nlpid—Use Cisco ATM network layer protocol identifier (NLPID) encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-mlppp-llc—For ATM2 IQ interfaces only, use Multilink Point-to-Point (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a Link Services or Voice Services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.

atm-nlpid—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-ppp-llc—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over AAL5 LLC encapsulation.

atm-ppp-vc-mux—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over ATM AAL5 multiplex encapsulation.

atm-snap—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM subnetwork attachment point (SNAP) encapsulation.

atm-tcc-snap—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.

atm-tcc-vc-mux—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

atm-vc-mux—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

ether-over-atm-llc—(All IP interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) For interfaces that carry IP traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.

ether-vpls-over-atm-llc—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

ether-vpls-over-fr—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, per RFC 2427, *Multiprotocol Interconnect over Frame Relay*.

NOTE: The SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, and the DS3/E3 MIC do not support Ethernet over Frame Relay encapsulation.

ether-vpls-over-ppp—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Point-to-Point Protocol (PPP) encapsulation to support Bridged Ethernet over PPP-encapsulated TDM interfaces for VPLS applications.

ethernet—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

ethernet-ccc—Use Ethernet CCC encapsulation on Ethernet interfaces.

ethernet-vpls—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

ethernet-vpls-fr—Use in a VPLS setup when a CE device is connected to a PE router over a time-division multiplexing (TDM) link. This encapsulation type enables the PE router to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

frame-relay-ether-type—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ether-type-tcc—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ppp—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only.

frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

gre-fragmentation—For adaptive services interfaces only, use GRE fragmentation encapsulation to enable fragmentation of IPv4 packets in GRE tunnels. This encapsulation clears the do not fragment (DF) bit in the packet header. If the packet's size exceeds the tunnel's maximum transmission unit (MTU) value, the packet is fragmented before encapsulation.

multilink-frame-relay-end-to-end—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

multilink-ppp—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

ppp-over-ether—Use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

ppp-over-ether-over-atm-llc—(MX Series routers with MPCs using the ATM MIC with SFP only) For underlying ATM interfaces, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

vlan-bridge—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible-ethernet-services, and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

vlan-ccc—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-vci-ccc—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-tcc—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

vlan-vpls—Use Ethernet VLAN encapsulation on VPLS circuits.

vxlan—Use VXLAN data plane encapsulation for EVPN.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.5.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (**flexible-ethernet-services**, **ethernet-ccc**, and **ethernet-tcc** options only).

Description

For M Series, MX Series, QFX Series, T Series, PTX Series, specify the physical link-layer encapsulation type.

For SRX Series, specify logical link layer encapsulation.

NOTE: Not all encapsulation types are supported on the switches. See the switch CLI.

Default

ppp—Use serial PPP encapsulation.

Physical Interface Options and Logical Interface Options

[Warning: element unresolved in stylesheets: <title> (in <config-options>). This is probably a new element that is not yet supported in the stylesheets.]

Physical Interface Options and Logical Interface Options

For physical interfaces:

NOTE: Frame Relay, ATM, PPP, SONET, and SATSOP options are not supported on EX Series switches.

- **atm-ccc-cell-relay**—Use ATM cell-relay encapsulation.
- **atm-pvc**—Defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. When you configure physical ATM interfaces with ATM PVC encapsulation, an RFC 2684-compliant ATM Adaptation Layer 5 (AAL5) tunnel is set up to route the ATM cells over a Multiprotocol Label Switching (MPLS) path that is typically established between two MPLS-capable routers using the Label Distribution Protocol (LDP).
- **cisco-hdlc**—Use Cisco-compatible High-Level Data Link Control (HDLC) framing. E1, E3, SONET/SDH, T1, and T3 interfaces can use Cisco HDLC encapsulation. Two related versions are supported:
 - CCC version (**cisco-hdlc-ccc**)—The logical interface does not require an encapsulation statement. When you use this encapsulation type, you can configure the **ccc** family only.
 - TCC version (**cisco-hdlc-tcc**)—Similar to CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **cisco-hdlc-ccc**—Use Cisco-compatible HDLC framing on CCC circuits.
- **cisco-hdlc-tcc**—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.
- **ethernet-bridge**—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.
- **ethernet-over-atm**—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.
- **ethernet-tcc**—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.
- **ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.
- **ethernet-vpls-ppp**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.
- **ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.
- **extended-frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC. When you use this encapsulation type, you can configure the **ccc** family only.
- **extended-frame-relay-ether-type-tcc**—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.
- **extended-frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.
- **extended-vlan-bridge**—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.
- **extended-vlan-ccc**—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. Extended VLAN CCC encapsulation supports TPIDs 0x8100, 0x9100, and 0x9901. When you use this encapsulation type, you can configure the **ccc** family only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.
- **extended-vlan-tcc**—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

- **extended-vlan-vpls**—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

- **flexible-ethernet-services**—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and for Gigabit Ethernet interfaces, use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.
- **flexible-frame-relay**—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.
- **frame-relay**—Use Frame Relay encapsulation is defined in RFC 1490, *Multiprotocol Interconnect over Frame Relay*. E1, E3, link services, SONET/SDH, T1, T3, and voice services interfaces can use Frame Relay encapsulation.
- **frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation is same as standard Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to CCC. The logical interface must also have **frame-relay-ccc** encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay. IETF frame relay encapsulation identifies the payload format using NLPID and SNAP formats. Cisco-compatible Frame Relay encapsulation uses the Ethernet type to identify the type of payload.

NOTE: When the encapsulation type is set to Cisco-compatible Frame Relay encapsulation, ensure that the LMI type is set to ANSI or Q933-A.

- **frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. This encapsulation is Cisco-compatible Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to TCC.

- **frame-relay-port-ccc**—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. The connection between the two CE routers can be either user-to-network interface (UNI) or network-to-network interface (NNI); this is completely transparent to the PE routers. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-tcc**—This encapsulation is similar to Frame Relay CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **generic-services**—Use generic services encapsulation for services with a hierarchical scheduler.
- **multilink-frame-relay-uni-nni**—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.
-
- **ppp**—Use serial PPP encapsulation. This encapsulation is defined in RFC 1661, *The Point-to-Point Protocol (PPP) for the Transmission of Multiprotocol Datagrams over Point-to-Point Links*. PPP is the default encapsulation type for physical interfaces. E1, E3, SONET/SDH, T1, and T3 interfaces can use PPP encapsulation.
- **ppp-ccc**—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.
- **ppp-tcc**—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.
- **vlan-ccc**—Use Ethernet VLAN encapsulation on CCC circuits. VLAN CCC encapsulation supports TPID 0x8100 only. When you use this encapsulation type, you can configure the **ccc** family only.
- **vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE:

- Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.
- Starting with Junos OS release 13.3, a commit error occurs when you configure **vlan-vpls** encapsulation on a physical interface and configure **family inet** on one of the logical units. Previously, it was possible to commit this invalid configuration.

For logical interfaces:

- **frame-relay**—Configure a Frame Relay encapsulation when the physical interface has multiple logical units, and the units are either point to point or multipoint.
- **multilink-frame-relay-uni-nni**—Link services interfaces functioning as FRF.16 bundles can use Multilink Frame Relay UNI NNI encapsulation.
- **ppp**—For normal mode (when the device is using only one ISDN B-channel per call). Point-to-Point Protocol is for communication between two computers using a serial interface.
- **ppp-over-ether**—This encapsulation is used for underlying interfaces of pp0 interfaces.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

interface-switch

Syntax

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],
[edit protocols connections]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure Layer 2 switching cross-connects. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

For Layer 2 switching cross-connects to work, you must also configure MPLS.

Options

connection-name—Connection name (up to 128 characters in Junos 12.3 and later).

interface interface-name.unit-number—Interface name. Include the logical portion of the name, which corresponds to the logical unit number.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration

l2circuit-control-passthrough

Syntax

```
l2circuit-control-passthrough;
```

Hierarchy Level

```
[edit forwarding-options]
```

Release Information

Statement introduced in Junos OS Release 19.3R1 for PTX Series routers.

Description

Configure the device to allow LACP, LLDP, OAM LFM, and OAM CFM packets to cross the Layer 2 circuit. If the **l2circuit-control-passthrough** statement is not configured, LACP, LLDP, OAM LFM, and OAM CFM packets are classified as control packets and are not transmitted across the Layer 2 circuit.

NOTE: For MX Series routers, the functionality that the **l2circuit-control-passthrough** command provides is performed automatically.

Default

By default, this statement is not configured.

Required Privilege Level

p2mp-transmit-switch

Syntax

```
p2mp-transmit-switch point-to-multipoint-transmit-switch-name {  
    input-interface interface-name.unit-number;  
    transmit-p2mp-lsp transmitting-point-to-multipoint-lsp;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],  
[edit protocols connections]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the CCC switch for the point-to-multipoint LSP on the ingress PE router.

Options

point-to-multipoint-transmit-switch-name—Point-to-multipoint CCC transmit switch name.

input-interface input-interface-name.unit-number—Specify the name of the interface carrying incoming traffic to be switched to the point-to-multipoint LSP.

transmit-p2mp-lsp transmitting-point-to-multipoint-lsp—Specify the name of the point-to-multipoint LSP carrying traffic to the CCC switch on the egress PE router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],  
[edit protocols connections]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure MPLS LSP tunnel cross-connects.

Options

connection-name—Connection name.

interface interface-name.unit-number—Interface name. Include the logical portion of the name, which corresponds to the logical unit number.

receive-lsp label-switched-path—Name of the LSP from the connection's source.

transmit-lsp label-switched-path—Name of the LSP to the connection's destination.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for the **realm** statement introduced in Junos OS Release 9.2.

Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Disable OSPF, an OSPF interface, or an OSPF virtual link.

By default, control packets sent to the remote end of a virtual link must be forwarded using the default topology. In addition, the transit area path consists only of links that are in the default topology. You can disable a virtual link for a configured topology, but not for a default topology. Include the **disable** statement at the **[edit protocols ospf area *area-id* virtual-link neighbor-id router-id transit-area *area-id* topology *name*]** hierarchy level.

NOTE: If you disable the virtual link by including the **disable** statement at the **[edit protocols ospf area *area-id* virtual-link neighbor-id router-id transit-area *area-id*]** hierarchy level, you disable the virtual link for all topologies, including the default topology. You cannot disable the virtual link only in the default topology.

Default

The configured object is enabled (operational) unless explicitly disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Apply one or more policies to routes being exported from the routing table into BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no routes match the filters, the routing table exports into BGP only the routes that it learned from BGP. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of **metric 500** defined in the next policy.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

hello-dead-interval milliseconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols link-management peer peer-name lmp-protocol],  
[edit protocols link-management peer peer-name lmp-protocol]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Description

Specify how long the Link Management Protocol (LMP) waits before declaring the control channel to be dead. This is an interval during which the router receives no LMP hello packets from the neighbor on a control that is active or up.

Options

milliseconds—Interval to wait before declaring the control channel to be dead.

Range: 500 through 300,000

Default: 500 milliseconds (three times the hello interval)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Apply one or more routing policies to routes being imported into the Junos OS routing table from BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no match is found, BGP places into the routing table only those routes that were learned from BGP routing devices. The policy framework software evaluates the routing policies in a chain sequentially. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of **metric 500** defined in the next policy.

It is also important to understand that in Junos OS, although an import policy (inbound route filter) might reject a route, not use it for traffic forwarding, and not include it in an advertisement to other peers, the router retains these routes as hidden routes. These hidden routes are not available for policy or routing purposes. However, they do occupy memory space on the router. A service provider filtering routes to

control the amount of information being kept in memory and processed by a router might want the router to entirely drop the routes being rejected by the import policy.

Hidden routes can be viewed by using the **show route receive-protocol bgp neighbor-address hidden** command. The hidden routes can then be retained or dropped from the routing table by configuring the **keep all | none** statement at the **[edit protocols bgp]** or **[edit protocols bgp group group-name]** hierarchy level.

The rules of BGP route retention are as follows:

- By default, all routes learned from BGP are retained, except those where the AS path is looped. (The AS path includes the local AS.)
- By configuring the **keep all** statement, all routes learned from BGP are retained, even those with the local AS in the AS path.
- By configuring the **keep none** statement, all routes received are discarded. When this statement is configured and the inbound policy changes, Junos OS re-advertises all the routes advertised by the peer.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

virtual-switch and **layer2-control** options introduced in Junos OS Release 8.4.

Statement introduced in Junos OS Release 9.2 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

mpls-internet-multicast option introduced in Junos OS Release 11.1 for the EX Series, M Series, MX Series, and T Series.

evpn option introduced in Junos OS Release 13.2 for MX 3D Series routers.

evpn option introduced in Junos OS Release 17.3 for the QFX Series.

forwarding option introduced in Junos OS Release 14.2 for the PTX Series.

mpls-forwarding option introduced in Junos OS Release 16.1 for the MX Series.

evpn-vpws option introduced in Junos OS Release 17.1 for MX Series routers.

Support for logical systems on MX Series routers added in Junos OS Release 17.4R1.

Description

Define the type of routing instance.

Options

NOTE: On ACX Series routers, you can configure only the forwarding, virtual router, and VRF routing instances.

type—Can be one of the following:

- **evpn**—(MX 3D Series routers, QFX switches and EX9200 switches)—Enable an Ethernet VPN (EVPN) on the routing instance.
hierarchy level.
- **evpn-vpws**—Enable an Ethernet VPN (EVPN) Virtual Private Wire Service (VPWS) on the routing instance.

- **forwarding**—Provide support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance. Other instances are used for populating RPD learned routes. For this instance type, there is no one-to-one mapping between an interface and a routing instance. All interfaces belong to the default instance inet.0.
- **l2backhaul-vpn**—Provide support for Layer 2 wholesale VLAN packets with no existing corresponding logical interface. When using this instance, the router learns both the outer tag and inner tag of the incoming packets, when the **instance-role** statement is defined as **access**, or the outer VLAN tag only, when the **instance-role** statement is defined as **nni**.
- **l2vpn**—Enable a Layer 2 VPN on the routing instance. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **layer2-control**—(MX Series routers only) Provide support for RSTP or MSTP in customer edge interfaces of a VPLS routing instance. This instance type cannot be used if the customer edge interface is multihomed to two provider edge interfaces. If the customer edge interface is multihomed to two provider edge interfaces, use the default BPDU tunneling.
- **mpls-forwarding**—(MX Series routers only) Allow filtering and translation of route distinguisher (RD) values in IPv4 and IPv6 VPN address families on both routes received and routes sent for selected BGP sessions. In particular, for Inter-AS VPN Option-B networks, this option can prevent the malicious injection of VPN labels from one peer AS boundary router to another.
- **mpls-internet-multicast**—(EX Series, M Series, MX Series, and T Series routers only) Provide support for ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, using MBGP or next-generation MVPN.
- **no-forwarding**—This is the default routing instance. Do not create a corresponding forwarding instance. Use this routing instance type when a separation of routing table information is required. There is no corresponding forwarding table. All routes are installed into the default forwarding table. IS-IS instances are strictly nonforwarding instance types.
- **virtual-router**—Enable a virtual router routing instance. This instance type is similar to a VPN routing and forwarding instance type, but used for non-VPN-related applications. You must configure the **interface** statement for this type of routing instance. You do not need to configure the **route-distinguisher**, **vrf-import**, and **vrf-export** statements.
- **virtual-switch**—(MX Series routers, EX9200 switches, and QFX switches only) Provide support for Layer 2 bridging. Use this routing instance type to isolate a LAN segment with its Spanning Tree Protocol (STP) instance and to separate its VLAN identifier space.

- **vpls**—Enable VPLS on the routing instance. Use this routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **vrf**—VPN routing and forwarding (VRF) instance. Provides support for Layer 3 VPNs, where interface routes for each instance go into the corresponding forwarding table only. Required to create a Layer 3 VPN. Create a VRF table (**instance-name.inet.0**) that contains the routes originating from and destined for a particular Layer 3 VPN. For this instance type, there is a one-to-one mapping between an interface and a routing instance. Each VRF instance corresponds with a forwarding table. Routes on an interface go into the corresponding forwarding table. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for the **realm** statement introduced in Junos OS Release 9.2.

Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Specify how long the routing device waits to receive a link-state acknowledgment packet before retransmitting link-state advertisements (LSAs) to an interface's neighbors.

Options

seconds—Interval to wait.

Range: 1 through 65,535 seconds

Default: 5 seconds

NOTE: You must configure LSA retransmit intervals to be equal to or greater than 3 seconds to avoid triggering a retransmit trap, because Junos OS delays LSA acknowledgments by up to 2 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Support at **[edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]**

hierarchy level introduced in Junos OS Release 11.2.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Support at **[edit routing-instances *routing-instance-name* protocols l2vpn mesh-group *mesh-group-name*]**

hierarchy level introduced in Junos OS Release 13.2.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches.

Statement introduced in cRPD Release 19.4R1.

Description

Specify an identifier attached to a route, enabling you to distinguish to which VPN or virtual private LAN service (VPLS) the route belongs. Each routing instance must have a unique route distinguisher (RD) associated with it. The RD is used to place bounds around a VPN so that the same IP address prefixes can be used in different VPNs without having them overlap. If the instance type is **vrf**, the **route-distinguisher** statement is required.

For Layer 2 VPNs and VPLS, if you configure the **l2vpn-use-bgp-rules** statement, you must configure a unique RD for each PE router participating in the routing instance.

For other types of VPNs, we recommend that you use a unique RD for each provider edge (PE) router participating in specific routing instance. Although you can use the same RD on all PE routers for the same VPN routing instance, if you use a unique RD, you can determine the customer edge (CE) router from which a route originated within the VPN.

For Layer 2 VPNs and VPLSs, if you configure mesh groups, the RD in each mesh group must be unique.

CAUTION: We strongly recommend that if you change an RD that has already been configured, or change the routing-instance type from **virtual-router** to **vrf**, make the change during a maintenance window, as follows:

1. Deactivate the routing instance.
2. Change the RD.
3. Activate the routing instance.

This is not required if you are configuring the RD for the first time.

Options

as-number:number—as-number is an assigned AS number, and **number** is any 2-byte or 4-byte value. The AS number can be from 1 through 4,294,967,295. If the AS number is a 2-byte value, the administrative number is a 4-byte value. If the AS number is 4-byte value, the administrative number is a 2-byte value. An RD consisting of a 4-byte AS number and a 2-byte administrative number is defined as a type 2 RD in RFC 4364 *BGP/MPLS IP VPNs*.

NOTE: In Junos OS Release 9.1 and later, the numeric range for AS numbers is extended to provide BGP support for 4-byte AS numbers, as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*. All releases of Junos OS support 2-byte AS numbers. To configure an RD that includes a 4-byte AS number, append the letter “L” to the end of the AS number. For example, an RD with the 4-byte AS number 7,765,000 and an administrative number of 1,000 is represented as **77765000L:1000**.

In Junos OS Release 9.2 and later, you can also configure a 4-byte AS number using the AS dot notation format of two integer values joined by a period: *<16-bit high-order value in decimal>.<16-bit low-order value in decimal>*. For example, the 4-byte AS number of 65,546 in the plain-number format is represented as 1.10 in AS dot notation format.

ip-address:id—IP address (**ip-address** is a 4-byte value) within your assigned prefix range and a 2-byte value for the **id**. The IP address can be any globally unique unicast address.

Range: 0 through 4,294,967,295 ($2^{32} - 1$). If the router you are configuring is a BGP peer of a router that does not support 4-byte AS numbers, you need to configure a local AS number. For more information, see *Using 4-Byte Autonomous System Numbers in BGP Networks Technology Overview*.

NOTE: For Ethernet VPN (EVPN), an RD that includes zero as the **id** value is reserved for the default EVPN routing instance by default. Because the same RD cannot be assigned for two routing instances, using a **ip-address:id** RD for another routing instance (default-switch), where the **id** value is zero, throws a commit error.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traceoptions (Protocols Link Management)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols link-management],
[edit protocols link-management]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for **hello-packets**, **packets**, and **state** flags added in Junos OS Release 8.1.

Description

Trace options for the LMP protocol.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory `/var/log`.

files number—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel
- **init**—Output from the initialization messages

- **packets**—Trace all packets other than hello packets on any LMP control channel
- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols
- **server**—Server processing operations
- **show**—**show** command servicing operations
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-world-readable—(Optional) Prevent all users from reading the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable log file access for all users.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for the **realm** statement introduced in Junos OS Release 9.2.

Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Set the estimated time required to transmit a link-state update on the interface. When calculating this time, make sure to account for transmission and propagation delays.

You should never have to modify the transit delay time.

Options

seconds—Estimated time, in seconds.

Range: 1 through 65,535 seconds

Default: 1 second

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

upstream-label

Syntax

```
upstream-label {  
  vlan-id vlan-id;  
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Specify the upstream label for the bidirectional label-switched path (LSP).

Options

vlan-id *vlan-id*—VLAN ID to be used for the Generalized MPLS (GMPLS) VLAN LSP at the ingress provider edge (PE) to customer edge (CE) link.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit switch-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches. **auto option** was also added at this time.

auto option added in Junos OS Release 19.1R1 for MX series.

Statement introduced in cRPD Release 19.4R1.

Description

Specify a virtual routing and forwarding (VRF) target community. If you configure the **community** option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. The purpose of the **vrf-target** statement is to simplify the configuration by allowing you to configure most statements at the **[edit routing-instances]** hierarchy level. In effect, this statement configures a single policy for import and a single policy for export to replace the per-VRF policies for every community.

You can still create more complex policies by explicitly configuring VRF import and export policies using the **import** and **export** options.

Options

community—Community name.

auto—Automatically derives the route target (RT). The auto-derived route targets have higher precedence over manually configured RT in vrf-target, vrf-export policies, and vrf-import policies.

NOTE: Auto-derived route targets are supported only in virtual switch and EVPN routing instances.

import community-name—Allowed communities accepted from neighbors.

export community-name—Allowed communities sent to neighbors.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

delegation-cleanup-timeout

Syntax

```
delegation-cleanup-timeout seconds;
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Specify the amount of time (in seconds) that a Path Computation Client (PCC) must wait before returning control of all LSPs to the routing protocol process after a PCEP session with the main active stateful Path Computation Element (PCE) is disconnected.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

Options

seconds—Time (in seconds) that a PCC must wait before returning control of all LSPs to the routing protocol process after a PCEP session with the main active stateful PCE is disconnected.

A value of 0 indicates immediate delegation cleanup.

Range: 0 through 2147483647 seconds

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

delegation-priority

Syntax

```
delegation-priority priority-number;
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Specify the priority number of the active stateful Path Computation Element (PCE). This value is used by the Path Computation Client (PCC) to elect a PCE to delegate LSPs. No two PCEs can have the same delegation-priority value. The PCC elects the PCE with a lower priority as the main active stateful PCE to delegate LSPs.

Options

priority-number—Priority number of the active stateful PCE.

Range: 1 through 65535

Default: 0 (no priority is set)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

label-switched-path-template

Syntax

```
label-switched-path-template {  
    (default-template | lsp-template-name);  
}
```

Hierarchy Level

```
[edit protocols mpls lsp-external-controller lsp-external-controller]
```

Release Information

Statement introduced in Junos OS Release 13.3.

Description

Specify the LSP template with parameters for setting up the PCE-initiated LSPs when the PCE initiating the LSP does not provide the PCE-initiated parameters. When **label-switched-path-template** is not configured, the default LSP parameters are used.

Options

default-template—Specify that the default LSP template be used for the dynamically generated PCE-initiated LSPs.

lsp-template-name—Specify the name of the LSP template to be used for setting up PCE-initiated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Syntax

```
lsp-cleanup-timer seconds;
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]  
[edit protocols pcep pce-group group-id]
```

Release Information

Statement introduced in Junos OS Release 13.3.

Description

Specify the amount of time (in seconds) that the Path Computation Client (PCC) must wait before deleting any non-delegated Path Computation Element (PCE)-initiated LSPs from the failed PCE after a PCEP session terminates.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

Options

seconds—Time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates. Non-delegated PCE-initiated LSPs are deleted immediately.

Range: 0 through 2147483647 seconds

Default: 60

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

lsp-cleanup-timer, **lsp-provisioning**, **max-unknown-requests**, **request-timer**, and **request-priority** options introduced in Junos OS Release 13.3.

authentication-key key, **authentication-key-chain key-chain**, and **p2mp-lsp-report-capability** options introduced in Junos OS Release 16.1.

max-sid-depth and **spring-capability** options introduced in Junos OS Release 17.2.

p2mp-lsp-init-capability and **p2mp-lsp-update-capability** options introduced in Junos OS Release 18.3R1 on all platforms.

pce_traffic_steering option introduced in Junos OS Release 19.4R1 on all platforms.

Description

Configure per-Path Computation Element (PCE) parameters.

Options

pce-id—IP address of the PCE.

authentication-key key—(Optional) Authentication password. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

It is recommended to define and bind an authentication key for securing a PCEP session, as opposed to binding an authentication keychain.

authentication-key-chain key-chain—(Optional) Authentication keychain password. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

local-address ip-address—(Optional) IP address of the local end of the PCEP session, the PCC.

lsp-retry-delegation—(Optional) Enable retry LSP delegation process.

lsp-retry-delegation-timer—(Optional) Specify the amount of time (in seconds) that the Path Computation Client (PCC) must wait before retrying delegation of Path Computation Element (PCE)-initiated LSPs in case of delegation failure or re-delegation.

Default: 3600 seconds

Range: 0 through 4294967294 seconds

max-sid-depth—(Optional) Specify the maximum value for service identifier (SID) depth.

Default: 5

Range: 1 through 5

p2mp-lsp-init-capability—(Optional) Capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable PCE-initiated point-to-multipoint LSPs.

p2mp-lsp-report-capability—(Optional) Capability to report point-to-multipoint RSVP-TE LSPs to a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable reporting of point-to-multipoint LSPs to a PCE.

p2mp-lsp-update-capability—(Optional) Capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable updating of PCE-initiated point-to-multipoint LSPs.

pce_traffic_steering—(Optional) Configure the flow specification capability (also called traffic steering functionality) for enabling the mapping of PCE-initiated point-to-multipoint LSPs to an MVPN routing-instance.

spring-capability—(Optional) Enable SPRING-based provisioning for the PCE.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Configure the path computation element (PCE) type:

- **active**—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegated control over their LSPs to the PCE.
- **stateful**—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update the LSP state. A PCC maintains synchronization with the PCE.

Required Privilege Level

traceoptions (PCE)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag (all | pcep);
  no-remote-trace;
}
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Description

Configure the Path Computation Element Protocol (PCEP) tracing options.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory `/var/log`.

files number—(Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`, then `trace-file.1`, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000 files

Default: 2 files. If you specify a maximum number of files, you must also include the ***size*** statement to specify the maximum file size.

flag—Area of path computation client process (pccd) to enable debugging output.

- **all**—Trace all areas of PCD code.
- **pcep**—Trace Path Computation Element Protocol (PCEP) operations.

no-remote-trace—(Optional) Disable remote tracing options.

no-world-readable—(Optional) Allow only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named `trace-file` reaches this size, it is renamed `trace-file.0`. When the trace-file again reaches this size, `trace-file.0` is renamed `trace-file.1` and `trace-file` is renamed `trace-file.0`. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB.

Range: 10 KB through the maximum file size supported on your system.

Default: 1 MB. If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

traceoptions (Protocols PCEP)

Syntax

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag;
    no-remote-trace;
}
```

Hierarchy Level

[edit protocols pcep]

Description

Configure the Path Computation Element Protocol (PCEP) tracing options.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory `/var/log`.

files number—(Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`, then `trace-file.1`, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000 files

Default: 2 files. If you specify a maximum number of files, you must also include the ***size*** statement to specify the maximum file size.

flag—Area of path computation client process (pccd) to enable debugging output.

PCEP Tracing Flags

- ***all***—Trace all areas of PCCD code
- ***pccd-config***—All configuration parsing operations
- ***pccd-core***—PCCD core operations
- ***pccd-functions***—PCCD function entries and outs
- ***pccd-main***—PCCD main module
- ***pccd-rpd***—PCCD communication with RPD
- ***pccd-ui***—PCCD user interface handling

no-remote-trace—(Optional) Disable remote tracing options.

no-world-readable—(Optional) Allow only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches this size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB.

Range: 10 KB through the maximum file size supported on your system.

Default: 1 MB. If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

| [pcep](#) | [3072](#)

update-rate-limit

Syntax

```
update-rate-limit updates-per-minute;
```

Hierarchy Level

```
[edit protocols pcep]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Specify the number of updates per minute that the Path Computation Client (PCC) can receive at maximum. Updates above this limit are ignored by the PCC.

Options

updates-per-minute—Number of updates per minute that the PCC can receive at maximum.

Range: 1 through 16384

Default: 0 (disabled or no limit)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

clear mpls lsp

List of Syntax

[Syntax on page 3103](#)

[Syntax \(EX and QFX Series Switches\) on page 3103](#)

Syntax

```
clear mpls lsp
<all>
<autobandwidth>
<counters>
<logical-system (all | logical-system-name)>
<name name>
<optimize | optimize-aggressive>
<path regular-expression>
<statistics>
```

Syntax (EX and QFX Series Switches)

```
clear mpls lsp
<all>
<autobandwidth>
<name name>
<optimize | optimize-aggressive>
<path regular-expression>
<statistics>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Release the routes and states associated with MPLS label-switched paths (LSPs), and start new LSPs.

CAUTION: This command disconnects existing Resource Reservation Protocol (RSVP) sessions on the ingress routing device. If there is a time lag between the old path being torn down and the new path being set up, this command might impact traffic traveling along the LSPs.

Options

all—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

autobandwidth—(Optional) Clear LSP autobandwidth counters.

counters—(Optional) Reset the flap and the MBB counters to zero.

logical-system (**all** | **logical-system-name**)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name **name**—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

optimize | **optimize-aggressive**—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

path **regular-expression**—(Optional) Clear the specific LSP path matching the specified regular expression.

statistics—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

Required Privilege Level

clear

Sample Output

```
clear mpls lsp all
```

```
user@host> clear mpls lsp all
```

clear mpls container-lsp

Syntax

```
clear mpls container-lsp
<autobandwidth>
<history>
<logical-system (all | logical-system-name)>
<member>
<name name>
<optimize | optimize-aggressive>
<statistics>
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Release the routes and states associated with MPLS container label-switched paths (LSPs), and start new LSPs.

