Differentiated Services domain	The routers in a network that have Differentiated Services enabled.
DiffServ-aware traffic engineering	A type of constraint-based routing. It can enforce different bandwidth constraints for different classes of traffic. It can also do CAC on each traffic engineering class when an LSP is established.
M	
MAM	The maximum allocation bandwidth constraint model divides the available bandwidth between the different classes. Sharing of bandwidth between the class types is not allowed.
Multiclass LSP	A multiclass LSP functions like a standard LSP, but it also allows you to reserve bandwidth from multiple class types. The EXP bits of the MPLS header are used to distinguish between class types.
R	
RDM	The Russian dolls bandwidth constraint model makes efficient use of bandwidth by allowing the class types to share bandwidth.
T	
Traffic engineering class	A paired class type and priority.
Traffic engineering class map	A map between the class types, priorities, and traffic engineering classes. The traffic engineering class mapping must be consistent across the Differentiated Services domain.

DiffServ-Aware Traffic Engineering Features

DiffServ-aware traffic engineering provides the following features:

- Traffic engineering at a per-class level rather than at an aggregate level
- Different bandwidth constraints for different class types (traffic classes)
- Different queuing behaviors per class, allowing the router to forward traffic based on the class type

In comparison, standard traffic engineering does not consider CoS, and it completes its work on an aggregate basis across all Differentiated Service classes.

DiffServ-aware traffic engineering provides the following advantages:

- Traffic engineering can be performed on a specific class type instead of at the aggregate level.
- Bandwidth constraints can be enforced on each specific class type.
- It forwards traffic based on the EXP bits.

This makes it possible to guarantee service and bandwidth across an MPLS network. With DiffServ-aware traffic engineering, among other services, you can provide ATM circuit emulation, VoIP, and a guaranteed bandwidth service.

The following describes how the IGP, Constrained Shortest Path First (CSPF), and RSVP participate in DiffServ-aware traffic engineering:

- The IGP can advertise the unreserved bandwidth for each traffic engineering class to the other members of the differentiated services domain. The traffic engineering database stores this information.
- A CSPF calculation is performed considering the bandwidth constraints for each class type. If all the constraints are met, the CSPF calculation is considered successful.
- When RSVP signals an LSP, it requests bandwidth for specified class types.

DiffServ-Aware Traffic Engineered LSPs

A DiffServ-aware traffic engineered LSP is an LSP configured to reserve bandwidth for one of the supported class types and to carry traffic for that class type. The following sections discuss this type of LSPs:

- [DiffServ-Aware Traffic Engineered LSPs Overview on page 1196](#)
- [DiffServ-Aware Traffic Engineered LSPs Operation on page 1197](#)

DiffServ-Aware Traffic Engineered LSPs Overview

A DiffServ-aware traffic engineered LSP is an LSP configured with a bandwidth reservation for a specific class type. This LSP can carry traffic for a single class type. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

The class type must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

For more information about topics related to LSPs and DiffServ-aware traffic engineering, see the following:

- For forwarding classes and class of service, see the *Class of Service User Guide (Routers and EX9200 Switches)*.
- For EXP bits, see [“MPLS Label Allocation” on page 420](#).
- For differentiated services, see RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*.
- For information about how the IGPs and RSVP have been modified to support Differentiated Services-aware MPLS traffic engineering, see RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*.

DiffServ-Aware Traffic Engineered LSPs Operation

When configuring a DiffServ-aware traffic engineered LSP, you specify the class type and the bandwidth associated with it. The following occurs when an LSP is established with bandwidth reservation from a specific class type:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for an LSP, CSPF is used to ensure that the bandwidth constraints are met for the class type carried by the LSP at the specified priority level.

CSPF also checks to ensure that the bandwidth model is configured consistently on each router participating in the LSP. If the bandwidth model is inconsistent, CSPF does not compute the path (except for LSPs from class type ct0).

3. Once a path is found, RSVP signals the LSP using the Classtype object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up.

An LSP that requires bandwidth from a particular class (except class type ct0) cannot be established through routers that do not understand the Classtype object. Preventing the use of routers that do not understand the Classtype object helps to ensure consistency throughout the Differentiated Services domain by preventing the LSP from using a router that cannot support Differentiated Services.

By default, LSPs are signaled with setup priority 7 and holding priority 0. An LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both LSPs configured for DiffServ-aware traffic engineering and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings (either by remarking the EXP settings or by assuming that the traffic arrived with the correct EXP settings from the upstream router).

Multiclass LSP Overview

A multiclass LSP is an LSP that can carry several class types. One multiclass LSP can be used to support up to four class types. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

Once a multiclass LSP is configured, traffic from all of the class types can:

- Follow the same path
- Be rerouted along the same path
- Be taken down at the same time

Class types must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network.

You can unambiguously map a class type to a queue. On each node router, the CoS queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

The combination of a class type and a priority level forms a traffic engineering class. The IGPs can advertise up to eight traffic engineering classes for each link.

For more information about the EXP bits, see [“MPLS Label Allocation” on page 420](#).

For more information about forwarding classes, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Multiclass LSPs

Multiclass LSPs function like standard LSPs, but they also allow you to configure multiple class types with guaranteed bandwidth. The EXP bits of the MPLS header are used to distinguish between class types. Multiclass LSPs can be configured for a variety of purposes. For example, you can configure a multiclass LSP to emulate the behavior of an ATM circuit. An ATM circuit can provide service-level guarantees to a class type. A multiclass LSP can provide a similar guaranteed level of service.

The following sections discuss multiclass LSPs:

- [Multiclass LSP Overview on page 1198](#)
- [Establishing a Multiclass LSP on the Differentiated Services Domain on page 1199](#)

Establishing a Multiclass LSP on the Differentiated Services Domain

The following occurs when a multiclass LSP is established on the differentiated services domain:

1. The IGP advertises how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for a multiclass LSP, CSPF is used to ensure that the constraints are met for all the class types carried by the multiclass LSP (a set of constraints instead of a single constraint).
3. Once a path is found, RSVP signals the LSP using an RSVP object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up. The RSVP object is a hop-by-hop object. Multiclass LSPs cannot be established through routers that do not understand this object. Preventing routers that do not understand the RSVP object from carrying traffic helps to ensure consistency throughout the differentiated services domain by preventing the multiclass LSP from using a router that is incapable of supporting differentiated services.

By default, multiclass LSPs are signaled with setup priority 7 and holding priority 0. A multiclass LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both multiclass LSPs and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings.

Configuring Routers for DiffServ-Aware Traffic Engineering

IN THIS SECTION

- [Configuring the Bandwidth Model | 1201](#)
- [Configuring Traffic Engineering Classes | 1202](#)
- [Configuring Class of Service for DiffServ-Aware Traffic Engineering | 1204](#)

To configure DiffServ-aware traffic engineering, include the **diffserv-te** statement:

```
diffserv-te {
  bandwidth-model {
    extended-mam;
    mam;
    rdm;
```

```

    }
    te-class-matrix {
        traffic-class {
            tnumber {
                priority priority;
                traffic-class ctnumber priority priority;
            }
        }
    }
}

```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

You must include the **diffserv-te** statement in the configuration on all routers participating in the Differentiated Services domain. However, you are not required to configure the traffic engineering class matrix (by including the **te-class-matrix** statement at the [edit protocols mpls **diffserv-te**] or [edit logical-systems *logical-system-name* protocols mpls **diffserv-te**] hierarchy level).

NOTE: To prevent the possibility of an incorrect configuration when migrating to Diffserv-aware traffic engineering, a policy control failure error might be triggered if there is conflict between the old LSPs and the newly configured TE-class matrix.

An old node might request an LSP with setup and hold priorities in such a way that the combination of the ct0 class and the priority does not match with the configured TE-class matrix. All LSPs on the router that are configured prior to configuring diffserv-aware traffic engineering are designated as being from class ct0.

The error appears in the RSVP tracing logs as a **Session preempted** error. For the router where the error originates, the error could appear as follows:

```
Jun 17 16:35:59 RSVP error for session 10.255.245.6(port/tunnel ID 31133)
  Proto 0: (class ct0, priority 2) is not a valid TE-class Jun 17 16:35:59
  RSVP originate PathErr 192.168.37.22->192.168.37.23 Session preempted
```

For the router receiving the error, the error can appear as follows:

```
Jun 17 16:37:51 RSVP recv PathErr 192.168.37.22->192.168.37.23 Session
preempted LSP to-f(2/31133)
```

To configure DiffServ-aware traffic engineering, complete the procedures in the following sections:

Configuring the Bandwidth Model

You must configure a bandwidth model on all routers participating in the Differentiated Services domain. The bandwidth models available are MAM, extended MAM, and RDM:

- Maximum allocation bandwidth constraints model (MAM)—Defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.
- Extended MAM—A proprietary bandwidth model that behaves much like standard MAM. If you configure multiclass LSPs, you must configure the extended MAM bandwidth model.
- Russian-dolls bandwidth allocation model (RDM)—Makes efficient use of bandwidth by allowing the class types to share bandwidth. RDM is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

To configure a bandwidth model, include the **bandwidth-model** statement and specify one of the bandwidth model options:

```
bandwidth-model {
  extended-mam;
  mam;
  rdm;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [diffserv-te](#)]
- [edit logical-systems *logical-system-name* protocols mpls [diffserv-te](#)]

NOTE: If you change the bandwidth model on an ingress router, all the LSPs enabled on the router are taken down and resignaled.

Configuring Traffic Engineering Classes

Configuring traffic engineering classes is optional. [Table 27 on page 1202](#) shows the default values for everything in the traffic engineering class matrix. The default mapping is expressed in terms of the default forwarding classes defined in the CoS configuration.

Table 27: Default Values for the Traffic Engineering Class Matrix

Traffic Engineering Class	Class Type	Queue	Priority
te0	ct0	0	7
te1	ct1	1	7
te2	ct2	2	7
te3	ct3	3	7
te4	ct0	0	0
te5	ct1	1	0
te6	ct2	2	0
te7	ct3	3	0

If you want to override the default mappings, you can configure traffic engineering classes 0 through 7. For each traffic engineering class, you configure a class type (or queue) from 0 through 3. For each class type, you configure a priority from 0 through 7.

To configure traffic engineering classes explicitly, include the **te-class-matrix** statement:

```
te-class-matrix {
  tnumber {
    priority priority;
    traffic-class {
      ctnumber priority priority;
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **diffserv-te**]
- [edit logical-systems *logical-system-name* protocols mpls **diffserv-te**]

The following example shows how to configure traffic engineering class **te0** with class type **ct1** and a priority of 4:

```
[edit protocols mpls diffserv-te]
te-class-matrix {
  te0 traffic-class ct1 priority 4;
}
```

NOTE: If you explicitly configure a value for one of the traffic engineering classes, all the default values in the traffic engineering class matrix are dropped.

When you explicitly configure traffic engineering classes, you must also configure a bandwidth model; otherwise, the configuration commit operation fails.

Requirements and Limitations for the Traffic Engineering Class Matrix

When you configure a traffic engineering class matrix, be aware of the following requirements and limitations:

- A mapping configuration is local and affects only the router on which it is configured. It does not affect other systems participating in the differentiated services domain. However, for a Differentiated Services domain to function properly, you need to configure the same traffic engineering class matrix on all the routers participating in the same domain.

- When explicitly configuring traffic engineering classes, you must configure the classes in sequence (**te0**, **te1**, **te2**, **te3**, and so on); otherwise, the configuration commit operation fails.

The first traffic engineering class you configure must be **te0**; otherwise, the configuration commit operation fails.

Configuring Class of Service for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, you must also configure class of service. The following example illustrates a class-of-service configuration that would allocate 25 percent of the link bandwidth to each class:

```
class-of-service {
  interfaces {
    all {
      scheduler-map simple-map;
    }
  }
  scheduler-maps {
    simple-map {
      forwarding-class assured-forwarding scheduler simple_sched;
      forwarding-class best-effort scheduler simple_sched;
      forwarding-class network-control scheduler simple_sched;
      forwarding-class expedited-forwarding scheduler simple_sched;
    }
  }
  schedulers {
    simple_sched {
      transmit-rate percent 25;
      buffer-size percent 25;
    }
  }
}
```

For more information on how to configure class of service, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

LSP Bandwidth Oversubscription Overview

LSPs are established with bandwidth reservations configured for the maximum amount of traffic you expect to traverse the LSP. Not all LSPs carry the maximum amount of traffic over their links at all times. For example, even if the bandwidth for link A has been completely reserved, actual bandwidth might still

be available but not currently in use. This excess bandwidth can be used by allowing other LSPs to also use link A, oversubscribing the link. You can oversubscribe the bandwidth configured for individual class types or specify a single value for all of the class types using an interface.

You can use oversubscription to take advantage of the statistical nature of traffic patterns and to permit higher utilization of links.

The following examples describe how you might use bandwidth oversubscription and undersubscription:

- Use oversubscription on class types where peak periods of traffic do not coincide in time.
- Use oversubscription of class types carrying best-effort traffic. You take the risk of temporarily delaying or dropping traffic in exchange for making better utilization of network resources.
- Give different degrees of oversubscription or undersubscription of traffic for the different class types. For instance, you configure the subscription for classes of traffic as follows:
 - Best effort—**ct0 1000**
 - Voice—**ct3 1**

When you undersubscribe a class type for a multiclass LSP, the total demand of all RSVP sessions is always less than the actual capacity of the class type. You can use undersubscription to limit the utilization of a class type.

The bandwidth oversubscription calculation occurs on the local router only. Because no signaling or other interaction is required from other routers in the network, the feature can be enabled on individual routers without being enabled or available on other routers which might not support this feature. Neighboring routers do not need to know about the oversubscription calculation, they rely on the IGP.

The following sections describe the types of bandwidth oversubscription available in the Junos OS:

- [LSP Size Oversubscription on page 1205](#)
- [LSP Link Size Oversubscription on page 1206](#)
- [Class Type Oversubscription and Local Oversubscription Multipliers on page 1206](#)

LSP Size Oversubscription

For LSP size oversubscription, you simply configure less bandwidth than the peak rate expected for the LSP. You also might need to adjust the configuration for automatic policers. Automatic policers manage the traffic assigned to an LSP, ensuring that it does not exceed the configured bandwidth values. LSP size oversubscription requires that the LSP can exceed its configured bandwidth allocation.

Policing is still possible. However, the policer must be manually configured to account for the maximum bandwidth planned for the LSP, rather than for the configured value.

LSP Link Size Oversubscription

You can increase the maximum reservable bandwidth on the link and use the inflated values for bandwidth accounting. Use the **subscription** statement to oversubscribe the link. The configured value is applied to all class type bandwidth allocations on the link. For more information about link size oversubscription, see [“Configuring the Bandwidth Subscription Percentage for LSPs” on page 1210](#).

Class Type Oversubscription and Local Oversubscription Multipliers

Local oversubscription multipliers (LOMs) allow different oversubscription values for different class types. LOMs are useful for networks where the oversubscription ratio needs to be configured differently on different links and where oversubscription values are required for different classes. You might use this feature to oversubscribe class types handling best-effort traffic, but use no oversubscription for class types handling voice traffic. An LOM is calculated locally on the router. No information related to an LOM is signaled to other routers in the network.

An LOM is configurable on each link and for each class type. The per-class type LOM allows you to increase or decrease the oversubscription ratio. The per-class-type LOM is factored into all local bandwidth accounting for admission control and IGP advertisement of unreserved bandwidths.

The LOM calculation is tied to the bandwidth model (MAM, extended MAM, and Russian dolls) used, because the effect of oversubscription across class types must be accounted for accurately.

NOTE: All LOM calculations are performed by the Junos OS and require no user intervention.

The formulas related to the oversubscription of class types are described in the following sections:

- [Class Type Bandwidth and the LOM on page 1207](#)
- [LOM Calculation for the MAM and Extended MAM Bandwidth Models on page 1207](#)
- [LOM Calculation for the Russian Dolls Bandwidth Model on page 1208](#)
- [Example: LOM Calculation on page 1208](#)

Class Type Bandwidth and the LOM

The following formula expresses the relationship between the bandwidth of the class type and the LOM. The normalized bandwidth of the class type (N_B) is equal to the reserved bandwidth of the class type (R_B) divided by the LOM of the class type (L_C):

$$N_B = R_B / L_C$$

When calculating available bandwidth, you need to subtract the normalized bandwidth from the relevant bandwidth constraint.

NOTE: When using an LOM, values advertised for the available bandwidth might be larger than the bandwidth constraint values. However, the values advertised in the maximum link bandwidth advertisement are not affected by local oversubscription.

LOM Calculation for the MAM and Extended MAM Bandwidth Models

The following formulas show how the LOM is calculated for the MAM and extended MAM bandwidth models.

$$\text{Unreserved TE-Class}(i) = \text{LOM}_c \times [\text{BC}_c - \text{SUM} (\text{Normalized} (\text{CT}_c, q))] \text{ for } q \leq p$$

Or

$$\text{Unreserved TE-Class}(i) = (\text{LOM}_c \times \text{BC}_c) - \text{SUM} (\text{Reserved} (\text{CT}_c, q)) \text{ for } q \leq p$$

where:

- LOM_c —LOM for class type c .
- BC_c —Bandwidth constraint for class type c .
- CT_c —Class type c .
- $\text{TE-Class}(i) \leftrightarrow (\text{CT}_c, \text{preemption } p)$ in the configured TE-Class mapping.

LOM Calculation for the Russian Dolls Bandwidth Model

The following formulas show how the LOM is calculated for the Russian dolls bandwidth model:

```
Unreserved TE-Class (i) = LOMc x MIN [
    [ BCc - SUM ( Normalized (CTb, q) ) ] for q ≤ p and c ≤ b ≤ 7,
    . . .
    [ BC0 - SUM ( Normalized (CTb, q) ) ] for q ≤ p and 0 ≤ b ≤ 7,
]
```

where:

- **LOM_c**—LOM for class type **c**.
- **BC_c**—Bandwidth constraint for class type **c**.
- **TE-Class(i)** <- ->(CT_c , preemption **p**) in the configured TE-Class mapping.

Note that the impact of an LSP on the unreserved bandwidth of a class type does not depend only on the LOM for that class type—it also depends on the LOM for the class type of the LSP.

Example: LOM Calculation

The following example illustrates how an LOM calculation is made for four classes of traffic: **ct0**, **ct1**, **ct2**, and **ct3**.

The class types have been assigned the following values:

```
ct0 = 40
ct1 = 30
ct2 = 20
ct3 = 10
```

These class type values yield the following bandwidth constraints:

```
BC0 = (ct3 + ct2 + ct1 + ct0) = 100
BC1 = (ct3 + ct2 + ct1) = 60
BC2 = (ct3 + ct2) = 30
BC3 = (ct3) = 10
```

LSPs from class type **ct0** can take up to 100 percent of bandwidth on the link. LSPs from class type **ct1** can take up to 60 percent of the bandwidth on the link, and so on.

If you assume for this example that the class types have the following LOM values:

```
LOM(ct0) = 8
LOM(ct1) = 4
LOM(ct2) = 2
LOM(ct3) = 1
```

In the absence of any other reservation, LSPs from class type **ct0** can take up to 800 percent of the available bandwidth ($8 \times 100 = 800$). In the absence of any other reservation, LSPs from class type **ct1** can take up to 240 percent of the available bandwidth ($4 \times 60 = 240$), and so on.

The maximum amount of bandwidth that can be reserved is:

```
ct0 = LOM(ct0) x BC0 = 800
ct1 = LOM(ct1) x BC1 = 240
ct2 = LOM(ct2) x BC2 = 60
ct3 = LOM(ct3) x BC3 = 10
```

For the undersubscribed class type **ct3**, the maximum reservable bandwidth is the same as the bandwidth constraint. For the overbooked class types, these values are not the values of the bandwidth constraint-taking into account the oversubscription for each class type separately. The oversubscription per class type in the sum is not taken into account because ultimately the entire bandwidth constraint can be filled with the bandwidth reservation of just one class type, so you have to account for that class type's bandwidth oversubscription only.

When calculating the available bandwidth for **CTc**, you need to express reservations from other classes as if they were from **CTc**. The reservation from class **ctx** is normalized with the LOM of **ctx**, but it is then multiplied by the LOM of **CTc**.

For the previous example, assume that **LSP1** has class type **ct3** configured with bandwidth of **10** and a priority of **0**.

The values for the reservable bandwidth will be:

```
ct0 = 8 x (100 - 10) = 720
ct1 = 4 x min((100-10), (60-10)) = 200
ct2 = 2 x min((100-10), (60-10), (30-10)) = 40
ct3 = 1 x min((100-10), (60-10), (30-10), (10-10)) = 0
```

These numbers can be rationalized as follows: the normalized reservation is 10 percent. If this bandwidth came from class type **ct0**, it would be equivalent to an overbooked reservation of 80 percent. You can see that 720 percent ($800 - 80 = 720$) of the bandwidth remains available for other LSPs.

Configuring the Bandwidth Subscription Percentage for LSPs

By default, RSVP allows all of a class type's bandwidth (100 percent) to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

If you want to oversubscribe or undersubscribe all of the class types on an interface using the same percentage bandwidth, configure the percentage using the **subscription** statement:

```
subscription percentage;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

To undersubscribe or oversubscribe the bandwidth for each class type, configure a percentage for each class type (**ct0**, **ct1**, **ct2**, and **ct3**) option for the **subscription** statement. When you oversubscribe a class type, an LOM is applied to calculate the actual bandwidth reserved. See [“Class Type Oversubscription and Local Oversubscription Multipliers” on page 1206](#) for more information.

```
subscription {  
    ct0 percentage;  
    ct1 percentage;  
    ct2 percentage;  
    ct3 percentage;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

percentage is the percentage of class type bandwidth that RSVP allows to be used for reservations. It can be a value from 0 through 65,000 percent. If you specify a value greater than 100, you are oversubscribing the interface or class type.

The value you configure when you oversubscribe a class type is a percentage of the class type bandwidth that can actually be used. The default subscription value is 100 percent.