Options

none—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

autobandwidth—(Optional) Clear LSP autobandwidth counters.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *name*—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

optimize | optimize-aggressive—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

statistics—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

Required Privilege Level

clear

monitor mpls delay rsvp

Syntax

```
monitor mpls delay rsvp lsp-name
<detail>
<count count>
<interval seconds>
<padding-size padding-size>
<traffic-class traffic-class>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Perform an on-demand delay measurement and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the delay measurement is performed.

detail—(Optional) Display detailed output of the LSP delay measurement.

count count—(Optional) Specify the number of delay measurements to be carried out for the MPLS UHP LSP. For LSP delay measurement, the number of queries sent is the specified count number plus one additional query, because the LSP delay is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval seconds—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

padding-size padding-size— (Optional) Specify the length of padding TLV to be included in the query message.

Range: 0 through 1500

traffic-class traffic-class—(Optional) Specify the traffic class for the LSP delay measurement. When the traffic-class value is not specified, the default traffic-class code-point of 111 is used.

Range: 0 though 7

Required Privilege Level

Output Fields

[Table 81 on page 3109](#) describes the output fields for the **monitor mpls delay rsvp** command. Output fields are listed in the approximate order in which they appear.

Table 81: monitor mpls delay rsvp Output Fields

Field Name	Field Description	Level of Output
Current two-way channel delay	Sum of packet delays, excluding the processing time of the remote provider edge (PE) router.	All Levels
Current round-trip-time	Total time taken for completing round-trip of packet.	All Levels
Best two-way channel delay	Best available two-way channel delay count.	All Levels
Worst two-way channel delay	Worst available two-way channel delay count.	All Levels
Average two-way channel delay	Average of the available two-way channel delay counts.	All Levels
Best round-trip-time	Best available round-trip-time count.	All Levels
Worst round-trip-time	Worst available round-trip-time count.	All Levels
Average round-trip-time	Average of the available round-trip-time counts.	All Levels
Average forward delay variation	Average of the variation in forward delay.	All Levels
Average reverse delay variation	Average of the variation in reverse delay.	All Levels

Table 81: monitor mpls delay rsvp Output Fields (continued)

Field Name	Field Description	Level of Output
DM queries sent	Number of queries sent for delay measurement.	All Levels
DM responses received	Number of responses received for delay measurement queries.	All Levels
DM queries timedout	Number of timed out queries sent for delay measurement.	All Levels
DM responses dropped due to errors	Number of loss measurement responses dropped due to errors.	All Levels
Response code	Status of the messages used for delay measurement. Response code can be one of the following: <ul style="list-style-type: none"> • Success—Successful response code. • Failed—Failed response code. 	detail
Querier transmit timestamp	Timestamp on the query message when the message is sent out the ingress PE router (querier). This is done in the hardware before packet is sent out of an interface.	detail
Responder receive timestamp	Timestamp on the response message when the message is received by the egress PE router (responder). This is done in the hardware before packet is received by an interface.	detail
Responder transmit timestamp	Timestamp on the query message when the message is sent out the egress PE router (responder). This is done in the hardware before packet is sent out of an interface.	detail
Querier receive timestamp	Timestamp on the response message when the message is received by the ingress PE router (querier). This is done in the hardware before packet is received by an interface.	detail

monitor mpls loss rsvp

Syntax

```
monitor mpls loss rsvp lsp-name
<detail>
<bytes>
<count count>
<interval seconds>
<traffic-class traffic-class>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Perform an on-demand loss measurement and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the loss measurement is performed.

detail—(Optional) Display detailed output of the LSP loss measurement.

bytes—(Optional) Specify the measurement quantity for the LSP loss measurement as bytes. By default, LSP loss is measured in packets.

NOTE: The byte count of a packet sent or received over a channel counts only the payload, including the total length of that packet and excluding the headers, labels, and framing of the channel itself.

count count—(Optional) Specify the number of loss measurements to be carried out for the MPLS UHP LSP. For LSP loss measurement, the number of queries sent is the specified count number plus one additional query, because the LSP loss is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval seconds—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

traffic-class *traffic-class*—(Optional) Specify the traffic class and enable traffic-class-statistics for the LSP loss measurement.

Range: 0 though 7

Required Privilege Level

Output Fields

[Table 81 on page 3109](#) describes the output fields for the **monitor mpls loss rsvp** command. Output fields are listed in the approximate order in which they appear.

Table 82: monitor mpls loss rsvp Output Fields

Field Name	Field Description	Level of Output
Current forward loss	Difference between the current forward transmit count and the current forward receive count.	All Levels
Current forward loss ratio	Total packet loss (current forward loss divided by current forward transmit count).	All Levels
Current forward throughput	Current forward transmit count divided by 1000.	All Levels
Current reverse loss	Difference between the current reverse transmit count and the current reverse receive count.	All Levels
Current reverse loss ratio	Total packet loss (current reverse loss divided by current reverse transmit count).	All Levels
Current reverse throughput	Current reverse transmit count divided by 1000.	All Levels

Table 82: monitor mpls loss rsvp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Cumulative forward transmit count	Cumulative forward transmit counter value at the time the loss measurement message was originated.	All Levels
Cumulative forward loss	Cumulative forward loss counter value at the time the loss measurement message was originated.	All Levels
Average forward loss ratio	Average packet loss (current forward loss divided by current forward transmit count).	All Levels
Average forward throughput	Average forward transmit count divided by 1000.	All Levels
Cumulative reverse transmit count	Cumulative reverse transmit counter value at the time the loss measurement message was originated.	All Levels
Cumulative reverse loss	Difference between the cumulative reverse transmit count and the cumulative reverse receive count.	All Levels
Average reverse loss ratio	Average packet loss (average reverse loss divided by average reverse transmit count).	All Levels
Average reverse throughput	Average reverse transmit count divided by 1000.	All Levels
LM queries sent	Number of queries sent for loss measurement.	All Levels
LM responses received	Number of responses received for loss measurement queries.	All Levels
LM queries timedout	Number of timed out queries sent for loss measurement.	All Levels
LM responses dropped due to errors	Number of loss measurement responses dropped due to errors.	All Levels
Response code	Status of the messages used for loss measurement. Response code can be one of the following: <ul style="list-style-type: none"> ● Success—Successful response code. ● Failed—Failed response code. 	detail
Origin timestamp	Time and date the loss measurement message is originated without any specific format (NTP and PTP).	detail

Table 82: monitor mpls loss rsvp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Forward transmit count	Forward transmit counter value at the time the loss measurement message was originated.	detail
Forward receive count	Forward receive counter value at the time the loss measurement message was originated.	detail
Reverse transmit count	Reverse transmit counter value at the time the loss measurement message was originated.	detail
Reverse receive count	Reverse receive counter value at the time the loss measurement message was originated.	detail
Current forward transmit count	Difference between the current forward transit count and the previous forward transit count.	detail
Current forward receive count	Difference between the current forward receive count and the previous forward receive count.	detail
Current reverse transmit count	Difference between the current reverse transit count and the previous reverse transit count.	detail
Current reverse receive count	Difference between the current reverse receive count and the previous reverse receive count.	detail

monitor mpls loss-delay rsvp

Syntax

```
monitor mpls loss-delay rsvp lsp-name
<detail>
<bytes>
<count count>
<interval seconds>
<padding-size padding-size>
<traffic-class traffic-class>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Perform a simultaneous on-demand loss and delay measurement using combined loss and delay messages, and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the delay measurement is performed.

detail—(Optional) Display detailed output of the LSP delay measurement.

bytes—(Optional) Specify the measurement quantity for the LSP loss measurement as bytes. By default, LSP loss is measured in packets.

NOTE: The byte count of a packet sent or received over a channel counts only the payload, including the total length of that packet and excluding the headers, labels, and framing of the channel itself.

count count—(Optional) Specify the number of delay measurements to be carried out for the MPLS UHP LSP. For LSP delay measurement, the number of queries sent is the specified count number plus one additional query, because the LSP delay is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval seconds—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

padding-size *padding-size*—(Optional) Specify the length of padding TLV to be included in the query message.

Range: 0 through 1500

traffic-class *traffic-class*—(Optional) Specify the traffic class for the LSP delay measurement. When the traffic-class value is not specified, the default traffic-class code-point of 111 is used.

Range: 0 though 7

Required Privilege Level

ping mpls bgp

Syntax

```
ping mpls bgp fec
<bottom-label-ttl>
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced in Junos OS Release 11.1.

Description

Check the operability of MPLS BGP-signaled label-switched path (LSP) connections. Press Ctrl+c to interrupt a **ping mpls bgp** command.

NOTE: The **ping mpls bgp fec** command only supports single paths.

Options

bottom-label-ttl—(Optional) Time-to-live (TTL) value for the bottom label in the label stack. The range of values is 1 through 255. The default value is **255**.

count count—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

destination address—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp forwarding-class—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping a BGP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance routing-instance-name—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

size bytes—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only BGP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

[ping mpls bgp fec count on page 3127](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with

error codes are not counted in the received packets count. They are accounted for separately. To display the error codes, use the **detail** option (for example, **ping mpls bgp 10.255.245.222 detail**).

Sample Output

ping mpls bgp fec count

user@host> **ping mpls bgp 10.255.245.222 count 10**

```
!!!xxx...x--- lsping statistics ---10 packets transmitted, 3 packets received, 70%  
packet loss 4 packets received with error status, not counted as received.
```

ping mpls lsp-end-point

Syntax

```
ping mpls lsp-end-point prefix-name
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **instance** option was introduced in Junos OS Release 10.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS label-switched path (LSP) endpoint connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

instance *routing-instance-name*—(Optional) Ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP connection.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

prefix-name—LDP forwarding equivalence class (FEC) prefix or RSVP LSP endpoint address.

size bytes—(Optional) Size of the LSP ping request packet. If the endpoint is LDP-based, the minimum size of the packet is **88** bytes. If the endpoint is RSVP-based, the minimum size of the packet is **100** bytes. The maximum size in either case is **65468** bytes.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

<size bytes>
<source source-address>
<sweep>
<v1>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

Description

Check the operability of the MPLS Layer 2 circuit connections. Type Ctrl+c to interrupt a **ping mpls l2circuit** command.

NOTE: This command is not supported on EX4500 and EX4550 switches.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

interface *interface-name*—Ping an interface configured for the Layer 2 circuit on the egress provider edge (PE) router.

logical-system (**all** | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

reply-mode—(Optional) Reply mode for the ping request. This option has the following suboptions:

application-level-control-channel—Reply using an application level control channel.

ip-udp—Reply using an IPv4 or IPv6 UDP packet.

no-reply—Do not reply to the ping request.

NOTE: The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

size bytes—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

v1—(Optional) Use the type 9 Layer 2 circuit type, length, and value (TLV).

virtual-circuit virtual-circuit-id neighbor address—Ping the virtual circuit identifier on the egress PE router or switch and the specified neighbor, testing the integrity of the Layer 2 circuit between the ingress and egress PE routers or switches.

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

ping mpls l2vpn

Syntax

```
ping mpls l2vpn (instance instance-name local-site-id local-site-id-number remote-site-id remote-site-id-number |
  interface interface-name)
<bottom-label-ttl>
<count count>
<destination address>
<detail>
<exp forwarding-class>
<logical-system (all | logical-system-name)>
reply-mode (application-level-control-channel | ip-udp | no-reply)
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

Description

Check the operability of MPLS Layer 2 virtual private network (VPN) connections. Type Ctrl+c to interrupt a **ping mpls l2vpn** command.

Options

bottom-label-ttl—(Optional) Display the time-to-live value for the bottom label in the label stack.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

instance *instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number*—Ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, testing the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the ingress and egress provider edge (PE) routers or switches.

interface *interface-name*—Ping an interface configured for the Layer 2 VPN on the egress PE router or switch.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

reply-mode—(Optional) Reply mode for the ping request. This option has the following suboptions:

application-level-control-channel—Reply using an application level control channel.

ip-udp—Reply using an IPv4 or IPv6 UDP packet.

no-reply—Do not reply to the ping request.

The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Check the operability of a MPLS Layer 3 virtual private network (VPN) connection. Type Ctrl+c to interrupt a **ping mpls l3vpn** command.

Options

bottom-label-ttl—(Optional) Display the time-to-live value for the bottom label in the label stack.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

l3vpn-name—(Optional) Layer 3 VPN name.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

prefix *prefix-name*—Ping to test whether a prefix is present in a provider edge (PE) router's or switch's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix. This option does not test the connection between a PE router or switch and a customer edge (CE) router or switch.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

If the Layer 3 VPN traffic transits a route reflector within the network, the **ping mpls l3vpn** command does not work.

Syntax

```
request mpls lsp adjust-autobandwidth
<logical-system (all | logical-system-name)>
<name lsp-name>
```

Syntax (EX and QFX Series Switches)

```
request mpls lsp adjust-autobandwidth
<name lsp-name>
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Manually trigger a bandwidth allocation adjustment for active label-switched paths (LSPs).

Without running this command, the bandwidth adjustment is recomputed at a configurable interval. The default interval is 5 minutes. If you do not want to wait for the periodic adjustment (for example, during a software demonstration), this command is useful.

During bandwidth allocation adjustment, the LSP stays up to enable the bandwidth to be changed without dropping any traffic. This functionality is often referred to as *make-before-break*.

Options

none—Manually trigger a bandwidth allocation adjustment for all active LSP paths.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Manually trigger a bandwidth allocation adjustment on the specified LSP only.

Additional Information

For this command to work properly, the following conditions must exist:

- Automatic bandwidth allocation must be enabled on the LSP. The parameters for adjustment interval and maximum average bandwidth are not reset after you issue the **request mpls lsp adjust-autobandwidth** command.
- The difference between the adjusted bandwidth and the current LSP path bandwidth must be greater than the threshold limit.

Required Privilege Level

clear, maintenance

Output Fields

[Table 84 on page 3149](#) lists the output fields for the **show dynamic-tunnels database** command. Output fields are listed in the approximate order in which they appear.

Table 84: show dynamic-tunnels database Output Fields

Field Name	Field Description
Table	Name of the routing table (for example, inet.0).
Destination-network	Destination IP address and subnet.
Tunnel to	Destination IP address and prefix of the tunnel.
State	State of the tunnel: Up , Up (expires in <i>nn:nn:nn</i>seconds) , or Dn (down).
Reference count	Number of routes across the dynamic tunnel that are currently being resolved.
Next-hop type	Type of tunnel: GRE or UDP (BGP-Signal). <ul style="list-style-type: none"> • GRE or UDP (BGP signal) • SRTE—Segment routing traffic-engineered LSP.
Source address	Source IP address of the tunnel.
Next-hop	IP address of the destination interface.
VPN Label	The label provided by the peer device to identify the VPN through which the packet needs to go. This label is used to identify the VRF for route lookup.
Ingress Route	The IGP route along with the corresponding metric that has been selected for forwarding the tunnel-encapsulated packet.
Localized PFE	Packet Forwarding Engine interface which is the anchor Packet Forwarding Engine for the localized next-hop-based dynamic tunnels. When the anchor Packet Forwarding Engine of the tunnel goes down, it is represented by a # near the Packet Forwarding Engine name.
LSP template name	Name of the segment routing traffic-engineered template configured for dynamic creation of segment routing LSPs.
State	State of the destination interface: Up , Dn , or Dn (no tunnel pic) .
Status	Status of the dynamic segment routing LSP.

Field Name	Field Description
Control address	Address to which a control channel is established.
CC local ID	Identifier assigned to the control channel by the local peer. The range of values is 1 through 4,294,967,296 .
CC remote ID	Identifier assigned to the control channel by the remote peer. The range of values is 1 through 4,294,967,296 .
State	State of the control channel: Up or Down .
TxSeqNum	Sequence number of the hello message being sent to the peer. The range of values is 1 through 4,294,967,295 .
RcvSeqNum	Sequence number of the last hello message received from the peer. The range of values is 0 through 4,294,967,295 .
Flags	Code that provides information about the control channel. Currently supports only code value R , which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts.
TE links	Traffic-engineered links that are managed by their peer.
TE link name	Name of the traffic-engineered link.
State	State of the traffic-engineered link: Up , Down , or Init .
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include SDH/SONET , Ethernet , Packet , and PDH .
Switching	Type of switching that can be performed on the traffic-engineered link. Supported values are PSC-1 and Packet .

Table 85: show link-management Output Fields (*continued*)

Field Name	Field Description
Minimum bandwidth	Smallest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link (in bps).
Maximum bandwidth	Largest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).
Total bandwidth	Sum of the bandwidth, in bits per second (bps) and megabits per second (Mbps), of all interfaces that are members of the link.
Available bandwidth	Sum of the bandwidths of all interfaces that are members of the link and that are not yet allocated (in bps).
Name	Name of the interface.
State	State of the interface: Up or Down .
Local ID	Identifier of the local side of the interface.
Remote ID	Identifier of the remote side of the interface.
Bandwidth	Bandwidth, in bps or Mbps, of the member interface.
Used	Whether the resource is allocated to an LSP: Yes or No .
LSP-name	LSP name.

Sample Output

show link-management

user@host> **show link-management**

```

Peer name: PEER-A, System identifier: 11973
State: Up, Control address: 10.255.245.4

Output Fields

[Table 86 on page 3157](#) describes the output fields for the **show link-management peer** command. Output fields are listed in the approximate order in which they appear.

Table 86: show link-management peer Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is 0 through 64,000.

Table 86: show link-management peer Output Fields (*continued*)

Field Name	Field Description
State	State of the peer: Up or Down .
Control address	Address to which a control channel is established.
Hello interval	How often the routing device sends Link Management Protocol (LMP) hello packets.
Hello dead interval	How long LMP waits before declaring the control channel to be dead. This is an interval during which the routing device receives no LMP hello packets from the neighbor on a control that is active or up.
CC local ID	Identifier assigned to the control channel by the local peer. The range of values is 1 through 4,294,967,296 .
CC remote ID	Identifier assigned to the control channel by the remote peer. The range of values is 1 through 4,294,967,296 .
State	State of the control channel: Up or Down .
TxSeqNum	Sequence number of the hello message being sent to the peer. The range of values is 1 through 4,294,967,295 .
RcvSeqNum	Sequence number of the last hello message received from the peer. The range of values is 0 through 4,294,967,295 .
Flags	Code that provides information about the control channel. Currently supports only code value R , which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts.
TE links	Traffic-engineered links that are managed by their peer.

Sample Output

show link-management peer

Output Fields

[Table 87 on page 3161](#) describes the output fields for the **show link-management routing** command. Output fields are listed in the approximate order in which they appear.

Table 87: show link-management routing Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is 0 through 64,000.
State	State of the peer: Up or Down .
Control address	Address to which a control channel is established.
Control channel	Interface over which control packets are sent.
State	State of the control channel.
TE link name	Traffic-engineered link name.
State	State of the traffic-engineered link: Up or Down .
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include SDH/SONET , Ethernet , and Packet .
Minimum bandwidth	Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link.
Maximum bandwidth	Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).
Total bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link.
Available bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.
Resource	Forwarding adjacency LSP information.

Table 87: show link-management routing Output Fields (*continued*)

Field Name	Field Description
Type	Type of resource. The type is always a forwarding adjacency LSP.
State	State of the LSP: Up or Down .
System Identifier	Internal identifier for the peer. The range of values is 0 through 64,000 .
Total bandwidth	Bandwidth resource, in bps or Mbps, on the TE-link learned from the routing process.
Traffic parameters	<ul style="list-style-type: none"> • Encoding—Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include SDH/SONET, Ethernet, and Packet. • Switching—Type of switching that can be performed on the traffic-engineered link: PSC-1 and Packet. • Granularity—Layer 2 data for switching Layer 2 LSPs for this resource. Not supported. This value is always unknown.

Output Fields

[Table 88 on page 3164](#) describes the output fields for the **show link-management statistics** command. Output fields are listed in the approximate order in which they appear.

Table 88: show link-management statistics Output Fields

Field Name	Field Description
Received packets	Number of received packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.

Table 88: show link-management statistics Output Fields (*continued*)

Field Name	Field Description
Received bad packets	Number of received bad packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Small packets	Number of packets that are too small.
Wrong protocol version	Number of packets specifying the wrong LMP version.
Messages for unknown peer	Number of packets destined for an unknown peer.
Messages for bad state	Number of packets indicating a state that does not match the recipient.
Stale acknowledgments	Number of configAck and LinkSummaryAck packets received that have a stale message ID.
Stale negative acknowledgments	Number of configNack and LinkSummaryNack packets received that have a stale message ID.
Sent packets	Number of sent packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Retransmitted packets	Number of retransmitted packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Dropped packets	Number of packets sent, by message type, that have been dropped by the receiver after the LMP retransmission interval has been exceeded. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.

show mpls association

Syntax

```
show mpls association (iif incoming-interface | oif outgoing-interface)
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 16.1 for the M Series, MX Series, and T Series.

Description

Display the Multiprotocol Label Switching (MPLS) label-switched paths (LSPs) based on the association with an incoming or outgoing LSP interface. The command output displays the list of RSVP-TE LSPs carrying traffic in and out of the same interface.

Options

iif *incoming-interface-name*—Display list of RSVP-TE LSPs that share the specified incoming interface to bring in traffic. This option works on transit label-switching routers (LSRs) and egress label edge routers (LERs).

oif *outgoing-interface-name*—Display list of RSVP-TE LSPs that share the specified outgoing interface to carry out traffic. This option works on ingress LERs and transit LSRs.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display Multiprotocol Label Switching (MPLS) label-switched path (LSP) call admission control (CAC) information.

Options

none—Display CAC information for all LSPs.

instance *instance-name*—(Optional) Display MPLS LSP CAC information for the specified instance. If *instance-name* is omitted, MPLS LSP CAC information for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-name—(Optional) Display CAC information for the specified LSP only.

Additional Information

The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by any Layer 2 connection at that class type.

Field Name	Field Description
Available bandwidth	Current available bandwidth on each LSP path. Depending on whether the LSP is an E-LSP or a regular LSP, either per-class bandwidth or a single bandwidth value (corresponding to best-effort bandwidth at ct0) is displayed. The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by some Layer 2 connections at that class type.
Layer2 connections	Different Layer 2 connections that had some bandwidth requirement and were admitted into an LSP path.
LSP name	LSP pathname.
Neighbor address	Neighbor address from which CAC and bandwidth booking are configured for Layer 2 circuits.
Circuit	Interface name and circuit information.
Primary	LSP's primary standby path.
Standby	LSP's secondary standby path.
VC bandwidth	Bandwidth constraints associated with a Layer 2 circuit route.

Sample Output

```

Release Information

Command introduced in Junos OS Release 14.2.

Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Display information about configured and active Multiprotocol Label Switching (MPLS) container label-switched paths (LSPs).

Options

none—Display standard information about all configured and active member LSPs of the container LSP.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

count-active-routes—(Optional) Show active routes for the container LSP.

defaults—(Optional) Display the default settings of the container LSP.

descriptions—(Optional) Display the container LSP descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls container-lsp]** hierarchy level. Only the LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

egress—(Optional) Display the LSPs ending at this device.

NOTE: The **egress** option displays all the LSPs including regular LSPs, members of container LSPs, and transit LSPs. This is an expected behavior for all platforms.

- ingress**—(Optional) Display the member LSPs originating from this device.
- logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.
- name *name***—(Optional) Display information about the specified LSP or group of LSPs.
- statistics**—(Optional) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.
- transit**—(Optional) Display LSPs transiting this routing device.
- unidirectional**—(Optional) Display unidirectional LSP information.

Output Fields

[Table 94 on page 3180](#) describes the output fields for the **show mpls container-lsp** command. Output fields are listed in the approximate order in which they appear.

Table 94: show mpls container-lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSP	Information about the member LSPs on the ingress routing device. Each LSP has one line of output.	All levels

Table 94: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Container LSP name	Name of the container LSP.	All levels
Member LSP count	Number of member LSPs in the container LSP.	All levels
To	Destination (egress routing device) of the session.	brief
From	Source (ingress routing device) of the session.	brief detail
State	State of the LSP handled by this RSVP session: <ul style="list-style-type: none"> • Up • Dn (down) • Restart 	brief detail
Rt	Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
P	Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.	brief
ActivePath	(Ingress LSP) Name of the active path: Primary or Secondary.	detail extensive
LSPname	Name of the member LSP.	brief detail
Egress LSP	Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output.	All levels
Transit LSP	Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
Min LSPs	Minimum number of member LSPs. Default: 1	extensive
Max LSPs	Number of member LSPs that the container LSP can have at maximum. Default: 64 (due to ECMP limit)	extensive

Table 94: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Aggregate bandwidth	Sum of the bandwidths of all member LSPs.	extensive
NormalizeTimer	Duration between two normalization events. When not configured, 21600 seconds (6 hours) is set as the default value.	extensive
NormalizeThreshold	Change in aggregate LSP utilization to trigger splitting or merging expressed in percentage.	extensive
Max Signaling BW	Maximum bandwidth used to signal LSPs after a normalization event. Default value is 0 bps. When not configured, the value is inherited from the splitting bandwidth configuration. NOTE: Between two normalization events, when auto-bandwidth adjustment happens, the per-LSP auto-bandwidth configuration and thresholds are used, instead of the maximum signaling bandwidth threshold.	extensive
Min Signaling BW	Minimum bandwidth used to signal LSPs after a normalization event. Default value is 0 bps. When not configured, the value is inherited from the merging bandwidth configuration. NOTE: Between two normalization events, when auto-bandwidth adjustment happens, the per-LSP auto-bandwidth configuration and thresholds are used, instead of the minimum signaling bandwidth threshold.	extensive
Splitting BW	Bandwidth used for LSP splitting and merging. Default value is 0 bps. When not configured, the value is inherited from the auto-bandwidth maximum bandwidth configuration.	extensive
Merging BW	Bandwidth used for LSP splitting and merging. Default value is 0 bps. When not configured, the value is inherited from the auto-bandwidth minimum bandwidth configuration.	extensive
LSPtype		extensive
LoadBalance		extensive
MinBW	Minimum LSP bandwidth in bps related to auto-bandwidth.	extensive

Table 94: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
AdjustTimer	Total amount of time in seconds allowed before LSP bandwidth adjustment take place. Range: 300 through 315360000 seconds	extensive
Max AvgBW util	Current value of the actual maximum average bandwidth utilization in bps.	extensive
Overflow limit	Threshold overflow limit.	extensive
Underflow limit	Threshold underflow limit.	extensive
Encoding type		extensive
Switching type		extensive
GPID		extensive
Priorities	Setup priority and hold priority values. For setup priority, 0 and 7 is the highest and lowest priority, respectively. When not explicitly configured, 7 and 0 are set as the default values for the setup priority and hold priority, respectively.	extensive
Bandwidth		extensive
SmartOptimizeTimer	Time in seconds allowed before path reoptimization.	extensive
Computed ERO	Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	extensive

Table 94: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Received RRO	<p>Received record route.</p> <p>RRO is a series of hops, each with an address followed by a flag. In most cases, the received RRO is the same as the computed ERO. If the received RRO is different from the computed ERO, there is a topology change in the network, and the route is taking a detour.</p> <p>The following flags identify the protection capability and status of the downstream node:</p> <ul style="list-style-type: none"> • 0x01—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding path message. • 0x02—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously). • 0x03—Combination of 0x01 and 0x02. • 0x04—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section. • 0x08—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the local protection available bit is set but the node protection bit is cleared. • 0x09—Detour is established. Combination of 0x01 and 0x08. • 0x10—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted. • 0x20—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently. • 0xb—Detour is in use. Combination of 0x01, 0x02, and 0x08. 	extensive
Make-before-break		extensive
Record Route		extensive

Table 94: show mpls container-lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Automatic Autobw adjustment succeeded		extensive
CSPF		extensive
Created	Date and time the LSP was created.	extensive

show mpls correlation label

Syntax

```
show mpls correlation label label-value  
<brief | detail | extensive | terse>  
<descriptions>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 15.2 for the M Series, MX Series, and T Series.

Description

Display the correlation information for the Multiprotocol Label Switching (MPLS) label-switched path (LSP) with the owner of the label.

Options

label-value—Display information about the specified label.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

descriptions—(Optional) Display the LSP descriptions. To view this information, you must configure the description statement at the [**edit protocol mpls lsp**] hierarchy level. Only the LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

logical-system (all | logical-system-name)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 97 on page 3195](#) describes the output fields for the **show mpls cspf** command. Output fields are listed in the approximate order in which they appear.

Table 97: show mpls cspf Output Fields

Field Name	Field Description
Queue length	Number of LSPs queued for automatic path computation.
current	Current queue length.
maximum	Maximum queue length (high-water mark).
dequeued	Number of aborted computation attempts.
Paths	Counters for label-switched path computations.
total	Sum of the next four fields.
successful	Number of path computations that were successfully completed.
no route	Number of path computations that failed because the destination is unreachable.
Sys Error	Number of path computations that failed because of lack of memory.
CSPFs	Total number of CSPF computations. A single path might require multiple CSPF computations.
Time	Time, in seconds, required to perform the label-switched path computation.
Total	Total amount of time consumed by the CSPF path computation algorithm.
CSPFs	Total number of CSPF computations.
Avg per CSPF	Average amount of time required for each CSPF computation.
% of rpd	Percentage of routing process CPU used in the CSPF computation.

Sample Output

show mpls interface

Syntax

```
show mpls interface
```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about MPLS-enabled interfaces. MPLS is enabled on an interface when the interface is configured with both the **set protocols mpls interface *interface-name*** and **set interfaces *interface-name* unit 0 family mpls** commands.

Required Privilege Level

view

Output Fields

[Table 99 on page 3199](#) describes the output fields for the **show mpls interface** command. Output fields are listed in the approximate order in which they appear.

Table 99: show mpls interface Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: Up or Dn (down).
Administrative groups	Administratively assigned colors of the link.

Sample Output

show mpls interface

user@switch> **show mpls interface**

Interface	State	Administrative groups
so-1/0/0.0	Up	Blue Yellow Red

show mpls egress-protection

Syntax

```
show mpls egress-protection  
<brief | detail>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 11.4R3.

Description

Display information about egress protection.

NOTE: Use this command on the device configured as the protector PE router to display information about egress protection. If you use this command on the device configured as the primary PE router, no output is displayed.

Options

none—Display standard information about egress protection.

brief | detail—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 95 on page 3189 describes the output fields for the **show mpls egress-protection detail** command. Output fields are listed in the approximate order in which they appear.

Table 100: show mpls lsp Output Fields

Field Name	Field Description
Instance	Indicates egress instance name
Type	Indicates type of the VRF. It can be either local-vrf or remote-vrf
RIB	Indicates the edge-protection created routing table
Context-Id	Indicates the context-ID associated with the RIB.
Interface/Enhanced-lookup	<p>Show VT interfaces associated with the backup RIB.</p> <p>Shows Enhanced-lookup for MX Series 5G Universal Routing Platforms with the Enhanced IP Network Services mode configured using the network-services enhanced-ip statement at the [edit chassis] hierarchy level.</p>

Sample Output

show mpls egress-protection detail (Centralized Protector)

```
user@host> show mpls egress-protection detail
```

Instance	Type	Protection-Type
rsite1	remote-vrf	Protector
RIB __99.99.1.4-rsite1__.inet.0, Context-Id 99.99.1.4, Enhanced-lookup		
Route Target 1:1		
rsite24	remote-vrf	Protector
RIB __99.99.1.4-rsite24__.inet.0, Context-Id 99.99.1.4, Enhanced-lookup		
Route Target 100:1023		

Sample Output

show mpls egress-protection detail (Collocated Protector)

```
user@host> show mpls egress-protection detail
```

```
Instance          Type      Protection-Type
site2             local-vrf  Protector
  RIB __66.6.6.6-site2__.inet.0, Context-Id 66.6.6.6, Interface vt-1/3/0.87031809

  Route Target 100:251
site12            local-vrf  Protector

[show mpls interface on page 3206](#)

Output Fields

Table 101 on page 3205 describes the output fields for the **show mpls interface** command. Output fields are listed in the approximate order in which they appear.

Table 101: show mpls interface Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: Up or Dn (down).
Administrative groups	Administratively assigned colors of the link.
Maximum labels	Maximum number of MPLS labels upon which MPLS can operate on a logical interface. This is configured using the maximum-labels statement at the [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] or the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] hierarchy levels.
Static protection revert time	Time (in seconds) that a static LSP must wait before traffic reverts from the bypass path to the original path. This is configured using the protection-revert-time statement at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels.
Always mark connection protection tlv	Enabled or Disabled : Enabled indicates that the always-mark-connection-protection-tlv statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. When this statement is configured, it marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, the switch-away-lsps statement must be configured.

Table 101: show mpls interface Output Fields (*continued*)

Field Name	Field Description
Switch away lsps	Enabled or Disabled : Enabled indicates that the switch-away-lsps statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. This enables you to switch an LSP away from a network node using a bypass LSP. This feature can be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.

Sample Output

show mpls interface

user@host> show mpls interface

```
Interface: ge-0/2/1.57
  State: Up
  Administrative group: <none>
  Maximum labels: 5
  Static protection revert time: 5 seconds
  Always mark connection protection tlv: Disabled
  Switch away lsps : Disabled
```

show mpls label usage

Syntax

```
show mpls label usage
<label label value>
<label-range range-start range-end>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 15.1.

Support for the **label** statement added in Junos OS Release 17.2.

Support for the **label-range** statement added in Junos OS Release 17.2.

Description

Show the available label space resource in RPD and also the applications that use the label space in RPD. There are four different label spaces currently used in MPLS—namely LSI, dynamic, block, and static. Each label space has a fixed number and cannot grow beyond the fixed value. Using this command, the administrator can monitor the available labels in each label space and the applications that are using the labels. Based on the availability of labels, the administrator can decide to stop any service and free some labels or use other service where the labels are available.

Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability.

When you set each member router's network services to **enhanced-ip**, only MPC or Modular Interface Cards (MICs) modules and Multiservices Dense Port Concentrator (MS-DPC) modules are powered on in the chassis. Non-service DPCs do not work with enhanced IP network services.

Options

none— Display the available labels in each label space and the applications using the labels.

label *label value*—(Optional) Display the information about which *label value* is used by which protocol, if any.

label-range *range-start range-end* —(Optional) Display the complete information about the **label-range** specified. With the **enhanced-ip** command enabled on the supported device, effective ranges and configured ranges along with details of different label spaces such as LSI, dynamic, block, and static types are displayed.

logical-system (*all* | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

Once the label space crosses the threshold, a new syslog message is added.

<label-space-name> label space usage crossed threshold limit of 90%.

For instance, LSI label space usage crossed threshold limit of 90%.

Required Privilege Level

List of Sample Output

[show mpls label usage on page 3208](#)

Output Fields

[Table 102 on page 3208](#) describes the output fields for the **show mpls label usage** command. Output fields are listed in the order in which they appear.

Table 102: show mpls label usage Fields

Field Name	Field Description
Label Space	Indicates the different types of labels currently used in MPLS.
Total	Indicates the total label space available.
Available	Indicates the number of freely available labels and also the percentage of the label space available.
Applications	Indicates the applications that use the MPLS label spaces.
Effective Ranges	Indicates actual ranges in use, which can be different from configured ranges, if conflicting with label already allocated.
Configured Ranges	Indicates the currently configured range assigned to different label spaces on the device.

Sample Output

show mpls label usage

user@host> **show mpls label usage**

Label space	Total	Available	Applications
LSI	999984	999971 (100.00%)	BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label			

```

Block          999984  999971 (100.00%) BGP/LDP VPLS with tunnel-services, BGP L2VPN
Dynamic        999984  999971 (100.00%) RSVP, LDP, PW, L3VPN, RSVP-P2MP, LDP-P2MP,
MVPN, EVPN, BGP
Static         48576   48576  (100.00%) Static LSP, Static PW

```

With **enhanced-ip** enabled on the supported device, you get the following additional output.

user@host> **show mpls label usage**

```

Label space Total    Available      Applications
LSI          996983  996983 (100.00%) BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label
Block        996983  996983 (100.00%) BGP/LDP VPLS with tunnel-services, BGP L2VPN

SRGB        1000    2999    OSPF
SRGB        3000    4000    GLOBAL

```

user@host> **show mpls label usage label 101**

```

Label 101 is used by protocol BGP

```

user@host> **show mpls label usage label 102**

```

Label 102 is used by protocol LDP

```

user@host> **show mpls label usage label 103**

Label 103 is not allocated to any protocol

show mpls label usage label-range

Syntax

```
show mpls label usage label-range
<block-label-range range-start range-end>
<dynamic-label-range range-start range-end>
<label-limit label-limit value>
<lsi-label-range range-start range-end>
<static-label-range range-start range-end>
```

Release Information

Command introduced in Junos OS Release 17.2.

Description

There are four different label spaces currently used in MPLS—namely LSI, dynamic, block, and static. Each label space has a fixed number and cannot grow beyond the fixed value. Using **show mpls label usage label-range** command, the administrator can monitor the available labels in each label space and the applications that are using the labels. Based on the availability of labels, the administrator can decide to stop any service and free some labels or use other service where the labels are available.

Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability.

When you set each member router's network services to **enhanced-ip**, only MPC or Modular Interface Cards (MICs) modules and Multiservices Dense Port Concentrator (MS-DPC) modules are powered on in the chassis. Non-service DPCs do not work with enhanced IP network services.

Options

block-label-range range-start range-end—Display the details of block label type.

dynamic-label-range range-start range-end —Display the details of dynamic label type.

label-limit label-limit value—Limit for the number of concurrent active labels.

lsi-label-range range-start range-end—Display the details of LSI label type.

static-label-range range-start range-end—Display the details of static label type.

Release Information

Command introduced before Junos OS Release 7.4.

defaults option added in Junos OS Release 8.5.

Command introduced in Junos OS Release 9.5 for EX Series switches.

autobandwidth option added in Junos OS Release 11.4.

externally-controlled option added in Junos OS Release 12.3.

externally-provisioned option added in Junos OS Release 13.3.

Command introduced in Junos OS Release 13.2X51-D15 for QFX Series.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display information about configured and active dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all configured and active dynamic MPLS LSPs.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

In the extensive command output, the duplicate back-to-back messages are recorded as aggregated messages. An additional timestamp is included for these aggregated messages, where if the aggregated messages are five or less, timestamp deltas are recorded for each message, and if the aggregated messages are greater than five, the first and last timestamp is recorded.

For example:

- All timestamps

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route [3
times - 13:21:00, 13:22:01, 13:23:10]
```

- Timestamp deltas

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route [3
times - 13:21:00, +1:01, +2:10]
```

- First and last timestamp

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route [6
times - 13:21:00, 13:23:10]
```

abstract-computation—(Optional) Display abstract computation preprocessing for LSPs.

See [show mpls lsp abstract-computation](#) for more details.

autobandwidth—(Optional) Display automatic bandwidth information. This option is explained separately (see [show mpls lsp autobandwidth](#)).

bidirectional | unidirectional—(Optional) Display bidirectional or unidirectional LSP information, respectively.

bypass—(Optional) Display LSPs used for protecting other LSPs.

count-active-routes—(Optional) Display active routes for LSPs.

defaults—(Optional) Display the MPLS LSP default settings.

descriptions—(Optional) Display the MPLS label-switched path (LSP) descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls lsp]** hierarchy level. Only LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

externally-controlled—(Optional) Display the LSPs that are under the control of an external Path Computation Element (PCE).

externally-provisioned—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

instance *instance-name*—(Optional) Display MPLS LSP information for the specified instance. If *instance-name* is omitted, MPLS LSP information is displayed for the master instance.

locally-provisioned—(Optional) Display LSPs that have been provisioned locally by the Path Computation Client (PCC).

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **egress**—Sessions that terminate on this routing device.
- **ingress**—Sessions that originate from this routing device.

- **pop-and-forward**—Sessions that originate from RSVP-TE pop-and-forward LSP tunnels.
- **transit**—Sessions that pass through this routing device.

name *name*—(Optional) Display information about the specified LSP or group of LSPs.

p2mp—(Optional) Display information about point-to-multipoint LSPs.

reverse-statistics—(Optional) Display packet statistics for reverse direction of LSPs.

segment—(Optional) Display segment identifier (SID) labels.

statistics—(Optional) (Ingress and transit routers only) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

NOTE: If a bypass LSP is configured for the primary static LSP, display cumulative statistics of packets traversing through the protected LSP and bypass LSP when traffic is re-optimized when the protected LSP link is restored. (Bypass LSPs are not supported on QFX Series switches.)

When used with the **bypass** option (**show mpls lsp bypass statistics**), display statistics for the traffic that flows only through the bypass LSP.

transit—(Optional) Display LSPs transiting this routing device.

Output Fields

Table 104 on page 3218 describes the output fields for the **show mpls lsp** command. Output fields are listed in the approximate order in which they appear.

Table 104: show mpls lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSP	Information about LSPs on the ingress routing device. Each session has one line of output.	All levels
Egress LSP	Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output.	All levels
Transit LSP	Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
P2MP name	Name of the point-to-multipoint LSP. Dynamically generated P2MP LSPs used for VPLS flooding use dynamically generated P2MP LSP names. The name uses the format <i>identifier:vppls:router-id:routing-instance-name</i> . The <i>identifier</i> is automatically generated by Junos OS.	All levels
P2MP branch count	Number of destination LSPs the point-to-multipoint LSP is transmitting to.	All levels
P	An asterisk (*) under this heading indicates that the LSP is a primary path.	All levels
address	(detail and extensive) Destination (egress routing device) of the LSP.	detail extensive
To	Destination (egress routing device) of the session.	brief
From	Source (ingress routing device) of the session.	brief detail
State	State of the LSP handled by this RSVP session: Up , Dn (down), or Restart .	brief detail

Table 104: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Active Route	Number of active routes (prefixes) installed in the forwarding table. For ingress LSPs, the forwarding table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (mpls.0).	detail extensive
Rt	Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
P	Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.	brief
ActivePath	(Ingress LSP) Name of the active path: Primary or Secondary .	detail extensive
LSPname	Name of the LSP.	brief detail
Statistics	Displays the number of packets and the number of bytes transmitted over the LSP. These counters are reset to zero whenever the LSP path is optimized (for example, during an automatic bandwidth allocation).	extensive
Aggregate statistics	Displays the number of packets and the number of bytes transmitted over the LSP. These counters continue to iterate even if the LSP path is optimized. You can reset these counters to zero using the clear mpls lsp statistics command.	extensive
Packets	Displays the number of packets transmitted over the LSP.	brief extensive
Bytes	Displays the number of bytes transmitted over the LSP.	brief extensive
DiffServeInfo	Type of LSP: multiclass LSP (multiclass diffServ-TE LSP) or Differentiated-Services-aware traffic engineering LSP (diffServ-TE LSP).	detail
LSPtype	Type of LSP: <ul style="list-style-type: none"> • Static configured—Static • Dynamic configured—Dynamic • Externally controlled—External path computing entity Also indicates if the LSP is a Penultimate hop popping LSP or an Ultimate hop popping LSP.	detail extensive

Table 104: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Bypass	(Bypass LSP) Destination address (egress routing device) for the bypass LSP.	All levels
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. LSPpath can be either primary or secondary and can be displayed on the ingress, egress, and transit routing devices.	detail
Bidir	(GMPLS) The LSP allows data to travel in both directions between GMPLS devices.	All levels
Bidirectional	(GMPLS) The LSP allows data to travel both ways between GMPLS devices.	All levels
FastReroute desired	Fast reroute has been requested by the ingress routing device.	detail
Link protection desired	Link protection has been requested by the ingress routing device.	detail
Node/Link protection desired	Link protection has been requested by the ingress routing device.	detail
LSP Control Status	<p>(Ingress LSP) LSP control mode:</p> <ul style="list-style-type: none"> • External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP. • Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control. <p>A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.</p>	extensive

Table 104: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
External Path CSPF status	(PCE-controlled LSPs) Status of the PCE-controlled LSP with per path attributes: <ul style="list-style-type: none"> • Local • External 	extensive
Externally Computed ERO	(PCE-controlled LSPs) Externally computed explicit route when the route object is not null or empty. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	extensive
EXTCTRL_LSP	(PCE-controlled LSPs) Display path history including the bandwidth, priority, and metric values received from the external controller.	extensive
flap counter	Counts the number of times a LSP flaps down or up.	extensive
LoadBalance	(Ingress LSP) CSPF load-balancing rule that was configured to select the LSP's path among equal-cost paths: Most-fill , Least-fill , or Random .	detail extensive
Signal type	Signal type for GMPLS LSPs. The signal type determines the peak data rate for the LSP: DS0 , DS3 , STS-1 , STM-1 , or STM-4 .	All levels
Encoding type	LSP encoding type: Packet , Ethernet , PDH , SDH/SONET , Lambda , or Fiber .	All levels
Switching type	Type of switching on the links needed for the LSP: Fiber , Lambda , Packet , TDM , or PSC-1 .	All levels
GPID	Generalized Payload Identifier (identifier of the payload carried by an LSP): HDLC , Ethernet , IPv4 , PPP , or Unknown .	All levels
Protection	Configured protection capability desired for the LSP: Extra , Enhanced , none , One plus one , One to one , or Shared .	All levels
Upstream label in	(Bidirectional LSPs) Incoming label for reverse direction traffic for this LSP.	All levels
Upstream label out	(Bidirectional LSPs) Outgoing label for reverse direction traffic for this LSP.	All levels
Suggested label received	(Bidirectional LSPs) Label the upstream interface suggests to use in the Resv message that is sent.	All levels

Table 104: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Suggested label sent	(Bidirectional LSPs) Label the downstream node suggests to use in the Resv message that is returned.	All levels
Autobandwidth	(Ingress LSP) The LSP is performing autobandwidth allocation.	detail extensive
Mbb counter	Counts the number of times a LSP incurs MBB.	extensive
MinBW	(Ingress LSP) Configured minimum value of the LSP, in bps.	detail extensive
MaxBW	(Ingress LSP) Configured maximum value of the LSP, in bps.	detail extensive
Dynamic MinBW	(Ingress LSP) Displays the current dynamically specified minimum bandwidth allocation for the LSP, in bps.	detail extensive
Dynamic MinBW	(Ingress LSP) Displays the current dynamically specified minimum bandwidth allocation for the LSP, in bps.	detail extensive
AdjustTimer	(Ingress LSP) Configured value for the adjust-timer statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.	detail extensive
Adjustment Threshold	(Ingress LSP) Configured value for the adjust-threshold statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization.	detail extensive
Time for Next Adjustment	(Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.	detail extensive
Time of Last Adjustment	(Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.	detail extensive
MaxAvgBW util	(Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps.	detail extensive
Overflow limit	(Ingress LSP) Configured value of the threshold overflow limit.	detail extensive
Overflow sample count	(Ingress LSP) Current value for the overflow sample count.	detail extensive

Table 104: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Bandwidth Adjustment in <i>nnn</i> second(s)	(Ingress LSP) Current value of the bandwidth adjustment timer, indicating the amount of time remaining until the bandwidth adjustment will take place, in seconds.	detail extensive
Underflow limit	(Ingress LSP) Configured value of the threshold underflow limit.	detail extensive
Underflow sample count	(Ingress LSP) Current value for the underflow sample count.	detail extensive
Underflow Max AvgBW	(Ingress LSP) The highest sample bandwidth among the underflow samples recorded currently. This is the signaling bandwidth if an adjustment occurs because of an underflow.	detail extensive
Active path indicator	(Ingress LSP) A value of * indicates that the path is active. The absence of * indicates that the path is not active. In the following example, "long" is the active path. *Primary long Standby short	detail extensive
Primary	(Ingress LSP) Name of the primary path.	detail extensive
Secondary	(Ingress LSP) Name of the secondary path.	detail extensive
Standby	(Ingress LSP) Name of the path in standby mode.	detail extensive
State	(Ingress LSP) State of the path: Up or Dn (down).	detail extensive
COS	(Ingress LSP) Class-of-service value.	detail extensive
Bandwidth per class	(Ingress LSP) Active bandwidth for the LSP path for each MPLS class type, in bps.	detail extensive
Priorities	(Ingress LSP) Configured value of the setup priority and the hold priority respectively (the setup priority is displayed first), where 0 is the highest priority and 7 is the lowest priority. If you have not explicitly configured these values, the default values are displayed (7 for the setup priority and 0 for the hold priority).	detail extensive
OptimizeTimer	(Ingress LSP) Configured value of the optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.	detail extensive

Table 104: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
SmartOptimizeTimer	(Ingress LSP) Configured value of the smart optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.	detail extensive
Reoptimization in xxx seconds	(Ingress LSP) Current value of the optimize timer, indicating the amount of time remaining until the path will be reoptimized, in seconds.	detail extensive
Computed ERO (S [L] denotes strict [loose] hops)	(Ingress LSP) Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	detail extensive
CSPF metric	(Ingress LSP) Constrained Shortest Path First metric for this path.	detail extensive

Table 104: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Received RRO	<p>(Ingress LSP) Received record route. A series of hops, each with an address followed by a flag. (In most cases, the received record route is the same as the computed explicit route. If Received RRO is different from Computed ERO, there is a topology change in the network, and the route is taking a detour.) The following flags identify the protection capability and status of the downstream node:</p> <ul style="list-style-type: none"> • 0x01—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the Local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding Path message. • 0x02—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously). • 0x03—Combination of 0x01 and 0x02. • 0x04—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section. • 0x08—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the Local protection available bit is set but the Node protection bit is cleared. • 0x09—Detour is established. Combination of 0x01 and 0x08. • 0x10—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted. • 0x20—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently. • 0xb—Detour is in use. Combination of 0x01, 0x02, and 0x08. 	detail extensive
Labels	<p>Labels of pop-and-forward LSP tunnel:</p> <ul style="list-style-type: none"> • P—Pop labels. • D—Delegation labels. 	extensive
Index number	(Ingress LSP) Log entry number of each LSP path event. The numbers are in chronological descending order, with a maximum of 50 index numbers displayed.	extensive

Table 104: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Date	(Ingress LSP) Date of the LSP event.	extensive
Time	(Ingress LSP) Time of the LSP event.	extensive
Event	(Ingress LSP) Description of the LSP event.	extensive
Created	(Ingress LSP) Date and time the LSP was created.	extensive
Resv style	(Bypass) RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	brief detail extensive
Labelin	Incoming label for this LSP.	brief detail
Labelout	Outgoing label for this LSP.	brief detail
LSPname	Name of the LSP.	brief detail
Time left	Number of seconds remaining in the lifetime of the reservation.	detail
Since	Date and time when the RSVP session was initiated.	detail
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	detail
Port number	Protocol ID and sender or receiver port used in this RSVP session.	detail
PATH rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this router, and number of packets received from the upstream neighbor.	detail
PATH sentto	Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor, and number of packets sent to the downstream routing device.	detail
RESV rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor. The output in this field, which is consistent with that in the PATH rcvfrom field, indicates that the RSVP negotiation is complete.	detail

Table 104: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Record route	Recorded route for the session, taken from the record route object.	detail
Pop-and-forward	Attributes of the pop-and-forward LSP tunnel.	extensive
ETLD In	Number of transport labels that the LSP-Hop can potentially receive from its upstream hop. It is recorded as Effective Transport Label Depth (ETLD) at the transit and egress devices.	extensive
ETLD Out	Number of transport labels the LSP-Hop can potentially send to its downstream hop. It is recorded as ETLD at the transit and ingress devices.	extensive
Delegation hop	Specifies if the transit hop is selected as a delegation label: <ul style="list-style-type: none"> • Yes • No 	extensive
Soft preempt	Number of soft preemptions that occurred on a path and when the last soft preemption occurred. Only successful soft preemptions are counted (those that actually resulted in a new path being used).	detail
Soft preemption pending	Path is in the process of being soft preempted. This display is removed once the ingress router has calculated a new path.	detail
MPLS-TE LSP Defaults	Default settings for MPLS traffic engineered LSPs: <ul style="list-style-type: none"> • LSP Holding Priority—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. • LSP Setup Priority—Determines whether a new LSP that preempts an existing LSP can be established. • Hop Limit—Specifies the maximum number of routers the LSP can traverse (including the ingress and egress). • Bandwidth—Specifies the bandwidth in bits per second for the LSP. • LSP Retry Timer—Length of time in seconds that the ingress router waits between attempts to establish the primary path. 	defaults

The XML tag name of the **bandwidth** tag under the **auto-bandwidth** tag has been updated to **maximum-average-bandwidth**. You can see the new tag when you issue the **show mpls lsp extensive** command with the **| display xml** pipe option. If you have any scripts that use the **bandwidth** tag, ensure that they are updated to **maximum-average-bandwidth**.

show mpls lsp abstract-computation

Syntax

```
show mpls lsp abstract-computation
<brief | detail | extensive>;
<logical-system (all | logical-system-name)>;
<name lsp-name>;
```

Release Information

Command introduced in Junos OS Release 17.1 for all platforms.

Description

Display the ingress to egress abstract hop computation used by the constrained shortest path in the preprocessing for LSPs. The command output displays the various computation passes involved per LSP, and the qualifying exit devices for each pass. It also displays the affinity per pass, and the current start device chosen for the pass.

Options

brief | detail | extensive—(Optional) Display the desired level of output.

logical-system (all | *logical-system-name*)—(Optional) Display the abstract computation for abstract hop constraints on all logical systems or on a particular logical system.

lsp-name—(Optional) Name of the LSP for which the abstract hop computation is displayed.

Required Privilege Level

Output Fields

[Table 105 on page 3241](#) describes the output fields for the **show mpls lsp abstract-computation** command. Output fields are listed in the approximate order in which they appear.

Table 105: show mpls lsp abstract-computation Output Fields

Field Name	Field Description
Path computation using abstract hops for LSP	Name of the LSP for which the abstract hop computation is performed.
Path type	The type of the path can be primary or secondary.
Path name	Name of the path.
Credibility	Credibility value associated with the interior gateway protocol in use.
Total no of CSPF passes	Number of constrained shortest path passes for the abstract hop.
CSPF pass no	Constrained shortest path pass number for the abstract hop computation.
Start address of the pass	IP address where the pass starts.
Affinity	Name of the abstract hop.
Destination	Destination IP address for a node in the pass.
State	State of the backtracking: <ul style="list-style-type: none"> • Valid • Disqualified

<name lsp-name>
```

Release Information

Statement introduced in Junos OS Release 11.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 15.1X54-D60 for the ACX5000 Series.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

name *lsp-name* option introduced in Junos OS Release 18.1R1 for all platforms.

Description

Display automatic bandwidth information for the LSP(s).

After a Routing Engine switchover, the output of the **show mpls autobandwidth** command might not be up-to-date, as the automatic bandwidth information for the LSP(s) is gathered by the new master Routing Engine during the first adjustment interval.

Options

brief | detail | extensive —(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Specify name of the LSP for which the automatic bandwidth information should be displayed.

Required Privilege Level

Output Fields

Table 106 on page 3244 describes the output fields for the **show mpls lsp autobandwidth** command. Output fields are listed in the approximate order in which they appear.

Table 106: show mpls lsp autobandwidth Output Fields

Field Name	Field Description	Level of Output
To	Destination (egress routing device) of the session.	All Levels
From	Source (ingress routing device) of the session.	All Levels
LSPname	Name of the LSP.	All Levels
Min BW	(Ingress LSP) Configured minimum value of the LSP, in bps.	detail extensive
Max BW	(Ingress LSP) Configured maximum value of the LSP, in bps.	detail extensive
Max AvgBW util	(Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps. NOTE: In calculating this value, the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.	detail extensive
Overflow limit	(Ingress LSP) Configured value of the threshold overflow limit.	detail extensive
Overflow sample count	(Ingress LSP) Current value for the overflow sample count.	detail extensive
Underflow limit	(Ingress LSP) Configured value of the threshold underflow limit.	detail extensive
Underflow sample count	(Ingress LSP) Current value for the underflow sample count.	detail extensive
Adjustment Timer	(Ingress LSP) Configured value for the adjust-timer statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.	detail extensive
Adjustment Threshold	(Ingress LSP) Configured value for the adjust-threshold statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization.	detail extensive
Time for Next Adjustment	(Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.	detail extensive

Table 106: show mpls lsp autobandwidth Output Fields (*continued*)

Field Name	Field Description	Level of Output
Time of Last Adjustment	(Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.	detail extensive
Last BW	Previous active bandwidth of the LSP.	detail extensive
Last Requested BW	Bandwidth requested in the previous automatic bandwidth adjustment.	detail extensive
Last Signaled BW	Bandwidth signaled in the previous automatic bandwidth adjustment.	detail extensive
Highest Watermark BW	Maximum bandwidth used by the LSP.	detail extensive
Total AutoBw Adjustments	Total number of attempts to adjust automatic bandwidth including failed and successful adjustments.	detail extensive
Successful Adjustments	Number of successful automatic bandwidth adjustments.	detail extensive
Failed Adjustments	Number of failed automatic bandwidth adjustments.	detail extensive

Sample Output

show mpls path
<instance instance-name>
<logical-system (all | logical-system-name)>
<path-name>
```

Syntax (EX Series Switches)

```
show mpls path
<path-name>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all MPLS LSPs.

instance *instance-name*—(Optional) Display the dynamic MPLS LSP for the specified instance. If *instance-name* is omitted, dynamic MPLS LSP for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

path-name—(Optional) Display information about the specified LSP only.

Output Fields

Table 107 on page 3247 describes the output fields for the **show mpls path** command. Output fields are listed in the approximate order in which they appear.

Table 107: show mpls path Output Fields

Field Name	Field Description
Path name	Information about ingress LSPs. Each path has one line of output.
Address	Addresses of the routing devices that form the LSP.
Strict/loose address	Whether the address is configured as a strict or loose address.