You can use the **subscription** statement to disable new RSVP sessions for one or more class types. If you configure a percentage of 0, no new sessions (including those with zero bandwidth requirements) are permitted for the class type.

Existing RSVP sessions are not affected by changing the subscription factor. To clear an existing session, issue the **clear rsvp session** command. For more information on the **clear rsvp session** command, see the [CLI Explorer](#).

Constraints on Configuring Bandwidth Subscription

Be aware of the following issues when configuring bandwidth subscription:

- If you configure bandwidth constraints at the **[edit class-of-service interface *interface-name*]** hierarchy level, they override any bandwidth configuration you specify at the **[edit protocols rsvp interface *interface-name* bandwidth]** hierarchy level for Diffserv-TE. Also note that either of the CoS or RSVP bandwidth constraints can override the interface hardware bandwidth constraints.
- If you configure a bandwidth subscription value for a specific interface that differs from the value configured for all interfaces (by including different values for the **subscription** statement at the **[edit protocols rsvp interface *interface-name*]** and **[edit protocols rsvp interface all]** hierarchy levels), the interface-specific value is used for that interface.
- You can configure subscription for each class type only if you also configure a bandwidth model. If no bandwidth model is configured, the commit operation fails with the following error message:

```
user@host# commit check
```

```
[edit protocols rsvp interface all]
  'subscription'
  RSVP: Must have a diffserv-te bandwidth model configured when configuring
  subscription per traffic class.
  error: configuration check-out failed
```

- You cannot include the **subscription** statement both in the configuration for a specific class type and the configuration for the entire interface. The commit operation fails with the following error message:

```
user@host# commit check
```

```
[edit protocols rsvp interface all]
  'subscription'
    RSVP: Cannot configure both link subscription and per traffic class
  subscription.
  error: configuration check-out failed
```

Configuring LSPs for DiffServ-Aware Traffic Engineering

IN THIS SECTION

- [Configuring Class of Service for the Interfaces | 1213](#)
- [Configuring IGP | 1213](#)
- [Configuring Traffic-Engineered LSPs | 1213](#)
- [Configuring Policing for LSPs | 1214](#)
- [Configuring Fast Reroute for Traffic-Engineered LSPs | 1214](#)

You must configure the Differentiated Services domain (see [“Configuring Routers for DiffServ-Aware Traffic Engineering” on page 1199](#)) before you can enable DiffServ-aware traffic engineering for LSPs. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in the LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the LSP to function properly.

NOTE: You must configure either MAM or RDM as the bandwidth model when you configure DiffServ-aware traffic engineering for LSPs. See [“Configuring the Bandwidth Model” on page 1201](#).

The actual data transmitted over this Differentiated Services domain is carried by an LSP. Each LSP relies on the EXP bits of the MPLS packets to enable DiffServ-aware traffic engineering. Each LSP can carry traffic for a single class type.

All the routers participating in the LSP must be Juniper Networks routers running Junos OS Release 6.3 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the DiffServ-aware traffic engineering LSP cannot traverse these routers.

NOTE: You cannot simultaneously configure multiclass LSPs and DiffServ-aware traffic engineering LSPs on the same router.

To enable DiffServ-aware traffic engineering for LSPs, you need to configure the following:

Configuring Class of Service for the Interfaces

The existing class-of-service (CoS) infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to accomplish this are configured using the existing Junos OS CoS features.

NOTE: The Junos OS does not support CoS on ATM interfaces.

For information about how to configure CoS, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Configuring IGP

You can configure either IS-IS or OSPF as the IGP. The IS-IS and OSPF configurations for routers supporting LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

Configuring Traffic-Engineered LSPs

You configure an LSP by using the standard LSP configuration statements and procedures. To configure DiffServ-aware traffic engineering for the LSP, specify a class type bandwidth constraint by including the **bandwidth** statement:

```
label-switched-path lsp-name {
  bandwidth {
    ctnumber bps;
  }
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for this statement.

If you do not specify a bandwidth for a class type, **ct0** is automatically specified as the queue for the LSP. You can configure only one class type for each LSP, unlike multiclass LSPs.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

You can configure setup and holding priorities for an LSP, but the following restrictions apply:

- The combination of class and priority must be one of the configured traffic engineering classes. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.
- For migration issues, see Internet draft draft-ietf-tewg-diff-te-proto-07.txt.

Configuring Policing for LSPs

Policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each LSP.

For information about how to configure a policer for an LSP, see [“Configuring Policers for LSPs” on page 121](#).

Configuring Fast Reroute for Traffic-Engineered LSPs

You can configure fast reroute for traffic engineered LSPs (LSPs carrying a single class of traffic). It is also possible to reserve bandwidth on the detour path for the class of traffic when fast reroute is enabled. The same class type number is used for both the traffic engineered LSP and its detour.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

You can configure the amount of bandwidth to reserve for detours using either the **bandwidth** statement or the **bandwidth-percent** statement. You can only configure one these statements at a time. If you do not configure either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path (the bandwidth guarantee will be lost if traffic is switched to the detour).

When you configure the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. For information, see [“Configuring Fast Reroute” on page 479](#).

The **bandwidth-percent** statement allows you to specify the bandwidth of the detour path as a percentage of the bandwidth configured for the protected path. For example, if you configure 100 millions bps of bandwidth for the protected path and configure 20 for the **bandwidth-percent** statement, the detour path will have 20 million bps of bandwidth reserved for its use.

To configure the percent of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]

Configuring Multiclass LSPs

IN THIS SECTION

- [Configuring Class of Service for the Interfaces | 1216](#)
- [Configuring the IGP | 1216](#)
- [Configuring Class-Type Bandwidth Constraints for Multiclass LSPs | 1216](#)
- [Configuring Policing for Multiclass LSPs | 1218](#)
- [Configuring Fast Reroute for Multiclass LSPs | 1218](#)

A multiclass LSP is an LSP configured to reserve bandwidth for multiple class types and also carries the traffic for these class types. The differentiated service behavior is determined by the EXP bits.

You must configure the Differentiated Services domain (see [“Configuring Routers for DiffServ-Aware Traffic Engineering” on page 1199](#)) before you can enable a multiclass LSP. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in a multiclass LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the multiclass LSP to function properly.

NOTE: You must configure extended MAM as the bandwidth model when you configure multiclass LSPs. See [“Configuring the Bandwidth Model” on page 1201](#).

All the routers participating in a multiclass LSP must be Juniper Networks routers running Junos OS Release 6.2 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the multiclass LSP cannot traverse these routers.

To enable multiclass LSPs, you need to configure the following:

Configuring Class of Service for the Interfaces

The existing class-of-service infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to consistently mark traffic are configured with the existing Junos OS CoS features.

NOTE: The Junos OS does not support ATM interfaces.

For information about how to configure CoS, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Configuring the IGP

You can configure either IS-IS or OSPF. The IS-IS and OSPF configurations for routers supporting multiclass LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

Configuring Class-Type Bandwidth Constraints for Multiclass LSPs

You configure a multiclass LSP by using the standard LSP configuration statements and procedures. To configure an LSP as a multiclass LSP, specify the class type bandwidth constraints by including the **bandwidth** statement:

```
bandwidth {  
  ct0 bps;  
  ct1 bps;  
  ct2 bps;  
  ct3 bps;  
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for these statements.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1

- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

For example, to configure 50 megabytes of bandwidth for class type 1 and 30 megabytes of bandwidth for class type 2, include the **bandwidth** statement as follows:

```
[edit protocols mpls]
label-switched-path traffic-class {
  bandwidth {
    ct1 50M;
    ct2 30M;
  }
}
```

You cannot configure a bandwidth for a class type and also configure a bandwidth at the **[edit protocols mpls label-switched-path *lsp-name* bandwidth]** hierarchy level. For example, the following configuration cannot be committed:

```
[edit protocols mpls]
label-switched-path traffic-class {
  bandwidth {
    20M;
    ct1 10M;
  }
}
```

You can configure setup and holding priorities for a multiclass LSP, but the following restrictions apply:

- The setup and holding priorities apply to all classes for which bandwidth is requested.
- The combination of class and priority must be one of the configured traffic engineering classes. The default traffic engineering class configuration results in multiclass LSPs that cannot preempt and cannot be preempted. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported for multiclass LSPs. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.

Configuring Policing for Multiclass LSPs

Policing allows you to control the amount of traffic forwarded through a particular multiclass LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each multiclass LSP. You can also enable automatic policing for multiclass LSPs.

For information about how to configure a policer for a multiclass LSP, see [“Configuring Policers for LSPs” on page 121](#) and [“Configuring Automatic Policers” on page 124](#).

Configuring Fast Reroute for Multiclass LSPs

You can enable fast reroute for multiclass LSPs. The bandwidth guarantees for the class types can be carried over to the detour path in case the primary path of the multiclass LSP fails. The same traffic class types configured for the primary multiclass LSP are also signaled for the detour LSP.

The bandwidth guarantee for the detour path is a percentage of the bandwidth configured for the class types of the primary path. For example, you configure a value of 50 percent for the detour path and the protected LSP carries traffic for class types CT0 through CT3. The detour path is signaled with the same class types (CT0 through CT3) but with 50 percent of the bandwidth configured for the protected LSP.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering, that all of the traffic class types needed are available, and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

The bandwidth percentage for fast reroute is signaled from the ingress router to the egress router. All of the intermediate devices must complete their own CSPF computations and signaling.

When you configure the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying by the bandwidth configured for the primary multiclass LSP. For information about how to configure the bandwidth for the multiclass LSP, see [“Configuring Traffic-Engineered LSPs” on page 1213](#).

To configure the percentage of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]

Configuring the MPLS Transport Profile for OAM

IN THIS SECTION

- [MPLS Transport Profile Overview | 1221](#)
- [Example: Configuring the MPLS Transport Profile for OAM | 1222](#)

MPLS Transport Profile Overview

RFC 5654, *Requirements of an MPLS Transport Profile*, describes the requirements for the MPLS Transport Profile (MPLS-TP) that extends capabilities for Operation, Administration, and Maintenance (OAM) when MPLS is used for transport services and transport network operations. These capabilities help in troubleshooting and maintenance of a pseudowire or label-switched path (LSP).

MPLS-TP mechanisms for OAM contain two main components:

- Generic Associated Channel Label (GAL)—A special label that enables an exception mechanism that informs the egress label-switching router (LSR) that a packet it receives on an LSP belongs to an associated control channel or the control plane.

- Generic Associated Channel Header (G-Ach)—A special header field that identifies the type of payload contained in the MPLS label-switched paths (LSPs). G-Ach has the same format as a pseudowire associated control channel header.

For more information about MPLS-TP, see RFC 5654, *Requirements of an MPLS Transport Profile*. For specific information about GAL and G-Ach, see RFC 5586, *MPLS Generic Associated Channel*.

The following capabilities are supported in the Junos OS implementation of MPLS-TP:

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.

Example: Configuring the MPLS Transport Profile for OAM

IN THIS SECTION

- [Requirements | 1222](#)
- [Overview | 1222](#)
- [Configuration | 1225](#)
- [Verification | 1236](#)

This example shows how to configure the MPLS Transport Profile (MPLS-TP) for sending and receiving of OAM GAL and G-Ach messages across a label-switched path (LSP).

Requirements

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series, MX Series, and T Series routers
- Junos OS Release 12.1 or later running on the devices

Overview

Junos OS Release 12.1 and later support MPLS Transport Profile (MPLS-TP) Operation, Administration, and Maintenance (OAM) capabilities. MPLS-TP introduces new capabilities for OAM when MPLS is used for transport services and transport network operations. This includes configuring Generic Associated Channel Label (GAL) and Generic Associated Channel Header (G-Ach) for OAM messages.

This example shows how to configure MPLS-TP OAM capability to send and receive GAL and G-Ach OAM messages without IP encapsulation. In addition, it also shows how to associate two unidirectional RSVP

label-switched paths (LSPs) between a pair of routers to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages.

Junos OS Release 12.1 and later support the following MPLS-TP capabilities:

- MPLS-TP OAM capability and the infrastructure required for MPLS applications to send and receive packets with GAL and G-Ach, without IP encapsulation.
- LSP-ping and Bidirectional Forwarding Detection (BFD) applications to send and receive packets using GAL and G-Ach, without IP encapsulation on transport LSPs.
- The association of two unidirectional RSVP LSPs, between a pair of routers, with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. The associated bidirectional LSP model is supported only for associating the primary paths. A single BFD session is established for the associated bidirectional LSP.

Junos OS Release 12.1 and later does not support the following MPLS-TP capabilities:

- Point-to-multipoint RSVP LSPs and BGP LSPs
- Loss Measurement and Delay Measurement

You can enable GAL and G-Ach OAM operation using the following configuration statements:

- **mpls-tp-mode**—Include this statement at the **[edit protocols mpls oam]** hierarchy level to enable GAL and G-Ach OAM operation, without IP encapsulation, on all LSPs in the MPLS network.

```
[edit protocols mpls oam]
mpls-tp-mode;
```

Include this statement at the **[edit protocols mpls label-switched-path *lsp-name* oam]** hierarchy level to enable GAL and G-Ach OAM operation without IP encapsulation on a specific LSP in the network.

```
[edit protocols mpls label-switched-path lsp-name oam]
mpls-tp-mode;
```

NOTE: Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the `mpls-tp-mode` statement. These additional channel types provide on-demand connectivity verification (CV) with and without IP/UDP encapsulation.

- On-demand CV (0x0025)—This channel type is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.
- IPv4 (0x0021)—This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

The GACH-TLV is used along with the default LSPING channel type. As per RFC 7026, GACH-TLV is deprecated for 0x0021 and 0x0025 channel types.

To configure a channel type for MPLS-TP, include the `lsping-channel-type channel-type` statement at the `[edit protocols mpls label-switched-path lsp-name oam mpls-tp-mode]` and `[edit protocols mpls oam mpls-tp-mode]` hierarchy levels.

- **associate-lsp *lsp-name* from *from-ip-address***—Include this statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level to configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls label-switched-path lsp-name ]
associate-lsp lsp-name {
    from from-ip-address;
}
```

The **from *from-ip-address*** configuration for the LSP is optional. If omitted, it is derived from the **to** address of the ingress LSP configuration.

- **transit-lsp-association**—Include this statement at the `[edit protocols mpls]` hierarchy level to associate two LSPs at a transit router.

```
[edit protocols mpls]
transit-lsp-association transit-association-lsp-group-name {
    lsp-name-1 name-of-associated-lsp-1;
    from-1 address-of-associated-lsp-1;
    lsp-name-2 name-of-associated-lsp-2;
    from-2 address-of-associated-lsp-2;
}
```

The association of the LSPs in the transit nodes is useful for the return LSP path for TTL-expired LSP ping packets or traceroute.

In this example, R0 is the ingress router and R4 is the egress router. R1, R2, R3, and R5 are transit routers. The associated bidirectional LSP is established between the transit routers for sending and receiving the GAL and G-Ach OAM messages.

Figure 99 on page 1225 shows the topology used in this example.

Figure 99: MPLS-TP OAM Associated Bidirectional LSPs

Configuration

CLI Quick Configuration

NOTE: This example shows the configuration on all devices and shows step-by-step procedures for configuring the ingress router, R0, and transit router R1. Repeat the step-by-step procedure described for the ingress router, R0, on the egress router, R4. Repeat the step-by-step procedure for the transit router, R1, on the other transit routers, R2, R3, and R5. Be sure to modify the appropriate interface names, addresses, and other parameters appropriately.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Configuring Device R0

Step-by-Step Procedure

To configure the ingress router, R0:

1. Configure the interfaces.

```
[edit interfaces]
user@R0# set ge-4/1/1 unit 0 family inet address 10.10.11.1/30
user@R0# set ge-4/1/1 unit 0 family iso
user@R0# set ge-4/1/1 unit 0 family inet6
user@R0# set ge-4/1/1 unit 0 family mpls
user@R0# set ge-5/0/0 unit 0 family inet address 10.10.10.1/30
user@R0# set ge-5/0/0 unit 0 family iso
user@R0# set ge-5/0/0 unit 0 family inet6
user@R0# set ge-5/0/0 unit 0 family mpls
```

2. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```

3. Configure an interior gateway protocol, such as OSPF.

```
[edit protocols ospf]
user@R0# set traffic-engineering
user@R0# set area 0.0.0.0 interface ge-5/0/0.0
user@R0# set area 0.0.0.0 interface ge-4/1/1.0
user@R0# set area 0.0.0.0 interface lo0.0 passive
```

4. Configure a signaling protocol, such as RSVP.

```
[edit protocols rsvp]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```

5. Configure the LSP.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 to 10.255.8.86
```

6. Enable GAL and G-Ach OAM operation without IP encapsulation on the LSPs.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 oam mpls-tp-mode
```

7. Configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 associate-lsp to-r0 from 10.255.8.86
```

8. After you are done configuring the device, commit the configuration.

```
[edit]
user@R0# commit
```

Results

Confirm your configuration by issuing the **show interfaces** and **show protocols** commands.

```
user@R0# show interfaces
ge-4/1/1 {
  unit 0 {
    family inet {
      address 10.10.11.1/30;
    }

  }
}
}

```

Configuring Device R1

Step-by-Step Procedure

To configure the transit router, R1:

1. Configure the interfaces.

```

[edit interfaces]
user@R1# set ge-0/0/5 unit 0 family inet address 10.10.10.2/30
user@R1# set ge-0/0/5 unit 0 family iso
user@R1# set ge-0/0/5 unit 0 family inet6
user@R1# set ge-0/0/5 unit 0 family mpls

```

```

user@R1# set ge-0/2/2 unit 0 family inet address 10.10.12.2/30
user@R1# set ge-0/2/2 unit 0 family iso
user@R1# set ge-0/2/2 unit 0 family inet6
user@R1# set ge-0/2/2 unit 0 family mpls
user@R1# set ge-2/0/2 unit 0 family inet address 10.10.11.2/30
user@R1# set ge-2/0/2 unit 0 family iso
user@R1# set ge-2/0/2 unit 0 family inet6
user@R1# set ge-2/0/2 unit 0 family mpls
user@R1# set ge-1/0/2 unit 0 family inet address 10.10.13.2/30
user@R1# set ge-1/0/2 unit 0 family iso
user@R1# set ge-1/0/2 unit 0 family inet6
user@R1# set ge-1/0/2 unit 0 family mpls

```

2. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0

```

3. Configure an interior gateway protocol, such as OSPF.

```

[edit protocols ospf]
user@R1# set traffic-engineering
user@R1# set area 0.0.0.0 interface ge-0/0/5.0
user@R1# set area 0.0.0.0 interface ge-2/0/2.0
user@R1# set area 0.0.0.0 interface ge-1/0/2.0
user@R1# set area 0.0.0.0 interface ge-0/2/2.0 metric 100
user@R1# set area 0.0.0.0 interface lo0.0 passive

```

4. Configure a signaling protocol, such as RSVP.

```

[edit protocols rsvp]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0

```

5. Configure the association of the two LSPs on the transit router.

```
[edit protocols mpls]
```

```
user@R1# set transit-lsp-association trace1 lsp-name-1 r0-to-r4
```

```
user@R1# set transit-lsp-association trace1 from-1 10.255.8.207
```

```
user@R1# set transit-lsp-association trace1 lsp-name-2 r4-to-r0
```

```
user@R1# set transit-lsp-association trace1 from-2 10.255.8.86
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
```

```
user@R1# commit
```

Results

Confirm your configuration by issuing the **show interfaces** and **show protocols** commands.

Configuring OAM Ingress Policies for LDP

Using the **ingress-policy** statement, you can configure an Operation, Administration, and Management (OAM) policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

You configure the OAM ingress policy at the **[edit policy-options]** hierarchy level. To configure an OAM ingress policy, include the **ingress-policy** statement:

```
ingress-policy ingress-policy-name;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols ldp oam]
- [edit logical-systems *logical-system-name* protocols ldp oam]

NOTE: ACX Series routers do not support [edit logical-systems] hierarchy level.

Tracing MPLS and LSP Packets and Operations

To trace MPLS and LSP packets and operations, include the **traceoptions** statement:

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can specify the following MPLS-specific flags in the MPLS **traceoptions** statement:

- **all**—Trace all operations.
- **connection**—Trace all circuit cross-connect (CCC) activity.
- **connection-detail**—Trace detailed CCC activity.
- **cspf**—Trace CSPF computations.
- **cspf-link**—Trace links visited during CSPF computations.
- **cspf-node**—Trace nodes visited during CSPF computations.
- **error**—Trace MPLS error conditions.
- **graceful-restart**—Trace MPLS graceful restart events.
- **lsping**—Trace LSP ping packets and return codes.
- **nsr-synchronization**—Trace nonstop routing (NSR) synchronization events.
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail.
- **state**—Trace all LSP state transitions.
- **static**—Trace static label-switched path.

When you configure trace options to track an MPLS LSP using the **cspf** option, the CSPF log displays information about the MPLS LSP using the term “generalized MPLS” (GMPLS). For example, a message in the CSPF log might state that the “link passes GMPLS constraints”. Generalized MPLS (GMPLS) is a superset of MPLS, so this message is normal and does not affect proper MPLS LSP operation.

For general information about tracing and global tracing options, see the *Junos OS Routing Protocols Library*.

Ethernet Pseudowire Overview

Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks. Ethernet or 802.3 PDUs are encapsulated within the pseudowire to provide a point-to-point Ethernet service. For the point-to-point Ethernet service, the following fault management features are supported:

- The IEEE 802.3ah standard for Operation, Administration, and Management (OAM). You can configure IEEE 802.3ah OAM link-fault management on Ethernet point-to-point direct links or links across Ethernet repeaters.

Ethernet OAM link-fault management can be used for physical link-level fault detection and management. It uses a new, optional sublayer in the data link layer of the OSI model. Ethernet OAM can be implemented on any full-duplex point-to-point or emulated point-to-point Ethernet link. A system-wide implementation is not required; OAM can be deployed on particular interfaces of a router. Transmitted Ethernet OAM messages or OAM PDUs are of standard length, untagged Ethernet frames within the normal frame length limits in the range 64–1518 bytes.

- Ethernet connectivity fault management (CFM) to monitor the physical link between two routers.

- Connection protection using the continuity check protocol for fault monitoring . The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
- Path protection using the linktrace protocol for path discovery and fault verification . Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

Release History Table

Release	Description
14.1X53	Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks.

- [Overview of an Ethernet Pseudowire Base Configuration](#) | [1243](#)
- [Configuring an Ethernet Pseudowire](#) | [1243](#)

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router

- Junos OS Release 12.2 or later

Overview of an Ethernet Pseudowire Base Configuration

The configuration shown here is the base configuration of an Ethernet pseudowire with Ethernet cross-connect for physical interface encapsulation on an ACX Series router. This configuration is for one provider edge router. To complete the configuration of an Ethernet pseudowire, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an Ethernet Pseudowire

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set interfaces ge-0/1/1 encapsulation ethernet-ccc
set interfaces ge-0/1/1 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
set protocols mpls no-cspf
set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface ge-0/1/1.0 virtual-circuit-id
1
```

NOTE: To configure an Ethernet pseudowire with 802.1Q tagging for cross-connect logical interface encapsulation, include the **vlan-ccc** statement at the **[edit interfaces ge-0/1/1 unit 0 encapsulation]** hierarchy level instead of the **ethernet-ccc** statement shown in this example.