Sample Output

show mpls path

user@host> **show mpls path**

Path name	Address	Strict/loose address
p1	123.456.55.6	Strict
	123.456.1.6	Loose
p2	191.456.1.4	Strict

show mpls srlg

Syntax

```
show mpls srlg
<logical-systems (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 11.4.

Description

Display Shared Risk Link Group (SRLG) cost and value configuration information.

NOTE: If an SRLG is associated with a link that is used by an ingress LSP in the router, then on deleting the SRLG configuration from that router, the SRLG gets removed from the SRLG table only on the next reoptimization of the LSP. Until then, the output of the **run show mpls srlg** command displays **Unknown-XXX** instead of the SRLG name and a non zero srlg-cost for that SRLG.

Options

logical-system (all | *logical-system-name*)—(Optional) View SRLG configuration information for all logical systems or a particular logical system.

Required Privilege Level

view

[Example: Configuring SRLG | 278](#)

Output Fields

[Table 108 on page 3248](#) lists the output fields for the **show mpls srlg** command. Output fields are listed in the approximate order in which they appear.

Table 108: show mpls srlg Output Fields

Field Name	Field Description
SRLG	Name of the SRLG.

Table 108: show mpls srlg Output Fields (continued)

Field Name	Field Description
Value	A group ID for the SRLG ranging from 1 through 4294967295 .
Cost	A cost for the Shared Risk Link Group (SRLG) ranging from 1 through 65535 .

Sample Output

user@host> show mpls srlg

SRLG	Value	Cost
srlg-a	101	10

show mpls static-lsp

Syntax

```
show mpls static-lsp
<brief | detail | extensive | terse>
<bypass>
<descriptions>
<down | up>
<ingress>
<instance instance-name>
<logical-system (all | logical-system-name)>
<lsp-type>
<name name>
<statistics>
<transit>
```

Release Information

Command introduced in Junos OS Release 10.1.

Command updated in Junos OS Release 14.1X53-D25 to accommodate the stitching feature of MPLS.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Display information about configured and active static Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all configured and active static MPLS LSPs.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The **extensive** option displays the same information as the **detail** option, but covers the most recent 50 events.

bypass—(Optional) Display LSPs used for protecting other static LSPs.

descriptions—(Optional) Display the MPLS static LSP descriptions. To view this information, you must configure the description statement at the [edit protocols mpls static-label-switched-path *path-name* bypass], [edit protocols mpls static-label-switched-path *path-name* ingress], or [edit protocols mpls static-label-switched-path *path-name* transit *incoming-label*] hierarchy levels. Only static LSPs with a description are displayed.

down | up—(Optional) Display only static LSPs that are inactive or active, respectively.

instance *instance-name*—(Optional) Display information about all configured and active static MPLS LSPs for the specified routing instance. If ***instance-name*** is omitted, information about all configured and active static MPLS LSPs for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that pass through this routing device.

name *name*—(Optional) Display information about the specified static LSP or group of LSPs.

statistics—(Optional) Display accounting information about static LSPs.

transit—(Optional) Display static LSPs transiting this routing device.

Required Privilege Level

Output Fields

[Table 94 on page 3180](#) describes the output fields for the **show mpls static-lsp** command. Output fields are listed in the approximate order in which they appear.

Table 109: show mpls static-lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSPs	Information about the static LSPs on the ingress routing device. Each session has one line of output.	All levels
Transit LSPs	Number of static LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
Bypass LSPs	Information about the bypass LSPs configured on the routing device. Each session has one line of output.	All levels
LSPname	Name of the static LSP.	All levels

Table 109: show mpls static-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
To	Destination (egress routing device) of the session.	All levels
State	State of the static LSP handled by this RSVP session: Up , Dn (down), or Restart .	All levels
Packets	Number of packet transiting the static LSP (statistics option only).	All levels
Bytes	Number of bytes transiting the static LSP (statistics option only).	All levels
Nexthop	IP address for the next-hop router for the static LSP.	detail, extensive
Bypass	(Bypass LSP) Destination address (egress routing device) for the bypass LSP.	All levels
Link protection desired	Link protection has been requested by the ingress routing device.	detail, extensive
LabelOperation	Label operation to perform: Push , Pop , Swap .	detail, extensive
Outgoing-label	Outgoing label to use for the MPLS packet in either push or swap label operations.	detail, extensive
Created	(Ingress LSP) Date and time the static LSP was created.	extensive
Bandwidth	Bandwidth configured for the static LSP.	detail, extensive
Resv style	(Bypass) RSVP reservation style. This field consists of two parts: the number of active reservations and the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	All levels

Sample Output

show mpls static-lsp extensive

user@host> **show mpls static-lsp extensive**

```
Ingress LSPs:
LSPname: alpha-to-beta, To: 192.168.14.1
State: Dn
```

```

Nexthop: 192.168.10.1
LabelOperation: Push, Outgoing-label: 1000001
Created: Thu Jan 14 16:44:43 2010
Bandwidth: 0 bps
Total 1, displayed 1, Up 0, Down 1

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

```

show mpls static-lsp statistics ingress

```
user@host> show mpls static-lsp statistics ingress
```

```

Ingress LSPs:
LSPname                To           State    Packets    Bytes
alpha-to-beta          192.168.14.1 Dn        NA         NA
Total 1, displayed 1, Up 0, Down 1

```

show mpls static-lsp (when MPLS stitching is used)

The show mpls static-lsp command was extended in Junos release 14.1X53-D25 to accommodate the stitching feature of MPLS. This example shows the LSP state as 'InProgress' because the LSP is waiting for protocol next-hop resolution. For more information, see

```
user@host> show mpls static-lsp
```

```

Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs: LSPname                Incoming-label  State
to-165                1000000        InProgress

```

show performance-monitoring mpls lsp

Syntax

```
show performance-monitoring mpls lsp  
<brief | detail | extensive>  
<name lsp name>
```

Release Information

Command introduced in Junos OS Release 15.1.

Description

Display the following performance monitoring data:

- Packet loss measurement
- Packet throughput measurement
- Two-way channel delay
- Round-trip delay
- Inter-packet delay variation (IPDV)

Options

none—Display standard information performance monitoring data.

brief | detail | extensive—(Optional) Display the specified level of output.

NOTE: The extensive option displays the same information as the detail option.

name *lsp name*—(Optional) Display information about the specified LSP.

Output fields are listed in the approximate order in which they appear.

Table 110: show performance-monitoring mpls lsp Output Fields

Field Name	Display Data	Field Description	Level of Output
Session	Total	Total number of performance monitoring sessions created.	All Levels
	Up	Number of performance monitoring sessions that are up and running.	All Levels
	Down	Number of performance monitoring sessions that are down.	All Levels
LSP name		Name of the LSP.	All Levels

Table 110: show performance-monitoring mpls lsp Output Fields (*continued*)

Field Name	Display Data		Field Description	Level of Output
Loss measurement Data	Traffic-class		Traffic class for which loss measurement is performed.	All Levels
	Queries sent		Total number of queries sent for loss measurement.	All Levels
	Responses received		Total number of responses received for loss measurement queries.	All Levels
	Responses dropped due to errors		Total number of loss measurement responses dropped due to errors.	All Levels
	Queries timeout		Number of timed out queries sent for loss measurement.	All Levels
	Forward loss measurement	Average packet loss	Average packet loss (total loss of packets divided by the total number of samples used since the session is up).	All Levels
		Average packet throughput	Total number of packets sent divided by the time considered for measurement.	All Levels
	Reverse loss measurement	Average packet loss	Average packet loss (total loss of packets divided by the total number of samples used since the session is up).	All Levels
		Average packet throughput	Total number of packets sent divided by the time considered for measurement.	All Levels

Table 110: show performance-monitoring mpls lsp Output Fields (*continued*)

Field Name	Display Data	Field Description	Level of Output
Delay measurement Data	Traffic-class	Traffic class for which delay measurement is performed.	All Levels
	Queries sent	Total number of queries sent for delay measurement.	All Levels
	Responses received	Total number of responses received for delay measurement queries.	All Levels
	Responses dropped due to errors	Total number of delay measurement responses dropped due to errors.	All Levels
	Queries timeout	Number of timed out queries sent for delay measurement.	All Levels
	Best 2-way channel delay	Best available two-way channel delay.	All Levels
	Worst 2-way channel delay	Worst available two-way channel delay.	All Levels
	Best round trip time	Best available round-trip time.	All Levels
	Worst round trip time	Worst available round-trip time.	All Levels
	Avg absolute fw delay variation	Average of the variation in forward delay.	All Levels
	Avg absolute rv delay variation	Average of the variation in reverse delay.	All Levels
	Two-way channel delay	Sum of packet delays, excluding the processing time of the remote provider edge (PE) router.	detail, extensive
	Two-way round trip delay	Total time taken for completing round-trip of packet.	detail, extensive

show route forwarding-table

Syntax

```
show route forwarding-table
<detail | extensive | summary>
<ccc ccc-interface-name>
<destination>
<family family-name>
<label label>
<matching ip_prefix>
<multicast>
<vpn vpn>
```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Command introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

Options

none—Display the routes in the forwarding table.

detail | extensive | summary—(Optional) Display the specified level of output.

ccc—(Optional) Display the specified circuit cross-connect interface name for entries to match.

destination—(Optional) Display the destination prefix.

family family-name—(Optional) Display routing table entries for the specified family: **ethernet-switching**, **inet**, **inet6**, **iso**, **mpls**, **vlan classification**.

label label—(Optional) Display route entries for the specified label name.

matching ip_prefix—(Optional) Display route entries for the specified IP prefix.

multicast—(Optional) Display route entries for multicast routes.

vpn vpn—(Optional) Display route entries for the specified VPN.

Output Fields

[Table 111 on page 3263](#) lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified or when the **detail** keyword is used instead of the **extensive** keyword.

Table 111: show route forwarding-table Output Fields

Field Name	Field Description	Level of Output
Routing table	Name of the routing table (for example, inet , inet6 , mpls).	All levels
Address family	Address family (for example, IP , IPv6 , ISO , MPLS).	All levels
Destination	Destination of the route.	detail , extensive

Table 111: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Route Type (Type)	<p>How the route was placed into the forwarding table. When the detail keyword is used, the route type might be abbreviated (as shown in parentheses):</p> <ul style="list-style-type: none"> • cloned (clon)—(TCP or multicast only) Cloned route. • destination (dest)—Remote addresses directly reachable through an interface. • destination down (iddn)—Destination route for which the interface is unreachable. • interface cloned (ifcl)—Cloned route for which the interface is unreachable. • route down (ifdn)—Interface route for which the interface is unreachable. • ignore (ignr)—Ignore this route. • interface (intf)—Installed as a result of configuring an interface. • permanent (perm)—Routes installed by the kernel when the routing table is initialized. • user—Routes installed by the routing protocol process or as a result of the configuration. 	All levels
Route reference (RtRef)	Number of routes to reference.	detail, extensive
Flags	<p>Route type flags:</p> <ul style="list-style-type: none"> • none—No flags are enabled. • accounting—Route has accounting enabled. • cached—Cache route. • incoming-iface interface-number —Check against incoming interface. • prefix load balance—Load balancing is enabled for this prefix. • sent to PFE—Route has been sent to the Packet Forwarding Engine. • static—Static route. 	extensive
Nexthop	IP address of the next hop to the destination.	detail, extensive

Table 111: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Next hop type (Type)	<p>Next-hop type. When the detail keyword is used, the next-hop type might be abbreviated (as indicated in parentheses):</p> <ul style="list-style-type: none"> • broadcast (bcst)—Broadcast. • deny—Deny. • hold—Next hop is waiting to be resolved into a unicast or multicast type. • indexed (idxd)—Indexed next hop. • indirect (indr)—Indirect next hop. • local (locl)—Local address on an interface. • routed multicast (mcrt)—Regular multicast next hop • multicast (mcst)—Wire multicast next hop (limited to the LAN). • multicast discard (mdsc)—Multicast discard. • multicast group (mgrp) —Multicast group member. • receive (recv)—Receive. • reject (rjct)—Discard. An ICMP unreachable message was sent. • resolve (rslv)—Resolving the next hop. • unicast (ucst)—Unicast. • unilist (ulst)—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list. 	detail, extensive
Index	Software index of the next hop that is used to route the traffic for a given prefix.	detail, extensive none
Route interface-index	Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.	extensive
Reference (NhRef)	Number of routes that refer to this next hop.	none detail, extensive
Next-hop interface (Netif)	Interface used to reach the next hop.	none detail, extensive
Alternate forward nh index	Index number of the alternate next hop interface. Seen with multicast option only.	extensive
Next-hop L3 Interface	The next hop layer 3 interface. This option can be expressed as a VLAN name and is only seen with the multicast option.	extensive

Table 111: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Next-hop L2 Interfaces	The next hop layer 2 interfaces. Seen with multicast option only.	extensive

```

Syntax (EX Series Switches, QFX Series Switches)

```
show route table routing-table-name
<brief | detail | extensive | terse>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 14.1X53-D15 for QFX Series switches.

Show route table evpn statement introduced in Junos OS Release 15.1X53-D30 for QFX Series switches.

Description

Display the route entries in a particular routing table.

Options

brief | detail | extensive | terse—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

routing-table-name—Display route entries for all routing tables whose names begin with this string (for example, inet.0 and inet6.0 are both displayed when you run the **show route table inet** command).

Required Privilege Level

Output Fields

Table 112 on page 3275 describes the output fields for the **show route table** command. Output fields are listed in the approximate order in which they appear.

Table 112: show route table Output Fields

Field Name	Field Description
<i>routing-table-name</i>	Name of the routing table (for example, inet.0).
Restart complete	<p>All protocols have restarted for this routing table.</p> <p>Restart state:</p> <ul style="list-style-type: none"> • Pending:protocol-name—List of protocols that have not yet completed graceful restart for this routing table. • Complete—All protocols have restarted for this routing table. <p>For example, if the output shows-</p> <ul style="list-style-type: none"> • LDP.inet.0 : 5 routes (4 active, 1 holddown, 0 hidden) <p>Restart Pending: OSPF LDP VPN</p> <p>This indicates that OSPF, LDP, and VPN protocols did not restart for the LDP.inet.0 routing table.</p> <ul style="list-style-type: none"> • vpls_1.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden) <p>Restart Complete</p> <p>This indicates that all protocols have restarted for the vpls_1.l2vpn.0 routing table.</p>
<i>number destinations</i>	Number of destinations for which there are routes in the routing table.
<i>number routes</i>	<p>Number of routes in the routing table and total number of routes in the following states:</p> <ul style="list-style-type: none"> • active (routes that are active) • holddown (routes that are in the pending state before being declared inactive) • hidden (routes that are not used because of a routing policy)

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
<i>route-destination</i> (entry, announced)	<p>Route destination (for example:10.0.0.1/24). The entry value is the number of routes for this destination, and the announced value is the number of routes being announced for this destination. Sometimes the route destination is presented in another format, such as:</p> <ul style="list-style-type: none"> • MPLS-label (for example, 80001). • interface-name (for example, ge-1/0/2). • neighbor-address:control-word-status:encapsulation type:vc-id:source (Layer 2 circuit only; for example, 10.1.1.195:NoCtrlWord:1:1:Local/96). • neighbor-address—Address of the neighbor. • control-word-status—Whether the use of the control word has been negotiated for this virtual circuit: NoCtrlWord or CtrlWord. • encapsulation type—Type of encapsulation, represented by a number: (1) Frame Relay DLCI, (2) ATM AAL5 VCC transport, (3) ATM transparent cell transport, (4) Ethernet, (5) VLAN Ethernet, (6) HDLC, (7) PPP, (8) ATM VCC cell transport, (10) ATM VPC cell transport. • vc-id—Virtual circuit identifier. • source—Source of the advertisement: Local or Remote. • inclusive multicast Ethernet tag route—Type of route destination represented by (for example, 3:100.100.100.10:100::0::10::100.100.100.10/384): <ul style="list-style-type: none"> • route distinguisher—(8 octets) Route distinguisher (RD) must be the RD of the EVPN instance (EVI) that is advertising the NLRI. • Ethernet tag ID—(4 octets) Identifier of the Ethernet tag. Can set to 0 or to a valid Ethernet tag value. • IP address length—(1 octet) Length of IP address in bits. • originating router's IP address—(4 or 16 octets) Must set to the provider edge (PE) device's IP address. This address should be common for all EVIs on the PE device, and may be the PE device's loopback address.
label stacking	<p>(Next-to-the-last-hop routing device for MPLS only) Depth of the MPLS label stack, where the label-popping operation is needed to remove one or more labels from the top of the stack. A pair of routes is displayed, because the pop operation is performed only when the stack depth is two or more labels.</p> <ul style="list-style-type: none"> • S=0 route indicates that a packet with an incoming label stack depth of 2 or more exits this routing device with one fewer label (the label-popping operation is performed). • If there is no S= information, the route is a normal MPLS route, which has a stack depth of 1 (the label-popping operation is not performed).

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
[<i>protocol, preference</i>]	<p>Protocol from which the route was learned and the preference value for the route.</p> <ul style="list-style-type: none"> • +—A plus sign indicates the active route, which is the route installed from the routing table into the forwarding table. • - —A hyphen indicates the last active route. • *—An asterisk indicates that the route is both the active and the last active route. An asterisk before a to line indicates the best subpath to the route. <p>In every routing metric except for the BGP LocalPref attribute, a lesser value is preferred. In order to use common comparison routines, Junos OS stores the 1's complement of the LocalPref value in the Preference2 field. For example, if the LocalPref value for Route 1 is 100, the Preference2 value is -101. If the LocalPref value for Route 2 is 155, the Preference2 value is -156. Route 2 is preferred because it has a higher LocalPref value and a lower Preference2 value.</p>
Level	(IS-IS only). In IS-IS, a single AS can be divided into smaller groups called areas. Routing between areas is organized hierarchically, allowing a domain to be administratively divided into smaller areas. This organization is accomplished by configuring Level 1 and Level 2 intermediate systems. Level 1 systems route within an area. When the destination is outside an area, they route toward a Level 2 system. Level 2 intermediate systems route between areas and toward other ASs.
Route Distinguisher	IP subnet augmented with a 64-bit prefix.
PMSI	Provider multicast service interface (MVPN routing table).
Next-hop type	Type of next hop. For a description of possible values for this field, see Table 113 on page 3282 .
Next-hop reference count	Number of references made to the next hop.
Flood nexthop branches exceed maximum message	Indicates that the number of flood next-hop branches exceeded the system limit of 32 branches, and only a subset of the flood next-hop branches were installed in the kernel.
Source	IP address of the route source.
Next hop	Network layer address of the directly reachable neighboring system.

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
via	<p>Interface used to reach the next hop. If there is more than one interface available to the next hop, the name of the interface that is actually used is followed by the word Selected. This field can also contain the following information:</p> <ul style="list-style-type: none"> • Weight—Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible. • Balance—Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a routing device is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.
Label-switched-path <i>lsp-path-name</i>	Name of the LSP used to reach the next hop.
Label operation	MPLS label and operation occurring at this routing device. The operation can be pop (where a label is removed from the top of the stack), push (where another label is added to the label stack), or swap (where a label is replaced by another label).
Interface	(Local only) Local interface name.
Protocol next hop	Network layer address of the remote routing device that advertised the prefix. This address is used to derive a forwarding next hop.
Indirect next hop	Index designation used to specify the mapping between protocol next hops, tags, kernel export policy, and the forwarding next hops.
State	State of the route (a route can be in more than one state). See Table 114 on page 3283 .
Local AS	AS number of the local routing devices.
Age	How long the route has been known.
AIGP	Accumulated interior gateway protocol (AIGP) BGP attribute.
Metricn	Cost value of the indicated route. For routes within an AS, the cost is determined by IGP and the individual protocol metrics. For external routes, destinations, or routing domains, the cost is determined by a preference value.
MED-plus-IGP	Metric value for BGP path selection to which the IGP cost to the next-hop destination has been added.

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
TTL-Action	For MPLS LSPs, state of the TTL propagation attribute. Can be enabled or disabled for all RSVP-signaled and LDP-signaled LSPs or for specific VRF routing instances.
Task	Name of the protocol that has added the route.
Announcement bits	<p>The number of BGP peers or protocols to which Junos OS has announced this route, followed by the list of the recipients of the announcement. Junos OS can also announce the route to the kernel routing table (KRT) for installing the route into the Packet Forwarding Engine, to a resolve tree, a Layer 2 VC, or even a VPN. For example, n-Resolve inet indicates that the specified route is used for route resolution for next hops found in the routing table.</p> <ul style="list-style-type: none"> • n—An index used by Juniper Networks customer support only.
AS path	<p>AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated:</p> <ul style="list-style-type: none"> • I—IGP. • E—EGP. • Recorded—The AS path is recorded by the sample process (sampled). • ?—Incomplete; typically, the AS path was aggregated. <p>When AS path numbers are included in the route, the format is as follows:</p> <ul style="list-style-type: none"> • []—Brackets enclose the number that precedes the AS path. This number represents the number of ASs present in the AS path, when calculated as defined in RFC 4271. This value is used in the AS-path merge process, as defined in RFC 4893. • []—If more than one AS number is configured on the routing device, or if AS path prepending is configured, brackets enclose the local AS number associated with the AS path. • { }—Braces enclose AS sets, which are groups of AS numbers in which the order does not matter. A set commonly results from route aggregation. The numbers in each AS set are displayed in ascending order. • ()—Parentheses enclose a confederation. • ([])—Parentheses and brackets enclose a confederation set. <p>NOTE: In Junos OS Release 10.3 and later, the AS path field displays an unrecognized attribute and associated hexadecimal value if BGP receives attribute 128 (attribute set) and you have not configured an independent domain in any routing instance.</p>

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
validation-state	<p>(BGP-learned routes) Validation status of the route:</p> <ul style="list-style-type: none"> • Invalid—Indicates that the prefix is found, but either the corresponding AS received from the EBGP peer is not the AS that appears in the database, or the prefix length in the BGP update message is longer than the maximum length permitted in the database. • Unknown—Indicates that the prefix is not among the prefixes or prefix ranges in the database. • Unverified—Indicates that the origin of the prefix is not verified against the database. This is because the database got populated and the validation is not called for in the BGP import policy, although origin validation is enabled, or the origin validation is not enabled for the BGP peers. • Valid—Indicates that the prefix and autonomous system pair are found in the database.
FECs bound to route	Indicates point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.
Primary Upstream	When multipoint LDP with multicast-only fast reroute (MoFRR) is configured, indicates the primary upstream path. MoFRR transmits a multicast join message from a receiver toward a source on a primary path, while also transmitting a secondary multicast join message from the receiver toward the source on a backup path.
RPF Nexthops	When multipoint LDP with MoFRR is configured, indicates the reverse-path forwarding (RPF) next-hop information. Data packets are received from both the primary path and the secondary paths. The redundant packets are discarded at topology merge points due to the RPF checks.
Label	Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.
weight	Value used to distinguish MoFRR primary and backup routes. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.
VC Label	MPLS label assigned to the Layer 2 circuit virtual connection.
MTU	Maximum transmission unit (MTU) of the Layer 2 circuit.
VLAN ID	VLAN identifier of the Layer 2 circuit.
Prefixes bound to route	Forwarding equivalent class (FEC) bound to this route. Applicable only to routes installed by LDP.

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
Communities	Community path attribute for the route. See Table 115 on page 3286 for all possible values for this field.
Layer2-info: encaps	Layer 2 encapsulation (for example, VPLS).
control flags	Control flags: none or Site Down .
mtu	Maximum transmission unit (MTU) information.
Label-Base, range	First label in a block of labels and label block size. A remote PE routing device uses this first label when sending traffic toward the advertising PE routing device.
status vector	Layer 2 VPN and VPLS network layer reachability information (NLRI).
Accepted Multipath	Current active path when BGP multipath is configured.
Accepted LongLivedStale	The LongLivedStale flag indicates that the route was marked LLGR-stale by this router, as part of the operation of LLGR receiver mode. Either this flag or the LongLivedStaleImport flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.
Accepted LongLivedStaleImport	<p>The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy. Either this flag or the LongLivedStale flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.</p> <p>Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and import into the inet.0 routing table</p>
ImportAccepted LongLivedStaleImport	<p>Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and imported into the inet.0 routing table</p> <p>The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy.</p>
Accepted MultipathContrib	Path currently contributing to BGP multipath.
Localpref	Local preference value included in the route.
Router ID	BGP router ID as advertised by the neighbor in the open message.

Table 112: show route table Output Fields (*continued*)

Field Name	Field Description
Primary Routing Table	In a routing table group, the name of the primary routing table in which the route resides.
Secondary Tables	In a routing table group, the name of one or more secondary tables in which the route resides.

Table 113 on page 3282 describes all possible values for the Next-hop Types output field.

Table 113: Next-hop Types Output Field Values

Next-Hop Type	Description
Broadcast (bcast)	Broadcast next hop.
Deny	Deny next hop.
Discard	Discard next hop.
Flood	Flood next hop. Consists of components called branches, up to a maximum of 32 branches. Each flood next-hop branch sends a copy of the traffic to the forwarding interface. Used by point-to-multipoint RSVP, point-to-multipoint LDP, point-to-multipoint CCC, and multicast.
Hold	Next hop is waiting to be resolved into a unicast or multicast type.
Indexed (idxd)	Indexed next hop.
Indirect (indr)	Used with applications that have a protocol next hop address that is remote. You are likely to see this next-hop type for internal BGP (IBGP) routes when the BGP next hop is a BGP neighbor that is not directly connected.
Interface	Used for a network address assigned to an interface. Unlike the router next hop, the interface next hop does not reference any specific node on the network.
Local (locl)	Local address on an interface. This next-hop type causes packets with this destination address to be received locally.
Multicast (mcst)	Wire multicast next hop (limited to the LAN).
Multicast discard (mdsc)	Multicast discard.

Table 113: Next-hop Types Output Field Values (*continued*)

Next-Hop Type	Description
Multicast group (mgrp)	Multicast group member.
Receive (recv)	Receive.
Reject (rjct)	Discard. An ICMP unreachable message was sent.
Resolve (rslv)	Resolving next hop.
Routed multicast (mcrt)	Regular multicast next hop.
Router	<p>A specific node or set of nodes to which the routing device forwards packets that match the route prefix.</p> <p>To qualify as a next-hop type router, the route must meet the following criteria:</p> <ul style="list-style-type: none"> • Must not be a direct or local subnet for the routing device. • Must have a next hop that is directly connected to the routing device.
Table	Routing table next hop.
Unicast (ucst)	Unicast.
Unilist (ulst)	List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.

[Table 114 on page 3283](#) describes all possible values for the State output field. A route can be in more than one state (for example, <Active NoReadvrt Int Ext>).

Table 114: State Output Field Values

Value	Description
Accounting	Route needs accounting.
Active	Route is active.
Always Compare MED	Path with a lower multiple exit discriminator (MED) is available.
AS path	Shorter AS path is available.

Table 114: State Output Field Values (*continued*)

Value	Description
Cisco Non-deterministic MED selection	Cisco nondeterministic MED is enabled, and a path with a lower MED is available.
Clone	Route is a clone.
Cluster list length	Length of cluster list sent by the route reflector.
Delete	Route has been deleted.
Ex	Exterior route.
Ext	BGP route received from an external BGP neighbor.
FlashAll	Forces all protocols to be notified of a change to any route, active or inactive, for a prefix. When not set, protocols are informed of a prefix only when the active route changes.
Hidden	Route not used because of routing policy.
IfCheck	Route needs forwarding RPF check.
IGP metric	Path through next hop with lower IGP metric is available.
Inactive reason	Flags for this route, which was not selected as best for a particular destination.
Initial	Route being added.
Int	Interior route.
Int Ext	BGP route received from an internal BGP peer or a BGP confederation peer.
Interior > Exterior > Exterior via Interior	Direct, static, IGP, or EBGp path is available.
Local Preference	Path with a higher local preference value is available.
Martian	Route is a martian (ignored because it is obviously invalid).
MartianOK	Route exempt from martian filtering.

Table 114: State Output Field Values (*continued*)

Value	Description
Next hop address	Path with lower metric next hop is available.
No difference	Path from neighbor with lower IP address is available.
NoReadvrt	Route not to be advertised.
NotBest	Route not chosen because it does not have the lowest MED.
Not Best in its group	Incoming BGP AS is not the best of a group (only one AS can be the best).
NotInstall	Route not to be installed in the forwarding table.
Number of gateways	Path with a greater number of next hops is available.
Origin	Path with a lower origin code is available.
Pending	Route pending because of a hold-down configured on another route.
Release	Route scheduled for release.
RIB preference	Route from a higher-numbered routing table is available.
Route Distinguisher	64-bit prefix added to IP subnets to make them unique.
Route Metric or MED comparison	Route with a lower metric or MED is available.
Route Preference	Route with lower preference value is available.
Router ID	Path through a neighbor with lower ID is available.
Secondary	Route not a primary route.
Unusable path	Path is not usable because of one of the following conditions: <ul style="list-style-type: none"> • The route is damped. • The route is rejected by an import policy. • The route is unresolved.
Update source	Last tiebreaker is the lowest IP address value.

Table 115 on page 3286 describes the possible values for the Communities output field.

Table 115: Communities Output Field Values

Value	Description
<i>area-number</i>	4 bytes, encoding a 32-bit area number. For AS-external routes, the value is 0 . A nonzero value identifies the route as internal to the OSPF domain, and as within the identified area. Area numbers are relative to a particular OSPF domain.
bandwidth: local AS number:link-bandwidth-number	Link-bandwidth community value used for unequal-cost load balancing. When BGP has several candidate paths available for multipath purposes, it does not perform unequal-cost load balancing according to the link-bandwidth community unless all candidate paths have this attribute.
domain-id	Unique configurable number that identifies the OSPF domain.
domain-id-vendor	Unique configurable number that further identifies the OSPF domain.
<i>link-bandwidth-number</i>	Link-bandwidth number: from 0 through 4,294,967,295 (bytes per second).
<i>local AS number</i>	Local AS number: from 1 through 65,535 .
<i>options</i>	1 byte. Currently this is only used if the route type is 5 or 7 . Setting the least significant bit in the field indicates that the route carries a type 2 metric.
origin	(Used with VPNs) Identifies where the route came from.
<i>ospf-route-type</i>	1 byte, encoded as 1 or 2 for intra-area routes (depending on whether the route came from a type 1 or a type 2 LSA); 3 for summary routes; 5 for external routes (area number must be 0); 7 for NSSA routes; or 129 for sham link endpoint addresses.
route-type-vendor	Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute 0x8000 . The format is area-number:ospf-route-type:options .
rte-type	Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute 0x0306 . The format is area-number:ospf-route-type:options .
target	Defines which VPN the route participates in; target has the format 32-bit IP address:16-bit number . For example, 10.19.0.0:100.
unknown IANA	Incoming IANA codes with a value between 0x1 and 0x7fff . This code of the BGP extended community attribute is accepted, but it is not recognized.

Table 115: Communities Output Field Values (*continued*)

Value	Description
unknown OSPF vendor community	Incoming IANA codes with a value above 0x8000 . This code of the BGP extended community attribute is accepted, but it is not recognized.
evpn-mcast-flags	Identifies the value in the multicast flags extended community and whether snooping is enabled. A value of 0x1 indicates that the route supports IGMP proxy.
evpn-l2-info	Identifies whether Multihomed Proxy MAC and IP Address Route Advertisement is enabled. A value of 0x20 indicates that the proxy bit is set. . Use the show bridge mac-ip-table extensive statement to determine whether the MAC and IP address route was learned locally or from a PE device.

Sample Output

List of Syntax

[Syntax on page 3329](#)

[Syntax \(EX Series Switches\) on page 3329](#)

Syntax

```
show ted database
<brief | detail | extensive>
<instance instance-name>
<logical-system (all | logical-system-name)>
<system-name>
<topology-id topology bgp-ls-epe>
```

Syntax (EX Series Switches)

```
show ted database
<brief | detail | extensive>
<system-name>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

topology-id *topology* option added in Junos OS Release 17.4R1 for MX Series and PTX Series.

Description

Display the entries in the Multiprotocol Label Switching (MPLS) traffic engineering database.

Options

none—Display standard information about all entries in the traffic engineering database.

brief | detail | extensive—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

system-name—(Optional) Display traffic engineering database information for a particular system.

topology-id *topology*— Display the topology information. By default, traffic engineering topology information is displayed.

Required Privilege Level

Output Fields

[Table 116 on page 3330](#) describes the output fields for the **show ted database** command. Output fields are listed in the approximate order in which they appear.

Table 116: show ted database Output Fields

Field Name	Field Description	Level of Output
TED database	Number of nodes and pseudonodes participating in IS-IS and OSPF domain routing.	All levels
ID	Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode. If the node contains a router ID, it is displayed in parentheses.	brief
NodeID	Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.	extensive
Type	Type of node. It can be either Rtr (router) or Net (pseudonode).	All levels
Age(s)	How long since the node was last refreshed, in seconds.	All levels
LnkIn	Number of nodes pointing toward this node.	All levels
LnkOut	Number of nodes to which this node points.	All levels
Protocol	Protocol that reported the node information: <ul style="list-style-type: none"> • IS-IS(1)—IS-IS Level 1. • IS-IS(2)—IS-IS Level 2. • OSPF (area-number)—OSPF from the specified area. 	All levels
To	Address on the far end of a link.	detail extensive

Table 116: show ted database Output Fields (*continued*)

Field Name	Field Description	Level of Output
Local	Address of the local interface being used to reach the remote node.	detail extensive
Remote	Address of the interface on the remote node.	detail extensive
Local interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	detail extensive
Remote interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	detail extensive
Metric	Configured traffic engineering metric.	extensive
IGP metric	Configured interior gateway protocol metric.	extensive
Static BW	Total interface bandwidth in bps.	extensive
Reservable bandwidth	Subscription factor for the interface, which is the percentage of the link bandwidth that can be used for the RSVP reservation process. You configure this by including the subscription statement when configuring RSVP.	extensive
Available BW [priority]	(Must include diffserv-te statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each priority level. The bandwidth shown is for the entire interface, not for each individual LSP.	extensive
Diffserv-TE BW Model	Bandwidth constraint model used by the LSPs.	extensive
Available BW [TE-class]	(Must include the diffserv-te statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each traffic engineering class.	extensive
Static BW [CT-class]	Total interface bandwidth used by an MPLS traffic class, in bps.	extensive

Table 116: show ted database Output Fields (*continued*)

Field Name	Field Description	Level of Output
Interface Switching Capability Descriptor (n)	<p>Information about the interface switching capability descriptor, which is a subtype length value (TLV) of the link TLV. <i>n</i> is the index number.</p> <ul style="list-style-type: none"> • Switching type—Type of switching to be performed on a particular link: <ul style="list-style-type: none"> • PSC-1—Packet switch-capable 1 • PSC-2—Packet switch-capable 2 • PSC-3—Packet switch-capable 3 • PSC-4—Packet switch-capable 4 • L2SC—Layer-2-switch-capable • TDM—Time-division-multiplexing-capable • LSC—Lambda switch-capable • FSC—Fiber switch-capable • Encoding type—Encoding of the LSP being requested: <ul style="list-style-type: none"> • Packet • Ethernet • ANSI/ETSI PDH • Reserved • SDH /SONET • Digital Wrapper • Lambda (photonic) • Fiber • FiberSDH/SONET • Maximum LSP BW [priority] bps—Maximum LSP bandwidth information. Amount of bandwidth actually reserved for each priority level. The bandwidth shown is for the entire interface. <ul style="list-style-type: none"> • [n]—Priority level. The range is from 0 (high) through 7 (low). • n Mbps—Amount of the maximum bandwidth. • Minimum LSP BW—Minimum LSP bandwidth in Mbps. Amount of bandwidth actually reserved for each priority level. The bandwidth shown is for the entire interface. Minimum LSP BW is displayed only when switching type is PSC-1 or TDM. • Interface MTU—Displayed only when switching type is TDM. • Interface supports standard SONET/SDH—Displayed only when switching type is TDM. 	extensive

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display Multiprotocol Label Switching (MPLS) traffic engineering database link information.

Options

none—Display standard information about traffic engineering database link information.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display information about the protocols from which the Multiprotocol Label Switching (MPLS) traffic engineering database learned about its nodes.

Options

none—Display standard information about the protocols from which the traffic engineering database learned about its nodes.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 118 on page 3347](#) describes the output fields for the **show ted protocol** command. Output fields are listed in the approximate order in which they appear.

Table 118: show ted protocol Output Fields

Field Name	Field Description
Protocol name	Protocol that reported the node information: <ul style="list-style-type: none"> • IS-IS(1)—IS-IS Level 1. • IS-IS(2)—IS-IS Level 2. • OSPF (<i>area-number</i>)—OSPF from the specified area.
Credibility	If the protocols provide conflicting information about a node, the protocol with the highest credibility value is the one that the traffic engineering database uses.
Self node	Address the protocol uses as the local address.

Sample Output

show ted protocol

```
user@host> show ted protocol
```

```

Protocol name      Credibility  Self node

traceroute mpls bgp

Syntax

```
traceroute mpls bgp fec
<destination destination-address>
<detail>
<exp exp>
<fanout fanout-number>
<logical-system logical system-name>
<no-resolve>
<paths paths-number>
<pipe-mode>
<retries retries-number>
<routing-instance routing-instance-name>
<source source-address>
<ttl value>
<wait seconds>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Trace route to a remote host for an MPLS label-switched path (LSP) signaled by the Border Gateway Protocol (BGP). Use **traceroute mpls bgp** as a debugging tool to locate MPLS BGP forwarding issues in a network. (Currently supported for IPv4 packets only.)

To use the **traceroute mpls bgp** command, make sure you have BGP routes with MPLS labels.

NOTE: The **traceroute mpls bgp fec** command only supports single paths.

Options

fec—Specify the IP address and optional prefix of the forwarding equivalence class (FEC). Suppose you are at PE1, use would want to use the IP address of PE2 to trace the BGP path to that router.

destination *destination-address*—(Optional) Specify the destination address to use when sending probes.

detail—(Optional) Display detailed output.

exp *exp*—(Optional) Specify the class of service to use when sending probes.

Range: 0 through 7

Default: 7

fanout *fanout-number*—(Optional) Specify the maximum number of next hops to search per node.

Range: 1 through 16

Default: 16

logical-system *logical-system-name*—(Optional) Specify the name of the logical system for the traceroute attempt.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

paths *paths-number*—(Optional) Specify the number of paths to search.

Range: 1 through 255

Default: 16

pipe-mode—(Optional) Specify to trace only the outermost FEC.

retries *retries-number*—(Optional) Specify the number of times to resend probe values.

Range: 1 through 9

Default: 3

routing-instance *routing-instance-name*—(Optional) Specify the name of the routing instance for the trace route attempt.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl *value*—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds.

Range: 1 through 125

Default: 64

wait *seconds*—(Optional) Specify the number of seconds to wait before resending a probe.

Range: 5 through 15

Default: 10

Required Privilege Level

Output Fields

Table 119 on page 3350 describes the output fields for the **traceroute mpls bgp fec** command and the **traceroute mpls bgp fec detail** command. Output fields are listed in the approximate order in which they appear.

Table 119: traceroute mpls bgp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the traceroute mpls bgp fec command.	All levels
ttl	Time to live value of the labeled packet.	None
Label	Outgoing label used for forwarding the packet along the label-switched paths.	None
Protocol	Signaling protocol used. For this command, it is BGP.	None
Address	Address of the next hop.	None
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null .	None
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).	None
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	detail
Parent	Address of the previous hop. Parent value for the first hop is null .	detail
Return Code	Return code for reporting the result of processing the echo request by the receiver.	detail
Response time	Time for the echo request to reach the receiver.	detail
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none .	detail
Label Stack	Label stack used to forward the packet.	detail

Sample Output

traceroute mpls bgp

user@host> traceroute mpls bgp fec

```

transit (Chained Composite Next Hops)

Syntax

```
transit {
  (all | no-all);
  (l2vpn | no-l2vpn);
  (l3vpn | no-l3vpn);
  (labeled-bgp | no-labeled-bgp);
  (ldp | no-ldp);
  (ldp-p2mp | no-ldp-p2mp);
  lsp-statistics-from-route;
  (rsvp | no-rsvp);
  (rsvp-p2mp | no-rsvp-p2mp);
  (static | no-static);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table chained-composite-next-hop],
[edit routing-options forwarding-table chained-composite-next-hop]
```

NOTE: The [edit logical-systems] hierarchy level is not supported on the QFX10000 switches.

Release Information

Statement introduced in Junos OS Release 12.1.

Statement introduced in Junos OS Release 15.1 for QFX10000 Series switches.

Description

Allows you to configure the chained composite next hops transit configuration options for devices handling transit traffic in the network. This statement and the associated functionality is available only on PTX Packet Transport Routers and QFX10000 switches.

Default

All of the **transit** statement options are enabled on PTX transport routers and QFX10000 switches. However, you can disable any of the statements with a **no** option.

Starting in Junos OS Release 14.1, the **transit l3vpn** statement is enabled by default on PTX Series Packet Transport Routers only.

Options

all | no-all—Enable or disable chained composite next-hops for all of the possible packet transit protocols and applications. The **all | no-all** statements do not apply to the **lsp-statistics-from-route** statement.

l2vpn | no-l2vpn—Enable or disable chained composite next-hops for Layer 2 VPNs.

l3vpn | no-l3vpn—Enable or disable chained composite next-hops for Layer 3 VPNs.

labeled-bgp | no-labeled-bgp—Enable or disable chained composite next-hops for labeled BGP.

ldp | no-ldp—Enable or disable chained composite next-hops for LDP.

ldp-p2mp | no-ldp-p2mp—Enable or disable chained composite next-hops for LDP-signaled P2MP LSPs.

NOTE: The **ldp-p2mp** and **rsvp-p2mp** statements are not supported on MX series routers.

On an MX series router with redundant Routing Engines and enhanced-ip mode configuration, enabling the **ldp-p2mp** and **rsvp-p2mp** statements under the **[edit routing-options forwarding-table chained-composite-next-hop transit]** hierarchy level causes ping from the current master logical system to fail at the time of a Routing Engine switchover.

lsp-statistics-from-route—Enable LSP statistics collection from the route.

rsvp | no-rsvp—Enable or disable chained composite next-hops for RSVP.

rsvp-p2mp | no-rsvp-p2mp—Enable or disable chained composite next-hops for RSVP-signaled P2MP LSPs.

NOTE: The **ldp-p2mp** and **rsvp-p2mp** statements are not supported on MX series routers.

On an MX series router with redundant Routing Engines and enhanced-ip mode configuration, enabling the **rsvp-p2mp** and **ldp-p2mp** statements under the **[edit routing-options forwarding-table chained-composite-next-hop transit]** hierarchy level causes ping from the current master logical system to fail at the time of a Routing Engine switchover.

static | no-static—Chained composite next hops are enabled for transit static LSPs by default. You can also disable this functionality for transit static LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

clear rsvp session

List of Syntax

[Syntax on page 3356](#)

[Syntax \(EX and QFX Series Switches\) on page 3356](#)

Syntax

```
clear rsvp session
<all>
<connection-destination address>
<connection-source address>
<gracefully>
<logical-system (all | logical-system-name)>
<lsp-id identifier>
<name name>
<optimize-fast-reroute>
<tunnel-id identifier>
```

Syntax (EX and QFX Series Switches)

```
clear rsvp session
<connection-destination address>
<connection-source address>
<gracefully>
<lsp-id identifier>
<name name>
<optimize-fast-reroute>
<tunnel-id identifier>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Reset and restart Resource Reservation Protocol (RSVP) sessions.

Options

all—Clear all RSVP sessions for which this routing device is the ingress, transit, or egress routing device.

connection-source *address*—(Optional) Source address for GMPLS and MPLS LSPs from the RSVP sender template.

connection-destination *address*—(Optional) Destination address for GMPLS and MPLS LSPs from the RSVP sender template.

gracefully—(Optional) Gracefully reset an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin-Status object is signaled along the path to the other endpoint of the RSVP session. In the second pass, the path used by the RSVP session is torn down. This option can only be used on the ingress or egress routing device of the RSVP session and is only valid for nonpacket LSPs.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-id *identifier*—(Optional) LSP identifier (source port) for the RSVP sender template.

name *name*—(Optional) Reset and restart the specified RSVP session.

optimize-fast-reroute—(Optional) Begin fast reroute optimization.

tunnel-id *identifier*—(Optional) Tunnel identifier (destination port) for the RSVP session.

```

monitor label-switched-path

Syntax

```
monitor label-switched-path lsp-name
<logical-system (logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Logical system support introduced in Junos OS Release 9.4.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Display the real-time status of the specified RSVP label-switched path (LSP). You can also use this command to monitor LSPs configured within logical systems.

Options

logical-system (*logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-name—Name of the LSP.

Additional Information

You can track the amount of traffic traversing an RSVP LSP and observe its essential parameters, such as uptime, ingress and egress addresses, labels, routes, and ports. Values are typically sampled every second. The display also allows you to scroll to other currently running LSPs. You cannot use this command to display information about static LSPs or LDP-signaled LSPs.

The output of this command shows how much each field has changed since you started the command or since you cleared the counters by using the **c** key. To control the output of the **monitor label-switched-path** command while it is running, use the keys listed in [Table 120 on page 3360](#). The keys are not case-sensitive.

Table 120: Output Control Keys for the monitor label-switched-path Command

Key	Action
c	Clears the screen and refreshes the display for this LSP.
f	Freezes the display, preventing new information from being displayed.
l	Monitors a different LSP. After you type l, you can type the new LSP name.
n	Displays information about the next LSP (whose name is alphabetically higher than the current LSP name) configured on the router.

Table 120: Output Control Keys for the monitor label-switched-path Command (*continued*)

Key	Action
p	Goes to the previous LSP (whose name is alphabetically lower than the current LSP name) configured on the router.
q or Esc	Quits the command and returns to the command prompt.
t	Thaws, or restarts, the data display for this LSP.

trace

List of Sample Output[monitor label-switched-path on page 3362](#)**Output Fields**

[Table 121 on page 3361](#) describes the output fields for the **monitor label-switched-path** command. Output fields are listed in the approximate order in which they appear.

Table 121: monitor label-switched-path Output Fields

Field Name	Field Description
(1)	<p>Displays the following information:</p> <ul style="list-style-type: none"> • hostname—Name of the router. • Seconds—Time elapsed since this display was started. • Time—Current local time.
(2)	<p>Delay—Length of the time delay, in milliseconds, required to obtain the information in the monitor display. The first number shows the current sampling delay. The second number shows the shortest delay recorded to date. The third number shows the worst delay recorded to date. This delay can vary substantially depending on the system load.</p>
(3)	<p>Displays the following:</p> <ul style="list-style-type: none"> • To—Destination address of the LSP. • From—Originating address of the LSP. • State—Current state of the LSP: Up or Down.
(4)	<p>Displays the following:</p> <ul style="list-style-type: none"> • LSPName—Name of the LSP. • Type—Type of LSP: Ingress, Egress, or Transit.

ping mpls rsvp

Syntax

```
ping mpls rsvp
<lsp-name>
<count count>
<destination address>
<detail>
<dynamic-bypass>
<egress egress-address>
<exp forwarding-class>
<interface interface-name>
<logical-system (all | logical-system-name)>
<manual-bypass>
<multipoint>
<size bytes>
<source source-address>
<standby standby-path-name>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

The **egress** and **multipoint** options were introduced in Junos OS Release 9.2.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **dynamic-bypass** and **manual-bypass** options were introduced in Junos OS Release 10.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS RSVP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count count—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination address—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

NOTE: When using the **detail** option, the reported time is based on the system time configured on the local and remote routers. Differences in these system times can result in inaccurate one way ping trip times being reported.

In practice, it is difficult to synchronize the system times of independent Juniper Networks routers with sufficient accuracy to provide a meaningful time value for the **detail** option (even when synchronized using NTP).

dynamic-bypass—(Optional) Ping dynamically generated bypass LSPs, used for protecting other LSPs.

egress egress-address—(Optional) Only the specified egress router or switch responds to the ping request.

exp forwarding-class—(Optional) Value of the forwarding class for the MPLS ping packets.

interface—(Optional) Specify the name of the interface protected by the manual bypass LSP. This option is only available when you have also used the **manual-bypass** option.

logical-system (all | logical-system-name)—(Optional) Perform this operation on all logical systems or on the specified logical system.

lsp-name—Ping an RSVP-signaled LSP using an LSP name.

manual-bypass—(Optional) Ping manually configured bypass LSPs, used for protecting other LSPs. For this option, you must also specify the interface protected by the manual bypass LSP using the **interface** option.

multipoint—(Optional) Send ping requests to each of the egress routers or switches participating in a point-to-multipoint LSP. You can also include the **egress** option to ping a specific egress router or switch participating in a point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (**100** through **65468** bytes). Packets are 4-byte aligned. For example, if you enter a size of 101, 102, 103, or 104, the router or switch uses a size value of 104 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 100-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface.

standby standby-path-name—(Optional) Name of the standby path.

sweep —(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

[ping mpls rsvp \(Echo Reply Received\) on page 3366](#)
[ping mpls rsvp \(Echo Reply with Error Code\) on page 3367](#)
[ping mpls rsvp detail on page 3367](#)

[ping mpls rsvp destination detail count size on page 3368](#)
[ping mpls rsvp destination detail sweep size on page 3369](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls rsvp (Echo Reply Received)

```
user@host> ping mpls rsvp test1
```

```
!!!!!-- lsping statistics ---5 packets transmitted, 5 packets received, 0% packet
loss

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display the status of Resource Reservation Protocol (RSVP)-enabled interfaces and packet statistics. The RSVP input/input module collects statistics for certain events on a per-interface basis. Most of these events were tracked on a routing-instance basis in Junos OS releases earlier than Release 17.2. The **show rsvp interface detail** command displays these event counters under the **Events** section of the output only when the values of these fields are higher than zero. These statistics are also maintained at the global level (per routing-instance) and are also displayed in the output of the **show rsvp statistics** command.

Options

none—Display standard information about the status of RSVP-enabled interfaces and packet statistics.

brief | detail | extensive | link-management—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display RSVP status information for the specified instance. If **instance-name** is omitted, RSVP status information is displayed for the master instance.

link-management—(Optional) Use the link-management option to display the control peers and corresponding TE-link information created by the Link Management Protocol (LMP).

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 122 on page 3372](#) lists the output fields for the **show rsvp interface** command. Output fields are listed in the approximate order in which they appear.

Table 122: show rsvp interface Output Fields

Field Name	Field Description	Level of Output
RSVP interface	Number of interfaces on which RSVP is active. Each interface has one line of output.	All levels
Interface	Name of the interface.	All levels
Index	Index of the interface.	detail
State	State of the interface. <ul style="list-style-type: none"> • Disabled—No traffic engineering information is displayed. • Down—Interface is not operational. • Enabled—Displays traffic engineering information. • Up—Interface is operational. 	All levels
NoAuthentication	Interface does not support RSVP authentication.	detail
NoAggregate	Interface does not support refresh reduction.	detail
NoReliable	Interface does not support refresh reduction message ID extension.	detail
NoLinkProtection	Interface does not support link protection.	detail

Table 122: show rsvp interface Output Fields (continued)

Field Name	Field Description	Level of Output
HelloInterval	Frequency at which RSVP hellos are sent on this interface (in seconds). Prior to Junos OS Release 18.2R2, when the no-interface-hello statement is configured under the [edit protocols rsvp] hierarchy, and there is no interface-specific configuration for the hello interval, the HelloInterval output field displayed the default hello interval time of 9 seconds. Starting in Junos OS Release 18.2R2, with a similar configuration, the HelloInterval output field displays 0 as the hello interval.	detail
Address	IP address of the local interface.	detail
Active control channel	Next-hop link address to transmit messages.	None specified
TElink	Traffic-engineered links that are managed by the peer they are associated with.	None specified
Active resv	Number of reservations that are actively reserving bandwidth on the interface.	All levels
PreemptionCnt	Number of times an RSVP session was preempted on this interface.	detail
Update threshold	Percentage change in reserved bandwidth to trigger an IGP update.	detail
Subscription	User-configured subscription factor.	All levels
Actual	Available RSVP bandwidth that is recalculated after considering SPRING bandwidth utilization.	extensive
bc number	Bandwidth allocated for the specified bandwidth constraint.	extensive
ct number	Bandwidth allocated for the specified class type.	extensive
Static BW	Total interface bandwidth, in bps.	All levels
Available BW	Amount of bandwidth that RSVP is allowed to reserve, in bps. It is equal to (static bandwidth * subscription factor).	al levels
Reserved BW	Currently reserved bandwidth, in bps.	All levels
SoftPreemptionCnt	Number of times a soft preemption occurred on this interface. This number is not included in the PreemptionCnt value.	detail

Table 122: show rsvp interface Output Fields (*continued*)

Field Name	Field Description	Level of Output
Overbooked BW	Currently overbooked bandwidth, in bps, by class type (ct0 through ct3).	detail
Highwater mark	Highest bandwidth that has ever been reserved on this interface, in bps.	brief
PacketType	Type of RSVP packet.	detail
Total Sent	Total number of packets sent.	detail
Total Received	Total number of packets received since RSVP was enabled.	detail
Last 5 seconds Sent	Number of packets sent in the last 5 seconds.	detail
Last 5 seconds Received	Number of packets received in the last 5 seconds.	detail
Path	Statistics about Path messages, which are sent from the RSVP sender along the data paths and store path state information in each node along the path.	detail
PathErr	Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.	detail
PathTear	Statistics about PathTear messages, which remove path states and dependent reservation states in any routers along a path.	detail
Resv	Statistics about Resv messages, which are sent from the RSVP receiver along the data paths and store reservation state information in each node along the path.	detail
ResvErr	Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.	detail
ResvTear	Statistics about ResvTear messages, which remove reservation states along a path.	detail
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.	detail
Ack	Acknowledge message for refresh reductions.	detail

Table 122: show rsvp interface Output Fields (continued)

Field Name	Field Description	Level of Output
Srefresh	Summary refresh messages.	detail
EndtoEnd RSVP	Statistics for the number of end-to-end RSVP messages sent.	detail
Queue	CoS transmit queue number and its associated forwarding class designation.	extensive
TxRate	Configured bandwidth in Mbps and configured bandwidth as a percentage of the specified queue.	extensive
Priority	Weight of the queue relative to other configured queues, in percentage.	extensive
queue-priority-value	Low, High, None, or Exact. None indicates no rate limiting. Exact indicates the queue transmits at the configured rate only.	extensive

[show rsvp neighbor detail on page 3384](#)

Output Fields

Table 123 on page 3380 lists the output fields for the **show rsvp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 123: show rsvp neighbor Output Fields

Field Name	Field Description	Level of Output
RSVP neighbor	Number of neighbors that the routing device has learned of. Each neighbor has one line of output.	All levels
via	Name of the interface where the neighbor has been detected. In the case of generalized MPLS (GMPLS) LSPs, the name of the peer where the neighbor has been detected.	detail
Address	Address of a learned neighbor.	All levels
Idle	Length of time the neighbor has been idle, in seconds. NOTE: Until Junos OS Release 15.1, in the output of the show rsvp neighbor command, the value under the Idle field immediately reflects the changed idle time when a link in the neighboring router is brought down. Starting with Junos OS Release 15.2, a router does not declare a neighbor as idle when a hello adjacency exists and has not timed out. When an interface is brought down, RSVP brings down the neighbor because of the notification it receives from IGP. The reason for considering the IGP-down notification is to support BFD-triggered fast reroute (FRR) and RSVP-TE is not directly a client for BFD notifications. When RSVP brings down the neighbor, the input/output process is not impacted. As a result, the idle time in the output of the show command is not immediately updated.	All levels
Up/Dn	Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.	All levels
Up cnt and Down cnt	Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.	detail

Table 123: show rsvp neighbor Output Fields (*continued*)

Field Name	Field Description	Level of Output
status	<p>State of the RSVP neighbor:</p> <ul style="list-style-type: none"> • Up—Routing device can detect RSVP Hello messages from the neighbor. • Down—Routing device has received one of the following indications: <ul style="list-style-type: none"> • Communication failure from the neighbor. • Communication from IGP that the neighbor is unavailable. • Change in the sequence numbers in the RSVP Hello messages sent by the neighbor. • Restarting—RSVP neighbor is unavailable and might be restarting. The neighbor remains in this state until it has restarted or is declared dead. This state is possible only when graceful restart is enabled. • Restarted—RSVP neighbor has restarted and is undergoing state recovery (graceful restart) procedures. • Dead—Routing device has lost all communication with the RSVP neighbor. Any RSVP sessions with that neighbor are torn down. 	detail
LastChange	Time elapsed since the neighbor state changed either from up to down or from down to up. The format is hh:mm:ss .	All levels
Last changed time	Time elapsed since the neighbor state changed either from up to down or from down to up.	detail
HelloInt	Frequency at which RSVP hellos are sent on this interface (in seconds).	All levels
HelloTx/Rx	Number of hello packets sent to and received from the neighbor.	All levels
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.	detail
Message received	Number of Path and Resv messages that this routing device has received from the neighbor.	detail
Remote Instance	Identification provided by the remote routing device during Hello message exchange.	detail
Local Instance	Identification sent to the remote routing device during Hello message exchange.	detail

Table 123: show rsvp neighbor Output Fields (*continued*)

Field Name	Field Description	Level of Output
Refresh reduction	<p>Measure of processing overhead requests of refresh messages. Refresh reduction extensions improve routing device performance by reducing the process overhead, thus increasing the number of LSPs a routing device can support. Refresh reduction can have the following values:</p> <ul style="list-style-type: none"> • operational—All four RSVP refresh reduction extensions—message ack, bundling, summary refresh, and staged refresh timer—are functional between the two neighboring routing devices. For a detailed explanation of these extensions, see RFC 2961. • incomplete—Some RSVP refresh reduction extensions are functional between the two neighboring routing devices. • not operational—Either the refresh reduction feature has been turned off, or the remote routing device cannot support the refresh reduction extensions. 	detail
Remote end	<p>Neighboring routing device's status with regard to refresh reduction:</p> <ul style="list-style-type: none"> • enabled—Remote routing device has requested refresh reduction during RSVP message exchanges. • disabled—Remote routing device does not require refresh reduction. 	detail
Pop label	Pop labels of the RSVP-TE pop-and-forward LSP tunnels.	detail
Ack-extension	<p>An RSVP refresh reduction extension:</p> <ul style="list-style-type: none"> • enabled—Both local and remote routing devices support the ack-extension (RFC 2961). • disabled—Remote routing device does not support the ack-extension. 	detail
Link protection	<p>Status of the MPLS fast reroute mechanism that protects traffic from link failure:</p> <ul style="list-style-type: none"> • enabled—Link protection feature has been turned on, protecting the neighbor with a bypass LSP. • disabled—No link protection feature has been enabled for this neighbor. 	detail
LSP name	Name of the bypass LSP.	detail

Table 123: show rsvp neighbor Output Fields (*continued*)

Field Name	Field Description	Level of Output
Bypass LSP	Status of the bypass LSP. It can have the following values: <ul style="list-style-type: none"> • does not exist—Bypass LSP is not available. • connecting—Routing device is in the process of establishing a bypass LSP, and the LSP is not available for link protection at the moment. • operational—Bypass LSP is up and running. • down—Bypass LSP has gone down, with the most probable cause a node or a link failure on the bypass path. 	detail
Backup routes	Number of user LSPs (or routes) that are being protected by a bypass LSP (before link failure).	detail
Backup LSPs	Number of LSPs that have been temporarily established to maintain traffic by refreshing the downstream LSPs during link failure (not a one-to-one correspondence).	detail
Bypass explicit route	Explicit route object's (ERO) path that is taken by the bypass LSP.	detail
Restart time	Length of time a neighbor waits to receive a Hello from the restarting node before declaring the node dead and deleting the states (in milliseconds).	detail
Recovery time	Length of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds). Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.	detail

```

show rsvp route-session-id

Syntax

```
show rsvp route-session-id
```

Release Information

Command introduced in Junos OS Release 16.1 for the MX Series.

Description

Display the session ID and the version information associated with the ingress route added by the Resource Reservation Protocol (RSVP) in the inet.3 table.

Session ID is a pre-populated identifier used for indirect next hops in BGP Prefix Independent Convergence (PIC) enabled router. Session ID is used to identify the session or path.

NOTE: `protect core` configuration is not required to display the `route-session-id`.

Options

none—Validate and display RSVP route session details.

Required Privilege Level

view

List of Sample Output

[show rsvp route-session-id on page 3386](#)

Output Fields

[Table 124 on page 3385](#) describes the output fields for the `show rsvp route-session-id` command. Output fields are listed in the approximate order in which they appear.

Table 124: show rsvp route-session-id Output Fields

Field Name	Field Description
Ingress Route Destination	Destination (egress routing device) of the session.
Ingress Route Preference	RSVP preference value of the ingress session.
Ingress Route Metric 1	Metric 1 associated with the RSVP ingress route.

Table 124: show rsvp route-session-id Output Fields (*continued*)

Field Name	Field Description
Ingress Route Metric 2	Metric 2 associated with the RSVP ingress route.
Ingress Route Session ID	Session ID associated with the RSVP ingress route.
Version	Version number associated with the RSVP ingress route.

Sample Output

show rsvp route-session-id

user@host> **show rsvp route-session-id**

```
RSVP Ingress Route Session ID Database:
=====
Ingress Route Destination: 1.1.1.5/32
Ingress Route Preference: 7
Ingress Route Metric 1:    20,          Metric 2: 0
Ingress Route Session ID: 0x146,       Version: 0
```

show rsvp pop-and-forward

Syntax

```
show rsvp pop-and-forward
<brief | detail | extensive>
<instance routing-instance-name>
<label label>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 18.1R1 on MX Series routers, PTX Series routers, and vMX series routers.

Description

Display RSVP-TE pop-and-forward LSP tunnel information. This information includes the set of in-labels (one-hop pop label or a delegation label), the number of session using each label and the next segment-label (if there is another delegation hop downstream), and whether the in-label is used for unprotected or protected LSPs.

Options

none—Display the standard level of information for the RSVP-TE pop-and-forward LSP tunnels.

brief | detail | extensive—(Optional) Display the desired level of output. The brief option is the default level of output.

The detail option provides more information about the hops in a delegation segment (whether its one-hop or multi-hop).

The extensive option lists the set of LSPs that are using a given pop or delegation label.

instance *routing-instance-name*—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for the specified routing instance.

label *label*—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for the specified label.

logical-system (all | *logical-system-name*)—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for all or the specified logical system.

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

externally-provisioned option added in Junos OS Release 13.3.

Command introduced in Junos OS Release 13.2X51-D15 for QFX Series.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display information about RSVP sessions.

Options

none—Display standard information about all RSVP sessions.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

bidirectional | unidirectional—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.

bypass—(Optional) Display RSVP sessions for bypass LSPs.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

externally-provisioned—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

instance *instance-name*—(Optional) Display RSVP sessions for the specified instance. If **instance-name** is omitted, RSVP session information is displayed for the master instance.

interface *interface-name*—(Optional) Display RSVP sessions for the specified interface only.

RSVP reserves resources only for outgoing LSPs of an interface. Because resources are not reserved for incoming LSPs, the **show RSVP sessions interface *interface-name*** command output displays only those RSVP sessions whose next hops correspond to the specified interface.

To identify the number of RSVP sessions formed over the uplink interface on the egress label-switching router (LSR), you can use the following command:

```
user@host> show RSVP session egress extensive | match "PATH rcvfrom:" | match interface-name | count
```

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

name *session-name*—(Optional) Display information about the named session.

p2mp—(Optional) Display point-to-multipoint information.

session-type—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this routing device.

To identify the number of RSVP sessions formed over the uplink interface on the egress label-switching router (LSR), you can use the following command:

```
user@host> show rsvp session egress extensive | match "PATH rcvfrom:" | match interface-name
| count
```

- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that transit through this routing device.

statistics—(Optional) Display packet statistics.

te-link te-link—(Optional) Display sessions with reservations on the specified TE link.