Step-by-Step Procedure

1. Create two Gigabit Ethernet interfaces, set the encapsulation mode on one interface and MPLS on the other interface. Create the loopback (**lo0**) interface:

```
[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ge-0/1/1 encapsulation ethernet-ccc
user@host# set ge-0/1/1 unit 0
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

2. Enable the MPLS and RSVP protocols on the interface configured with MPLS—**ge-0/2/0.0**:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

3. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set protocols ldp interface ge-0/2/0.0
user@host# set protocols ldp interface lo0.0
```

4. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

5. Configure OSPF and enable traffic engineering on the MPLS interface—**ge-0/2/0.0**, and on the loopback (**lo0**) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

6. Uniquely identify a Layer 2 circuit for the Ethernet pseudowire:

```
[edit protocols]
user@host# set l2circuit neighbor 40.1.1.1 interface ge-0/1/1.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
interfaces {

Pseudowire Overview for ACX Series Universal Metro Routers

A pseudowire is a Layer 2 circuit or service, which emulates the essential attributes of a telecommunications service—such as a T1 line, over an MPLS packet-switched network. The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required degree of faithfulness for the given service definition. On the ACX Series routers, Ethernet, Asynchronous Transfer Mode (ATM), and time-division multiplexing (TDM) pseudowires are supported. The following pseudowire features are supported:

- Pseudowire transport service carrying Layer 1 and Layer 2 information over an IP and MPLS network infrastructure. Only similar end points are supported on the ACX Series—for example, T1 to T1, ATM to ATM, and Ethernet to Ethernet.
- Redundant pseudowires backup connections between PE routers and CE devices, maintaining Layer 2 circuits and services after certain types of failures. Pseudowire redundancy improves the reliability of

certain types of networks (metro for example) where a single point of failure could interrupt service for multiple customers. The following pseudowire redundancy features are supported:

- Maintenance of Layer 2 circuit services after certain types of failures with a standby pseudowire, which backs up the connection between PE routers and CE devices.
- In case of failure, a protect interface, which backs up the primary interface. Network traffic uses the primary interface only so long as the primary interface functions. If the primary interface fails, traffic is switched to the protect interface.
- Hot and cold standby enabling swift cut over to the backup or standby pseudowire.
- Ethernet connectivity fault management (CFM), which can be used to monitor the physical link between two routers. The following major features of CFM for Ethernet pseudowires only are supported:
 - Connection protection using the continuity check protocol for fault monitoring. The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
 - Path protection using the linktrace protocol for path discovery and fault verification. Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

Understanding Multisegment Pseudowire

A pseudowire is a Layer 2 circuit or service that emulates the essential attributes of a telecommunications service, such as a T1 line, over an MPLS packet-switched network (PSN). The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required resiliency requirements for the given service definition.

When a pseudowire originates and terminates on the edge of the same PSN, the pseudowire label is unchanged between the originating and terminating provider edge (T-PE) devices. This is called a single-segment pseudowire (SS-PW). [Figure 100 on page 1248](#) illustrates an SS-PW established between two PE routers. The pseudowires between the PE1 and PE2 routers are located within the same autonomous system (AS).

Figure 100: L2VPN Pseudowire

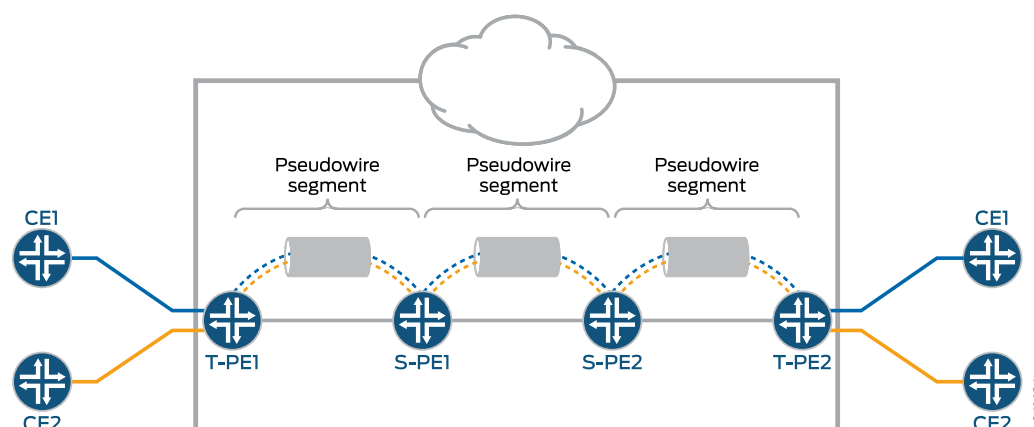

In cases where it is impossible to establish a single pseudowire from a local to a remote PE, either because it is unfeasible or undesirable to establish a single control plane between the two PEs, a multisegment pseudowire (MS-PW) is used.

An MS-PW is a set of two or more contiguous SS-PWs that are made to function as a single point-to-point pseudowire. It is also known as switched pseudowire. MS-PWs can go across different regions or network domains. A region can be considered as an interior gateway protocol (IGP) area or a BGP autonomous system that belongs to the same or different administrative domain. An MS-PW spans multiple cores or ASs of the same or different carrier networks. A Layer 2 VPN MS-PW can include up to 254 pseudowire segments.

Figure 101 on page 1249 illustrates a set of two or more pseudowire segments that function as a single pseudowire. The end routers are called terminating PE (T-PE) routers, and the switching routers are called switching PE (S-PE) routers. The S-PE router terminates the tunnels of the preceding and succeeding pseudowire segments in an MS-PW. The S-PE router can switch the control and data planes of the preceding and succeeding pseudowire segments of the MS-PW. An MS-PW is declared to be up when all the single-segment pseudowires are up.

Figure 101: Multisegment Pseudowire

Using FEC 129 for Multisegment Pseudowire

Currently, there are two types of attachment circuit identifiers (AIs) defined under FEC 129:

- Type 1 AI
- Type 2 AI

The support of an MS-PW for FEC 129 uses type 2 AI. A type 2 AI is globally unique by definition of RFC 5003.

Single-segment pseudowires (SS-PWs) using FEC 129 on an MPLS PSN can use both type 1 and type 2 All. For an MS-PW using FEC 129, a pseudowire itself is identified as a pair of endpoints. This requires that the pseudowire endpoints be uniquely identified.

In the case of a dynamically placed MS-PW, there is a requirement for the identifiers of attachment circuits to be globally unique, for the purposes of reachability and manageability of the pseudowire. Thus, individual globally unique addresses are allocated to all the attachment circuits and S-PEs that make up an MS-PW.

Type 2 All is composed of three fields:

- Global_ID—Global identification, which is usually the AS number.
- Prefix—IPv4 address, which is usually the router ID.
- AC_ID—Local attachment circuit, which is a user-configurable value.

Since type 2 All already contains the T-PE's IP address and it is globally unique, from the FEC 129 pseudowire signaling point of view, the combination (AGI, SAll, TAll) uniquely identifies an MS-PW across all interconnected pseudowire domains.

Establishing a Multisegment Pseudowire Overview

An MS-PW is established by dynamically and automatically selecting the predefined S-PEs and placing the MS-PW between two T-PE devices.

When S-PEs are dynamically selected, each S-PE is automatically discovered and selected using the BGP autodiscovery feature, without the requirement of provisioning the FEC 129 pseudowire-related information on all the S-PEs. BGP is used to propagate pseudowire address information throughout the PSN.

Since there is no manual provisioning of FEC 129 pseudowire information on the S-PEs, the Attachment Group Identifier (AGI) and Attachment Individual Identifier (AII) are reused automatically, and choosing the same set of S-PEs for the pseudowire in both the forwarding and reverse direction is achieved through the active and passive role of each T-PE device.

- Active—The T-PE initiates an LDP label mapping message.
- Passive—The T-PE does not initiate an LDP label mapping message until it receives a label mapping message initiated by the active T-PE. The passive T-PE sends its label mapping message to the same S-PE from where it received the label mapping message originated from its active T-PE. This ensures that the same set of S-PEs are used in the reverse direction.

Pseudowire Status Support for Multisegment Pseudowire

Pseudowire Status Behavior on T-PE

The following pseudowire status messages are relevant on the T-PE:

- 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.

- 0x00000001—Generic nonforwarding fault code. This is set as the local fault code. The local fault code is set at the local T-PE, and LDP sends a pseudowire status TLV message with the same fault code to the remote T-PE.
- Fault codes are bit-wise OR'ed and stored as remote pseudowire status codes.

Pseudowire Status Behavior on S-PE

The S-PE initiates the pseudowire status messages that indicate the pseudowire faults. The SP-PE in the pseudowire notification message hints where the fault was originated.

- When a local fault is detected by the S-PE, a pseudowire status message is sent in both directions along the pseudowire. Since there are no attachment circuits on an S-PE, only the following status messages are relevant:
 - 0x00000008—Local PSN-facing pseudowire (ingress) receive fault.
 - 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- To indicate which SS-PW is at fault, an LDP SP-PE TLV is attached with the pseudowire status code in the LDP notification message. The pseudowire status is passed along from one pseudowire to another unchanged by the control plane switching function.
- If an S-PE initiates a pseudowire status notification message with one particular pseudowire status bit, then for the pseudowire status code an S-PE receives, the same bit is processed locally and not forwarded until the S-PE's original status error is cleared.
- An S-PE keeps only two pseudowire status codes for each SS-PW it is involved in – local pseudowire status code and remote pseudowire status code. The value of the remote pseudowire status code is the result of logic or operation of the pseudowire status codes in the chain of SS-PWs preceding this segment. This status code is incrementally updated by each S-PE upon receipt and communicated to the next S-PE. The local pseudowire status is generated locally based on its local pseudowire status.
- Only transmit fault is detected at the SP-PE. When there is no MPLS LSP to reach the next segment, a local transmit fault is detected. The transmit fault is sent to the next downstream segment, and the receive fault is sent to the upstream segment.
- Remote failures received on an S-PE are just passed along the MS-PW unchanged. Local failures are sent to both segments of the pseudowire that the S-PE is involved in.

Pseudowire TLV Support for MS-PW

MS-PW provides the following support for the LDP SP-PE TLV [RFC 6073]:

- The LDP SP-PE TLVs for an MS-PW include:
 - Local IP address
 - Remote IP address

- An SP-PE adds the LDP SP-PE TLV to the label mapping message. Each SP-PE appends the local LDP SP-PE TLV to the SP-PE list it received from the other segment.
- The pseudowire status notification message includes the LDP SP-PE TLV when the notification is generated at the SP-PE.

Supported and Unsupported Features

Junos OS supports the following features with MS-PW:

- MPLS PSN for each SS-PW that builds up the MS-PW.
- The same pseudowire encapsulation for each SS-PW in an MS-PW – Ethernet or VLAN-CCC.
- The generalized PWid FEC with T-LDP as an end-to-end pseudowire signaling protocol to set up each SS-PW.
- MP-BGP to autodiscover the two endpoint PEs for each SS-PW associated with the MS-PW.
- Standard MPLS operation to stitch two side-by-side SS-PWs to form an MS-PW.
- Automatic discovery of S-PE so that the MS-PW can be dynamically placed.
- Minimum provisioning of S-PE.
- Operation, administration, and maintenance (OAM) mechanisms, including end-to-end MPLS ping or end-to-any-S-PE MPLS ping, MPLS path trace, end-to-end VCCV, and Bidirectional Forwarding Detection (BFD).
- Pseudowire swithing point (SP) PE TLV for the MS-PW.
- Composite next hop on MS-PW.
- Pseudowire status TLV for MS-PW.

Junos OS does not support the following MS-PW functionality:

- Mix of LDP FEC 128 and LDP FEC 129.
- Static pseudowire where each label is provisioned statically.
- Graceful Routing Engine switchover.
- Nonstop active routing.
- Multihoming.
- Partial connectivity verification (originating from an S-PE) in OAM.

Example: Configuring a Multisegment Pseudowire

IN THIS SECTION

- [Requirements | 1253](#)
- [Overview | 1254](#)
- [Configuration | 1260](#)
- [Verification | 1286](#)
- [Troubleshooting | 1297](#)

This example shows how to configure a dynamic multisegment pseudowire (MS-PW), where the stitching provider edge (S-PE) devices are automatically and dynamically discovered by BGP, and pseudowires are signaled by LDP using FEC 129. This arrangement requires minimum provisioning on the S-PEs, thereby reducing the configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Packet Transport Routers.
 - Two remote PE devices configured as terminating PEs (T-PEs).
 - Two S-PEs configured as:
 - Route reflectors, in the case of interarea configuration.
 - AS boundary routers or route reflectors, in the case of inter-AS configuration.
- Junos OS Release 13.3 or later running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure LDP.
5. Configure MPLS.

Overview

Starting with Junos OS Release 13.3, you can configure an MS-PW using FEC 129 with LDP signaling and BGP autodiscovery in an MPLS packet-switched network (PSN). The MS-PW feature also provides operation, administration, and management (OAM) capabilities, such as ping, traceroute, and BFD, from the T-PE devices.

To enable autodiscovery of S-PEs in an MS-PW, include the **auto-discovery-mspw** statement at the **[edit protocols bgp group group-name family l2vpn]** hierarchy level.

```
family l2vpn {
  auto-discovery-mspw;
}
```

The automatic selection of S-PE and dynamic setting up of an MS-PW rely heavily on BGP. BGP network layer reachability information (NLRI) constructed for the FEC 129 pseudowire to autodiscover the S-PE is called an MS-PW NLRI [draft-ietf-pwe3-dynamic-ms-pw-15.txt]. The MS-PW NLRI is essentially a prefix consisting of a route distinguisher (RD) and FEC 129 source attachment identifier (SAII). It is referred to as a BGP autodiscovery (BGP-AD) route and is encoded as **RD:SAII**.

Only T-PEs that are provisioned with type 2 AIs initiate their own MS-PW NLRI respectively. Since a type 2 AI is globally unique, an MS-PW NLRI is used to identify a PE device to which the type 2 AI is provisioned. The difference between a type 1 AI and a type 2 AI requires that a new address family indicator (AFI) and subsequent address family identifier (SAFI) be defined in BGP to support an MS-PW. The proposed AFI and SAFI value pair used to identify the MS-PW NLRI is 25 and 6, respectively (pending IANA allocation).

The AFI and SAFI values support autodiscovery of S-PEs and should be configured on both T-PEs that originate the routes, and the S-PEs that participate in the signaling.

[Figure 102 on page 1255](#) illustrates an inter-area MS-PW setup between two remote PE routers—T-PE1 and T-PE2. The Provider (P) routers are P1 and P2, and the S-PE routers are S-PE1 and S-PE2. The MS-PW is established between T-PE1 and T-PE2, and all the devices belong to the same AS—AS 100. Since S-PE1 and S-PE2 belong to the same AS, they act as route reflectors and are also known as RR 1 and RR 2, respectively.

Figure 103 on page 1255 illustrates an inter-AS MS-PW setup. The MS-PW is established between T-PE1 and T-PE2, where T-PE1, P1, and S-PE1 belong to AS 1, and S-PE2, P2, and T-PE2 belong to AS 2. Since S-PE1 and S-PE2 belong to different ASs, they are configured as ASBR routers and are also known as ASBR 1 and ASBR 2, respectively.

Figure 102: Interarea Multisegment Pseudowire

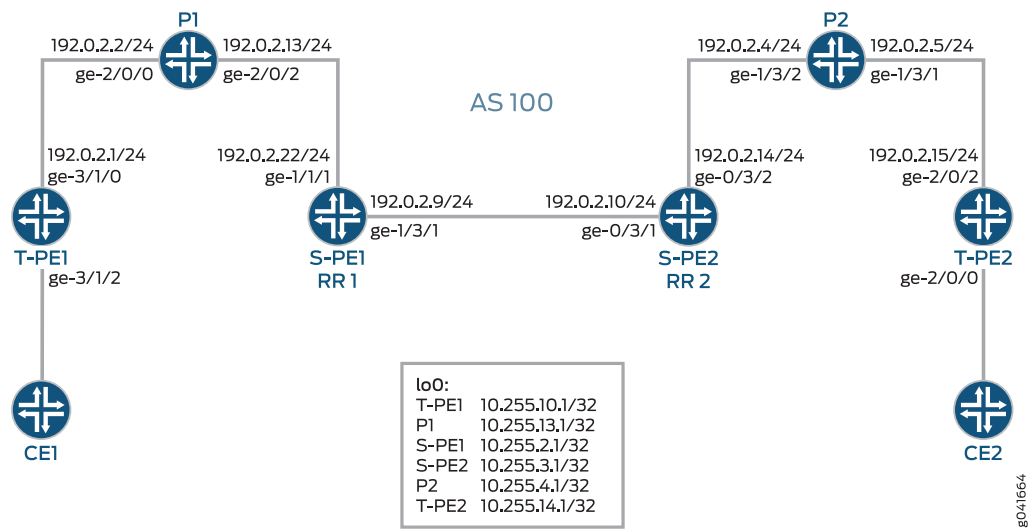

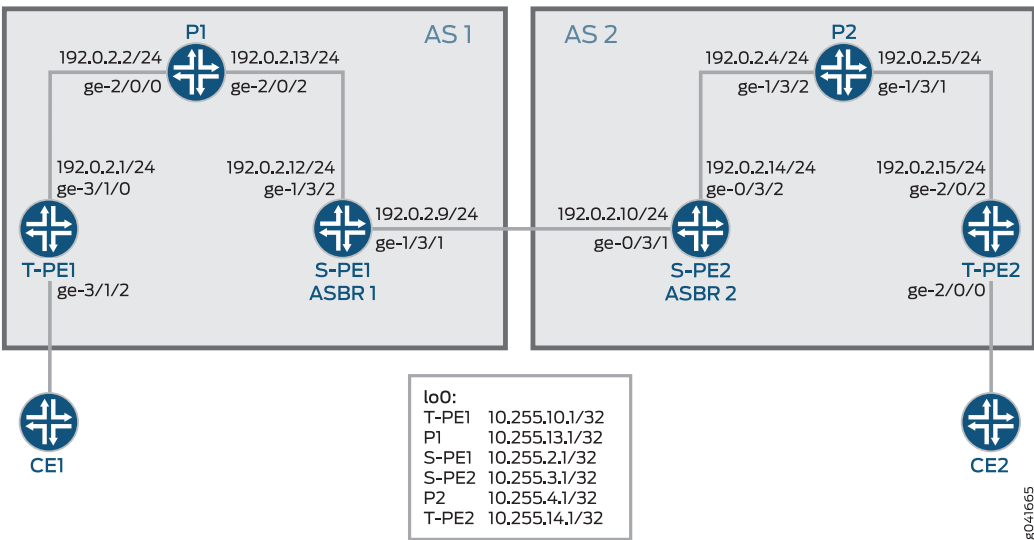

Figure 103: Inter-AS Multisegment Pseudowire

The following sections provide information about how an MS-PW is established in an interarea and inter-AS scenario.

Minimum Configuration Requirements on S-PE

In order to dynamically discover both ends of an SS-PW and set up a T-LDP session dynamically, the following is required:

- For interarea MS-PW, each S-PE plays both an ABR and BGP route reflector role.

In the interarea case, as seen in [Figure 102 on page 1255](#), the S-PE plays a BGP route reflector role and reflects the BGP-AD route to its client. A BGP-AD route advertised by one T-PE eventually reaches its remote T-PE. Because of the next-hop-self set by each S-PE, the S-PE or T-PE that receives a BGP-AD route can always discover the S-PE that advertises the BGP-AD in its local AS or local area through the BGP next hop.

- For inter-AS MS-PW, each S-PE plays either an ASBR or a BGP route reflector role.

In an MS-PW, the two T-PEs initiate a BGP-AD route respectively. When the S-PE receives the BGP-AD route through either the IBGP session with the T-PE or through a regular BGP-RR, it sets the next-hop-self before re-advertising the BGP-AD route to one or more of its EBGPs peers in the inter-AS case, as seen in [Figure 103 on page 1255](#).

- Each S-PE must set next-hop-self when re-advertising or reflecting a BGP-AD route for the MS-PW.

Active and Passive Role of T-PE

To ensure that the same set of S-PEs are being used for a MS-PW in both directions, the two T-PEs play different roles in terms of FEC 129 signaling. This is to avoid different paths being chosen by T-PE1 and T-PE2 when each S-PE is dynamically selected for an MS-PW.

When an MS-PW is signaled using FEC 129, each T-PE might independently start signaling the MS-PW. The signaling procedure can result in an attempt to set up each direction of the MS-PW through different S-PEs.

To avoid this situation, one of the T-PEs must start the pseudowire signaling (active role), while the other waits to receive the LDP label mapping before sending the respective pseudowire LDP label mapping message (passive role). When the MS-PW path is dynamically placed, the active T-PE (the Source T-PE) and the passive T-PE (the Target T-PE) must be identified before signaling is initiated for a given MS-PW. The determination of which T-PE assumes the active role is done based on the SAll value, where the T-PE that has a larger SAll value plays the active role.

In this example, the SAll values of T-PE1 and T-PE 2 are **800:800:800** and **700:700:700**, respectively. Since T-PE1 has a higher SAll value, it assumes the active role and T-PE2 assumes the passive role.

Directions for Establishing an MS-PW

The directions used by the S-PE for setting up the MS-PW are:

- Forwarding direction—From an active T-PE to a passive T-PE.

In this direction, the S-PEs perform a BGP-AD route lookup to determine the next-hop S-PE to send the label mapping message.

- Reverse direction—From a passive T-PE to an active T-PE.

In this direction, the S-PEs do not perform a BGP-AD route lookup, because the label mapping messages are received from the T-PEs, and the stitching routes are installed in the S-PEs.

In this example, the MS-PW is established in the forwarding direction from T-PE1 to T-PE2. When the MS-PW is placed from T-PE2 to T-PE1, the MS-PW is established in the reverse direction.

Autodiscovery and Dynamic Selection of S-PE

A new AFI and SAFI value is defined in BGP to support the MS-PWs based on type 2 All. This new address family supports autodiscovery of S-PEs. This address family must be configured on both the TPEs and SPEs.

It is the responsibility of the Layer 2 VPN component to dynamically select the next S-PE to use along the MS-PW in the forwarding direction.

- In the forwarding direction, the selection of the next S-PE is based on the BGP-AD route advertised by the BGP and pseudowire FEC information sent by the LDP. The BGP-AD route is initiated by the passive T-PE (T-PE2) in the reverse direction while the pseudowire FEC information is sent by LDP from the active T-PE (T-PE1) in the forwarding direction.
- In the reverse direction, the next S-PE (S-PE2) or the active T-PE (T-PE1) is obtained by looking up the S-PE (S-PE1) that it used to set up the pseudowire in the forwarding direction.

Provisioning a T-PE

To support FEC 129 type 2 All, the T-PE needs to configure its remote T-PE's IP address, a global ID, and an attachment circuit ID. Explicit paths where a set of S-PEs to use is explicitly specified on a T-PE is not supported. This eliminates the need to provision each S-PE with a type 2 All.

Stitching an MS-PW

An S-PE performs the following MPLS label operations before forwarding the received label mapping message to the next S-PE:

1. Pops the MPLS tunnel label.
2. Pops the VC label.
3. Pushes a new VC label.
4. Pushes an MPLS tunnel label used for the next segment.

Establishing an MS-PW

After completing the necessary configuration, an MS-PW is established in the following manner:

1. The SAll values are exchanged between T-PE1 and T-PE2 using BGP.
T-PE1 assumes the active T-PE role, because it is configured with a higher SAll value. T-PE2 becomes the passive T-PE.
2. T-PE1 receives the BGP-AD route originated by T-PE2. It compares the All values obtained from T-PE2 in the received BGP-AD route against the All values provisioned locally.
3. If the All values match, T-PE1 performs a BGP-AD route lookup to elect the first S-PE (S-PE1).
4. T-PE1 sends an LDP label mapping message to S-PE1.
5. Using the BGP-AD route originated from T-PE2, and the LDP label mapping message received from T-PE1, S-PE1 selects the next S-PE (S-PE2) in the forwarding direction.
To do this, S-PE1 compares SAll obtained from the BGP-AD route against the TAI from the LDP label mapping message.
6. If the All values match, S-PE1 finds S-PE2 through the BGP next hop associated with the BGP-AD route.
7. The process of selecting S-PE goes on until the last S-PE establishes a T-LDP session with T-PE2. When T-PE2 receives the LDP label mapping message from the last S-PE (S-PE2), it initiates its own label mapping message and sends it back to S-PE2.
8. When all the label mapping messages are received on S-PE1 and S-PE2, the S-PEs install the stitching routes. Thus, when the MS-PW is established in the reverse direction, the S-PEs need not perform BGP-AD route lookup to determine its next hop as it did in the forwarding direction.

OAM Support for an MS-PW

After the MS-PW is established, the following OAM capabilities can be executed from the T-PE devices:

- Ping
 - End-to-End Connectivity Verification Between T-PEs

If T-PE1, S-PEs, and T-PE2 support Control Word (CW), the pseudowire control plane automatically negotiates the use of the CW. Virtual Circuit Connectivity Verification (VCCV) Control Channel (CC) Type 3 will function correctly whether or not the CW is enabled on the pseudowire. However, VCCV Type 1, which is used for end-to-end verification only, is only supported if the CW is enabled.

The following is a sample:

```
user@T-PE1> ping mpls l2vpn fec129 instance instance-name local-id SAll of T-PE1 remote-pe-address  
address of T-PE2 remote-id TAll of T-PE2
```

or

```
user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface
```

- Partial Connectivity Verification from T-PE to Any S-PE

To trace part of an MS-PW, the TTL of the pseudowire label can be used to force the VCCV message to pop out at an intermediate node. When the TTL expires, the S-PE can determine that the packet is a VCCV packet either by checking the CW or by checking for a valid IP header with UDP destination port 3502 (if the CW is not in use). The packet should then be diverted to VCCV processing.

If T-PE1 sends a VCCV message with the TTL of the pseudowire label equal to 1, the TTL expires at the S-PE. T-PE1 can thus verify the first segment of the pseudowire.

The VCCV packet is built according to RFC 4379. All the information necessary to build the VCCV LSP ping packet is collected by inspecting the S-PE TLVs. This use of the TTL is subject to the caution expressed in RFC 5085. If a penultimate LSR between S-PEs or between an S-PE and a T-PE manipulates the pseudowire label TTL, the VCCV message might not emerge from the MS-PW at the correct S-PE.

The following is a sample:

```
user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface bottom-label-ttl segment
```

The **bottom-label-ttl** value is 1 for S-PE1 and 2 for S-PE2.

The **bottom-label-ttl** statement sets the correct VC label TTL, so the packets are popped to the correct SS-PW for VCCV processing.

NOTE: Junos OS supports VCCV Type 1 and Type 3 for the MS-PW OAM capability. VCCV Type 2 is not supported.

- Traceroute

Traceroute tests each S-PE along the path of the MS-PW in a single operation similar to LSP trace. This operation is able to determine the actual data path of the MS-PW, and is used for dynamically signaled MS-PWs.

```
user@T-PE1> traceroute mpls l2vpn fec129 interface CE1-facing interface
```

- Bidirectional Forwarding Detection

Bidirectional Forwarding Detection (BFD) is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. In addition to fast forwarding path failure detection, BFD provides a consistent failure detection method

for network administrators. The router or switch can be configured to log a system log (syslog) message when BFD goes down.

```
user@T-PE1> show bfd session extensive
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure T-PE1 in the interarea scenario:

NOTE: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```

[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary

```

2. Set the autonomous system number.

```
[edit routing-options]
user@T-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier 800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0 target-attachment-identifier
700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (RR 1) in the interarea scenario:

NOTE: Repeat this procedure for the S-PE2 (RR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the S-PE1 interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for S-PE1.

```
[edit protocols]
user@S-PE1# set bgp group mspw type internal
```

6. Configure S-PE1 to act as a route reflector.

```
[edit protocols]
user@S-PE1# set bgp group mspw export next-hop-self
user@S-PE1# set bgp group mspw cluster 203.0.113.0
```

7. Assign local and neighbor addresses to the mspw group for S-PE1 to peer with T-PE1 and S-PE2.

```
[edit protocols]
user@S-PE1# set bgp group mspw local-address 10.255.2.1
user@S-PE1# set bgp group mspw neighbor 10.255.10.1 (to T-PE1)
user@S-PE1# set bgp group mspw neighbor 10.255.3.1 (to S-PE2)
```

8. Configure OSPF on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0
```

9. Configure LDP on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

10. Define the policy for enabling next-hop-self and accepting BGP traffic on S-PE1.

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
user@S-PE1# set policy-statement send-inet0 from protocol bgp
user@S-PE1# set policy-statement send-inet0 then accept
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```
user@T-PE1# show interfaces
ge-3/1/0 {

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the T-PE1 router in the inter-AS scenario:

NOTE: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```

[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary

```

2. Set the autonomous system number.

```

[edit routing-options]
user@T-PE1# set autonomous-system 1

```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```

[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable

```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
```

```
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier 800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0 target-attachment-identifier
700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (ASBR 1) in the inter-AS scenario:

NOTE: Repeat this procedure for the S-PE2 (ASBR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure S-PE1 (ASBR 1) interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the IBGP group for S-PE1 (ASBR 1) to peer with T-PE1.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 type internal
```

6. Configure the IBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 local-address 10.255.2.1
user@S-PE1# set bgp group to_T-PE1 export next-hop-self
user@S-PE1# set bgp group to_T-PE1 neighbor 10.255.10.1
```

7. Configure the EBGP group for S-PE1 (ASBR 1) to peer with S-PE2 (ASBR 2).

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 type external
```

8. Configure the EBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 local-address 10.255.2.1
user@S-PE1# set bgp group to_S-PE2 peer-as 2
user@S-PE1# set bgp group to_S-PE2 neighbor 10.255.3.1 multihop ttl 1
```

9. Configure OSPF on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

10. Configure LDP on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

11. Define the policy for enabling next-hop-self on S-PE1 (ASBR 1).

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```

  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Routes | 1286](#)
- [Verifying the LDP Database | 1289](#)
- [Checking the MS-PW Connections on T-PE1 | 1290](#)
- [Checking the MS-PW Connections on S-PE1 | 1292](#)
- [Checking the MS-PW Connections on S-PE2 | 1293](#)
- [Checking the MS-PW Connections on T-PE2 | 1295](#)

Confirm that the configuration is working properly.

Verifying the Routes

Purpose

Verify that the expected routes are learned.

Action

From operational mode, run the **show route** command for the **bgp.l2vpn.1**, **ldp.l2vpn.1**, **mpls.0**, and **ms-pw.l2vpn.1** routing tables.

From operational mode, run the **show route table bgp.l2vpn.1** command.

user@T-PE1> **show route table *bgp.l2vpn.1***

```
bgp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

10.10.10.10:15:700:0.0.2.188:700/160 AD2

```
*[BGP/170] 16:13:11, localpref 100, from 10.255.2.1
  AS path: 2 I, validation-state: unverified
  > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

From operational mode, run the **show route table *ldp.l2vpn.1*** command.

user@T-PE1> **show route table *ldp.l2vpn.1***

```
ldp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2

```
*[LDP/9] 16:21:27
  Discard
```

From operational mode, run the **show route table *mpls.0*** command.

user@T-PE1> **show route table *mpls.0***

```
mpls.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
0          *[MPLS/0] 1w6d 00:28:26, metric 1
           Receive
1          *[MPLS/0] 1w6d 00:28:26, metric 1
           Receive
2          *[MPLS/0] 1w6d 00:28:26, metric 1
           Receive
13         *[MPLS/0] 1w6d 00:28:26, metric 1
           Receive
299920     *[LDP/9] 1w5d 01:26:08, metric 1
           > to 203.0.113.2 via ge-3/1/0.0, Pop

```

Meaning

The output shows all the learned routes, including the autodiscovery (AD) routes.

The AD2 prefix format is **RD:SAIL-type2**, where:

- **RD** is the route distinguisher value.
- **SAIL-type2** is the type 2 source attachment identifier value.

The PW2 prefix format is **Neighbor_Addr:C:PWtype:l2vpn-id:SAll-type2:TAIl-type2**, where:

- **Neighbor_Addr** is the loopback address of neighboring S-PE device.
- **C** indicates if Control Word (CW) is enabled or not.
 - **C** is **CtrlWord** if CW is set.
 - **C** is **NoCtrlWord** if CW is not set.
- **PWtype** indicates the type of the pseudowire.
 - **PWtype** is **4** if it is in Ethernet tagged mode.
 - **PWtype** is **5** if it is Ethernet only.
- **l2vpn-id** is the Layer 2 VPN ID for the MS-PW routing instance.
- **SAll-type2** is the type 2 source attachment identifier value.
- **TAIl-type2** is the type 2 target attachment identifier value.

Verifying the LDP Database

Purpose

Verify the MS-PW labels received by T-PE1 from S-PE1 and sent from T-PE1 to S-PE1.

Action

From operational mode, run the **show ldp database** command.

user@T-PE1> **show ldp database**

```
Input label database, 10.255.10.1:0--10.255.2.1:0

```

Meaning

The labels with **FEC129** prefix are related to the MS-PW.

Checking the MS-PW Connections on T-PE1

Purpose

Make sure that all of the FEC 129 MS-PW connections come up correctly.

Action

From operational mode, run the **show l2vpn connections extensive** command.

```
user@T-PE1> show l2vpn connections extensive
```

```
Layer-2 VPN connections:

To troubleshoot the MS-PW connection, see:

Ping

Problem

How to check the connectivity between the T-PE devices and between a T-PE device and an intermediary device.

Solution

Verify that T-PE1 can ping T-PE2. The **ping mpls l2vpn fec129** command accepts SAs and TAs as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters (**instance**, **local-id**, **remote-id**, **remote-pe-address**).

Checking Connectivity Between T-PE1 and T-PE2

```
user@T-PE1> ping mpls l2vpn fec129 instance FEC129-VPWS local-id 800:800:800 remote-pe-address
10.255.14.1 remote-id 700:700:700
```

```
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2
```

```

!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

Checking Connectivity Between T-PE1 and S-PE2

user@T-PE1> **ping mpls l2vpn fec129 interface ge-3/1/2 bottom-label-ttl 2**

```

!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

Bidirectional Forwarding Detection

Problem

How to use BFD to troubleshoot the MS-PW connection from the T-PE device.

Solution

From operational mode, verify the **show bfd session extensive** command output.

user@T-PE1> **show bfd session extensive**

```

MPLS Stitching For Virtual Machine Connection

IN THIS SECTION

- [When Would I Use Stitching? | 1300](#)
- [How Does MPLS Stitching Work? | 1300](#)
- [How Do I Configure Stitching? | 1301](#)

- Which Switches Support Stitching? | 1301
- Q&A | 1302

By using MPLS, the stitching feature of Junos OS provides connectivity between virtual machines that reside either on opposite sides of data center routers or in different data centers. An external controller, programmed in the data-plane, assigns MPLS labels to both virtual machines and servers. Then, the signaled MPLS labels are used between the data center routers, generating static link switched paths (LSPs), resolved over either BGP labeled unicast, RSVP or LDP, to provide the routes dictated by the labels.

When Would I Use Stitching?

There are several ways to connect virtual machines. One option when you have virtual machines on opposite sides of a router (or different data centers) is to use MPLS stitching. A typical topology for using MPLS stitching is shown in [Figure 104 on page 1300](#).

Figure 104: Virtual Machines on Either Side of Routers

The above topology consists of the following MPLS layers: VMs | Servers | ToRs | Router Router | ToRs | Servers | VMs

NOTE: The label on the left is the top of the label stack.

How Does MPLS Stitching Work?

With stitching, the MPLS static allocation of labels demultiplexes incoming traffic onto any device/entity in the next layer in the direction of traffic flow. Essentially, there is a label hierarchy that picks up labels for the correct top-of-rack switch, server, and virtual machine that receives traffic. Static label assignments are done between the top-of-rack switches and the virtual machines.

For example, imagine that traffic is sent from VM1 to VM3 in [Figure 104 on page 1300](#). When traffic exits Server1, its label stack is L1 | L2 | L3 where:

- L1 represents the egress top-of-rack switch ToR1.
- L2 represents the physical server, Server2, towards which the egress-side ToR will forward the traffic.
- L3: represents the virtual machine on Server2 to which the Server2 should deliver the traffic.

Traffic arriving at ToR1 needs to be sent to ToR2. Since ToR1 and ToR2 are not directly connected, traffic must flow from ToR1 to ToR2 using label-switching starting on the outermost (top) label. Stitching has been added to static-LSP functionality to SWAP L1 to a I-BGP label that ToR2 advertises to ToR1. The label stack now must contain another label at the top to enable forwarding of the labeled packets between ToR1 and ToR2. An L-Top label is added if L-BGP is resolved over RSVP/LDP. If static LSP is resolved over L-BGP, then the top label is swapped with the L-BGP label and there is no L-Top label. When the traffic exits ToR1, the stack is: L-top | L-BGP | L2 | L3.

Traffic from ToR1 to ToR2 is then label switched over any signaled LSP.

When traffic arrives at ToR2, the top label is removed with PHP (popped) and the label stack becomes L-BGP | L2 | L3. Since L-BGP is a implicit null label, ToR2 pops the static LSP label L2 that corresponds to the egress server and then forwards the packet to the egress server using the static-LSP configuration on ToR2, which corresponds to a single-hop implicit-NULL LSP.

The outgoing stack becomes L3 and the next-hop is the egress server Server2.

When traffic arrives at the egress server Server2, Server2 pops L3 and delivers the packet to VM3.

How Do I Configure Stitching?

The new keyword **stitch** has been added under **transit** to resolve the remote next-hop. For example, instead of **set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 next-hop 10.9.82.47**, a top-of-rack switch redirects packets to another top-of-rack switch with **set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 stitch**. The [show mpls static-lsp](#) command has been extended to show the LSP state as 'InProgress' whenever the LSP is waiting for protocol next-hop resolution by resolver.

See the complete example for stitching at *Using MPLS Stitching with BGP to Connect Virtual Machines* for more information.

Which Switches Support Stitching?

See [Feature Explorer](#) for the list of switches that support the [MPLS Stitching For Virtual Machine Connections](#) feature.

Q&A

Q: Is link and node protection for the next-hop provided by MPLS stitching?

A: Link and node protection for the next-hop of transit LSP stitched to L-BGP LSP are not needed. That is provided by L-BGP LSP.

Using MPLS Stitching with BGP to Connect Virtual Machines

TDM Pseudowires Overview

A TDM pseudowire acts as Layer 2 circuit or service for T1 and E1 circuit signals across an MPLS packet-switched network. On ACX Series routers, you configure a TDM pseudowire with Structure-Agnostic Time Division Multiplexing (TDM) over Packet (SAToP) on the ACX Series built-in channelized T1 and E1 interfaces. When you configure a TDM pseudowire, the network between the customer edge (CE) routers appears transparent to the CE routers, making it seem that the CE routers are directly connected. With the SAToP configuration on the provider edge (PE) router's T1 and E1 interfaces, the interworking function (IWF) forms a payload (frame) that contains the CE router's T1 and E1 Layer 1 data and control word. This data is transported to the remote PE over the pseudowire. The remote PE removes all the Layer 2 and MPLS headers added in the network cloud and forwards the control word and the Layer 1 data to the remote IWF, which in turn forwards the data to the remote CE router.

IN THIS SECTION

- [Requirements | 1303](#)
- [Overview of a TDM Pseudowire Base Configuration | 1303](#)
- [Configuring an TDM Pseudowire | 1303](#)

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router
- Junos OS Release 12.2 or later

Overview of a TDM Pseudowire Base Configuration

The configuration shown here is the base configuration of an TDM pseudowire with T1 framing on an ACX Series router. This configuration is for one provider edge router. To complete the TDM pseudowire configuration, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an TDM Pseudowire

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set chassis fpc 0 pic 0 framing t1
set interfaces ct1-0/0/0 no-partition interface-type t1
set interfaces t1-0/0/0 encapsulation satop
set interfaces t1-0/0/0 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
```

```

set protocols mpls no-cspf
set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id
1

```

NOTE: To configure a TDM pseudowire with E1 framing, include the **e1** statement at the **[edit chassis fpc 0 pic 0 framing]** hierarchy level instead of the **t1** statement shown in this example.

Step-by-Step Procedure

1. Configure the framing format:

```

[edit]
user@host# edit chassis
[edit chassis]
user@host# set fpc 0 pic 0 framing t1

```

2. Create a T1 interface on a channelized T1 interface (**ct1**) and enable full channelization with the **no-partition** statement. On the logical T1 interface, set the Structure-Agnostic TDM over Packet (SAToP) encapsulation mode.

```

[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ct1-0/0/0 no-partition interface-type t1
user@host# set t1-0/0/0 encapsulation satop
user@host# set t1-0/0/0 unit 0

```

3. Create a Gigabit Ethernet interface and enable MPLS on that interface. Create the loopback (**lo0**) interface:

```
[edit interfaces]
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

4. Enable the MPLS and RSVP protocols on the MPLS interface—**ge-0/2/0.0**:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

5. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set ldp interface ge-0/2/0.0
user@host# set ldp interface lo0.0
```

6. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

7. Configure OSPF and enable traffic engineering on the MPLS interface—**ge-0/2/0.0**, and on the loopback (**lo0**) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Uniquely identify a Layer 2 circuit for the TDM pseudowire:

```
[edit protocols]
user@host# set l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
chassis {
    fpc 0 {
        pic 0 {
            framing t1;
        }
    }
}
interfaces {
    ct1-0/0/0 {
        no-partition interface-type t1;
    }
    t1-0/0/0 {
        encapsulation satop;
        unit 0;
    }
    ge-0/2/0 {
        unit 0 {
            family inet {
                address 20.1.1.2/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 70.1.1.1/32;
            }
        }
    }
}
protocols {
    rsvp {
        interface ge-0/2/0.0;
```

```

}

[TDM Pseudowires Overview](#) | 1302

Configuring Load Balancing for Ethernet Pseudowires

You can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

NOTE: This feature is supported only on M120, M320, MX Series, and T Series routers.

To configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires, include the **ether-pseudowire** statement at the **[edit forwarding-options hash-key family mpls payload]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ether-pseudowire;
    }
  }
}
```

NOTE: You must also configure either the **label-1** or the **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

You can also configure load balancing for Ethernet pseudowires based on IP information. This functionality provides support for load balancing for Ethernet cross-circuit connect (CCC) connections. To include IP information in the hash key, include the **ip** statement at the **[edit forwarding-options hash-key family mpls payload]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ip;
    }
  }
}
```

NOTE: You must also configure either the **label-1** or **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

You can configure load balancing for IPv4 traffic over Ethernet pseudowires to include only Layer 3 IP information in the hash key. To include only Layer 3 IP information, include the **layer-3-only** option at the **[edit forwarding-options family mpls hash-key payload ip]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ip {
        layer-3-only;
      }
    }
  }
}
```

NOTE: You must also configure either the **label-1** or **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

Configuring Load Balancing Based on MAC Addresses

The hash key mechanism for load-balancing uses Layer 2 media access control (MAC) information such as frame source and destination address. To load-balance traffic based on Layer 2 MAC information, include the **family multiservice** statement at the **[edit forwarding-options hash-key]** hierarchy level:

```
family multiservice {
  destination-mac;
  source-mac;
}
```

To include the destination-address MAC information in the hash key, include the **destination-mac** option. To include the source-address MAC information in the hash key, include the **source-mac** option.

NOTE: Any packets that have the same source and destination address will be sent over the same path.

NOTE: You can configure per-packet load balancing to optimize VPLS traffic flows across multiple paths.

NOTE: Aggregated Ethernet member links will now use the physical MAC address as the source MAC address in 802.3ah OAM packets.

NOTE: ACX Series routers do not support VPLS.

Configuring Class of Service for MPLS LSPs

IN THIS SECTION

- [Class of Service for MPLS Overview | 1312](#)
- [Configuring the MPLS CoS Values | 1312](#)
- [Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value | 1314](#)

The following sections provide an overview of MPLS class of service (CoS) and describe how to configure the MPLS CoS value:

Class of Service for MPLS Overview

When IP traffic enters an LSP tunnel, the ingress router marks all packets with a CoS value, which is used to place the traffic into a transmission priority queue. On the router, for SDH/SONET and T3 interfaces, each interface has four transmit queues. The CoS value is encoded as part of the MPLS header and remains in the packets until the MPLS header is removed when the packets exit from the egress router. The routers within the LSP utilize the CoS value set at the ingress router. The CoS value is encoded by means of the CoS bits (also known as the EXP or experimental bits). For more information, see [“MPLS Label Allocation” on page 420](#).

MPLS class of service works in conjunction with the router’s general CoS functionality. If you do not configure any CoS features, the default general CoS settings are used. For MPLS class of service, you might want to prioritize how the transmit queues are serviced by configuring weighted round-robin, and to configure congestion avoidance using random early detection (RED)..

Configuring the MPLS CoS Values

When traffic enters an LSP tunnel, the CoS value in the MPLS header is set in one of three ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet’s CoS value. This behavior is the default, and no configuration is required. *Default MPLS EXP Classifier* explains the default MPLS CoS values, and summarizes how the CoS values are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.
- You set an MPLS EXP rewrite rule to override the default behavior.

To set a fixed CoS value on all packets entering the LSP, include the **class-of-service** statement:

```
class-of-service cos-value;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit protocols mpls label-switched-path *path-name*]
- [edit protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit protocols rsvp interface *interface-name* link-protection]
- [edit protocols rsvp interface *interface-name* link-protection bypass *destination*]
- [edit logical-systems *logical-system-name* protocols mpls]

- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *destination*]

The CoS value set using the **class-of-service** statement at the [edit protocols mpls] hierarchy level supersedes the CoS value set at the [edit class-of-service] hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

The **class-of-service** statement at the [edit protocols mpls label-switched-path] hierarchy level assigns an initial EXP value for the MPLS shim header of packets in the LSP. This value is initialized at the ingress routing device only and overrides the rewrite configuration established for that forwarding class. However, the CoS processing (weighted round robin [WRR] and RED) of packets entering the ingress routing device is not changed by the **class-of-service** statement on an MPLS LSP. Classification is still based on the behavior aggregate (BA) classifier at the [edit class-of-service] hierarchy level or the multifield classifier at the [edit firewall] hierarchy level.

BEST PRACTICE: We recommend configuring all routing devices along the LSP to have the same input classifier for EXP, and, if a rewrite rule is configured, all routing devices should have the same rewrite configuration. Otherwise, traffic at the next LSR might be classified into a different forwarding class, resulting in a different EXP value being written to the EXP header.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that RED will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see *Managing Congestion Using RED Drop Profiles and Packet Loss Priorities*.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 28 on page 1314 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in *Understanding How Forwarding Classes Assign Classes to Output Queues*.

Table 28: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only as they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

To configure class of service (CoS) for Multiprotocol Label Switching (MPLS) packets in a label-switched path (LSP):

1. Specify the CoS value

If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value

For Ethernet interfaces installed on a T Series router or an M320 router with a peer connection to an M Series router or a T Series router, you can rewrite both MPLS CoS and IEEE 802.1p values to a configured value (the MPLS CoS values are also known as the EXP or experimental bits). Rewriting these values allows you to pass the configured value to the Layer 2 VLAN path. To rewrite both the MPLS CoS and IEEE 802.1p values, you must include the EXP and IEEE 802.1p rewrite rules in the class of service interface configuration. The EXP rewrite table is applied when you configure the IEEE 802.1p and EXP rewrite rules.

For information about how to configure the EXP and IEEE 802.1p rewrite rules, see *Rewriting Packet Headers to Ensure Forwarding Behavior*.

Configuring MPLS Rewrite Rules

IN THIS SECTION

- [Rewriting the EXP Bits of All Three Labels of an Outgoing Packet | 1315](#)
- [Rewriting MPLS and IPv4 Packet Headers | 1316](#)

You can apply a number of different rewrite rules to MPLS packets.

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

The following sections describe how you can apply rewrite rules to MPLS packets:

Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

In interprovider, carrier-of-carrier, and complex traffic engineering scenarios, it is sometimes necessary to push three labels on the next hop.

By default, on M Series routers except the M320, the top MPLS EXP label of an outgoing packet is not rewritten when you configure swap-push-push and triple-push operations. You can rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining the class of service (CoS) of an incoming MPLS or non-MPLS packet.

To push three labels on incoming MPLS packets, include the **exp-swap-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-swap-push-push default;
```

To push three labels on incoming non-MPLS packets, include the **exp-push-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-push-push-push default;
```

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Rewriting MPLS and IPv4 Packet Headers

You can apply a rewrite rule to MPLS and IPv4 packet headers simultaneously. This allows you to initialize MPLS EXP and IP precedence bits at LSP ingress. You can configure different rewrite rules depending on whether the traffic is VPN or non-VPN.

To rewrite MPLS and IPv4 packet headers, include the **protocol** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules exp *rewrite-rule-name*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp rewrite-rule-name]
protocol types;
```

Use the **protocol** statement to specify the types of MPLS packets and packet headers to which to apply the rewrite rule. The MPLS packet can be a standard MPLS packet or an MPLS packet with an IPv4 payload. Specify the type of MPLS packet by using the following options:

- **mpls-any**—Applies the rewrite rule to MPLS packets and writes the code point value to MPLS headers.
- **mpls-inet-both**—Applies the rewrite rule to VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series (except T4000 routers) and M320 routers. On M Series routers, except the M320, the **mpls-inet-both** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.
- **mpls-inet-both-non-vpn**—Applies the rewrite rule to any non-VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series and M320 routers. On M Series routers, except the M320, the **mpls-inet-both-non-vpn** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.

For a detailed example on how to configure rewrite rules for MPLS and IPv4 packets and for more information about how to configure class of service, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Configuring CoS Bits for an MPLS Network (CLI Procedure)

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The [Junos OS Class of Service Configuration Guide](#) explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: The CoS value set using the **class-of-service** statement at the **[edit protocols mpls]** hierarchy level supersedes the CoS value set at the **[edit class-of-service]** hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

[Configuring CoS on Provider Switches of an MPLS Network \(CLI Procedure\) | 1323](#)

Defining CoS Rewrite Rules (CLI Procedure)

Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS (CLI Procedure)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using IP Over MPLS.

This task describes how to create a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE switch. It includes configuring a policer firewall filter and applying it to the customer-edge interface of the ingress PE switch. The policer firewall filter ensures that the amount of traffic forwarded through the MPLS tunnel never exceeds the requested bandwidth allocation.

Before you begin, configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\)” on page 95.](#)
- Configure one or more provider switches. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 99.](#)

This topic includes:

1. [Configuring CoS | 1318](#)
2. [Configuring an LSP Policer | 1319](#)

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add a forwarding class to this custom DSCP classifier and specify a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-priority
loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
```

```
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-priority
code-points code-point
```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the customer-edge-interface:

```
[edit firewall]
user@switch# set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
user@switch# set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
user@switch# set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family inet filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the customer-edge interface:

```
[edit interfaces]
user@switch# set ge-2/0/3 unit 0 family inet address 192.168.121.1/16 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

RELATED DOCUMENTATION

[Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\) | 95](#)

Assigning CoS Components to Interfaces (CLI Procedure)

Configuring Policers to Control Traffic Rates (CLI Procedure)

Understanding the Use of Policers in Firewall Filters

Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect (CLI Procedure)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using MPLS over circuit-cross connect (CCC).

NOTE: On EX Series switches other than EX8200 switches, if you are using MPLS over CCC, you can use only one DSCP or IP precedence classifier and only one IEEE 802.1p classifier on the CCC interfaces.

This procedure is for creating a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE. It also includes enabling a policer on the label-switched path (LSP) of the ingress PE to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This topic includes:

1. [Configuring CoS | 1321](#)
2. [Configuring an LSP Policer | 1322](#)

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-priority loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-priority code-point code-point
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit ]
user@switch# set class-of-service interfaces interface unit unit classifier classifier-name
```

5. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the policer, which will later be applied to the LSP:

```
[edit firewall]  
set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]  
set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]  
set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]  
user@switch# set family any filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the LSP:

```
[edit protocols mpls]  
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

[Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\) | 95](#)

Configuring CoS on Provider Switches of an MPLS Network (CLI Procedure)

You can add class-of-service (CoS) components to your MPLS networks on EX Series switches to achieve end-to-end Differentiated Services to match your specific business requirements. The configuration of CoS components on the provider switches is the same regardless of whether the provider edge (PE) switches are using MPLS over CCC or IP over MPLS.

This task shows how to configure a custom EXP classifier and custom EXP rewrite rule on the provider switch.

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces ge-0/0/2 unit 0 rewrite-rules exp e1
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

- [Policer | 1328](#)
- [Schedulers | 1329](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. See *EX Series Switch Software Features Overview* for a complete list of the Junos OS MPLS features that are supported on specific EX Series switches.

Juniper Networks EX Series Ethernet Switches support Differentiated Service Code Point (DSCP) or IP precedence and IEEE 802.1p CoS classifiers on the customer-edge interfaces of the ingress provider edge (PE) switch. DSCP or IP precedence classifiers are used for Layer 3 packets. IEEE 802.1p is used for Layer 2 packets.

When a packet enters a customer-edge interface of the ingress PE switch, the switch associates the packet with a particular CoS servicing level before putting the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch. The CoS value that was embedded in the classifier is translated and encoded in the MPLS header by means of the EXP or experimental bits. EX Series switches enable a default EXP classifier and a default EXP rewrite rule. For more information about EXP classifiers and EXP rewrite rules, see *EXP Classifiers and EXP rewrite Rules*.

This topic includes:

EXP Classifiers and EXP rewrite Rules

EX Series switches enable a default EXP classifier and a default EXP rewrite rule. You can configure a custom EXP classifier and a custom EXP rewrite rule if you prefer. However, the switch supports only one type of EXP classifier (default or custom) and only one EXP rewrite rule (default or custom).

You do not bind the EXP classifier or the EXP rewrite rule to individual interfaces. The switch automatically and implicitly applies the default or the custom EXP classifier and the default or the custom EXP rewrite rule to the appropriate MPLS-enabled interfaces. Because rewrite rules affect only egress interfaces, the switch applies the EXP rewrite rule only to those MPLS interfaces that are transmitting MPLS packets (not to the MPLS interfaces that are receiving the packets).

After traversing the MPLS tunnel, the traffic flows out from the egress provider edge (PE) switch. Before the traffic leaves the egress interface, the egress PE switch copies the EXP bits from the MPLS header to the most significant bits in the original IP packet--- that is, to the IP precedence bits. Note that this is the default behavior only on Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis) that are configured for MPLS.

Guidelines for Using CoS Classifiers on CCCs

When you are configuring CoS for MPLS over circuit cross-connect (CCC), there are some additional guidelines, as follows:

- You *must* explicitly bind a CoS classifier to the CCC interface on the ingress PE switch.
- You *must* use the same DSCP, IP precedence, or IEEE 802.1p classifier on CCC interfaces. However, if the CCC interfaces are on the same switch, you cannot configure both a DSCP and an IP precedence

classifier on these interfaces. Thus, if you configure one CCC interface to use a DSCP classifier DSCP1, you cannot configure another CCC interface to use another DSCP classifier DSCP2. All the CCC interfaces on the switch must use the same DSCP (or IP precedence) classifier and the same IEEE 802.1p classifier.

- You *cannot* configure one CCC interface to use a DSCP classifier and another CCC interface to use an IP precedence classifier, because these classifier types overlap.
- You *can* configure one CCC interface to use a DSCP classifier and another CCC interface to use IEEE 802.1p classifier.
- You *can* configure one CCC interface to use both a DSCP and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the DSCP classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.
- You *can* configure one CCC interface to use both an IP precedence and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the IP precedence classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.

NOTE: These guidelines are not applicable to Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis).

You can define multiple DSCP, IP precedence, and IEEE 802.1p classifiers for the non-CCC interfaces on a switch.

Using CoS Classifiers with IP over MPLS

When you are configuring CoS for IP over MPLS, the customer-edge interface uses the CoS configuration for the switch as the default. You do not have to bind a classifier to the customer-edge interface in this case. There are no restrictions on using multiple DSCP, IP precedence, and IEEE 802.1p classifiers on the same switch.

- You can modify the CoS classifier for a particular interface, but it is not required.
- You can configure a DSCP classifier, DSCP1 on the first interface, another DSCP classifier, DSCP2 on the second interface, and an IP precedence classifier on a third interface, and so forth.

Setting CoS Bits in an MPLS Header

When traffic enters an LSP tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service User Guide (Routers and EX9200 Switches)* explains the IP CoS values, and summarizes how the CoS bits are treated.

- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that random early detection (RED) will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 29 on page 1327 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in the *Class of Service User Guide (Routers and EX9200 Switches)*.

Table 29: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only while they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

NOTE: On EX8200 switches that run MPLS-based Layer 2 virtual private networks (VPNs):

- If you configure an LSP CoS, the EXP bits of the MPLS packet continue to use the same CoS values that are configured at the interface level.
- For Virtual Chassis, if the input and output interfaces are on different line cards, then the loss priority value that you configured on the first line card is not carried to the subsequent line cards. The loss priority for the outgoing traffic from the subsequent line cards is always set to low.

EXP Rewrite Rules

When traffic passes from the customer-edge interface to an MPLS interface, the DSCP, IP precedence, or IEEE 802.1p CoS classifier is translated into the EXP bits within the MPLS header. You cannot disable the default EXP rewrite rule, but you can configure your own custom EXP classifier and a custom EXP rewrite rule. You cannot bind the EXP classifier to individual MPLS interfaces; the switch applies it globally to all the MPLS-enabled interfaces on the switch.

Only one EXP rewrite rule (either default or custom) is supported on a switch. The switch applies it to all the egress interfaces on which MPLS is enabled.. This is, however, not the case with EX8200 switches. With EX8200 switches, you must explicitly apply the rewrite rule on each of the egress interfaces.

Policer

Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. During periods of congestion (when the total rate of queuing packets exceeds the rate of transmission), any new packets being sent to an interface can be dropped because there is no place to store them. You can configure a policer on the ingress PE switch to prevent this:

- If you are using MPLS over CCC, you bind the policer to the LSP. You cannot bind a policer to a CCC interface.
- If you are using IP over MPLS, you bind the policer to the **inet-family** customer-edge interface. You cannot bind a policer to the LSP when you are using IP over MPLS.

NOTE: You cannot configure LSP policers on EX8200 switches.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on EX Series switches. Default schedulers are provided for best-effort and network-control forwarding classes. If you are using assured-forwarding, expedited-forwarding, or any custom forwarding class, we recommend that you configure a scheduler to support that forwarding class. See *Understanding CoS Schedulers*.

Example: Combining CoS with MPLS on EX Series Switches

IN THIS SECTION

- [Requirements | 1330](#)
- [Overview and Topology | 1330](#)
- [Configuring the Local PE Switch | 1333](#)
- [Configuring the Remote PE Switch | 1336](#)
- [Configuring the Provider Switch | 1337](#)
- [Verification | 1338](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. The CoS value is included within the MPLS label, which is passed through the network, enabling end-to-end CoS across the network.

MPLS services are often used to ensure better performance for low-latency applications such as VoIP and other business-critical functions. These applications place specific demands on a network for successful

transmission. CoS gives you the ability to control the mix of bandwidth, delay, jitter, and packet loss while taking advantage of the MPLS labeling mechanism.

This example shows how to configure CoS on an MPLS network that is using a unidirectional circuit cross-connect (CCC) from the ingress provider edge (PE) switch to the egress PE switch. for the customer-edge interface of the ingress provider edge (PE) switch. It describes adding the configuration of CoS components to the ingress PE switch, the egress PE switch, and the core provider switches of the existing MPLS network. Because of the unidirectional configuration, the DSCP classifier needs to be configured only on the ingress PE switch.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for EX Series switches
- Three EX Series switches

Before you configure CoS with MPLS, be sure you have:

Configured an MPLS network with two PE switches and one provider switch. See [“Example: Configuring MPLS on EX8200 and EX4500 Switches” on page 59](#). This example assumes that an MPLS network has been configured using a cross circuit-connect (CCC).

Overview and Topology

This example describes adding custom classifiers and custom rewrite rules to switches in an MPLS network that is using MPLS over CCC.

It is a unidirectional configuration. Therefore, you need to configure custom classifiers and custom rewrite rules as follows:

- On the ingress PE switch: custom DSCP classifier and custom EXP rewrite rule
- On the egress PE switch: custom EXP classifier
- On the provider switch: customer EXP classifier and custom EXP rewrite rule

NOTE: You can also configure schedulers and shapers as needed. If you are using **assured-forwarding**, **expedited-forwarding**, or other custom forwarding classes, we recommend that you configure a scheduler to support that forwarding class. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

The example creates a custom DSCP classifier (**dscp1**) on the ingress PE switch and binds this classifier to the CCC interface. It includes configuration of a policer on the ingress PE switch. The policer is applied as

a filter on the label-switched path (LSP) **lsp_to_pe2_ge1**(created in [“Example: Configuring MPLS on EX8200 and EX4500 Switches” on page 59](#)) to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This example creates a custom EXP rewrite rule (**exp1**) on the ingress PE switch, specifying a loss-priority and code point to be used for the expedited-forwarding class as the packet travels through the LSP. The switch applies this custom rewrite rule on the core interfaces **ge-0/0/5.0** and **ge-0/0/6.0**, which are the egress interfaces for this switch.

[Table 30 on page 1331](#) shows the CoS configuration components added to the ingress PE switch.

Table 30: CoS Configuration Components on the Ingress PE Switch

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Policing filter configured and applied to the LSP.	policing filter mypolicer filter myfilter	Name of the rate-limiting policer. Name of the filter, which refers to the policer
Custom DSCP classifier	dscp1	Specifies the name of the custom DSCP classifier
Custom EXP rewrite rule	e1	Name of the custom EXP rewrite rule.
Customer-edge interface	ge-0/0/1.0	Interface that receives packets from devices outside the network. The custom DSCP classifier must be specified on this CCC interface.
Core interfaces	ge-0/0/5.0 and ge-0/0/6.0	Interfaces that transmit MPLS packets to other switches within the MPLS network. The EXP rewrite rule is applied implicitly to these interfaces.

[Table 31 on page 1332](#) shows the CoS configuration components added to the egress PE switch in this example.

Table 31: CoS Configuration Components of the Egress PE Switch

Property	Settings	Description
Remote provider edge switch hardware	EX Series switch	PE-2
Custom EXP classifier	exp1	Name of custom EXP classifier
Customer-edge interface	ge-0/0/1.0	Interface that transmits packets from this network to devices outside the network. No CoS classifier is specified for this interface. A scheduler can be specified.
Core interfaces	ge-0/0/7.0 and ge-0/0/8.0	Core interfaces on PE-2 that receive MPLS packets from the provider switch. The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.

[Table 32 on page 1332](#) shows the MPLS configuration components used for the provider switch in this example.

Table 32: CoS Configuration Components of the Provider Switch

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Custom EXP classifier	exp1	Name of the custom EXP classifier.
Custom EXP rewrite rule	e1	Name of the custom EXP rewrite rule.
Core interfaces receiving packets from other MPLS switches.	ge-0/0/5.0 and ge-0/0/6.0	Interfaces that connect the provider switch to the ingress PE switch (PE-1). The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.

Table 32: CoS Configuration Components of the Provider Switch (*continued*)

Property	Settings	Description
Core interfaces transmitting packets to other switches within the MPLS network.	ge-0/0/7.0 and ge-0/0/8.0	Interfaces that transmit packets to the egress PE (PE-2). The EXP rewrite rule is applied implicitly on these interfaces. Schedulers can also be specified and will be applied to these interfaces.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the local PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]
set class-of-service classifiers dscp dscp1 import default
set class-of-service classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority low
code-points 000111
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
set firewall policer mypolicer if-exceeding bandwidth-limit 500m
set firewall policer mypolicer if-exceeding burst-size-limit 33553920
set firewall policer mypolicer then discard
set firewall family any filter myfilter term t1 then policer mypolicer
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3 policing filter myfilter
```

Step-by-Step Procedure

To configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the ingress PE switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp dscp1 import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
```

```
user@switch# set classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority low
code-points 000111
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit ]
user@switch# set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
```

5. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

6. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

7. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

8. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family any filter myfilter term t1 then policer mypolicer
```

9. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

Results

Display the results of the configuration:

```

[edit]
user@switch# show
class-of-service {
  classifiers {
    dscp dscp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 000111;
      }
    }
  }
}
interfaces {
  ge-0/0/1 {
    unit 0 {
      classifiers {
        dscp dscp1;
      }
    }
  }
}
rewrite-rules {
  exp e1 {
    forwarding-class expedited-forwarding {
      loss-priority low code-point 111;
    }
  }
}
firewall {
  family any {
    filter myfilter {
      term t1 {
        then policer mypolicer;
      }
    }
  }
  policer mypolicer {
    if-exceeding {
      bandwidth-limit 500m;
      burst-size-limit 33553920;
    }
    then discard;
  }
}

```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure a custom EXP classifier on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Step-by-Step Procedure

To configure a custom EXP classifier on the egress PE switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 010;
      }
    }
  }
}
```

Configuring the Provider Switch

CLI Quick Configuration

To quickly configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch, copy the following commands and paste them into the switch terminal window of the provider switch:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Step-by-Step Procedure

To configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
```

```

import default;
forwarding-class expedited-forwarding {
    loss-priority low code-points 010;
}
}
rewrite-rules {
    exp e1 {
        forwarding-class expedited-forwarding {
            loss-priority low code-point 111;
        }
    }
}
}

```

Verification

IN THIS SECTION

- [Verifying That the Policer Firewall Filter Is Operational | 1338](#)
- [Verifying That the CoS Classifiers Are Going to the Right Queue | 1339](#)
- [Verifying the CoS Forwarding Table Mapping | 1343](#)
- [Verifying the Rewrite Rules | 1343](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying That the Policer Firewall Filter Is Operational

Purpose

Verify the operational state of the policer that is configured on the ingress PE switch.