Output Fields

[Table 125 on page 3393](#) describes the output fields for the **show rsvp session** command. Output fields are listed in the approximate order in which they appear.

Table 125: show rsvp session Output Fields

Field Name	Field Description	Level of Output
Ingress RSVP	Information about ingress RSVP sessions.	detail
Ingress RSVP	Information about ingress RSVP sessions. Each session has one line of output.	All levels
Egress RSVP	Information about egress RSVP sessions.	All levels
Transit RSVP	Information about the transit RSVP sessions.	All levels
P2MP name	(Appears only when the p2mp option is specified). Name of the point-to-multipoint LSP path.	All levels
P2MP branch count	(Appears only when the p2mp option is specified). Number of LSPs receiving packets from the point-to-multipoint LSP.	All levels
To	Destination (egress routing device) of the session.	All levels
From	Source (ingress routing device) of the session.	All levels
State	State of the path: Up , Down , or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	All levels
Address	Destination (egress routing device) of the LSP.	detail
From	Source (ingress routing device) of the session.	detail
LSPstate	State of the LSP that is being handled by this RSVP session. It can be either Up , Dn (down), or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	brief detail
Rt	Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
Active Route	Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (mpls.0).	detail
LSPname	Name of the LSP.	brief detail

Table 125: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. LSPpath can be either primary or secondary and can be displayed on the ingress, egress, and transit routing devices. LSPpath can also indicate when a graceful LSP deletion has been triggered.	detail
Bypass	(Egress routing device) Destination address for the bypass LSP.	detail
Bidir	(When LSP is bidirectional) LSP will allow data to travel in both directions between GMPLS devices.	detail
Bidirectional	(When LSP is bidirectional) LSP will allow data to travel both ways between GMPLS devices.	detail
Upstream label in	(When LSP is bidirectional) Incoming label for reverse direction traffic for this LSP.	detail
Upstream label out	(When LSP is bidirectional) Outgoing label for reverse direction traffic for this LSP.	detail
Recovery label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Recovery label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.	detail
Suggested label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Suggested label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.	detail
Resv style or Style	RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	brief detail
Label in	Incoming label for this LSP.	brief detail
Label out	Outgoing label for this LSP.	brief detail
Time left	Number of seconds remaining in the lifetime of the reservation.	brief detail

Table 125: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
Since	Date and time when the RSVP session was initiated.	detail
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	detail
DiffServ info	Indicates whether the LSP is a multiclass LSP (multiclass diffServ-TE LSP) or a Differentiated-Services-aware traffic engineering LSP (diffServ-TE LSP).	detail
bandwidth	Bandwidth for each class type (ct0 , ct1 , ct2 , or ct3).	detail
Port number	Protocol ID and sender/receiver port used in this RSVP session.	detail
Attrib flags	Non-PHP indicates that ultimate hop popping has been requested by the LSP using this RSVP session	extensive
FastReroute desired	Fast reroute has been requested by the ingress routing device.	detail
Soft preemption desired	Soft preemption has been requested by the ingress routing device.	detail
FastReroute desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Fast reroute (one-to-one backup) has been requested by the ingress routing device.	detail extensive
Link protection desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Link protection (many-to-one backup) has been requested by the ingress routing device.	detail extensive
Node/Link protection desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Node and link protection (many-to-one backup) has been requested by the ingress routing device.	detail extensive

Table 125: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Type	<p>LSP type:</p> <ul style="list-style-type: none"> • Link protected LSP—LSP has been protected by link protection at the outgoing interface. The name of the bypass used is also listed here (extensive). • Node/Link protected LSP—LSP has been protected by node and link protection at the outgoing interface. The name of the bypass used is also listed here (extensive). • Protection down—LSP is not currently protected. • Bypass LSP—LSP that is used to protected one or more user LSPs in case of link failure. • Backup LSP at Point-of-Local-Repair (PLR)—LSP that has been temporarily established to protected a user LSP at the ingress of a failed link. • Backup LSP at Merge Point (MP)—LSP that has been temporarily established to protected a user LSP at the egress of a failed link. 	detail extensive
New bypass	New bypass (the bypass name is also displayed) has been activated to protect the LSP.	extensive
Link protection up, using <i>bypass-name</i>	Link protection (the bypass name is also displayed) has been activated for the LSP.	extensive
Creating backup LSP, link down	A link down event occurred, and traffic is being switched over to the bypass LSP.	extensive
Deleting backup LSP, protected LSP restored	Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.	extensive
Path mtu	Displays the value of the path MTU received from the network (through signaling) and the value used for forwarding. This value is only displayed on ingress routing devices with the allow-fragmentation statement configured at the [edit protocols mpls path-mtu] hierarchy level. If there is a detour LSP, the path MTU for the detour is also displayed.	detail

Table 125: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Egress protection PLR as protector	RSVP state on the Protector or the point-of-local-repair (PLR) routing device: <ul style="list-style-type: none"> • Active— Egress protection is available at the Protector or the PLR routing device. • In Use— Local repair has been completed. 	detail
PATH rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor.	detail
Adspec	MTU signaled from the ingress routing device to the egress routing device by means of the adspec object.	detail
PATH sentto	Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor (or peer-name in the GMPLS LSP case), and number of packets sent to the downstream routing device.	detail
Explct route	Explicit route for the session. Normally this value will be the same as that of record route. Differences indicate that path rerouting has occurred, typically during fast reroute.	detail
Record route	Recorded route for the session, taken from the record route object. Normally this value will be the same as that of explct route. Differences indicate that path rerouting has occurred, typically during fast reroute.	detail

```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about Resource Reservation Protocol (RSVP) sessions.

Options

none—Display standard information about all RSVP sessions.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

bidirectional | unidirectional—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

interface *interface-name*—(Optional) Display RSVP sessions for the specified interface only.

lsp-type —(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

name *session-name*—(Optional) Display information about the named session.

session-type—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this switch.
- **ingress**—Sessions that originate from this switch.

- **transit**—Sessions that transit through this switch.

statistics—(Optional) Display packet statistics.

te-link *te-link*—(Optional) Display sessions with reservations on the specified traffic-engineered link name.

Output Fields

[Table 126 on page 3406](#) describes the output fields for the **show rsvp session** command. Output fields are listed in the approximate order in which they appear.

Table 126: show rsvp session Output Fields

Field Name	Field Description	Level of Output
Ingress RSVP	Information about ingress RSVP sessions.	detail
Ingress RSVP	Information about ingress RSVP sessions. Each session has one line of output.	All levels
Egress RSVP	Information about egress RSVP sessions.	All levels
Transit RSVP	Information about the transit RSVP sessions.	All levels
To	Destination (egress switch) of the session.	All levels
From	Source (ingress switch) of the session.	All levels

Table 126: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
State	State of the path: Up , Down , or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	All levels
Address	Destination (egress switch) of the LSP.	detail
LSPstate	State of the LSP that is being handled by this RSVP session. It can be either Up , Dn (down), or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	brief, detail
Rt	Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
ActiveRoute	Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (mpls.0).	detail
LSPname	Name of the LSP.	brief, detail
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. LSPpath can be either primary or secondary and can be displayed on the ingress, egress, and transit switches. LSPpath can also indicate when a graceful LSP deletion has been triggered.	detail
Recovery label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Recovery label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.	detail
Suggested label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Suggested label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.	detail
Resv style or Style	RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	brief detail

Table 126: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
Label in	Incoming label for this LSP.	brief, detail
Label out	Outgoing label for this LSP.	brief, detail
Time left	Number of seconds remaining in the lifetime of the reservation.	brief, detail
Since	Date and time when the RSVP session was initiated.	detail
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	detail
Port number	Protocol ID and sender/receiver port used in this RSVP session.	detail
Creating backup LSP, link down	A link down event occurred, and traffic is being switched over to the bypass LSP.	extensive
Deleting backup LSP, protected LSP restored	Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.	extensive
PATH rcvfrom	Address of the previous-hop (upstream) switch or client, interface the neighbor used to reach this switch, and number of packets received from the upstream neighbor.	detail

<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switches)

```
show rsvp statistics
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display Resource Reservation Protocol (RSVP) packet and error statistics. The RSVP input/output module collects statistics for certain events on a per-interface basis. Most of these events were tracked on a routing-instance basis in Junos OS releases earlier than Release 17.2. The "show rsvp interface detail" command displays these event counters under the Events section of the output only when the values of these fields are higher than zero. These statistics are also maintained at the global level (per routing-instance) and are also displayed in the output of the "show rsvp statistics" command.

Options

none—Display RSVP packet and error statistics.

instance *instance-name*—(Optional) Display RSVP packet and error statistics for the specified instance. If **instance-name** is omitted, RSVP statistics are displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 127 on page 3412](#) describes the output fields for the **show rsvp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 127: show rsvp statistics Output Fields

Field Name	Field Description
Packet Type	Statistics about different RSVP messages.
Total Sent	Total number of packets sent since RSVP was enabled.
Total Received	Total number of packets received since RSVP was enabled.
Last 5 seconds Sent	Total number of packets sent in the last 5 seconds.
Last 5 seconds Received	Number of packets received in the last 5 seconds.
Path	Statistics about Path messages, which are sent from the RSVP sender along the data paths and which store path state information in each node along the path.
PathErr	Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.
PathTear	Statistics about PathTear messages, which remove path states and dependent reservation states in any routing devices along a path.
Resv FF	Statistics about fixed-filter reservation style messages, which consist of distinct reservations among explicit senders.
Resv WF	Statistics about wildcard-filter reservation style messages, which consist of shared reservations among wildcard senders.
Res SE	Statistics about shared-explicit reservation style messages, which consist of shared reservations among explicit senders.
ResvErr	Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.

Table 127: show rsvp statistics Output Fields (*continued*)

Field Name	Field Description
ResvTear	Statistics about ResvTear messages, which remove reservation states along a path.
ResvConf	Statistics about ResvConfirm messages, which are responses to confirm a reservation request.
Ack	Acknowledge message for refresh reductions.
SRefresh	Summary refresh messages.
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.
EndtoEnd RSVP	Statistics for the number of End-to-end RSVP messages.
Errors	Statistics about errored RSVP packets.
Rcv pkt bad length	The packet was not processed because its length is inappropriate.
Rcv pkt unknown type	The packet is not one of the well-known RSVP types, as defined in RFC 2205, <i>Resource ReSerVation Protocol (RSVP)</i> .
Rcv pkt bad version	The packet is not an RSVP version 1 packet.
Rcv pkt auth fail	The packet failed authentication checks.
Rcv pkt bad checksum	The RSVP checksum check failed.
Rcv pkt bad format	General packet processing failed because the packet was badly formed.
Memory allocation fail	An internal resource failure occurred.
No path information	A reservation was received, but no sender is active.
Resv style conflict	The same session contains inconsistent reservation styles.
Port conflict	There were inconsistent port numbers for the same session.
Resv no interface	An interface for the receive reservation packets cannot be located.
PathErr to client	Number of PathErr packets delivered to the local client.

Table 127: show rsvp statistics Output Fields (*continued*)

Field Name	Field Description
ResvErr to client	Number of ResvErr packets delivered to the local client.
Path timeout	Number of times the sender timed out because the path was removed.
Resv timeout	Number of times the receiver timed out because the reservation was removed.
Message out-of-order	Records the number of RSVP incoming messages that are considered out of order. This is detected from the message ID object's sequence number.
Unknown ack msg	A neighboring routing device replies with an ACK object that contains an unknown message ID. This can indicate a message ID handshake problem. For example, a router receives an ACK for message IDs 1, 2, and 3. However, it only has state for message IDs 1 and 3. The router increments the unknown ack counter by 1.
Recv nack	If a neighboring router receives an unknown message ID in an RSVP refresh message, the router sends a Resv nack message back to the sender. This can happen if that neighbor has been rebooted. For this case, the router sends a regular RSVP refresh message to recover the state and start the message-ID handshake process again.
Recv duplicated msg-id	Number of times the same message ID is used by two different RSVP messages. This duplication is usually caused when a neighboring routing device restarts.
No TE-link to recv Hop	Counter of packets discarded because a TE link was not found.
Rcv pkt disabled interface	Number of RSVP packets received on an interface that is not enabled for RSVP.
Transmit buffer full	Number of times the buffer for assembling an outgoing RSVP message was not large enough.
Transmit failure	Number of times the RSVP task failed to send out a packet.
Receive failure	Number of times the RSVP task failed to read an incoming packet.
P2MP RESV discarded by appl	Number of Resv messages discarded because the MPLS label is not valid for the P2MP LSP application.
Rate limit	Number of RSVP packets dropped due to rate limiting.
Err msg loop detected	Number of RSVP error messages that have looped back to their originator. This is detected by checking the error node address in the ERROR_SPEC object.

Sample Output

show rsvp statistics

Starting in Junos OS Release 16.1, this command also shows conditional PathTear statistics and the number of times an LSP state has been retained because of Link Protecting Merge Point (LP-MP) or Node Protecting Merge Point (NP-MP) determination.

```

[show rsvp version on page 3422](#)

Output Fields

[Table 128 on page 3420](#) describes the output fields for the **show rsvp version** command. Output fields are listed in the approximate order in which they appear.

Table 128: show rsvp version Output Fields

Field Name	Field Description
Resource ReSerVation Protocol, version	RSVP software version.
RSVP protocol	Status of RSVP: Enabled or Disabled .
R(refresh timer)	Configured time interval used to generate periodic RSVP messages.
K(keep multiplier)	Number of RSVP messages that can be lost before an RSVP state is declared stale.
Preemption	Currently configured preemption capability: Aggressive , Disabled , or Normal . The default is Normal .
Soft-preemption cleanup	Time, in seconds, that an LSP is kept after it has been soft preempted. This is a global property of the RSVP protocol.
Graceful deleting timeout	Currently configured value for the graceful-deletion-timeout statement. The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.
NSR Mode	Status of the nonstop active routing feature for RSVP on the restarting device: Disabled , Enabled/Master , or Enabled/Standby .
NSR State	<p>State of the nonstop active routing feature for RSVP on the restarting device.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> • Idle • TE-link sync complete • Neighbor sync complete • Path state sync complete • Resv state sync complete • Bypass sync complete • Init sync complete
Setup protection	Status of point-to-point and point-to-multipoint LSP setup protection configuration on the device: Enabled or Disabled .

Table 128: show rsvp version Output Fields (continued)

Field Name	Field Description
Route Session-Id count	<p>Total count of session IDs associated with the combination of all the RSVP ingress routes.</p> <p>NOTE: Starting in Junos OS Release 16.1, the show rsvp version command output displays the Route Session-Id count output field by default, irrespective of the presence of associated session IDs.</p> <p>When there are no session IDs associated with any RSVP ingress route, the <i>Route Session-Id count</i> value is zero (0).</p>
Graceful restart	Status of the graceful restart feature for RSVP on the restarting routing device: Enabled or Disabled .
Restart helper mode	Status of the helper mode feature: Enabled or Disabled . When this feature is enabled, the restarting routing device can help the neighbor with its RSVP restart procedures.
Maximum helper restart time	Number of milliseconds (ms) configured for the maximum helper restart time. The maximum helper restart time is the length of time the routing device waits before declaring that an RSVP neighbor attempting to restart gracefully is down.
Maximum helper recovery time	Number of milliseconds configured for the maximum helper recovery time. The maximum helper recovery time is the amount of time the routing device maintains the state of an RSVP neighbor attempting to restart gracefully.
Restart time	Number of milliseconds that a neighbor waits to receive a Hello message from the restarting node before declaring the node dead and deleting the states.
Recovery time	Number of milliseconds during which the restarting node attempts to recover its lost states with help from its neighbors. Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.
P2p transit LSP nexthop mode	Point-to-point transit LSP next-hop mode on PTX Series devices. The possible values are Chained or Unchained .
P2mp transit LSP nexthop mode	Point-to-multipoint transit LSP next-hop mode on PTX Series devices. The possible values are Chained or Unchained .

Sample Output

show rsvp version

Starting with Junos OS Release 16.1, this command also shows whether enhanced FRR procurers are enabled on the router.

```
user@host> show rsvp version
```

```
Resource ReSerVation Protocol, version 1. rfc2205
  RSVP protocol:                Enabled
  R(refresh timer):              30 seconds
  K(keep multiplier):            3
  Preemption:                    Normal
  Soft-preemption cleanup:       30 seconds
  Graceful deletion timeout:     30 seconds
  NSR mode:                      Enabled/Master

```

traceroute mpls rsvp

Syntax

```
traceroute mpls <rsvp> lsp-name  
<detail>  
<egress>  
<exp>  
<logical-system>  
<multipoint>  
<no-resolve>  
<retries>  
<source source-address>  
<ttl>
```

Release Information

Command introduced in Junos OS Release 9.2.

egress, **multipoint**, and **ttl** options added in Junos OS Release 11.2.

Description

Trace route to a remote host for an MPLS LSP signaled by RSVP. Use **traceroute mpls rsvp** as a debugging tool to locate MPLS label-switched path (LSP) forwarding issues in a network. (Currently supported for IPv4 packets only.)

Options

lsp-name—Specify the name of the LSP to be traced.

detail—(Optional) Display detailed output.

egress—(Optional) Request that a specific point-to-multipoint egress node reply to the trace route. The trace route would follow the associated sub-LSP to the egress node.

exp—(Optional) Specify the class of service to use when sending probes. The range of values is 0 through 7. The default value is 7.

logical-system—(Optional) Specify the name of the logical system for the traceroute attempt.

multipoint—(Optional) Perform a trace route on a point-to-multipoint LSP.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

retries—(Optional) Specify the number of times to resend probe. The range of values is 1 through 9. The default value is 3.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl—(Optional) Specify the number of hops to follow before forcing the trace route to quit.

Required Privilege Level

network

[traceroute mpls rsvp on page 3425](#)

[traceroute mpls rsvp detail on page 3425](#)

[traceroute mpls rsvp multipoint \(branch node for sub-LSPs\) on page 3426](#)

[traceroute mpls rsvp multipoint \(single-hop sub-LSPs\) on page 3427](#)

Output Fields

[Table 129 on page 3424](#) describes the output fields for the **traceroute mpls rsvp *lsp-name*** and **traceroute mpls rsvp *lsp-name* detail** commands. Output fields are listed in the approximate order in which they appear.

Table 129: traceroute mpls rsvp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the traceroute mpls rsvp <i>lsp-name</i> command.	all levels
ttl	Time-to-live value of the labeled packet.	none specified
Label	MPLS label used to forward the packets along the LSP.	none specified
Protocol	Signaling protocol used. For this command, it is RSVP-TE.	none specified
Address	Address of the next hop.	none specified
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null.	none specified
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths). Displays Success if the trace to a hop is successful or Egress if the trace has reached the last router on the path.	none specified
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	detail
Parent	Address of the previous hop. Parent value for the first hop is null.	detail
Return Code	Return code for reporting the result of processing the echo request by the receiver.	detail

Table 129: traceroute mpls rsvp Output Fields (continued)

Field Name	Field Description	Level of Output
Sender timestamp	Displays the timestamp when the MPLS echo request is sent to the next hop.	detail
Receiver timestamp	Timestamp when the echo request from the previous hop is received and acknowledged with an echo response by the next hop.	detail
Response time	Time for the echo request to reach the receiver.	detail
MTU	Size of the largest packet that includes the label stack forwarded to the next hop.	detail
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none.	detail
Label stack	Label stack used to forward the packet.	detail
Path	Displays the sub-lsp path number for this traceroute, the interface used, and the destination address.	all levels

Sample Output

traceroute mpls rsvp

```

- show ldp path | 3467
- show ldp route | 3469
- show ldp session | 3480
- show ldp statistics | 3488
- show ldp traffic-statistics | 3494
- show security keychain | 3499
- traceroute mpls ldp | 3502
- traceroute mpls segment-routing ospf | 3507
- traceroute mpls segment-routing isis | 3511

clear ldp neighbor

Syntax

```
clear ldp neighbor  
<instance instance-name>  
<logical-system (all | logical-system-name)>  
<neighbor>
```

Description

Tear down Label Distribution Protocol (LDP) neighbor connections.

Options

none—Tear down connections with all LDP neighbors for all routing instances.

instance *instance name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

neighbor—(Optional) Clear an LDP session for the specified neighbor (IP address) only.

Required Privilege Level

clear

RELATED DOCUMENTATION

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

```
clear ldp neighbor
```

```
user@host> clear ldp neighbor
```

clear ldp session

Syntax

```
clear ldp session  
<all>  
<destination>  
<instance instance-name>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Clear Label Distribution Protocol (LDP) sessions.

Options

all—Clear LDP sessions for all destinations for all routing instances.

destination—(Optional) Clear an LDP session for the specified destination (IP address).

instance *instance-name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

Sample Output

clear ldap session

```
user@host> clear ldap session all
```

clear ldp statistics

Syntax

```
clear ldp statistics  
<instance instance-name>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Set all Label Distribution Protocol (LDP) statistics to zero.

Options

none—Set all LDP statistics to zero for all routing instances.

instance *instance-name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

Sample Output

```
clear ldp statistics
```

```
user@host> clear ldp statistics
```

ping mpls ldp

Syntax

```
ping mpls ldp fec
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<p2mp root-addr ip-address lsp-id identifier>
<size bytes>
<source source-address>
<stitched-protocol>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

size and **sweep** options introduced in Junos OS Release 9.6.

instance option introduced in Junos OS Release 10.0.

p2mp, **root-address**, and **lsp-id** options introduced in Junos OS Release 11.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS LDP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (**all** | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr ip-address lsp-id identifier—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (**88** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

stitched-protocol—(Optional) Protocol stitched on intermediate node.

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

You can configure the ping interval for the **ping mpls ldp** command by specifying a new time in seconds using the **lsp-ping-interval** statement at the **[edit protocols ldp oam]** hierarchy level. For more information, see the *MPLS Applications User Guide*.

In asymmetric MTU scenarios, the echo response may be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

[ping mpls ldp fec count on page 3436](#)

[ping mpls ldp p2mp root-addr lsp-id on page 3436](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls ldp fec count

```
user@host> ping mpls ldp 10.255.245.222 count 10
```

```
!!!xxx...x--- lsping statistics ---10 packets transmitted, 3 packets received, 70%
packet loss 4 packets received with error status, not counted as received.
```

ping mpls ldp p2mp root-addr lsp-id

```
user@host> ping mpls ldp p2mp root-addr 10.1.1.1/32 lsp-id 1 count 1
```

```

<source source-address>
<stitched-protocol>
<sweep>
```

Release Information

Command introduced in Junos OS Release 19.1R1

Description

Check the operability of MPLS segment routing label-switched path (LSP) connections added by ospf protocol. Type Ctrl+c to interrupt a **ping mpls segment routing ospf** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr *ip-address* *lsp-id identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

stitched-protocol—(Optional) Protocol stitched on intermediate node.

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

```

ping mpls segment routing isis

Syntax

```
ping mpls segment routing isis fec
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<p2mp root-addr ip-address lsp-id identifier>
<size bytes>
<source source-address>
<stitched-protocol>
<sweep>
```

Release Information

Command introduced in Junos OS Release 19.1R1

Description

Check the operability of MPLS segment routing label-switched path (LSP) connections added by ISIS protocol. Type Ctrl+c to interrupt a **ping mpls segment routing isis** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (*all* | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr *ip-address* *lsp-id identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

stitched-protocol—(Optional) Protocol stitched on intermediate node.

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Required Privilege Level

network

List of Sample Output

[ping mpls segment-routing isis on page 3441](#)

[ping mpls segment-routing isis on page 3441](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls segment-routing isis

```
user@host>ping mpls segment-routing isis 6.6.6.6
```

```

show ldp database

Syntax

```
show ldp database
<brief | detail | extensive>
<inet | l2circuit>
<instance instance-name>
<logical-system (all | logical-system-name)>
<p2mp>
<session session>
<summary>
```

Release Information

Command introduced before Junos OS Release 7.4.

summary option introduced in Junos OS Release 14.2.

Description

Display entries in the LDP database.

Options

none—Display standard information about all entries in the LDP database for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

inet | l2circuit—(Optional) Display only IPv4 or Layer 2 circuit bindings.

instance *instance-name*—(Optional) Display routing instance information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

p2mp—(Optional) Display point-to-multipoint binding information.

session *session*—(Optional) Display database for the specified session only. ***session*** is the destination address of the LDP session.

summary—(Optional)—Display summary output. This option displays the number of labels received and advertised for each LDP session.

Output Fields

[Table 130 on page 3444](#) describes the output fields for the **show ldp database** command. Output fields are listed in the approximate order in which they appear.

Table 130: show ldp database Output Fields

Field Name	Field Description	Level of Output
Input label database	Label received from the other router.	All levels
Output label database	Label advertised to the other router.	All levels
<i>session-identifier</i>	Session identifier, which includes the local and remote label space identifiers.	All levels
Labels received	Number of labels received from the other router.	All levels
Labels advertised	Number of labels advertised to the other router.	All levels.
Label	Label binding to a route prefix.	All levels

Table 130: show ldp database Output Fields (*continued*)

Field Name	Field Description	Level of Output
Prefix	<p>Route prefix.</p> <p>It can be one of the following values:</p> <ul style="list-style-type: none"> • IP prefix. • Point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured. • Layer 2 encapsulation type. <p>Layer 2 encapsulation types are displayed in the format L2CKT control word status encapsulation-type vc-number, for example, L2CKT CtlfWord FRAME RELAY VC 2</p> <ul style="list-style-type: none"> • control-word-status—Displays whether the use of the control word has been negotiated for this virtual circuit: <ul style="list-style-type: none"> • NoCtrlWord • CtrlWord • encapsulation-type—Encapsulation type: <ul style="list-style-type: none"> • FRAME RELAY • ATM AAL5 • ATM CELL • VLAN • ETHERNET • CISCO_HDLC • PPP • VC number—Virtual circuit number. It can have any numeric value. • (Stale)—When you display the LDP database for the neighbor of a restarting router, the bindings learned from the restarting neighbor are displayed as (Stale). Stale bindings are deleted if they are not refreshed within the recovery time. 	All levels
MTU	MTU of the Layer 2 circuit. MTU is displayed for all encapsulation types except ATM cell encapsulations.	detail
VCCV Control Channel types	<p>Virtual Circuit Connection Verification (VCCV) control channel types.</p> <ul style="list-style-type: none"> • MPLS router alert label • MPLS PW label with TTL=1 	extensive

Table 130: show ldp database Output Fields (*continued*)

Field Name	Field Description	Level of Output
VCCV Control Verification types	The only valid VCCV control verification type is LSP ping .	extensive
TDM payload size	Size of the Time Division Multiplex (TDM) payload.	All levels
TDM bitrate	Bit rate for the TDM traffic.	All levels
Requested VLAN ID	(VLANs) VLAN identifier of the Layer 2 circuit.	detail
Cell bundle size	(ATM cell encapsulations) Maximum number of cells that the Layer 2 circuit can receive in a packet.	detail
State	State of the label binding: <ul style="list-style-type: none"> • Active—Label binding has been installed and distributed appropriately. A label binding is almost always in this state. • New—New label that has not yet been distributed. <ul style="list-style-type: none"> • MapRcv—Waiting to receive a label mapping message. • MapSend—Waiting to send a label mapping message. • RelRcv—Waiting to receive a label release message. • RelRsnd—Waiting to receive a label release message before resending label mapping message. • RelSend—Waiting to send a label release message. • ReqSend—Waiting to send a label request message. • W/dSend—Waiting to send a label withdrawal message. 	detail
Age	Time elapsed since the binding was created.	detail

show ldp fec-filters

Syntax

```
show ldp fec-filters
<fec>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display information about configured Label Distribution Protocol (LDP) forwarding equivalence class (FEC) filters.

Options

- fec**—(Optional) Display FEC filter information for the specified FEC.
- instance instance-name**—(Optional) Display FEC filter information for the specified instance.
- logical-system (all | logical-system-name)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 131 on page 3454](#) lists the output fields for the **show ldp fec-filters** command. Output fields are listed in the approximate order in which they appear.

Table 131: show ldp fec-filters Output Fields

Field Name	Field Description
Ingress	Names of the FEC filters on the ingress routers.
Transit	Names of the FEC filters on the transit routers.

Sample Output

show ldp fec-filters

user@host> **show ldp fec-filters 10/8**

```
10.22.1.2/32
  Ingress: f1-10.22.1.2/32 (index: 3)
  Transit: (null) (index: 0)
```

show ldp interface

Syntax

```
show ldp interface
<brief | detail | extensive>
<interface-name>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display the status of Label Distribution Protocol (LDP)-enabled interfaces.

Options

- none**—Display standard status information about all LDP-enabled interface for all routing instances.
- interface-name**—(Optional) Display information for the specified interface.
- brief | detail | extensive**—(Optional) Display the specified level of output.
- instance instance-name**—(Optional) Display information for the specified routing instance.
- logical-system (all | logical-system-name)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 132 on page 3456](#) describes the output fields for the **show ldp interface** command. Output fields are listed in the approximate order in which they appear.

Table 132: show ldp interface Output Fields

Field Name	Field Description	Level of Output
Interface	Interface name.	All levels

Table 132: show ldp interface Output Fields (*continued*)

Field Name	Field Description	Level of Output
Label space ID	Label space identifier that the router is advertising on the interface.	All levels
Nbr count	Number of neighbors on the interface.	All levels
Next hello	How long until the next hello packet is sent on this interface, in seconds.	All levels
Hello interval	One-third of the negotiated hold time (in seconds). If the user-configured value for the hello interval is smaller than the computed value, the user-configured value is used.	detail extensive
Hold time	Configured hold time, in seconds.	detail extensive
Transport address	Address to which the neighbor wants the local route to establish the LDP session.	extensive
Local hello interval	Locally configured hello interval.	extensive

Sample Output

show ldp interface extensive

user@host> **show ldp interface extensive**

```
Interface          Label space ID      Nbr count  Next hello
fe-0/0/3.0         10.255.245.6:0      2          0
  Hello interval: 1, Hold time: 15, Transport address: 10.255.245.6
  Local hello interval: 2, Index: 69
```

show ldp neighbor

Syntax

```
show ldp neighbor  
<brief | detail | extensive>  
<auto-targeted>  
<instance instance-name>  
<logical-system (all | logical-system-name)>  
<neighbor-address>
```

Release Information

Command introduced before Junos OS Release 7.4.

neighbor-address option added in Junos OS Release 8.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

auto-targeted option added in Junos OS Release 14.2.

Description

Display Label Distribution Protocol (LDP) neighbor information.

Options

none—Display standard information about LDP neighbors for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

auto-targeted—(Optional) Display information about LDP neighbors that are automatically targeted using the loopback addresses.

instance *instance-name*—(Optional) Display information for the specified routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

neighbor-address—(Optional) Display information about the specified LDP neighbor.

Output Fields

[Table 133 on page 3459](#) describes the output fields for the **show ldp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 133: show ldp neighbor Output Fields

Field Name	Field Description	Level of Output
Address	IP address of the neighbor.	All levels
Interface	Interface over which the neighbor was discovered.	All levels
Label space ID	Label space identifier advertised by the neighbor.	All levels
Hold time	Remaining hold time before the neighbor expires, in seconds.	All levels
Transport address	Address to which the neighbor wants the local route to establish the LDP session.	detail
Configuration sequence	Counter that increments whenever the neighbor changes its configuration.	detail
Up for	Length of time the LDP neighbor has been in operation.	detail extensive
Reference count	Reference count for the LDP neighbor.	extensive
Hold time	Displays the neighbor's hold time. The hold time is the proposed hold times for the local and peer routers.	extensive
Proposed local/peer	Hold time value proposed by the local router and the peer router.	extensive

Sample Output

show ldp neighbor extensive

```
user@host> show ldp neighbor extensive
```

```

Address          Interface      Label space ID      Hold Time
192.168.37.23    so-1/0/0.0    10.255.245.5:0      44

```

Release Information

Command introduced in Junos OS Release 11.2.

Description

Display LDP overview information.

Options

none— Display standard overview information about LDP for all routing instances.

instance *instance-name*— (Optional) Display LDP overview information for the specified routing instance.

logical-system (all | *logical-system-name*)— (Optional) Display LDP information from systems or a particular logical system on the devices.

Output Fields

[Table 134 on page 3461](#) lists the output fields for the **show ldp overview** command. Output fields are listed in the approximate order in which they appear.

Table 134: show ldp overview Output Fields

Field Name	Field description	Level of Output
Instance	LDP routing instance.	All Levels
Router ID	Router ID of the routing device.	All Levels

Table 134: show ldp overview Output Fields (*continued*)

Field Name	Field description	Level of Output
Message ID	Unique identifier of message.	All Levels
Configuration sequence	Value of configuration sequence.	All Levels
Deaggregate	Status of control forwarding equivalence class (FEC) deaggregation on the router. By default it is disabled on the router.	All Levels
Explicit null	Advertise label 0 to the egress routing device of an LSP. Explicit null: enabled or disabled . NOTE: If you do not include the explicit-null statement in the configuration, label 3 (implicit null) is advertised.	All Levels
IPv6 tunneling	Internet Protocol version 6 tunneling: enabled or disabled .	All Levels
Strict targeted hellos	Prevent LDP sessions from being established with remote neighbors that have not been specifically configured. Strict targeted hellos: enabled or disabled . NOTE: LDP peers will not respond to targeted hellos coming from a source that is not one of the configured remote neighbors.	All Levels
Loopback if added	Loopback interface is added: yes or no .	All Levels
Route preference	Default preference value (also known as an administrative distance) assigned to each route that the routing table receives. LDP preference is: 9	All Levels
Unicast transit LSP chaining	Unicast transit LSP chaining: enabled or disabled .	All Levels
P2MP transit LSP chaining	P2MP transit LSP chaining: enabled or disabled .	All Levels
Transit LSP statistics based on route statistics	Transit LSP statistics based on route statistics: enabled or disabled .	All Levels
Longest match	Longest match for label mapping: enabled or disabled .	All Levels
Capabilities enabled	Enabled capabilities: none	All Levels

Table 134: show ldp overview Output Fields (*continued*)

Field Name	Field description	Level of Output
Timers	<ul style="list-style-type: none"> • Keepalive interval: Keepalive interval value. • Keepalive timeout: Time interval for which the neighbor LDP node waits before determining session failure. • Link hello interval: Specify how often the router sends Link Management Protocol (LMP) hello packets. • Link hello hold time: Time interval for which an LDP node waits for a hello message before declaring a neighbor is down. • Targeted hello interval: Specify how often LDP sends targeted hello messages. • Targeted hello hold time: Time interval for which a sending LSR maintains a record of targeted hello messages from the receiving LSR without receipt of another targeted hello message from that LSR. • Label withdraw delay: Time interval for withdrawing labels to reduce router workload during IGP convergence. 	All Levels
Graceful restart	<p>Graceful restart attributes.</p> <ul style="list-style-type: none"> • Restart– Graceful restart capability: enabled or disabled. • Helper– Standard graceful restart helper capability: enabled or disabled. • Restart in process– Graceful restart in process. • Reconnect time– Period of time that a restarting LSR (label switched router) designates to LDP neighbors to wait until the former reestablishes the session after restarting. • Max neighbor reconnect time– Maximum reconnect time. • Recovery time– Period of time that an LSR preserves its state across the restart. • Max neighbor recovery time– Maximum recovery time designated to LDP neighbors by a restarting LSR. 	All Levels
Traffic Engineering	<ul style="list-style-type: none"> • Bgp igp– BGP and IGP destinations: enabled or disabled. When enabled, IGP's use MPLS paths for forwarding traffic. • Both ribs– BGP and IGP destinations with routes in both RIBs: enabled or disabled. • Mpls forwarding– MPLS routes used for forwarding: enabled or disabled. 	All Levels

Table 134: show ldp overview Output Fields (*continued*)

Field Name	Field description	Level of Output
IGP	<ul style="list-style-type: none"> • Tracking igp metric—Cause the IGP route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1). • Sync session up delay— Time interval to synchronize LDP session. 	All Levels
Session protection	<ul style="list-style-type: none"> • Session protection— Remote neighbor added to LDP configuration which enables protection for all sessions in the corresponding LDP instance: enabled or disabled. • Session protection timeout— Period of time until which the remote neighbor is connected to LSR in the absence of link neighbors. 	All Levels
Interface addresses advertising	Advertises interface address.	All Levels
Label allocation	<p>Label accounting information.</p> <ul style="list-style-type: none"> • Current number of LDP labels allocated—Number of labels currently in use. • Total number of LDP labels allocated—Cumulative number of labels being allocated. • Total number of LDP labels freed—Cumulative number of labels being freed. • Total number of LDP label allocation failures—Cumulative number of failures for allocating a label. • Current number of labels allocated by all protocols—Number of labels currently being used by routing protocols. 	All Levels

Sample Output

show ldp overview

```

show ldp path

Syntax

```
show ldp path
<brief | detail | extensive>
<destination>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) label-switched paths (LSPs).

Options

- none**—Display standard information about all LDP LSPs for all routing instances.
- brief | detail | extensive**—(Optional) Display the specified level of output.
- destination**—(Optional) Restrict the output to entries that match the specified destination prefix.
- instance instance-name**—(Optional) Display information for the specified routing instance only.
- logical-system (all | logical-system-name)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 135 on page 3467](#) describes the output fields for the **show ldp path** command. Output fields are listed in the approximate order in which they appear.

Table 135: show ldp path Output Fields

Field Name	Field Description
Output Session (label)	Session ID and labels that this system has sent using LDP. These correspond to MPLS packets received.

Table 135: show ldp path Output Fields (*continued*)

Field Name	Field Description
Input Session (label)	Session ID and labels that this system has received using LDP. These correspond to MPLS packets transmitted.
route	MPLS route.
Attached route	Route corresponding to the LSP.
Ingress route	The router acts as the ingress for the LSP.
Reference count	Reference count for the LDP neighbor.
Transit route	Names of the forwarding equivalence class (FEC) filters on the transit routers.
Global label	MPLS label that is used globally.

Sample Output

show ldp path extensive

user@host> **show ldp path extensive**

```

Output Session (label)      Input Session (label)
10.255.14.220:0(3)          ( )
    Attached route: 10.255.14.221/32
    Reference count: 3, Global label: 3
10.255.14.220:0(100000)     10.255.14.220:0(3)

10.255.14.220:0(100001)     10.255.14.220:0(100001)
    Attached route: 10.255.14.214/32, Ingress route
    Reference count: 2, Transit route, Global label: 100001

```

show ldp route

Syntax

```
show ldp route
<brief | detail | extensive>
<destination>
<fec-and-route>
<fec-only>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display the entries in the Label Distribution Protocol (LDP) internal topology table. The internal topology table contains routes from inet.0 and inet.3 and is used when binding a label to a forwarding equivalence class (FEC).

Options

none—Display standard information about all entries in the LDP internal topology table for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

destination—(Optional) Restrict the output to entries that are longer than the specified destination prefix and prefix length.

fec-and-route—Display the show routes and the FECs.

fec-only—Display only LDP FECs.

instance *instance-name*—(Optional) Display entries for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 136 on page 3470 describes the output fields for the **show ldp route** command. Output fields are listed in the approximate order in which they appear.

Table 136: show ldp route Output Fields

Field Name	Field Description
Destination	Destination prefix.
Next-hop intf/lsp/table	Interface that is the next hop to the destination prefix.
Next-hop address	IP address of the next hop.
Session ID	LDP session ID.
Route flags	Information about the route. For example, the Ingress TTL propagate flag indicates that the time-to-live (TTL) value is being propagated with the route.
Bound to outgoing label	The route has been bound to LSPs with the label being distributed for that LSP.
Topology entry	The topology that the route is bound to.
Ingress route status	Status of the ingress route. For example, it could be Active or Inactive .
Last modified	The length of time since the ingress route status last changed.
Last event(s)	The last event that occurred.

show ldp session

Syntax

```
show ldp session
<brief | detail | extensive>
<auto-targeted>
<destination>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

auto-targeted option added in Junos OS Release 14.2.

Description

Display information about Label Distribution Protocol (LDP) sessions.

Options

none—Display standard information about all LDP sessions for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

auto-targeted—(Optional) Display information about LDP sessions that are automatically targeted using loopback addresses.

destination—(Optional) Restrict LDP session display to the specified address.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 137 on page 3481 describes the output fields for the **show ldp session** command. Output fields are listed in the approximate order in which they appear.

Table 137: show ldp session Output Fields

Field Name	Field Description	Level of Output
Address	Transport address of the session.	any
State	State of the session: Nonexistent , Connecting , Initialized , OpenRec , OpenSent , Operational , or Closing . The states correspond to the state diagram specified in Internet Draft LDP Specification draft-ietf-mpls-rfc3036bis-01.txt.	any
Connection	TCP connection state: Closed , Opening , or Open .	any
Hold time	Time remaining until the session will be closed, in seconds.	any
Session ID	LDP identifiers of the peers of this session.	detail extensive
Next keepalive	Time until next keepalive is sent, in seconds.	detail extensive
Active	Whether the local router is playing the active role in the session and during session establishment.	detail extensive
Passive	Whether the local router is playing the passive role in the session and during session establishment.	detail extensive
Maximum PDU	Maximum protocol data unit (PDU) size (packet size) for the session.	detail extensive
Hold time	Time remaining until the session will be closed, in seconds. This value corresponds to the one configured using the keepalive-timeout statement configured at the [edit protocols ldp] hierarchy level.	detail extensive
Neighbor count	Number of neighbors that are contributing to the session.	detail extensive
Neighbor types	Category of LDP session: discovered or auto-targeted .	any
Keepalive interval	Keepalive interval, in seconds.	detail extensive

Table 137: show ldp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Connect retry interval	TCP connection retry interval, in seconds.	detail extensive
Local address	Local transport address.	detail extensive
Remote address	Remote transport address.	detail extensive
Up for	Time that this session has been up.	detail extensive
Last down	Time since the session last went down.	detail extensive
Reason	Reason the session went down: <ul style="list-style-type: none"> • Aborted graceful restart • Authentication key was changed • Bad type length value (TLV) • Bad protocol data unit (PDU) packets • Command-line interface (CLI) command • Connect time expired • Connection error • Connection reset • Error during initialization • Hold time expired • No adjacency or all adjacencies down • Notification received • Received notification from peer • Unexpected End of File (EOF) • Unknown reason 	detail extensive
Number of session flaps	Number of times the session changes from up to down.	detail extensive
Restarting	LDP is in the process of gracefully restarting.	detail extensive
Capabilities advertised	LDP capabilities advertised to a peer.	detail extensive
Capabilities received	LDP capabilities received from a peer.	detail extensive

Table 137: show ldp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Protection	Information about the status of MPLS LDP session protection.	detail extensive
restart complete in <i>nnn</i> msec	Amount of time (in milliseconds) remaining until graceful restart is declared complete.	detail extensive
Authentication type	Shows the longest match MD5 authentication	detail extensive
Local	<p>Information about graceful restart for the local end of an LDP session. Graceful restart and helper mode are independent.</p> <ul style="list-style-type: none"> • Restart—Status of the graceful restart feature at the local end of the LDP session: enabled or disabled. • Helper mode—Status of the helper mode feature at the local end of the LDP session: enabled or disabled. When this feature is enabled, the local end of the LDP session can help the restarting router with its LDP restart procedures. • Reconnect time—Amount of time to wait from when a restart is initiated until the router can exchange LDP messages with its neighbors. The default is 60000 msec and is not configurable. (Reconnect timeout refers to "FT Reconnect timeout" in draft-ietf-mpls-ldp-restart-06, <i>Internet Draft Graceful Restart Mechanism for LDP</i>.) 	detail extensive
Remote	<p>Information about graceful restart at the remote end of an LDP session. Graceful restart and helper mode are independent.</p> <ul style="list-style-type: none"> • Restart—Status of the graceful restart feature at the remote end of the LDP session: enabled or disabled. • Helper mode—Status of the helper mode feature at the remote end of the LDP session: enabled or disabled. When this feature is enabled, the remote end of the LDP session can help the restarting router with its LDP restart procedures. • Reconnect time—Amount of time in milliseconds from when a restart is initiated until the remote router can exchange LDP messages with its neighbors. 	detail extensive
Local maximum recovery time	Amount of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds).	detail extensive
Next-hop addresses received	Next-hop addresses received on the session.	detail extensive

Table 137: show ldp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Queue depth	Number of messages that are queued for sending to the peers in the group.	extensive
Message type	<p>Type of message being sent:</p> <ul style="list-style-type: none"> • Initialization—Session initialization negotiation messages sent by an LSR to an LDP peer when the transport connection is established. • Keepalive—Keepalive timer messages sent by an LSR to an LDP peer to keep the session active when there is no information or PDU exchanged between them. • Notification—Notification messages (such as state of the LDP session) or error information (such as bad PDU length) sent by an LSR to an LDP peer. • Address—Message sent by an LSR to an LDP peer to advertise interface addresses. • Address withdraw—Message sent by an LSR to an LDP peer to withdraw a previously advertised interface address. • Label mapping—Message sent by an LSR to an LDP peer to advertise label mapping for a forwarding equivalence class (FEC). • Label request—Message sent by an LSR to an LDP peer to request a label mapping for an FEC. • Label withdraw—Message sent by an LSR to an LDP peer to withdraw a previously advertised FEC-label mapping. • Label release—Message sent by an LSR to an LDP peer to notify the peer that a specific FEC-label mapping has been released. • Label abort—Message sent by an LSR to an LDP peer to abort a label request message. • Total—Messages sent and received during the lifetime of the session. • Last 5 seconds—Messages sent and received during the current session. 	extensive

List of Sample Output

[show ldp statistics on page 3492](#)

Output Fields

[Table 138 on page 3488](#) lists the output fields for the **show ldp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 138: show ldp statistics Output Fields

Field Name	Field Description
Total Sent, Received	Total number of each message type sent and received.

Table 138: show ldp statistics Output Fields (*continued*)

Field Name	Field Description
Last 5 seconds Sent, Received	Number of each message type sent and received in the last 5 seconds.
Message type	<p>LDP message types:</p> <ul style="list-style-type: none"> • Hello—Messages that enable LDP nodes to discover one another and to detect the failure of a neighbor or of the link to the neighbor. • Initialization—Messages that indicate an LDP session has started. • Keepalive—Messages that ensure that the keepalive timeout is not exceeded. • Notification—Advisory information and signal error information. • Address—Messages with address information. • Address withdrawal—Messages regarding address withdrawal. • Label mapping—Messages with label mapping information. • Label request—Request for a label mapping from a neighboring router. • Label withdrawal—Withdrawal message sent by the downstream LSR to recall a label that it previously mapped. If an LSR that has received a label mapping subsequently determines that it no longer needs that label, it can send a label release message that frees the label for use. • Label release—Message sent by the downstream LSR to recall a label that it previously mapped. If an LSR that has received a label mapping subsequently determines that it no longer needs that label, it can send a label release message that frees the label for use. • Label abort—Messages about label interruptions. • All UDP—All hello messages sent by LSRs to the well-known UDP port, 646. • All TCP—All LDP session messages.

Table 138: show ldp statistics Output Fields *(continued)*

Field Name	Field Description
Event type	

Table 138: show ldp statistics Output Fields (*continued*)

Field Name	Field Description
	<p>LDP events and errors:</p> <ul style="list-style-type: none"> • Sessions opened—Number of LDP sessions that have been opened. • Sessions closed—Number of LDP sessions that have been closed. • Topology changes—Number of changes to the known LDP topology. • No interface—Number of missing interface address messages. When a new LDP session is initialized and before sending label lapping or label request messages, the LSR advertises its interface addresses with one or more address messages. • No session—Number of missing session messages. Session messages are used to establish, maintain, and terminate sessions between LDP peers. • No adjacency—The exchange of hello adjacency messages results in the creation of an adjacency. The LDP identifier, together with the sender's LDP identifier in the PDU header, enables the receiver to match the initialization message with one of its hello adjacencies. If there is no matching hello adjacency, the LSR sends a session the initialization message is rejected. • Unknown version—The LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment. • Malformed PDU—An LDP PDU received on a TCP connection for an LDP session is malformed if the LDP identifier in the PDU header is unknown to the receiver, or if it is known but is not the LDP identifier associated by the receiver with the LDP peer for this LDP session. <p>An LDP PDU is considered to be malformed if the LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment.</p> <p>An LDP PDU is considered malformed if the PDU length field is too small (less than 14) or too large (greater than maximum PDU length).</p> <ul style="list-style-type: none"> • Malformed message—Malformed LDP messages that are part of the LDP discovery mechanism are handled by silently discarding them. <p>An LDP message is malformed if the message type is unknown. If the message type is less than 0x8000 (high order bit = 0), it is an error signaled by the unknown message type status code.</p> <p>An LDP message is considered to be malformed If the message length is too large, meaning that the message extends beyond the end of the containing LDP PDU.</p> <p>The LDP message is considered to be malformed if the message length is too small, meaning that it is smaller than the smallest possible value component.</p> <p>The LDP message is considered to be malformed if the message is missing one or more mandatory parameters.</p> <ul style="list-style-type: none"> • Unknown message type—If the message type is less than 0x8000 (high order bit = 0) or greater than or equal to 0x8000 (high order bit = 1) it is considered to be an unknown message. • Inappropriate message—The message is not of the type that the receiver expects to receive. • Malformed TLV—The TLV ILength is too large or the receiver cannot decode the TLV value. This can indicate an issue in either the sending or receiving LSR.

Table 138: show ldp statistics Output Fields (*continued*)

Field Name	Field Description
	<ul style="list-style-type: none"> • Bad TLV value—The TLV Length is too large. • Missing TLV—The TLV is missing one or more mandatory parameters. • PDU too large—The PDF is greater than the maximum PDU length. Section "Initialization Message" in RFC 5036 describes how the maximum PDU length for a session is determined.
Total	Total number of each event or error.
Last 5 seconds	Number of each event or error in the last 5 seconds.

show ldp traffic-statistics

Syntax

```
show ldp traffic-statistics  
<instance instance-name>  
<logical-system (all | logical-system-name)>  
<p2mp>
```

Release Information

Command introduced before Junos OS Release 7.4.

p2mp option added in Junos OS Release 11.2.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) traffic statistics.

NOTE: If nonstop active routing features is configured, **show ldp traffic-statistics** command is not supported on backup Routing Engines.

Options

none—Display LDP traffic statistics for all routing instances.

instance *instance-name*—(Optional) Display LDP traffic statistics for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

p2mp—(Optional) Display only the data traffic statistics for a point-to-multipoint LSP.

Additional Information

To collect output from this command on a periodic basis, configure the [traffic-statistics](#) statement for the LDP protocol. For more information, see the *Junos MPLS Applications Configuration Guide*.

Output Fields

Table 139 on page 3495 lists the output fields for the **show ldp traffic-statistics** command. Output fields are listed in the approximate order in which they appear.

Table 139: show ldp traffic-statistics Output Fields

Field Name	Field Description
Message type	LDP message types.
FEC	Forwarding equivalence class (FEC) for which LDP traffic statistics are collected. For P2MP LSPs, FEC appears as a combination of root address and the LSP ID (root_addr:lsp_id). For M-LDP P2MP LSPs, FEC appears as a combination of root address multicast source address, and multicast group address (root_addr:lsp_id/grp,src).
Type	Type of traffic originating from a router, either Ingress (originating from this router) or Transit (forwarded through this router).
Packets	Number of packets passed by the FEC since its LSP came up.
Bytes	Number of bytes of data passed by the FEC since its LSP came up.
Shared	Whether a label is shared by prefixes: Yes or No . A Yes value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
Nexthop	The next hop address for P2MP LSPs. (This is the downstream LDP Session ID.)

Table 139: show ldp traffic-statistics Output Fields (*continued*)

Field Name	Field Description
Label	<p>For multipoint LDP with multicast-only fast reroute (MoFRR), the multipoint LDP node selects two separate upstream peers and sends two separate labels, one to each upstream peer. The same algorithm described in RFC 6388 is used to select the primary upstream path. The backup upstream path selection again uses the same algorithm but excludes the primary upstream LSR as a candidate. Two streams of MPLS traffic are sent to the egress node from the two different upstream peers. The MPLS traffic from only one of the upstream neighbors is selected as the primary path to accept the traffic, and the other becomes the backup path. The traffic on the backup path is dropped. When the primary upstream path fails, the traffic from the backup path is then accepted. The multipoint LDP node selects the two upstream paths based on the interior gateway protocol (IGP) root node next hop.</p> <p>Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.</p>
Backup route	For multipoint LDP with MoFRR, the route that is used if the primary route becomes unavailable.

show security keychain

Syntax

```
show security keychain  
<brief | detail>
```

Release Information

Command introduced in Junos OS Release 11.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display information about authentication keychains configured for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol.

Options

none—Display information about authentication keychains.

brief | detail—(Optional) Display the specified level of output.

Required Privilege Level

view

[show security keychain detail on page 3501](#)

Output Fields

[Table 140 on page 3499](#) describes the output fields for the **show security keychain** command. Output fields are listed in the approximate order in which they appear.

Table 140: show security keychain Output Fields

Field Name	Field Description	Level of Output
keychain	The name of the keychain in operation.	All levels
Active-ID Send	Number of routing protocols packets sent with the active key.	All levels
Active-ID Receive	Number of routing protocols packets received with the active key.	All levels
Next-ID Send	Number of routing protocols packets sent with the next key.	All levels

Table 140: show security keychain Output Fields *(continued)*

Field Name	Field Description	Level of Output
Next-ID Receive	Number of routing protocols packets received with the next key.	All levels
Transition	Amount of time until the current key will be replaced with the next key in the keychain.	All levels
Tolerance	Configured clock-skew tolerance, in seconds, for accepting keys for a key chain.	All levels
Id	Identification number configured for the current key.	detail
Algorithm	Authentication algorithm configured for the current key.	detail
State	<p>State of the current key.</p> <p>The value can be:</p> <ul style="list-style-type: none"> • receive • send • send-receive <p>For the active key, the State can be send-receive, send, or receive. For keys that have a future start time, the State is inactive. Compare the State field to the Mode field.</p>	detail
Option	<p>For IS-IS only, the option determines how Junos OS encodes the message authentication code in routing protocol packets.</p> <p>The values can be:</p> <ul style="list-style-type: none"> • basic—Based on RFC 5304. • isis-enhanced—Based on RFC 5310. <p>The default value is basic. When you configure the isis-enhanced option, Junos OS sends RFC 5310-encoded routing protocol packets and accepts both RFC 5304-encoded and RFC 5310-encoded routing protocol packets that are received from other devices.</p> <p>When you configure basic (or do not include the options statement in the key configuration) Junos OS sends and receives RFC 5304-encoded routing protocols packets, and drops 5310-encoded routing protocol packets that are received from other devices.</p> <p>Because this setting is for IS-IS only, the TCP and the BFD protocol ignore the encoding option configured in the key.</p>	detail

Table 140: show security keychain Output Fields (continued)

Field Name	Field Description	Level of Output
Start-time	Time that the current key became active.	detail
Mode	<p>Mode of each key (Informational only.)</p> <p>The value can be</p> <ul style="list-style-type: none"> ● receive ● send ● send-receive <p>The mode of the key is based on the configuration. Suppose you configure two keys, one with a start-time of today and the other with a start-time of next week. For both keys, the Mode can be send-receive, send, or receive, regardless of the configured start-time. Compare the Mode field to the State field.</p>	detail

traceroute mpls ldp

Syntax

```
traceroute mpls <ldp> fec
<destination ip-address>
<detail>
<exp exp>
<fanout fanout-number>
<logical-system logical-system-name>
<no-resolve>
<paths maximum-paths>
<pipe-mode>
<retries retries-number>
<routing-instance routing-instance-name>
<source ip-address>
<ttl value>
<update>
<wait seconds>
```

Release Information

Command introduced in Junos OS Release 8.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Trace route to a remote host for an MPLS label-switched path signaled by the LDP. Use **traceroute mpls ldp** as a debugging tool to locate MPLS label-switched path forwarding issues in a network. (Currently supported for IPv4 packets only.)

Options

fec—Specify the IP address and optional prefix of the forwarding equivalence class (FEC).

destination ip-address—(Optional) Specify the destination address to use when sending probes.

Values: The destination IP address must be within the 127.0.0.0/8 IP address space for Operation, Administration, and Maintenance (OAM) packets.

detail—(Optional) Display detailed output.

exp exp—(Optional) Specify the class-of-service to use when sending probes.

Range: 0 through 7

Default: 7

fanout *fanout-number*—(Optional) Specify the maximum number of nexthops to search per node.

Range: 1 through 16

Default: 16

logical-system—(Optional) Specify the name of the logical system for the traceroute attempt.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

paths *maximum-paths*—(Optional) Specify the maximum number of paths to search.

Range: 1 through 255

Default: 16

pipe-mode—(Optional) Specify to trace only nodes that understand LDP FEC.

In an interoperation with other vendor devices or devices running Junos OS Release that do not support tracing of hierarchical LSPs as described in RFC 6424, continuous non-complaint probe status is displayed in the **traceroute mpls ldp** command output. To avoid this LDP loop creation, use the **pipe-mode** option with the **traceroute mpls ldp fec** command.

NOTE: Even after using the **traceroute mpls ldp fec pipe-mode** command, one or more intermediate transit nodes that do not understand LDP FEC can return non-complaint probe status in the command output.

retries *retries-number*—(Optional) Specify the number of times to resend probe values.

Range: 1 through 9

Default: 3

routing-instance *routing-instance-name*—(Optional) Specify the name of the routing instance for the traceroute attempt.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl *value*—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds.

Range: 1 through 125

Default: 64

update—(Optional) Update database contents with traceroute results.

wait *seconds*—(Optional) Specify the number of seconds to wait before resending a probe.

Range: 5 through 15

Default: 10

Required Privilege Level

Output Fields

Table 119 on page 3350 describes the output fields for the **traceroute mpls ldp fec** command and the **traceroute mpls ldp fec detail** commands. Output fields are listed in the approximate order in which they appear.

Table 141: traceroute mpls ldp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the traceroute mpls ldp fec command.	all levels
ttl	Time to live value of the labeled packet.	none specified
Label	Outgoing label used for forwarding the packet along the label-switched paths.	none specified
Protocol	Signaling protocol used. For this command, it is LDP.	none specified
Address	Address of the next hop.	none specified
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null .	none specified
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).	none specified
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	detail
Parent	Address of the previous hop. Parent value for the first hop is null .	detail
Return Code	Return code for reporting the result of processing the echo request by the receiver.	detail
Response time	Time for the echo request to reach the receiver.	detail
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none .	detail

Table 141: traceroute mpls ldp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Label Stack	Label stack used to forward the packet.	detail

CCC and TCC Operational Commands

IN THIS CHAPTER

- [show connections | 3516](#)
- [show route ccc | 3520](#)
- [show route forwarding-table | 3522](#)

show connections

List of Syntax

[Syntax on page 3516](#)

[Syntax \(EX Series Switches\) on page 3516](#)

Syntax

```
show connections
<brief | extensive>
<all | interface-switch | lsp-switch | p2mp-receive-switch | p2mp-transmit-switch | remote-interface-switch>
<down | up | up-down>
<history>
<labels>
<logical-system (all | logical-system-name)>
<name>
<status>
```

Syntax (EX Series Switches)

```
show connections
<brief | extensive>
<all | interface-switch | lsp-switch | p2mp-receive-switch | p2mp-transmit-switch | remote-interface-switch>
<down | up | up-down>
<history>
<labels>
<name>
<status>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about the configured circuit cross-connect (CCC) connections.

Options

none—Display the standard level of output for all configured CCC connections.

all—(Optional) Display all connections.

brief | extensive—(Optional) Display the specified level of output. Use history to display information about connection history. Use labels to display labels used for transmit and receive LSPs. Use status to display information about the connection and interface status.

- interface-switch**—(Optional) Display interface switch connections only.
- lsp-switch**—(Optional) Display LSP switch connections only.
- p2mp-receive-switch**—(Optional) Display point-to-multipoint LSP to local interfaces switch connections only.
- p2mp-transmit-switch**—(Optional) Display local interface to point-to-multipoint LSP switch connections only.
- remote-interface-switch**—(Optional) Display remote interface switch connections only.
- down | up | up-down**—(Optional) Display nonoperational, operational, or both kinds of connections.
- history**—(Optional) Display information about connection history.
- labels**—(Optional) Display labels used for transmit and receive.
- logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.
- name**—(Optional) Display information about the specified connection only.
- status**—(Optional) Display information about the connection and interface status.

Required Privilege Level

view

Output Fields

[Table 83 on page 3145](#) describes the output fields for the **show connections** command. Output fields are listed in the approximate order in which they appear.

Table 144: show connections Output Fields

Field Name	Field Description
CCC and TCC connections [Link Monitoring On Off]	Whether link monitoring is enabled: On or Off .
Legend for Status (St)	Connection or circuit status. See the output's legend for an explanation of the status field values.