Action

user@switch> **show firewall**

```

Filter: myfilter
Policers:
Name                               Packets
mypolicer-t1                       0

```

Meaning

This output shows that the firewall filter **mypolicer** has been created.

Verifying That the CoS Classifiers Are Going to the Right Queue**Purpose**

Verify that the CoS classifiers are going to the right queue.

Action

```
user@switch> show class-of-service forwarding-table classifier
```

```
Classifier table index: 7, # entries: 64, Table type: DSCP
```

Meaning

This output shows that a new DSCP classifier has been created, index **9346**, on the ingress PE switch (PE-1).

Verifying the CoS Forwarding Table Mapping

Purpose

For each logical interface, display either the table index of the classifier for a given code point type or the queue number (if it is a fixed classification) in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table classifier mapping
```

Interface	Index	Table Index/	
		Q num	Table type
ge-0/0/1.0	92	9346	DSCP

Meaning

The results show that the new DSCP classifier, index number **9346**, is bound to interface **ge-0/0/1.0**.

Verifying the Rewrite Rules

Purpose

Display mapping of the queue number and loss priority to code point value for each rewrite rule as it exists in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table rewrite-rule
```

```
Rewrite table index: 31, # entries: 4, Table type: DSCP
```

Understanding CoS MPLS EXP Classifiers and Rewrite Rules

IN THIS SECTION

- [EXP Classifiers | 1346](#)
- [EXP Rewrite Rules | 1348](#)
- [Schedulers | 1348](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion by applying packet classifiers and rewrite rules to the MPLS traffic. MPLS classifiers are global and apply to all interfaces configured as **family mpls** interfaces.

When a packet enters a customer-edge interface on the ingress provider edge (PE) switch, the switch associates the packet with a particular CoS servicing level before placing the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch to determine the CoS service level. The CoS value embedded in the classifier is translated and encoded in the MPLS header by means of the experimental (EXP) bits.

EXP classifiers map incoming MPLS packets to a forwarding class and a loss priority, and assign MPLS packets to output queues based on the forwarding class mapping. EXP classifiers are behavior aggregate (BA) classifiers.

EXP rewrite rules change (rewrite) the CoS value of the EXP bits in outgoing packets on the egress queues of the switch so that the new (rewritten) value matches the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

NOTE: On QFX5200, QFX5100, QFX3500, QFX3600, and EX4600 switches, and on QFabric systems, there is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global EXP classifier applies to all MPLS traffic on interfaces configured as **family mpls**.

On QFX10000 switches, there is a no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure EXP classifiers and apply them to logical interfaces configured as **family mpls**. (You cannot apply classifiers to physical interfaces.). You can configure up to 64 EXP classifiers.

There is no default EXP rewrite rule. If you want to rewrite the EXP bit value at the egress interface, you must configure EXP rewrite rules and apply them to logical interfaces.

EXP classifiers and rewrite rules are applied only to interfaces that are configured as **family mpls** (for example, **set interfaces xe-0/0/35 unit 0 family mpls.**)

This topic includes:

EXP Classifiers

On QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, unlike DSCP and IEEE 802.1p BA classifiers, EXP classifiers are global to the switch and apply to all switch interfaces that are configured as **family mpls**. On QFX10000 switches, you apply EXP classifiers to individual logical interfaces, and different interfaces can use different EXP classifiers.

When you configure and apply an EXP classifier, MPLS traffic on all **family mpls** interfaces uses the EXP classifier, even on interfaces that also have a fixed classifier. If an interface has both an EXP classifier and a fixed classifier, the EXP classifier is applied to MPLS traffic and the fixed classifier is applied to all other traffic.

Also unlike DSCP and IEEE 802.1p BA classifiers, there is no default EXP classifier. If you want to classify MPLS traffic based on the EXP bits, you must explicitly configure an EXP classifier and apply it to the switch interfaces. Each EXP classifier has eight entries that correspond to the eight EXP CoS values (0 through 7, which correspond to CoS bits 000 through 111).

You can configure up to 64 EXP classifiers.

However, on QFX5200, QFX5100, EX4600, and legacy CLI switches, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure that classifier as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy level. All switch interfaces configured as **family mpls** use the global EXP classifier to classify MPLS traffic.

On these switches, only one EXP classifier can be configured as the global EXP classifier at any time. If you want to change the global EXP classifier, delete the global EXP classifier configuration (use the **user@switch# delete class-of-service system-defaults classifiers exp** configuration statement), then configure the new global EXP classifier.

QFX10000 switches do not support global EXP classifiers. You can configure one EXP classifier and apply it to multiple logical interfaces, or configure multiple EXP classifiers and apply different EXP classifiers to different logical interfaces.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. (Switches that have a default EXP classifier use the default classifier.) If no EXP classifier and no fixed classifier are applied to the interface, MPLS traffic is treated as best-effort traffic using the 802.1 default untrusted classifier. DSCP classifiers are not applied to MPLS traffic.

On QFX5200, QFX5100, EX4600, and legacy CLI switches, because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier.

NOTE: The switch uses only the outermost label of incoming EXP packets for classification.

NOTE: MPLS packets with 802.1Q tags are not supported.

EXP Rewrite Rules

As MPLS packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. EXP rewrite rules set the value of the EXP CoS bits within the header of the outgoing MPLS packet on **family mpls** interfaces. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table, and writes that CoS value into the packet header, replacing the old CoS value. EXP rewrite rules apply only to MPLS traffic.

EXP rewrite rules apply only to logical interfaces. You cannot apply EXP rewrite rules to physical interfaces.

There are no default EXP rewrite rules. If you want to rewrite the EXP value in MPLS packets, you must configure EXP rewrite rules and apply them to logical interfaces. If no rewrite rules are applied, all MPLS labels that are pushed have a value of zero (0). The EXP value remains unchanged on MPLS labels that are swapped.

You can configure up to 64 EXP rewrite rules, but you can only apply 16 EXP rewrite rules at any time on the switch. On a given logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

You can apply an EXP rewrite rule to an interface that has a DSCP, DSCP IPv6, or IEEE 802.1p rewrite rule. Only MPLS traffic uses the EXP rewrite rule. MPLS traffic does not use DSCP or DSCP IPv6 rewrite rules.

If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on the switch. Default schedulers are provided only for the best-effort, fcoe, no-loss, and network-control default forwarding classes. If you configure a custom forwarding class for MPLS traffic, you need to configure a scheduler to support that forwarding class and provide bandwidth to that forwarding class.

RELATED DOCUMENTATION

| *Understanding Applying CoS Classifiers and Rewrite Rules to Interfaces*

Configuring Rewrite Rules for MPLS EXP Classifiers

You configure EXP rewrite rules to alter CoS values in outgoing MPLS packets on the outbound **family mpls** interfaces of a switch to match the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

To configure an EXP CoS rewrite rule, create the rule by giving it a name and associating it with a forwarding class, loss priority, and code point. This creates a rewrite table. After the rewrite rule is created, enable it on a logical **family mpls** interface. EXP rewrite rules can only be enabled on logical **family mpls** interfaces, not on physical interfaces or on interfaces of other family types. You can also apply an existing EXP rewrite rule on a logical interface.

NOTE: There are no default rewrite rules.

You can configure up to 64 EXP rewrite rules, but you can only use 16 EXP rewrite rules at any time on the switch. On a given **family mpls** logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

NOTE: To replace an existing rewrite rule on the interface with a new rewrite rule of the same type, first explicitly remove the existing rewrite rule and then apply the new rule.

To create an EXP rewrite rule for MPLS traffic and enable it on a logical interface:

1. Create an EXP rewrite rule:

```
user@switch# set class-of-service rewrite-rules exp rewrite-rule-name forwarding-class
forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

For example, to configure an EXP rewrite rule named **exp-rr-1** for a forwarding class named **mpls-1** with a loss priority of **low** that rewrites the EXP code point value to **001**:

```
user@switch# set class-of-service rewrite-rules exp exp-rr-1 forwarding-class mpls-1 loss-priority
low code-points 001
```

2. Apply the rewrite rule to a logical interface:

```
user@switch # set class-of-service interfaces interface-name unit logical-unit rewrite-rules exp
rewrite-rule-name
```

For example, to apply a rewrite rule named **exp-rr-1** to logical interface **xe-0/0/10.0**:

```
user@switch# set class-of-service interfaces xe-0/0/10 unit 0 rewrite-rules exp exp-rr-1
```

NOTE: In this example, all forwarding classes assigned to port xe-0/0/10 must have rewrite rules. Do not mix forwarding classes that have rewrite rules with forwarding classes that do not have rewrite rules on the same interface.

[Defining CoS Rewrite Rules](#)

Configuring CoS Bits for an MPLS Network

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service User Guide (Routers and EX9200 Switches)* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: The CoS value set using the **class-of-service** statement at the **[edit protocols mpls]** hierarchy level supersedes the CoS value set at the **[edit class-of-service]** hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

[Configuring Rewrite Rules for MPLS EXP Classifiers | 1349](#)

Defining CoS Rewrite Rules

Configuring a Global MPLS EXP Classifier

EXP packet classification associates incoming packets with a particular MPLS CoS servicing level. EXP behavior aggregate (BA) classifiers examine the MPLS EXP value in the packet header to determine the CoS settings applied to the packet. EXP BA classifiers allow you to set the forwarding class and loss priority of an MPLS packet based on the incoming CoS value.

You can configure up to 64 EXP classifiers, however, the switch uses only one MPLS EXP classifier as a global classifier, which is applied only on interfaces configured as **family mpls**. All **family mpls** switch interfaces use the global EXP classifier to classify MPLS traffic.

There is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global classifier applies to all MPLS traffic on all **family mpls** interfaces.

If a global EXP classifier is configured, MPLS traffic on **family mpls** interfaces uses the EXP classifier. If a global EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

To configure an MPLS EXP classifier using the CLI:

1. Create an EXP classifier and associate it with a forwarding class, a loss priority, and a code point:

```
[edit class-of-service classifiers]
user@switch# set (dscp | ieee-802.1 | exp) classifier-name forwarding-class forwarding-class-name
loss-priority level code-points [aliases] [bit-patterns]
```

2. Apply the EXP classifier to the switch interfaces:

```
[edit class-of-service]
user@switch# set system-defaults classifiers exp classifier-name
```

Introduction to GMPLS

Traditional MPLS is designed to carry Layer 3 IP traffic using established IP-based paths and associating these paths with arbitrarily assigned labels. These labels can be configured explicitly by a network administrator, or can be dynamically assigned by means of a protocol such as LDP or RSVP.

GMPLS generalizes MPLS in that it defines labels for switching varying types of Layer 1, Layer 2, or Layer 3 traffic. GMPLS nodes can have links with one or more of the following switching capabilities:

- Fiber-switched capable (FSC)
- Lambda-switched capable (LSC)
- Time-division multiplexing (TDM) switched-capable (TSC)
- Packet-switched capable (PSC)

Label-switched paths (LSPs) must start and end on links with the same switching capability. For example, routers can establish packet-switched LSPs with other routers. The LSPs might be carried over a TDM-switched LSP between SONET add/drop multiplexers (ADMs), which in turn might be carried over a lambda-switched LSP.

The result of this extension of the MPLS protocol is an expansion in the number of devices that can participate in label switching. Lower-layer devices, such as OXCs and SONET ADMs, can now participate in GMPLS signaling and set up paths to transfer data. A router can participate in signaling optical paths across a transport network.

Two service models determine the visibility that a client node (a router, for example) has into the optical core or transport network. The first is through a user-to-network interface (UNI), which is often referred to as the overlay model. The second is known as the peer model. Juniper Networks supports both models.

NOTE: There is not necessarily a one-to-one correspondence between a physical interface and a GMPLS interface. If a GMPLS connection uses a nonchannelized physical connector, the GMPLS label can use the physical port ID. However, the label for channelized interfaces often is based on a channel or time slot. Consequently, it is best to refer to GMPLS labels as identifiers for a resource on a traffic engineering link.

To establish LSPs, GMPLS uses the following mechanisms:

- An out-of-band control channel and a data channel—RSVP messages for LSP setup are sent over an out-of-band control network. Once the LSP setup is complete and the path is provisioned, the data channel is up and can be used to carry traffic. The Link Management Protocol (LMP) is used to define and manage the data channels between a pair of nodes. You can optionally use LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- RSVP-TE extensions for GMPLS—RSVP-TE is already designed to signal the setup of packet LSPs. This has been extended for GMPLS to be able to request path setup for various kinds of LSPs (nonpacket) and request labels like wavelengths, time slots, and fibers as label objects.
- Bidirectional LSPs—Data can travel both ways between GMPLS devices over a single path, so nonpacket LSPs are signaled to be bidirectional.

GMPLS Terms and Acronyms

F

Forwarding adjacency A forwarding path for sending data between GMPLS-enabled devices.

G

Generalized MPLS (GMPLS) An extension to MPLS that allows data from multiple layers to be switched over label-switched paths (LSPs). GMPLS LSP connections are possible between similar Layer 1, Layer 2, and Layer 3 devices.

GMPLS label Layer 3 identifiers, fiber port, time-division multiplexing (TDM) time slot, or dense wavelength-division multiplexing (DWDM) wavelength of a GMPLS-enabled device used as a next-hop identifier.

GMPLS LSP types The four types of GMPLS LSPs are:

- Fiber-switched capable (FSC)—LSPs are switched between two fiber-based devices, such optical cross-connects (OXC) that operate at the level of individual fibers.
- Lambda-switched capable (LSC)—LSPs are switched between two DWDM devices, such as such as OXC that operate at the level of individual wavelengths.
- TDM-switched capable (TDM)—LSPs are switched between two TDM devices, such as SONET ADMs.
- Packet-switched capable (PSC)—LSPs are switched between two packet-based devices, such as routers or ATM switches.

L

Link Management Protocol A protocol used to define a forwarding adjacency between peers and to maintain and allocate resources on the traffic engineering links.

T

Traffic engineering link A logical connection between GMPLS-enabled devices. Traffic engineering links can have addresses or IDs and are associated with certain resources or interfaces. They also have certain attributes (encoding-type, switching capability, bandwidth, and so on). The logical addresses can be routable, although this is not required because they are acting as link identifiers. Each traffic engineering link represents a forwarding adjacency between a pair of devices.

Supported GMPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for Generalized MPLS (GMPLS).

- RFC 3471, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Functional Description*

Only the following features are supported:

- Bidirectional LSPs (upstream label only)
- Control channel separation
- Generalized label (suggested label only)
- Generalized label request (bandwidth encoding only)

- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions*

Only Section 9, "Fault Handling," is supported.

- RFC 4202, *Routing Extensions in Support of Generalized Multi-Protocol Label Switching*

Only interface switching is supported.

- RFC 4206, *Label Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*

- Internet draft draft-ietf-ccamp-gmpls-rsvp-te-ason-02.txt, *Generalized MPLS (GMPLS) RSVP-TE Signalling in support of Automatically Switched Optical Network (ASON)* (expires January 2005)

- Internet draft draft-ietf-ccamp-gmpls-sonet-sdh-08.txt, *Generalized Multi-Protocol Label Switching Extensions for SONET and SDH Control*

Only S,U,K,L,M-format labels and SONET traffic parameters are supported.

- Internet draft draft-ietf-ccamp-lmp-10.txt, *Link Management Protocol (LMP)*

- Internet draft draft-ietf-ccamp-ospf-gmpls-extensions-12.txt, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching*

The following sub-TLV types for the Link type, link, value (TLV) are not supported:

- Link Local/Remote Identifiers (type 11)
- Link Protection Type (type 14)
- Shared Risk Link Group (SRLG) (type 16)

The features described in Section 2 of the draft, “Implications on Graceful Restart,” are also not supported.

The Interface Switching Capability Descriptor (type 15) sub-TLV type is implemented, but only for packet switching.

- Internet draft draft-ietf-mpls-bundle-04.txt, *Link Bundling in MPLS Traffic Engineering*

[Accessing Standards Documents on the Internet](#)

GMPLS Operation

The basic functionality of GMPLS requires close interaction between RSVP and LMP. It works in the following sequence:

1. LMP notifies RSVP of the new entities:
 - Traffic engineering link (forwarding adjacency)
 - Resources available for the traffic engineering link
 - Control peer
2. GMPLS extracts the LSP attributes from the configuration and requests RSVP to signal one or more specific paths, which are specified by the traffic engineering link addresses.
3. RSVP determines the local traffic engineering link, corresponding control adjacency and active control channel, and transmission parameters (such as IP destination). It requests that LMP allocate a resource from the traffic engineering link with the specified attributes. If LMP finds a resource matching the

attributes, label allocation succeeds. RSVP sends a PathMsg hop by hop until it reaches the target router.

4. When the target router receives the PathMsg, RSVP again requests that LMP allocate a resource based on the signaled parameters. If label allocation succeeds, the router sends back a ResvMsg.
5. If the signaling is successful, a bidirectional optical path is provisioned.

GMPLS and OSPF

You can configure OSPF for GMPLS. OSPF is an interior gateway protocol (IGP) that routes packets within a single autonomous system (AS). OSPF uses link-state information to make routing decisions.

GMPLS and CSPF

GMPLS introduces extra constraints for computing paths for GMPLS LSPs that use CSPF. These additional constraints affect the following link attributes:

- Signal type (minimum LSP bandwidth)
- Encoding type
- Switching type

These new constraints are populated in the traffic engineering database with the exchange of an interface-switching capability descriptor type, length, value (TLV) through an IGP.

The ignored constraints that are exchanged through the interface switching capability descriptor include:

- Maximum LSP bandwidth
- Maximum transmission unit (MTU)

The CSPF path computation is the same as in non-GMPLS environments, except that the links are also limited by GMPLS constraints.

Each link can have multiple interface-switching capability descriptors. All the descriptors are checked before a link is rejected.

The constraints are checked in the following order:

1. The signal type configured for the GMPLS LSP signifies the amount of bandwidth requested. If the desired bandwidth is less than the minimum LSP bandwidth, the interface-switching descriptor is rejected.

2. The encoding type of the link for the ingress and the egress interfaces should match. The encoding type is selected and stored at the ingress node after all the constraints are satisfied by the link and is used to select the link on the egress node.
3. The switching type of the links of the intermediate switches should match that of the GMPLS LSP specified in the configuration.

GMPLS Features

The Junos OS includes the following GMPLS functionality:

- An out-of-band control plane makes it possible to signal LSP path setup.
- RSVP-TE extensions support additional objects beyond Layer 3 packets, such as ports, time slots, and wavelengths.
- The LMP protocol creates and maintains a database of traffic engineering links and peer information. Only the static version of this protocol is supported in the Junos OS. You can optionally configure LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- Bidirectional LSPs are required between devices.
- Several GMPLS label types that are defined in RFC 3471, *Generalized MPLS—Signaling Functional Description*, such as MPLS, Generalized, SONET/SDH, Suggested, and Upstream, are supported. Generalized labels do not contain a type field, because the nodes should know from the context of their connection what type of label to expect.
- Traffic parameters facilitate GMPLS bandwidth encoding and SONET/SDH formatting.
- Other supported attributes include interface identification and errored interface identification, user-to-network (UNI)-style signaling, and secondary LSP paths.

LMP Configuration Overview

You need to configure the Link Management Protocol (LMP) to define the data channel connection and the control channel connection between devices. Include the following statements at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
peer peer-name {
  address address;
  control-channel control-channel-name;
```

```

lmp-control-channel control-channel-interface {
    remote-address ip-address;
}
lmp-protocol {
    hello-dead-interval milliseconds;
    hello-interval milliseconds;
    retransmission-interval milliseconds;
    retry-limit number;
    passive;
}
te-link te-link-name;
}
te-link te-link-name {
    disable;
    interface interface-name {
        disable;
        local-address ip-address;
        remote-address ip-address;
        remote-id id-number;
    }
    label-switched-path lsp-name;
    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
}
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}

```

NOTE: Although you can include GMPLS configuration statements at the **[edit logical-systems logical-system-name]** hierarchy level, GMPLS is not supported on logical systems.