Table 144: show connections Output Fields (*continued*)

Field Name	Field Description
Legend for connection types	Type of connection: <ul style="list-style-type: none"> • if-sw—Layer 2 switching cross-connect. • rmt-if—Remote interface switch. While graceful restart is in progress, rmt-if will display a state (St) of Restart. • lsp-sw—LSP stitching cross-connect. While graceful restart is in progress, lsp-sw will display a state (St) of Restart.
Legend for circuit types	Type of circuits: <ul style="list-style-type: none"> • intf—Interface circuit. • tlsp—Transmit LSP circuit. • rlsp—Receive LSP circuit.
Connection/Circuit	Name of the configured CCC connection.
Type	Type of connection.
St	State of the connection.
Time last up	Time that the connection or circuit last transitioned to the Up (operational) state.
# Up trans	Number of times that the connection or circuit has transitioned to the Up (operational) state.

Sample Output

show connections

user@switch> **show connections**

```
CCC and TCC connections [Link Monitoring On]
Legend for status (St)           Legend for connection types
UN -- uninitialized             if-sw:  interface switching
NP -- not present               rmt-if: remote interface switching
WE -- wrong encapsulation       lsp-sw: LSP switching
DS -- disabled
Dn -- down                      Legend for circuit types
-> -- only outbound conn is up  intf -- interface
```

```
<- -- only inbound conn is up      tlsp -- transmit LSP
Up -- operational                    rlsp -- receive LSP
RmtDn -- remote CCC down
Restart -- restarting
```

CCC Graceful restart : Restarting

Connection/Circuit	Type	St	Time last up	# Up trans
IFSW-ed	if-sw	Up	Aug 5 15:39:15	1
so-1/0/2.0	intf	Up		
t1-0/1/2.0	intf	Up		
SW-db	rmt-if	Restart		0
so-1/0/3.0	intf	Up		
pro4-ca	tlsp	Dn		
pro4-ac	rlsp	NP		

show route ccc

Syntax

```
show route ccc ccc  
<brief | detail | extensive | terse>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Description

Display circuit cross-connect (CCC) entries in the Multiprotocol Link Switching (MPLS) routing table.

Options

ccc—Name of an entry with a circuit cross-connect interface.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

```

Release Information

Command introduced before Junos OS Release 7.4.

Option **bridge-domain** introduced in Junos OS Release 7.5

Option **learning-vlan-id** introduced in Junos OS Release 8.4

Options **all** and **vlan** introduced in Junos OS Release 9.6.

Command introduced in Junos OS Release 11.3 for the QFX Series.

Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

NOTE: The Routing Engine copies the forwarding table to the Packet Forwarding Engine, the part of the router that is responsible for forwarding packets. To display the entries in the Packet Forwarding Engine's forwarding table, use the **show pfe route** command.

Options

none—Display the routes in the forwarding tables. By default, the **show route forwarding-table** command does not display information about private, or internal, forwarding tables.

detail | extensive | summary—(Optional) Display the specified level of output.

all—(Optional) Display routing table entries for all forwarding tables, including private, or internal, tables.

bridge-domain (**all** | **bridge-domain-name**)—(MX Series routers only) (Optional) Display route entries for all bridge domains or the specified bridge domain.

ccc interface-name—(Optional) Display route entries for the specified circuit cross-connect interface.

destination destination-prefix—(Optional) Destination prefix.

family family—(Optional) Display routing table entries for the specified family: **bridge** (**ccc** | **destination** | **detail** | **extensive** | **interface-name** | **label** | **learning-vlan-id** | **matching** | **multicast** | **summary** | **table** | **vlan** | **vpn**), **ethernet-switching**, **evpn**, **fibre-channel**, **fmembers**, **inet**, **inet6**, **iso**, **mcsnoop-inet**, **mcsnoop-inet6**, **mpls**, **satellite-inet**, **satellite-inet6**, **satellite-vpls**, **tnp**, **unix**, **vpls**, or **vlan-classification**.

interface-name interface-name—(Optional) Display routing table entries for the specified interface.

label name—(Optional) Display route entries for the specified label.

lcc number—(TX Matrix and TX matrix Plus routers only) (Optional) On a routing matrix composed of a TX Matrix router and T640 routers, display information for the specified T640 router (or line-card chassis) connected to the TX Matrix router. On a routing matrix composed of the TX Matrix Plus router and T1600 or T4000 routers, display information for the specified router (line-card chassis) connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

learning-vlan-id learning-vlan-id—(MX Series routers only) (Optional) Display learned information for all VLANs or for the specified VLAN.

matching matching—(Optional) Display routing table entries matching the specified prefix or prefix length.

multicast—(Optional) Display routing table entries for multicast routes.

table —(Optional) Display route entries for all the routing tables in the main routing instance or for the specified routing instance. If your device supports logical systems, you can also display route entries for the specified logical system and routing instance. To view the routing instances on your device, use the **show route instance** command.

vlan (all | vlan-name)—(Optional) Display information for all VLANs or for the specified VLAN.

vpn vpn—(Optional) Display routing table entries for a specified VPN.

Output Fields

[Table 111 on page 3263](#) lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified, or when the **detail** keyword is used instead of the **extensive** keyword.

Table 145: show route forwarding-table Output Fields

Field Name	Field Description	Level of Output
Logical system	Name of the logical system. This field is displayed if you specify the table logical-system-name/routing-instance-name option on a device that is configured for and supports logical systems.	All levels
Routing table	Name of the routing table (for example, inet, inet6, mpls).	All levels

Table 145: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Enabled protocols		All levels

Table 145: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
	<p>The features and protocols that have been enabled for a given routing table. This field can contain the following values:</p> <ul style="list-style-type: none"> • BUM hashing—BUM hashing is enabled. • MAC Stats—Mac Statistics is enabled. • Bridging—Routing instance is a normal layer 2 bridge. • No VLAN—No VLANs are associated with the bridge domain. • All VLANs—The vlan-id all statement has been enabled for this bridge domain. • Single VLAN—Single VLAN ID is associated with the bridge domain. • MAC action drop—New MACs will be dropped when the MAC address limit is reached. • Dual VLAN—Dual VLAN tags are associated with the bridge domain • No local switching—No local switching is enabled for this routing instance.. • Learning disabled—Layer 2 learning is disabled for this routing instance. • MAC limit reached—The maximum number of MAC addresses that was configured for this routing instance has been reached. • VPLS—The VPLS protocol is enabled. • No IRB I2-copy—The no-irb-layer-2-copy feature is enabled for this routing instance. • ACKed by all peers—All peers have acknowledged this routing instance. • BUM Pruning—BUM pruning is enabled on the VPLS instance. • Def BD VXLAN—VXLAN is enabled for the default bridge domain. • EVPN—EVPN protocol is enabled for this routing instance. • Def BD OVSDb—Open vSwitch Database (OVSDb) is enabled on the default bridge domain. • Def BD Ingress replication—VXLAN ingress node replication is enabled on the default bridge domain. • L2 backhaul—Layer 2 backhaul is enabled. • FRR optimize—Fast reroute optimization • MAC pinning—MAC pinning is enabled for this bridge domain. • MAC Aging Timer—The MAC table aging time is set per routing instance. • EVPN VXLAN—This routing instance supports EVPN with VXLAN encapsulation. • PBBN—This routing instance is configured as a provider backbone bridged network. 	

Table 145: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
	<ul style="list-style-type: none"> • PBN—This routing instance is configured as a provider bridge network. • ETREE—The ETREE protocol is enabled on this EVPN routing instance. • ARP/NDP suppression—EVPN ARP NDP suppression is enabled in this routing instance. • Def BD EVPN VXLAN—EVPN VXLAN is enabled for the default bridge domain. • MPLS control word—Control word is enabled for this MPLS routing instance. 	
Address family	Address family (for example, IP , IPv6 , ISO , MPLS , and VPLS).	All levels
Destination	Destination of the route.	detail extensive
Route Type (Type)	<p>How the route was placed into the forwarding table. When the detail keyword is used, the route type might be abbreviated (as shown in parentheses):</p> <ul style="list-style-type: none"> • cloned (clon)—(TCP or multicast only) Cloned route. • destination (dest)—Remote addresses directly reachable through an interface. • destination down (iddn)—Destination route for which the interface is unreachable. • interface cloned (ifcl)—Cloned route for which the interface is unreachable. • route down (ifdn)—Interface route for which the interface is unreachable. • ignore (ignr)—Ignore this route. • interface (intf)—Installed as a result of configuring an interface. • permanent (perm)—Routes installed by the kernel when the routing table is initialized. • user—Routes installed by the routing protocol process or as a result of the configuration. 	All levels
Route Reference (RtRef)	Number of routes to reference.	detail extensive

Table 145: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Flags	<p>Route type flags:</p> <ul style="list-style-type: none"> • none—No flags are enabled. • accounting—Route has accounting enabled. • cached—Cache route. • incoming-iface <i>interface-number</i>—Check against incoming interface. • prefix load balance—Load balancing is enabled for this prefix. • rt nh decoupled—Route has been decoupled from the next hop to the destination. • sent to PFE—Route has been sent to the Packet Forwarding Engine. • static—Static route. 	extensive
Next hop	<p>IP address of the next hop to the destination.</p> <p>NOTE: For static routes that use point-to-point (P2P) outgoing interfaces, the next-hop address is not displayed in the output.</p>	detail extensive
Next hop Type (Type)	<p>Next-hop type. When the detail keyword is used, the next-hop type might be abbreviated (as indicated in parentheses):</p> <ul style="list-style-type: none"> • broadcast (bcst)—Broadcast. • deny—Deny. • discard (dscd)—Discard. • hold—Next hop is waiting to be resolved into a unicast or multicast type. • indexed (idxd)—Indexed next hop. • indirect (indr)—Indirect next hop. • local (loc)—Local address on an interface. • routed multicast (mcrt)—Regular multicast next hop. • multicast (mcst)—Wire multicast next hop (limited to the LAN). • multicast discard (mdsc)—Multicast discard. • multicast group (mgrp)—Multicast group member. • receive (rcv)—Receive. • reject (rjct)—Discard. An ICMP unreachable message was sent. • resolve (rslv)—Resolving the next hop. • unicast (ucst)—Unicast. • unilist (ulst)—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list. 	detail extensive

Table 145: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Index	Software index of the next hop that is used to route the traffic for a given prefix.	detail extensive none
Route interface-index	Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.	extensive
Reference (NhRef)	Number of routes that refer to this next hop.	detail extensive none
Next-hop interface (Netif)	Interface used to reach the next hop.	detail extensive none
Weight	Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible (see the Balance field description).	extensive
Balance	Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a router is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.	extensive
RPF interface	List of interfaces from which the prefix can be accepted. Reverse path forwarding (RPF) information is displayed only when rpf-check is configured on the interface.	extensive

show route forwarding-table extensive (RPF)

The next example is based on the following configuration, which enables an RPF check on all routes that are learned from this interface, including the interface route:

```
so-1/1/0 {
  unit 0 {
    family inet {
      rpf-check;
      address 192.0.2.2/30;
    }
  }
}
```

user@host> **show route forwarding-table extensive**

```
Routing table: inet [Index 0]
Internet:
...
...
Destination: 192.0.2.3/32
  Route type: destination
  Route reference: 0                      Route interface-index: 67
  Flags: sent to PFE
  Nexthop: 192.0.2.3
  Next-hop type: broadcast                Index: 328      Reference: 1
  Next-hop interface: so-1/1/0.0
  RPF interface: so-1/1/0.0
```

show route forwarding-table extensive (PIM using point-to-multipoint mode)

user@host> **show route forwarding-table extensive**

```
Destination: 198.51.100.0/24
  Route type: user
  Route reference: 0                      Route interface-index: 335
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: cached, check incoming interface , accounting, sent to PFE, rt nh
decoupled
  Next-hop type: indirect                  Index: 1048575  Reference: 4

```

show route forwarding-table (dynamic list next hop)

The **show route forwarding table** output shows the two next hop elements for a multihomed EVPN destination.

```
user@host> show route forwarding-table label 299952 extensive
```

```

MPLS:

Destination: 299952
Route type: user
Route reference: 0          Route interface-index: 0
Multicast RPF nh index: 0
P2mpidx: 0
Flags: sent to PFE, rt nh decoupled
Next-hop type: indirect          Index: 1048575  Reference: 2
Nexthop:
Next-hop type: composite          Index: 601      Reference: 2
Next-hop type: indirect          Index: 1048574  Reference: 3
Nexthop: 1.0.0.4
Next-hop type: Push 301632, Push 299776(top) Index: 600 Reference: 2
Load Balance Label: None
Next-hop interface: ge-0/0/1.0
Next-hop type: indirect          Index: 1048577  Reference: 3

clear path-computation-client statistics

Syntax

```
clear path-computation-client statistics  
<pce-id | all>
```

Release Information

Statement introduced in Junos OS Release 12.3.

Statement introduced in Junos OS Release 16.1R3 for QFX Series switches.

Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Clear Path Computation Element (PCE) statistics.

Options

pce-id—(Optional) Clear statistics of the specified PCE.

all—(Optional) Clear statistics of all available PCEs configured on the path computation client (PCC).

Required Privilege Level

clear

RELATED DOCUMENTATION

[clear path-computation-client statistics pce-id on page 3548](#)

[clear path-computation-client statistics all on page 3549](#)

Output Fields

When you enter this command, you are not provided feedback on the status of your request.

Sample Output

```
clear path-computation-client statistics pce-id
```

```
user@host> clear path-computation-client statistics pce1
```

clear path-computation-client statistics all

user@host> clear path-computation-client statistics all

request path-computation-client active-pce

Syntax

```
request path-computation-client active-pce pce-id
```

Release Information

Command introduced in Junos OS Release 12.3.

Command introduced in Junos OS Release 16.1R3 for QFX Series switches.

Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Request a new active Path Computation Element (PCE).

Options

pce-id—Unique user defined ID for this PCE.

retry-delegation—Retry label-switched path (LSP) delegation

Required Privilege Level

request

RELATED DOCUMENTATION

[request path-computation-client active-pce pce-id](#) on page 3550

Sample Output

```
request path-computation-client active-pce pce-id
```

```
user@host> request path-computation-client active-pce pce1
```

show isis spring sensor info

Syntax

```
show isis spring sensor info
logical-system (all | logical-system-name)
```

Release Information

Command introduced in 19.1R1 on MX Series routers with MPC and MIC interfaces, and PTX series routers.

Description

Displays a list of sensors associated with the label IS-IS route and next hops for segment routing traffic. The command only displays the information related to the sensors and not the traffic statistics.

Options

none— Display the sensor information of an IS-IS SPRING route.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

view

RELATED DOCUMENTATION

Output Fields

[Table 147 on page 3554](#) describes the output fields for the **show path-computation-client active-pce** command. Output fields are listed in the approximate order in which they appear.

Table 147: show path-computation-client active-pce Output Fields

Field Name	Field Description	Level of Output
IP address	IP address of the current active PCE.	All levels
Priority	Active PCE priority.	All levels

Table 147: show path-computation-client active-pce Output Fields (*continued*)

Field Name	Field Description	Level of Output
PCE status	<p>Active PCE state:</p> <ul style="list-style-type: none"> • PCE_STATE_NEW—Initial PCEP session state. • PCE_STATE_RECONNECT—Trying to re-establish TCP connection with the PCEP peer. • PCE_STATE_CONNECTING—Establishing TCP connection with the PCEP peer. • PCE_STATE_CONNECTED—TCP connection established with the PCEP peer. • PCE_STATE_SYNC—Open messages exchanged with the PCEP peer and entering SYNC state. • PCE_STATE_UP—PCEP session established. 	All levels
Session type	<p>Active PCE type:</p> <ul style="list-style-type: none"> • PCE_TYPE_STATELESS—Does not learn LSP state information from PCC. • PCE_TYPE_STATEFUL—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update LSP state. A PCC maintains synchronization with the PCE. • PCE_TYPE_STATEFULACTIVE—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegate control of their LSPs to the PCE. 	All levels
PCE-mastership	<p>PCE mastership state:</p> <ul style="list-style-type: none"> • main—Current active PCE. • backup—Backup PCE. 	All levels
PCRpts	Number of PC report (PCRpt) messages sent by PCC to a stateful PCE to report current state of LSP(s).	All levels
PCUpdates	Number of PC update (PCUpd) messages sent by a PCE to a PCC to update LSP parameters.	All levels
Local Keepalive timer	Keepalive timer used by or for the PCC.	All levels
Local Dead timer	Dead timer used by or for the PCC.	All levels
Remote Keepalive timer	Keepalive timer used by or for the PCE.	All levels

Table 147: show path-computation-client active-pce Output Fields (*continued*)

Field Name	Field Description	Level of Output
Remote Dead timer	Dead timer used by or for the PCE.	All levels
PCErr-recv	Information about type, value, and number of PC Error messages received.	All levels
Max unknown messages	Maximum number of unknown messages received for a PCEP session. Recommended value is 5. If the number of unknown messages received by a PCC or PCE is greater than or equal to the maximum number, the PCEP session is closed.	detail
Keepalives received	Number of Keepalive messages received by a PCC from a PCE.	detail
Keepalives sent	Number of Keepalive messages sent by a PCC to a PCE.	detail
Dead timer	Dead timer used by the current active PCE.	detail
Elapsed as main current	Time (in seconds) the PCE is in the main mastership state.	detail
Elapsed as main total	Time (in seconds) the PCE became main from the last PCCD restart.	detail
Unknown msgs/min rate	Number of unknown messages received per minute.	detail
Session failures	Number of PCEP session failures with the PCE.	detail
Delegation timeout in	Time (in seconds) left for LSP delegation to timeout.	detail
Delegation failures	Number of LSP delegation failures.	detail
Connection down	Time (in seconds) since the PCEP session is down.	detail
PCErr-sent	Information about type, value, and number of PC Error messages sent.	All levels

show path-computation-client lsp

Syntax

```
show path-computation-client lsp
<extensive>
<p2mp>
```

Release Information

Command introduced in Junos OS Release 17.2R1 on MX Series routers.

extensive and **p2mp** options introduced in Junos OS Release 18.3R1 on MX Series routers.

Description

Display the state of label-switched paths (LSPs) known to the Path Computation Client (PCC).

Options

none—Display information about LSPs known to the PCC.

extensive—(Optional) Display extensive level of output about each known LSP - point-to-point and point-to-multipoint LSPs.

p2mp—(Optional) Display information about known point-to-multipoint Path Computation Element (PCE)-initiated LSPs.

Required Privilege Level

Output Fields

[Table 148 on page 3560](#) describes the output fields for the **show path-computation-client lsp** command. Output fields are listed in the approximate order in which they appear.

Table 148: show path-computation-client lsp Output Fields

Field Name	Field Description
LSP Name	Name of the LSP.
Status	LSP status: <ul style="list-style-type: none"> • Primary(Act)—Primary LSP. • Bypass—PCE-initiated bypass LSP.
PLSP-Id	PCEP-specific unique identifier for each LSP. The ID is created by the PCC for the lifetime of a PCEP session.
LSP-Type	Type of LSP: <ul style="list-style-type: none"> • External provisioned • Local
Controller	Name of the external path computing entity.
Path-Setup-Type	Protocol used to set up the LSP: <ul style="list-style-type: none"> • RSVP-TE • SPRING-TE
Template	Name of template used.
P2MP name	Name of the point-to-multipoint tree that includes the sub-LSPs of the PCE-initiated LSP.
P2MP Branch Name	Name of the branch sub-LSP that makes up the point-to-multipoint tree of the PCE-initiated LSP.
PathName	Name of LSP path.
From	Ingress IP address of LSP.
To	Egress IP address of LSP.
State	LSP state: up, down.
Active Path	Name of active path.
Link Protection	LSP Link protection.

Table 148: show path-computation-client lsp Output Fields (*continued*)

Field Name	Field Description
P2mp tree	Name of the point-to-multipoint tree that includes the sub-LSPs of the PCE-initiated LSP.
Path cspf status	CSPF computation done by an external controller or local router.
LSP-ID	LSP identifier.
RSVP Error	RSVP error ID.
Priorities	Setup and hold priorities.
Bandwidth	LSP bandwidth.
Requested AutoBw	Requested bandwidth to controller for auto-bandwidth.
Controller	Name of external controller.
Record Route	LSP record route object.
From PCE ERO (received)	Explicit Route Object (ERO) received by controller from the routing protocol process.
From RPD ERO (reported)	ERO reported from the routing protocol process.
Configured ERO on PCC	ERO configured on router.
PCE Traffic Steering	MVPN flow specification capability.
FS-ID	Flow specification ID.
Route Distinguisher	Route Distinguisher of MVPN instance.
Source Prefix	Matching source address of MVPN flow specification.
Multicast Group Prefix	Matching group address of MVPN flow specification.
State	Flow specification state of specific flow specification ID.
Last Rpt/Pcreqest received from RPD at	Time the last PC report or PE request message was received.
Last Update sent to PCE at	Time the last update was sent to PCE.

Table 148: show path-computation-client lsp Output Fields (*continued*)

Field Name	Field Description
Last PcUpdate/PcCreate received from PCE at	Time the last PC update message was received from the controller.
Last error sent to PCE at	Time the last PC error was sent to the controller.
Last 5 reasons to send Report/Pcrequest	<ul style="list-style-type: none"> • Reconfig • Down • Get_info • Up • Active

Release Information

Command introduced in Junos OS Release 12.3.

Command introduced in Junos OS Release 16.1R3 for QFX Series switches.

Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Display statistics about the Path Computation Element (PCE).

Options

none—Display statistics about the primary PCE.

brief | detail—(Optional) Display the specific level of output.

all—(Optional) Display the statistics about all PCEs configured on the PCC.

Required Privilege Level

Output Fields

[Table 149 on page 3566](#) describes the output fields for the **show path-computation-client statistics** command. Output fields are listed in the approximate order in which they appear.

Table 149: show path-computation-client statistics Output Fields

Field Name	Field Description	Level of Output
IP address	IP address of the PCE.	All levels
Priority	PCE priority.	All levels
PCE status	PCE state: <ul style="list-style-type: none"> • PCE_STATE_NEW—Initial PCEP session state. • PCE_STATE_RECONNECT—Trying to re-establish TCP connection with the PCEP peer. • PCE_STATE_CONNECTING—Establishing TCP connection with the PCEP peer. • PCE_STATE_CONNECTED—TCP connection established with the PCEP peer. • PCE_STATE_SYNC—Open messages exchanged with the PCEP peer and entering SYNC state. • PCE_STATE_UP—PCEP session established. 	All levels
Session type	Active PCE type: <ul style="list-style-type: none"> • PCE_TYPE_STATELESS—Does not learn LSP state information from PCC. • PCE_TYPE_STATEFUL—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update LSP state. A PCC maintains synchronization with the PCE. • PCE_TYPE_STATEFULACTIVE—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegate control of their LSPs to the PCE. 	All levels
PCE-mastership	PCE mastership state: <ul style="list-style-type: none"> • main • primary • backup 	All levels

Table 149: show path-computation-client statistics Output Fields (*continued*)

Field Name	Field Description	Level of Output
PCRpts	Number of PC report (PCRpt) messages sent by PCC to a stateful PCE to report current state of LSP(s).	All levels
PCUpdates	Number of PC update (PCUpd) messages sent by a PCE to a PCC to update LSP parameters.	All levels
Local Keepalive timer	Keepalive timer used by or for the PCC.	All levels
Local Dead timer	Dead timer used by or for the PCC.	All levels
Remote Keepalive timer	Keepalive timer used by or for the PCE.	All levels
Remote Dead timer	Dead timer used by or for the PCE.	All levels
PCErr-recv	Information about type, value, and number of PC Error messages received.	All levels
PCErr-sent	Information about type, value, and number of PC Error messages sent.	All levels
Max unknown messages	Maximum number of unknown messages received for a PCEP session. Recommended value is 5. If the number of unknown messages received by a PCC or PCE is greater than or equal to the maximum number, the PCEP session is closed.	detail
Keepalives received	Number of Keepalive messages received by a PCC from a PCE.	detail
Keepalives sent	Number of Keepalive messages sent by a PCC to a PCE.	detail
Elapsed as main current	Time (in seconds) the PCE is in the main mastership state.	detail
Elapsed as main total	Time (in seconds) the PCE became main from the last PCCD restart.	detail

Table 149: show path-computation-client statistics Output Fields (*continued*)

Field Name	Field Description	Level of Output
Unknown msgs/min rate	Number of unknown messages received per minute.	detail
Session failures	Number of PCEP session failures with the PCE.	detail
Delegation timeout in	Time (in seconds) left for LSP delegation to timeout.	detail
Delegation failures	Number of LSP delegation failures.	detail
Connection down	Time (in seconds) since the PCEP session is down.	detail
Local IP address	IP address of the PCC.	detail
LSP provisioning allowed	LSP provisioning capability.	detail
P2MP LSP report allowed	Report capability of point-to-multipoint LSP.	detail
P2MP LSP update allowed	Update capability of point-to-multipoint LSP.	detail
P2MP LSP init allowed	Initiate capability of point-to-multipoint LSP.	detail
PCE Traffic Steering	Traffic steering capability of the PCE.	detail

show path-computation-client status  
<extensive>
```

Release Information

Command introduced in Junos OS Release 17.2R1 on MX Series routers.

extensive option introduced in Junos OS Release 18.3R1 on MX Series routers.

Description

Display the status of the Path Computation Client (PCC).

Options

none—Display the status of the PCC.

extensive—(Optional) Display extensive information about the PCC including point-to-point and point-to-multipoint PCE-initiated LSPs.

For point-to-multipoint PCE-initiated LSPs, the extensive output displays the point-to-multipoint LSP tree and branches separately for a PCEP session.

```

Release Information

Command introduced in Junos OS Release 19.4R1 on all platforms.

Description

Display information on flow specification capability (also called traffic steering functionality). This is used for enabling the mapping of PCE-initiated point-to-multipoint LSPs to an MVPN routing-instance.

Options

none—Display information about the flow specification capability.

pce pce-id—(Optional) Display information about the flow specification capability for the specified PCE ID.

<logical-system (all | logical-system-name)>
<name lsp-name>
```

Release Information

Command introduced in Junos OS Release 17.2 on MX Series routers.

sbfd option introduced in Junos OS Release 19.4R1 on all platforms.

Description

Display ingress details of SPRING traffic engineering.

Options

brief | detail—(Optional) Display the specific level of output.

lsp—Display details of SPRING traffic engineered LSPs on the ingress router or the Path Computation Client (PCC).

overview—Display overview of SPRING traffic engineered LSPs on the ingress router, or the PCC.

sbfd—Display SPRING Traffic Engineered BFD session.

name *lsp-name*—(Optional) Regular expression for LSP names to match for displaying SPRING traffic engineering details.

List of Sample Output

[show spring-traffic-engineering lsp name on page 3580](#)

[show spring-traffic-engineering lsp detail on page 3580](#)

[show spring-traffic-engineering overview on page 3580](#)

[show spring-traffic-engineering sbfd detail on page 3580](#)

[show spring-traffic-engineering sbfd name <name> detail on page 3581](#)

Output Fields

Table 152 on page 3579 describes the output fields for the **show spring-traffic-engineering** command. Output fields are listed in the approximate order in which they appear.

Table 152: show spring-traffic-engineering Output Fields

Field Name	Field Description
To	IP address of the SPRING-TE LSP destination.
State	State of the SPRING-TE LSP: <ul style="list-style-type: none"> • Up • Down
LSP Name	Name of the SPRING-TE LSP.
S-ERO	Source Explicit Route Object (ERO), or LSP path.
Bandwidth	Bandwidth allocated for the SPRING-TE LSP.
Route preference	Route preference of the SPRING-TE LSP.
Number of LSPs	Statistics of the total number of SPRING-TE LSPs and the LSP state.
External controllers	Name of the LSP external controller. By default the only supported external controller is pccd .
BFD name	Name of the BFD session. The name is auto-generated in the V4-srte_bfd_session-id for IPv6. The name is based on the Explicit Route Object (ERO) stack of the LSP path, that is, if multiple LSPs have same path they share the same BFD session name.
BFD status	Status of the BFD session: UP, DOWN.
Referencing LSPs	Name of referencing LSP. If the LSP does not have a path name, then the referencing LSP is displayed as unnamed path .
SR-ERO hop count	Number of hops in the segment routing ERO.
Hop 1	Represents the path of the BFD session. If any other LSP is on same path, it has the same BFD session.
Total displayed BFD sessions	Total count of all the BFD sessions.

Sample Output

show spring-traffic-engineering lsp name

```
user@host> show spring-traffic-engineering lsp name lsp-name
```

To	State	LSP Name
10.1.1.7	Up	to-R1

show spring-traffic-engineering lsp detail

```
user@host> show spring-traffic-engineering lsp detail
```

```
10.1.1.7
  State: Up
  S-ERO: 24.1.1.1(80001) 10.1.1.3(4509) 11.2.1.2(9875)
  Bandwidth: 100M
  The above line is in IP address(label) format.
```

show spring-traffic-engineering overview

```
user@host> show spring-traffic-engineering overview
```

```
Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 0 (Up: 0, Down: 0)
  External controllers:
    pccd
```

show spring-traffic-engineering sbfd detail

```
user@host> show spring-traffic-engineering sbfd detail
```

```
BFD name: V4-srte_bfd_session-1
BFD status: Down
Referencing LSPs:
  sr-lsp1:path1
  sr-lsp2:path1
SR-ERO hop count: 2
Hop 1 (Strict):
  NAI: IPv4 Adjacency ID, 1.2.1.1 -> 1.2.1.2
  SID type: 20-bit label, Value: 299776
Hop 2 (Strict):
```

```
NAI: IPv4 Adjacency ID, 2.3.0.1 -> 2.3.0.2
SID type: 20-bit label, Value: 299824
```

```
Total displayed BFD sessions: 2 (Up: 2, Down: 0)
```

show spring-traffic-engineering sbfd name <name> detail

```
user@host> show spring-traffic-engineering sbfd name V4-srte_bfd_session-1 detail
```

```
BFD name: V4-srte_bfd_session-1
BFD status: Up
Referencing LSPs:
  sr-lsp1:path1
  sr-lsp2:path1
SR-ERO hop count: 2
Hop 1 (Strict):
  NAI: IPv4 Adjacency ID, 1.2.1.1 -> 1.2.1.2
  SID type: 20-bit label, Value: 299776
Hop 2 (Strict):
  NAI: IPv4 Adjacency ID, 2.3.0.1 -> 2.3.0.2
  SID type: 20-bit label, Value: 299824
```