For information about configuring LMP, see the following sections:

- [Configuring LMP Traffic Engineering Links on page 1361](#)
- [Configuring LMP Peers on page 1363](#)
- [Configuring RSVP and OSPF for LMP Peer Interfaces on page 1369](#)
- [Configuring MPLS Paths for GMPLS on page 1371](#)
- [Tracing LMP Traffic on page 1371](#)

Configuring LMP Traffic Engineering Links

IN THIS SECTION

- [Configuring the Local IP Address for Traffic Engineering Links | 1361](#)
- [Configuring the Remote IP Address for Traffic Engineering Links | 1362](#)
- [Configuring the Remote ID for Traffic Engineering Links | 1362](#)

An LMP traffic engineering link acts as a data channel connection between GMPLS devices.

To configure a traffic engineering link, include the **te-link** statement at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
te-link te-link-name {
  disable;
  interface interface-name {
    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
  }
  label-switched-path lsp-name;
  local-address ip-address;
  remote-address ip-address;
  remote-id id-number;
}
```

Complete the procedures in the following sections to configure an LMP traffic engineering link:

When you configure a traffic engineering link that contains interfaces for an LMP peer, you must also configure a control channel. However, no control channel is required for a traffic engineering link that contains an LSP. For information about configuring control channels, see [“Configuring LMP Peers” on page 1363](#).

Configuring the Local IP Address for Traffic Engineering Links

Use the **local-address** statement to configure the local IP address associated with the traffic engineering link.

We recommend that you configure an IP address subnet for your traffic engineering link addresses that is different from the subnet configured for your physical interfaces. This configuration enables you to identify which addresses are physical and which addresses belong to the traffic engineering link.

To configure the local IP address for the traffic engineering link, include the **local-address** statement:

```
te-link te-link-name {
  interface interface-name {
    local-address ip-address;
  }
  local-address ip-address;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the Remote IP Address for Traffic Engineering Links

You need to specify the address of the remote end of the data channel for each traffic engineering link. Use the **remote-address** statement to configure the remote IP address.

We recommend that you configure an IP address subnet for your traffic engineering link addresses that is different from the subnet configured for your physical interfaces. This enables you to identify which addresses are physical and which addresses belong to the traffic engineering link.

To configure the remote IP address for the traffic engineering link, include the **remote-address** statement:

```
te-link te-link-name {
  interface interface-name {
    remote-address ip-address;
  }
  remote-address ip-address;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring the Remote ID for Traffic Engineering Links

The local ID for the traffic engineering link is automatically assigned by LMP. The port identifier and labels for the interfaces (resources) in the traffic engineering link are also assigned automatically. However, you need to explicitly configure the remote ID for the traffic engineering link and the remote ID traffic engineering link interface. The remote ID for the interface must be based on the post-ID assignment of the peer node. The remote IDs are needed for static mapping of remote labels to local labels.

Before you can obtain the remote IDs for the traffic engineering link and traffic engineering link interface on the peer node, you must first configure the LMP peer, as described in [“Configuring LMP Peers” on page 1363](#). Once you have configured the LMP peer, you can obtain the traffic engineering link local ID and interface local ID by issuing the **show link-management te-link** command. Once you have these IDs, you can configure them as the remote IDs on the peer node.

To configure the remote ID for a traffic engineering link and for the traffic engineering link interface, include the **remote-id** statement:

```
te-link te-link-name {
  interface interface-name {
    remote-id id-number;
  }
  remote-id id-number;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring LMP Peers

IN THIS SECTION

- [Configuring the ID for LMP Peers | 1364](#)
- [Configuring the Interface for Control Channels Between LMP Peers | 1364](#)
- [Configuring the LMP Control Channel Interface for the Peer | 1365](#)
- [Configuring the Remote IP Address for LMP Control Channels | 1366](#)
- [Configuring Hello Message Intervals for LMP Control Channels | 1366](#)
- [Controlling Message Exchange for LMP Control Channels | 1367](#)
- [Preventing the Local Peer from Initiating LMP Negotiation | 1367](#)
- [Associating Traffic Engineering Links with LMP Peers | 1368](#)
- [Disabling the Traffic Engineering Link for LMP Peers | 1368](#)

You need to configure network peers for GMPLS. A peer is a network device that your router communicates with when setting up the control and data channels. The peer is often an optical cross-connect (OXC).

To configure an LMP peer name, include the **peer** statement at the [edit protocols link-management] hierarchy level:

```
peer peer-name {
  address ip-address;
  control-channel control-channel-interface;
  lmp-control-channel control-channel-interface {
    remote-address ip-address;
  }
  lmp-protocol {
    hello-dead-interval milliseconds;
    hello-interval milliseconds;
    retransmission-interval milliseconds;
    retry-limit number;
    passive;
  }
  te-link te-link-name;
}
```

The following sections describe how to configure an LMP peer:

Configuring the ID for LMP Peers

To configure the LMP peer ID, include the **address** statement at the [edit protocols link-management peer *peer-name*] hierarchy level. The default value for the LMP peer ID is the loopback address.

```
[edit protocols link-management peer peer-name]
address ip-address;
```

Configuring the Interface for Control Channels Between LMP Peers

You must configure one or more control channels between the LMP peers. The control channels must travel across either a point-to-point link or a tunnel.

To configure the interface for the control channel, include the **control-channel** statement at the [edit protocols link-management peer *peer-name*] hierarchy level:

```
[edit protocols link-management peer peer-name]
control-channel [ interface-names ];
```

You can configure a generic routing encapsulation (GRE) interface (gre-x/y/z) for the control channel. This type of interface does not require a Tunnel PIC.

NOTE: You can configure GRE interfaces (gre-x/y/z) only for GMPLS control channels. GRE interfaces are not supported or configurable for other applications. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring the LMP Control Channel Interface for the Peer

In an environment that uses LMP to establish and maintain an LMP control channel between peers, you can configure a number of attributes associated with LMP. To configure the interface to be associated with the LMP control channel for the peer, include the **lmp-control-channel** statement:

```
lmp-control-channel control-channel-interface;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name*]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name*]

You can configure a GRE interface for the LMP control channel. This type of interface does not require a Tunnel PIC.

NOTE: You can configure GRE interfaces only for GMPLS control channels. GRE interfaces are not supported or configurable for other applications. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

When this LMP control channel interface comes up, the peers use LMP to negotiate channel parameters and configure the control channel.

The local peer repeatedly sends a Config message to the remote peer. The Config message contains the local control channel ID, the local peer's node ID, a message ID, and a CONFIG object that includes hello message attributes (the hello interval and the hello dead interval).

The channel is activated when the remote peer responds with a ConfigAck message. The remote peer does so only when its own configured hello interval and hello dead interval match the values in the received Config message or the default values. If these values do not match, the remote peer responds with a ConfigNack message. The local peer logs this event and resends the Config message until the message retry limit is reached. When the message retry limit is reached, the local peer logs that event and restarts the configuration process.

Configuring the Remote IP Address for LMP Control Channels

You need to specify the address of the remote end of the LMP control channel.

To configure the remote IP address for the LMP control channel, include the **remote-address** statement:

```
remote-address address;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name* **lmp-control-channel** *control-channel-interface*]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name* **lmp-control-channel** *control-channel-interface*]

Configuring Hello Message Intervals for LMP Control Channels

Hello messages are exchanged between LMP peers to maintain the control channel after LMP has activated the control channel. The LMP control channel is considered to be up only when the hello negotiation is successful. Successful negotiation consists of the local peer sending a hello message to the remote peer and receiving a hello message in response.

The LMP peers continue to exchange hello messages after the LMP control channel is up in order to maintain the channel.

The hello interval specifies the interval between periodic hello messages. The hello dead interval specifies how long the local peer waits for a hello response before it declares the LMP control channel to be down. When the channel goes down, the local peer restarts the LMP control channel negotiation and configuration process.

You can specify a hello interval from 150 through 300,000 milliseconds. The default hello interval is 150 milliseconds.

You can specify a hello dead interval from 500 through 300,000 milliseconds. The default hello dead interval is 500 milliseconds.

To configure the attributes for hello messages exchanged between LMP peers, include the **hello-interval** and **hello-dead-interval** statements:

```
hello-dead-interval milliseconds;  
hello-interval milliseconds;
```

You can configure these statements at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name* **lmp-protocol**]

- [edit logical-systems *logical-system-name* protocols link-management *peer peer-name* *lmp-protocol*]

When an LMP control channel comes up after a successful exchange of hello messages between LMP peers, LMP uses link property correlation to verify the traffic engineering and data link information on both sides of a link. To do so, the local peer sends a LinkSummary message for each traffic engineering link governed by the LMP control channel. The LinkSummary message contains information that characterizes the traffic engineering link and each data link in the traffic engineering link.

The local peer continues sending a LinkSummary message for each link until the remote peer responds with a LinkSummaryAck message or until the message retry limit is reached. When the message retry limit is reached, the local peer logs that event and restarts the link property correlation process.

When the remote peer receives a LinkSummary message, it examines its own link information. If this information agrees with that in the LinkSummary message, the remote peer responds with a LinkSummaryAck message. If the information is different, the remote peer responds with a LinkSummaryNack message.

Controlling Message Exchange for LMP Control Channels

You can configure message attributes that control the exchange of LMP Config and LinkSummary messages. The retransmission interval specifies the interval between resubmitted LMP messages. The retry limit specifies how many times LMP sends a message before restarting the process.

You can specify a retransmission interval from 500 through 300,000 milliseconds. The default retransmission interval is 500 milliseconds.

You can specify a retry limit from 3 through 1000 attempts. The default number of retry attempts is three.

To configure attributes governing the exchange of LMP messages between peers, include the **retransmission-interval** and **retry-limit** statements:

```
retransmission-interval milliseconds;  
retry-limit number;
```

You can configure these statements at the following hierarchy levels:

- [edit protocols link-management *peer peer-name* *lmp-protocol*]
- [edit logical-systems *logical-system-name* protocols link-management *peer peer-name* *lmp-protocol*]

Preventing the Local Peer from Initiating LMP Negotiation

You can specify that the local peer does not initiate LMP negotiation. Instead, the local peer waits for the remote peer to configure the LMP control channel.

To configure the local peer to wait for the remote peer to configure the LMP control channel, include the **passive** statement:

```
passive;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name* **lmp-protocol**]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name* **lmp-protocol**]

Associating Traffic Engineering Links with LMP Peers

To specify the name of a traffic engineering link to be associated with this peer, include the **te-link** statement at the [edit protocols link-management **peer** *peer-name*] hierarchy level:

```
[edit protocols link-management peer peer-name]  
te-link te-link-name;
```

For information about how to configure a traffic engineering link, see “[Configuring LMP Traffic Engineering Links](#)” on page 1361.

Disabling the Traffic Engineering Link for LMP Peers

To disable a specific traffic engineering link, include the **disable** statement:

```
disable;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **te-link** *te-link-name*]
- [edit logical-systems *logical-system-name* protocols link-management **te-link** *te-link-name*]

Configuring RSVP and OSPF for LMP Peer Interfaces

IN THIS SECTION

- [Configuring RSVP Signaling for LMP Peer Interfaces | 1369](#)
- [Configuring OSPF Routing for LMP Peer Interfaces | 1370](#)
- [Configuring the Hello Interval for LMP Peer Interfaces | 1370](#)

After you have configured the LMP peers as described in [“Configuring LMP Peers” on page 1363](#), add the peer interfaces to RSVP and OSPF. The peer interface name must match the peer name configured in LMP. Once the peer interfaces are added to the protocols, the traffic engineering link local and remote addresses can be signaled and advertised to peers like any other interface enabled for RSVP and OSPF. These addresses act as virtual interfaces for GMPLS.

NOTE: When adding the virtual peer interfaces to RSVP and OSPF, do not configure the corresponding physical control channel interface in either protocol. If you include the **interface all** statement, you must disable RSVP and OSPF protocols manually on the control channel interface.

To configure peer interfaces in RSVP and OSPF, complete the procedures in the following sections:

Configuring RSVP Signaling for LMP Peer Interfaces

To configure RSVP signaling for LMP peers, configure the LMP peer interface by including the **peer-interface** statement at the **[edit protocols rsvp]** hierarchy level:

```
[edit protocols rsvp]
peer-interface peer-interface-name {
  (aggregate | no-aggregate);
  authentication-key key;
  disable;
  hello-interval seconds;
  (reliable | no-reliable);
}
```

The statements configured at the `[edit protocols rsvp peer-interface peer-interface-name]` hierarchy level have the same functionality as the statements configured at the `[edit protocols rsvp interface interface-name]` hierarchy level.

Configuring OSPF Routing for LMP Peer Interfaces

To configure OSPF routing for LMP peers, configure the name of the LMP peer by including the `peer-interface` statement at the `[edit protocols ospf area area-number]` hierarchy level:

```
[edit protocols ospf area area-number]
peer-interface peer-interface-name {
  dead-interval seconds;
  disable;
  hello-interval seconds;
  retransmit-interval seconds;
  transit-delay seconds;
}
```

For information about how to configure OSPF statements, see the *Junos OS Routing Protocols Library*.

Configuring the Hello Interval for LMP Peer Interfaces

Hello packets are used to indicate to neighboring routers that the peer interface is still up and running. The hello interval must be the same for all routers on a shared logical IP network. You can specify a hello interval from 1 through 255 seconds. The default hello interval is normally 10 seconds. For nonbroadcast networks, the default hello interval is 120 seconds.

To specify how often the router sends hello packets out the peer interface, configure the `hello-interval` statement:

```
hello-interval seconds;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols ospf area area-number peer-interface peer-interface-name]`
- `[edit logical-systems logical-system-name protocols ospf area area-number peer-interface peer-interface-name]`

Configuring MPLS Paths for GMPLS

As part of the configuration for GMPLS, you need to establish an MPLS path for each unique device connected through GMPLS. Configure the traffic engineering link remote address as the address at the `[edit protocols mpls path path-name]` hierarchy level. Constrained Shortest Path First (CSPF) is supported so you can choose either the **strict** or **loose** option with the address.

See [“LMP Configuration Overview” on page 1359](#) for information about how to obtain a traffic engineering link remote address.

To configure the MPLS path, include the **path** statement at the `[edit protocols mpls]` hierarchy level:

```
[edit protocols mpls]
path path-name {
    next-hop-address (strict | loose);
}
```

For information about how to configure MPLS paths, see [“Creating Named Paths” on page 516](#).

Tracing LMP Traffic

To trace LMP protocol traffic, include the **traceoptions** statement at the `[edit protocols link-management]` hierarchy level:

```
[edit protocols link-management]
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`.

The following trace flags display the operations associated with the sending and receiving of various LMP messages:

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel
- **init**—Output from the initialization messages
- **packets**—Trace all packets other than hello packets on any LMP control channel

- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols
- **server**—Server processing operations
- **show**—Servicing operations for **show** commands
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

Each flag can carry one or more of the following flag modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

Configuring MPLS LSPs for GMPLS

IN THIS SECTION

- [Configuring the Encoding Type | 1373](#)
- [Configuring the GPID | 1373](#)
- [Configuring the Signal Bandwidth Type | 1374](#)
- [Configuring GMPLS Bidirectional LSPs | 1374](#)
- [Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS | 1374](#)

To enable the proper GMPLS switching parameters, configure the label-switched path (LSP) attributes that are appropriate for your network connection. The default value for **switching-type** is **psc-1**, which is also appropriate for standard MPLS.

To configure the LSP attributes, include the **lsp-attributes** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name]
lsp-attributes {
  encoding-type type;
```

```

gpid gpid;
signal-bandwidth type;
switching-type type;
}

```

If you include the **no-cspf** statement in the label-switched path configuration, you must also configure primary and secondary paths, or the configuration cannot be committed.

The following sections describe how to configure each of the LSP attributes for a GMPLS LSP:

Configuring the Encoding Type

You need to specify the encoding type of the payload carried by the LSP. It can be any of the following:

- **ethernet**—Ethernet
- **packet**—Packet
- **pdh**—Plesiochronous digital hierarchy (PDH)
- **sonet-sdh**—SONET/SDH

The default value is **packet**.

To configure the encoding type, include the **encoding-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```

[edit protocols mpls label-switched-path lsp-name lsp-attributes]
encoding-type type;

```

Configuring the GPID

You need to specify the type of payload carried by the LSP. The payload is the type of packet underneath the MPLS label. The payload is specified by the generalized payload identifier (GPID).

You can specify the GPID with any of the following values:

- **hdlc**—High-Level Data Link Control (HDLC)
- **ethernet**—Ethernet
- **ipv4**—IP version 4 (default)
- **pos-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-scrambling-crc-32**—For interoperability with other vendors' equipment

- **pos-no-scrambling-crc-32**—For interoperability with other vendors' equipment
- **ppp**—Point-to-Point Protocol (PPP)

To configure the GPID, include the **gpipid** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  gpipid gpipid;
```

Configuring the Signal Bandwidth Type

The signal bandwidth type is the encoding used for path computation and admission control. To configure the signal bandwidth type, include the **signal-bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  signal-bandwidth type;
```

Configuring GMPLS Bidirectional LSPs

Because MPLS and GMPLS use the same configuration hierarchy for LSPs, it is helpful to know which LSP attributes control LSP functionality. Standard MPLS packet-switched LSPs are unidirectional, whereas GMPLS nonpacket LSPs are bidirectional.

If you use the default packet-switching type of **psc-1**, your LSP becomes unidirectional. To enable a GMPLS bidirectional LSP, you must select a non-packet-switching type option, such as **lambda**, **fiber**, or **ethernet**. Include the **switching-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  switching-type (lambda | fiber | ethernet);
```

Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS

By setting the A-bit in the Admin Status object, you can enable nonpacket GMPLS LSPs to establish paths through routers that run Junos. When an ingress router sends an RSVP PATH message with the Admin Status A-bit set, an external device (not a router running the Junos OS) can either perform a Layer 1 path setup test or help bring up an optical cross-connect.

When set, the A-bit in the Admin Status object indicates the administrative down status for a GMPLS LSP. This feature is used specifically by nonpacket GMPLS LSPs. It does not affect control path setup or data forwarding for packet LSPs.

Junos does not distinguish between the control path setup and data path setup. Other nodes along the network path use RSVP PATH signaling using the A-bit in a meaningful way.

To configure the Admin Status object for a GMPLS LSP, include the **admin-down** statement:

```
admin-down;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]

Gracefully Tearing Down GMPLS LSPs

IN THIS SECTION

- [Temporarily Deleting GMPLS LSPs | 1375](#)
- [Permanently Deleting GMPLS LSPs | 1376](#)
- [Configuring the Graceful Deletion Timeout Interval | 1376](#)

You can gracefully tear down nonpacket GMPLS LSPs. An LSP that is torn down abruptly, a common process in a packet-switched network, can cause stability problems in nonpacket-switched networks. To maintain the stability of nonpacket-switched networks, it might be necessary to tear down LSPs gracefully.

The following sections describe how to tear down GMPLS LSPs gracefully:

Temporarily Deleting GMPLS LSPs

You can gracefully tear down a GMPLS LSP using the **clear rsvp session gracefully** command.

This command gracefully tears down an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin Status object is signaled along the path to the endpoint of the LSP. During the second pass, the LSP is taken down. Using this command, the LSP is taken down temporarily. After the appropriate interval, the GMPLS LSP is resignaled and then reestablished.

The **clear rsvp session gracefully** command has the following properties:

- It only works on the ingress and egress routers of an RSVP session. If used on a transit router, it has the same behavior as the **clear rsvp session** command.
- It only works for nonpacket LSPs. If used with packet LSPs, it has the same behavior as the **clear rsvp session** command.

For more information, see the [CLI Explorer](#).

Permanently Deleting GMPLS LSPs

When you disable an LSP in the configuration, the LSP is permanently deleted. By configuring the **disable** statement, you can disable a GMPLS LSP permanently. If the LSP being disabled is a nonpacket LSP, then the graceful LSP tear-down procedures that use the Admin Status object are used. If the LSP being disabled is a packet LSP, then the regular signaling procedures for LSP deletion are used.

To disable a GMPLS LSP, include the **disable** statement at any of the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**—Disable the LSP.
- **[edit protocols link-management *te-link* *te-link-name*]**—Disable a traffic engineering link.
- **[edit protocols link-management *te-link* *te-link-name* *interface* *interface-name*]**—Disable an interface used by a traffic engineering link.

Configuring the Graceful Deletion Timeout Interval

The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.

The ingress router initiates the graceful deletion procedure by sending the Admin Status object in the path message with the **D** bit set. The ingress router expects to receive an Resv message with the **D** bit set from the egress router. If the ingress router does not receive this message within the time specified by the graceful deletion timeout interval, it initiates a forced tear-down of the LSP by sending a PathTear message.

To configure the graceful deletion timeout interval, include the **graceful-deletion-timeout** statement at the **[edit protocols rsvp]** hierarchy level. You can configure a time between 1 through 300 seconds. The default value is 30 seconds.

```
graceful-deletion-timeout seconds;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**

- [edit logical-systems *logical-system-name* protocols rsvp]

You can use the **show rsvp version** command to determine the current value configured for the graceful deletion timeout.

GMPLS RSVP-TE VLAN LSP Signaling Overview

Understanding GMPLS RSVP-TE Signaling

Signaling is the process of exchanging messages within the control plane to set up, maintain, modify, and terminate data paths (label-switched paths (LSPs)) in the data plane. Generalized MPLS (GMPLS) is a protocol suite that extends the existing control plane of MPLS to manage further classes of interfaces and to support other forms of label switching, such as time-division multiplexing (TDM), fiber (port), Lambda, and so on.

GMPLS extends intelligent IP/MPLS connections from Layer 2 and Layer 3 all the way to Layer 1 optical devices. Unlike MPLS, which is supported mainly by routers and switches, GMPLS can also be supported by optical platforms, including SONET/SDH, optical cross-connects (OXCs), and dense wave division multiplexing (DWDM).

In addition to labels, which are primarily used to forward data in MPLS, other physical entries, such as wavelengths, time slots, and fibers can be used as label objects to forward data in GMPLS, thereby leveraging the existing control plane mechanisms to signal different kinds of LSPs. GMPLS uses RSVP-TE to be able to request the other label objects to signal the various kinds of LSPs (nonpacket). Bidirectional LSPs and

an out-of-band control channel and a data channel using the Link Management Protocol (LMP) are the other mechanisms that are used by GMPLS to establish LSPs.

Need for GMPLS RSVP-TE VLAN LSP Signaling

The traditional Layer 2 point-to-point services use Layer 2 circuits and Layer 2 VPN technologies that are based on LDP and BGP. In the traditional deployment, the customer edge (CE) devices do not participate in the signaling of the Layer 2 service. The provider edge (PE) devices manage and provision the Layer 2 service to provide end-to-end connectivity between the CE devices.

One of the biggest challenges of having the PE devices provision the Layer 2 services for each Layer 2 circuit between a pair of CE devices is the network management burden on the provider network.

Figure 105 on page 1378 illustrates how the Layer 2 service is set up and used by the CE routers in a LDP/BGP-based Layer 2 VPN technology. Two CE routers CE1 and CE2 are connected to a provider MPLS network through the PE routers PE1 and PE2 respectively. The CE routers are connected to the PE routers by Ethernet links. Routers CE1 and CE2 are configured with VLAN1 and VLAN2 logical Layer 3 interfaces, so they appear to be directly connected. Routers PE1 and PE2 are configured with Layer 2 circuit (pseudowire) to carry the Layer 2 VLAN traffic between the CE routers. The PE routers use packet MPLS LSPs within the provider MPLS network to carry the Layer 2 VLAN traffic.

Figure 105: Traditional Layer 2 Point-to-Point Services

With the introduction of GMPLS-based VLAN LSP signaling, the need for the PE (also called server-layer) network to provision each individual Layer 2 connection between the CE (also called client) devices is minimized. The client router requests the server-layer router to which it is directly connected, for setting up the Layer 2 service to connect with a remote client router through GMPLS signaling.

The server-layer devices extend the signaling through the server-layer network to connect with the remote client routers. In the process, the server-layer device sets up the data plane for the Layer 2 service at the server-client border, and sets up the data plane for carrying the Layer 2 traffic within the server-layer network. With the Layer 2 service setup, the client routers can run IP/MPLS directly on top of the Layer 2 service and have IP/MPLS adjacency with each other.

In addition to reducing the provisioning activity needed on the server-layer devices, GMPLS signaling also provides the client routers with the flexibility of bringing up the Layer 2 circuits on an on-demand basis without depending on the server-layer administration for the provisioning of the Layer 2 service.

Using the same topology as in Figure 1, [Figure 106 on page 1379](#) illustrates how the Layer 2 service is set up and used by the client routers in GMPLS RSVP-TE-based Layer 2 VPN technology.

Figure 106: GMPLS RSVP-TE VLAN LSP

In [Figure 106 on page 1379](#), instead of configuring a pseudowire to carry the Layer 2 VLAN traffic between the client routers, Routers PE1 and PE2 are configured with an IP-based communication channel and other GMPLS-specific configurations (identification of Ethernet links as TE-links) for allowing the exchange of GMPLS RSVP-TE signaling messages with the client routers. Routers CE1 and CE2 are also configured with an IP-based communication channel and relevant GMPLS configuration for exchanging the GMPLS RSVP-TE signaling messages with the server-layer routers. Routers CE1 and CE2 establish an IP/MPLS adjacency on top of this Layer 2 service.

GMPLS RSVP-TE VLAN LSP Signaling Functionality

Based on [Figure 106 on page 1379](#), the client router establishes the Layer 2 service in the server-layer network as follows:

1. Router CE1 initiates GMPLS RSVP-TE signaling with Router PE1. In this signaling message, Router CE1 indicates the VLAN on the Ethernet link for which it needs the Layer 2 service and the remote CE router, Router CE2, with which the VLAN should be connected.

Router CE1 also indicates the remote PE router, Router PE2, to which Router CE2 is connected, and the exact Ethernet link connecting Router CE2 to Router PE2 on which the Layer 2 service is required in the signaling message.

2. Router PE1 uses the information from Router CE1 in the signaling message and determines the remote PE router, Router PE2, with which Router CE2 is attached. Router PE1 then establishes a packet MPLS LSP (associated bidirectional) through the server-layer MPLS network for carrying the VLAN traffic and then passes the GMPLS RSVP-TE signaling message to Router PE2 using the LSP hierarchy mechanism.

3. Router PE2 propagates the GMPLS RSVP-TE signaling message to Router CE2 with the VLAN to be used on the PE2-CE2 Ethernet link.
4. Router CE2 responds with an acknowledgment to the GMPLS RSVP-TE signaling message to Router PE2. Router PE2 then propagates it to Router PE1, which in turn propagates it to Router CE1.
5. As part of this message propagation, Routers PE1 and PE2 set up the forwarding plane to enable bidirectional flow of VLAN Layer 2 traffic between Routers CE1 and CE2.

LSP Hierarchy with GMPLS RSVP-TE VLAN LSP

The Layer 2 service in GMPLS RSVP-TE VLAN LSP signaling is brought up using a hierarchy mechanism in which two different RSVP LSPs are created for the Layer 2 service:

- An end-to-end VLAN LSP that has state information at the client and server-layer routers.
- An associated bidirectional packet transport LSP that is present in the server-layer routers (PE and P) of the server-layer network.

The LSP hierarchy avoids sharing information about technology-specific LSP characteristics with the core nodes of the server-layer network. This solution cleanly separates the VLAN LSP state and the transport LSP state, and ensures that the VLAN LSP state is only present on the nodes (PE, CE) where it is needed.

Path Specification for GMPLS RSVP-TE VLAN LSP

The path for the GMPLS RSVP-TE LSP is configured as an Explicit Route Object (ERO) at the initiating client router. As this LSP traverses different network domains (initiating, terminating at client network, and traversing the server-layer network), the LSP setup falls under the category of an interdomain LSP setup. In an interdomain scenario, one network domain generally does not have full visibility into the topology of the other network domain. Hence, the ERO that gets configured at the initiating client router does not have full hop information for the server-layer portion. This feature requires that the ERO configured at the CE router has three hops, with the first hop being a strict hop identifying the CE1-PE1 Ethernet link, the second hop being a loose hop identifying the egress PE router (PE2), and the third hop being a strict hop identifying the CE2-PE2 Ethernet link.

GMPLS RSVP-TE VLAN LSP Configuration

The configuration required to set up a GMPLS VLAN LSP at the client and server routers uses the existing GMPLS configuration model with some extensions. The Junos OS GMPLS configuration model for nonpacket LSPs is targeted toward bringing the physical interfaces up and running through GMPLS RSVP-TE signaling, whereas signaling a GMPLS RSVP-TE VLAN LSP aims at bringing up individual VLANs on top of a physical interface. The **ethernet-vlan** configuration statement under the **[edit protocols link-management te-link]** hierarchy enables this.

The client router has physical interfaces connected to a server network, and the server network provides a point-to-point connection between two client routers over the attached physical interfaces. The physical interface is brought into an operational state by GMPLS RSVP-TE as follows:

1. The client router maintains a routing or signaling adjacency with the server network node to which the physical interface is connected, typically through a control channel different from the physical interface, because the physical interface itself is brought up and running only after the signaling.
2. The client router and the server network node identify the physical interfaces connecting them using the TE-link mechanism.
3. The client router and the server network node use the TE-link identifier (IP address) as the GMPLS RSVP hop and the physical interface identifier as the GMPLS label values in the GMPLS RSVP-TE signaling messages to bring the physical interface into an operational state.

In the existing GMPLS configuration, the server and client network nodes use the **protocols link-management peer *peer-name*** configuration statement to specify the adjacent peer node. Because a client router can have one or more physical interfaces connected to the server network node, these physical interfaces are grouped and identified by an IP address through the **protocols link-management te-link *link-name*** configuration statement. The TE-link is assigned a local IP address, a remote IP address, and a list of physical interfaces. The TE-link is then associated with the **protocols link-management peer *peer-name* te-link *te-link-list*** configuration statement.

The out-of-band control channel that is required for exchanging signaling messages is specified using the **protocols link-management peer *peer-name* control-channel *interface-name*** configuration statement. The existence of the server or client network node is made visible to the RSVP and IGP (OSPF) protocols through the **peer-interface *interface-name*** configuration statement under the **[edit protocols rsvp]** and **[edit protocols ospf]** hierarchy levels.

In the existing GMPLS configuration, the label (upstream label and resv label) that is carried in the signaling message is an integer identifier that identifies the physical interface that is required to be brought up. As the label is used to identify the physical interface, the existing GMPLS configuration allows multiple interfaces to be grouped under a single TE-link. In the existing GMPLS configuration, there is sufficient information in the GMPLS RSVP-TE signaling message, such as TE-link address and label value, to identify the physical interface that is required to be brought up. In contrast, for GMPLS RSVP-TE VLAN LSP configuration, the VLAN ID value is used as the label in the signaling message.

In the GMPLS RSVP-TE VLAN LSP configuration, if multiple interfaces are allowed to be configured under a single TE-link, using VLAN ID as the label value in the signaling message can cause ambiguity as to which physical interface on which the VLAN has to be provisioned. Therefore, the TE-link is configured with the **ethernet-vlan** configuration statement, if the number of physical interfaces that can be configured under the TE-link is restricted to only one.

In the existing GMPLS configuration, the bandwidth for a nonpacket LSP is a discrete quantity that corresponds to the bandwidth of the physical interface that needs to be brought up. So, the GMPLS LSP configuration does not allow any bandwidth to be specified, but allows the bandwidth to be specified only

through the **signal-bandwidth** configuration statement under the **[protocols mpls label-switched-path lsp-name lsp-attributes]** hierarchy level. In the GMPLS VLAN LSP configuration, bandwidth is specified similar to that of a packet LSP. In the GMPLS VLAN LSP configuration, the **bandwidth** option is supported and **signal-bandwidth** is not supported.

Associated Bidirectional Packet LSP

The GMPLS RSVP-TE VLAN LSP is carried on an associated bidirectional transport LSP within the server-layer network, which is a single-sided provisioned LSP. The transport LSP signaling is initiated as a unidirectional LSP from the source router to the destination router in the forward direction, and the destination router in turn initiates the signaling of the unidirectional LSP in the reverse direction back to the source router.

Make-Before-Break for Associated Bidirectional Packet and GMPLS RSVP-TE VLAN LSP

The make-before-break support for an associated bidirectional transport LSP follows a similar model, where the destination router for the forward direction of the bidirectional LSP does not perform any make-before-break operations on the reverse direction of the bidirectional LSP. It is the source router (initiator of the associated bidirectional LSP) that initiates the make-before-break newer instance of the associated bidirectional LSP, and the destination router in turn initiates the make-before-break newer instance in the other direction.

For instance, in [Figure 106 on page 1379](#), the unidirectional transport LSP is initiated from Router PE1 to Router PE2 in the forwarding direction, and in turn Router PE2 initiates the transport LSP to Router PE1 in the reverse direction. When a make-before-break instance occurs, only Router PE1 as the initiating client router can establish a new instance of the associated bidirectional LSP. Router PE2 in turn initiates the make-before-break newer instance in the reverse direction.

The make-before-break support for the associated bidirectional transport LSP is used only in scenarios where the transport LSP gets into a state of being locally protected due to link or node failure on the path of the LSP. The GMPLS RSVP-TE VLAN LSP uses the make-before-break mechanism for adjusting seamless bandwidth changes.

NOTE: Periodic re-optimization is not enabled for the associated bidirectional transport LSPs.

The newer make-before-break instance of the GMPLS VLAN LSP is supported under the following constraints:

- It should originate from the same client router as the older instance and be destined to the same client router as the older instance.
- It should use the same server-client links at both the server-client ends as the older instance.

- It should use the same VLAN label at the server-client links as the older instance.
- The GMPLS VLAN LSP should be configured as **adaptive** when the bandwidth change is initiated from the CLI, or else the current instance of the VLAN LSP is torn down and a new VLAN LSP instance is established.

The make-before-break operation for the GMPLS VLAN LSP on the server-layer edge router is rejected if these constraints are not met.

On the server-layer edge routers, when a make-before-break instance of the GMPLS VLAN LSP is seen, a completely new, separate associated bidirectional transport LSP is created to support this make-before-break instance. The existing associated bidirectional LSP (supporting the older instance) is not triggered to initiate a make-before-break instance at the transport LSP level. An implication of this choice (of initiating a new transport LSP) is that at the server-layer resource/bandwidth sharing does not happen when a make-before-break operation is performed for the GMPLS VLAN LSP.

Supported and Unsupported Features

Junos OS supports the following features with the GMPLS RSVP-TE VLAN LSP:

- Request for specific bandwidth and local protection for the VLAN LSP on the client router to the server-layer router.
- Nonstop active routing (NSR) support for the GMPLS VLAN LSP at the client routers, server-layer edge routers, and associated bidirectional transport LSP at the server-layer edge routers.
- Multichassis support.

Junos OS does **not** support the following GMPLS RSVP-TE VLAN LSP functionality:

- Graceful restart support for associated bidirectional packet LSP and GMPLS VLAN LSP.
- End-to-end path computation for GMPLS VLAN LSP using CSPF algorithm at the client router.
- Non-CSPF routing-based discovery of next-hop routers by the different client, server-layer edge routers.
- Automatic provisioning of the client Layer 3 VLAN interfaces upon the successful setup of the VLAN LSP at the client routers.
- MPLS OAM (LSP-ping, BFD).
- Packet MPLS applications, such as next-hop in static route and in IGP shortcuts.
- Local cross connect mechanism, where a client router connects to a remote client router which is connected to the same server router.
- Junos OS Services Framework.
- IPv6 support.
- Logical systems.
- Aggregated Ethernet/SONET/IRB interfaces at the server-client link.

Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling

IN THIS SECTION

- [Requirements](#) | 1384
- [Overview](#) | 1385
- [Configuration](#) | 1391
- [Verification](#) | 1405

This example shows how to configure GMPLS RSVP-TE VLAN LSP signaling on the client routers to enable one client router to connect with a remote client router through a server-layer network using the LSP hierarchy. This enables the client routers to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers
- Junos OS Release 14.2 or later running on the client routers and server-layer edge routers

Before you begin:

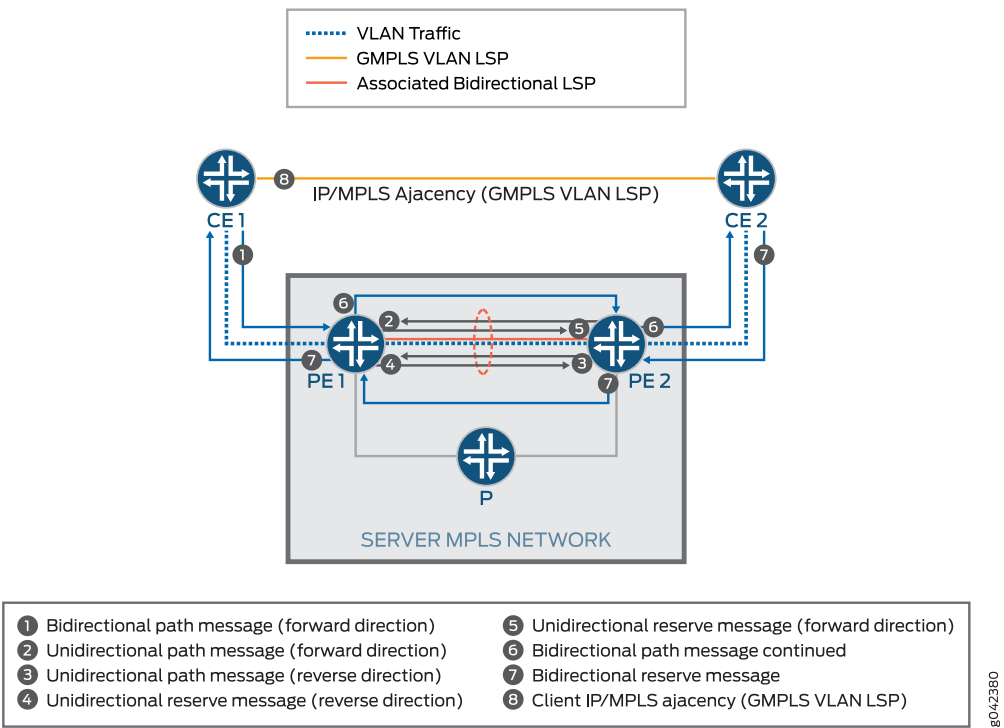

1. Configure the device interfaces.
2. Configure the interface-associated VLANs.
3. Configure the following routing protocols:
 - RSVP
 - MPLS
 - LMP

Overview

Starting with Junos OS Release 14.2, the Layer 2 services between two client routers across an external/third-party server-layer network are set up by the client routers on an on-demand basis through GMPLS RSVP-TE signaling. This feature provides the client routers the flexibility to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network. In traditional Layer 2 VPN technology based on LDP and BGP, the provider network handled the provisioning activity for each Layer 2 circuit established between two client routers.

Figure 107 on page 1385 illustrates the setting up and signaling of the GMPLS VLAN LSP between two client routers, CE1 and CE2, across a server-layer network with two server-layer edge routers, PE1 and PE2, and one server-layer core router, P.

Figure 107: Setting Up a GMPLS VLAN LSP

The signaling of GMPLS VLAN LSP is executed as follows:

1. Initiating GMPLS VLAN LSP at CE1

Router CE1 initiates the GMPLS VLAN LSP setup by sending the GMPLS RSVP-TE path message to Router PE1. The signaling between CE1 and PE1 is over an out-of-band control channel, which is a separate control VLAN configured on the Ethernet link connecting the two routers.

The GMPLS RSVP-TE path message initiated by Router CE1 is used to perform the following:

- a. Identify the Ethernet link on which the VLAN is active.
- b. Abstract the Ethernet link as a TE-link and assign an IP address to identify the Ethernet link.
- c. Allocate a VLAN ID from the pool of free VLANs managed by Router CE1 for every Ethernet link connecting Router PE1 to the identified Ethernet link.

This VLAN ID can also be used for the GMPLS VLAN LSP at the CE2-PE2 Ethernet link.

- d. Identify the VLAN for which the Layer 2 service is required to be set up using the allocated VLAN ID as the upstream label object and the upstream direction label value.
- e. Include an ERO object that helps Router PE1 in establishing the VLAN LSP through the server-layer network to the remote client router, CE2. The ERO object in the path message includes three hops:
 - First hop—Strict hop identifying the initiating client-server Ethernet link, PE1-CE1.
 - Second hop—Loose hop identifying the remote server-layer router, PE2.
 - Third hop—Strict hop identifying the remote client-server Ethernet link, PE2-CE2.
- f. Include the bandwidth required for the GMPLS VLAN LSP.
- g. Include any local-protection required within the server-layer network for the VLAN LSP.

2. Initiating Associated Bidirectional Transport LSP at PE1

After Router PE1 receives the path message from Router CE1, the message is validated to check the availability of the Ethernet link and VLAN ID. In the server-layer network, the Layer 2 services between the server-layer routers, PE1 and PE2, are provided at the data plane in a manner similar to Layer 2 circuits. Router PE1 brings up a transport LSP to Router PE2 and then extends the GMPLS VLAN LSP as a hierarchical LSP running on top of the PE1-PE2 transport LSP. The PE1-PE2 transport LSP is a packet LSP and is bidirectional in nature. This is because the GMPLS VLAN LSP is bidirectional and each server-layer router needs to be able to do the following:

- Receive traffic from the server-client Ethernet link (for example, the PE1-CE1 link) and send it to the remote server-layer router, PE2.
- Receive traffic from remote Router PE2 and send it on the PE1-CE1 Ethernet link.

For each GMPLS VLAN LSP, a packet transport LSP is set up within the server-layer network. The transport LSP is exclusively used to carry traffic of the GMPLS VLAN LSP for which it was created. The

transport LSP is dynamically created at the time of receiving the GMPLS VLAN LSP; thus, no configuration is required to trigger its creation. The transport LSP established for the VLAN LSP inherits the bandwidth and the local-protection attributes from the VLAN LSP.

Router PE1 signals the PE1-PE2 transport LSP to Router PE2. Router PE1 determines the destination for the transport LSP from the loose hop specified in the ERO object of the GMPLS RSVP-TE path message from Router CE1 and then signals the VLAN LSP. However, if the PE1-PE2 transport LSP fails to establish, Router PE1 sends back a path error message to Router CE1, and the GMPLS VLAN LSP is not established as well.

3. Setting Up the Associated Bidirectional Transport LSP Between the Server-Layer Routers

The associated bidirectional LSP between routers PE1 and PE2 consists of two unidirectional packet LSPs:

- PE1-to-PE2
- PE2-to-PE1

Router PE1 initiates signaling of a unidirectional packet LSP to Router PE2. This unidirectional packet LSP constitutes the forward direction (PE1-to-PE2) of the associated bidirectional LSP, and the path message carries the Extended Association Object indicating this is a single-sided provisioning model. On receiving the path message for the LSP, Router PE2 responds with a Resv message and triggers the signaling of a unidirectional packet LSP to Router PE1 with the same path as (PE1-to-PE2) in the reverse direction. This unidirectional packet LSP uses the PE2-to-PE1 direction of the associated bidirectional LSP, and this path message carries the same Extended Association Object seen in the PE1-to-PE2 path message.

When Router PE1 receives the Resv message for the PE1-to-PE2 unidirectional LSP and the path message for the PE2-to-PE1 unidirectional LSP, PE1 binds the PE1-to-PE2 and PE2-to-PE1 unidirectional LSPs by matching the Extended Association Objects carried in the respective path messages. For the path message for the PE2-to-PE1 unidirectional LSP, Router PE1 responds with the Resv Message. On receiving the Resv message for the PE1-to-PE2 LSP and the path message for the PE2-to-PE1 LSP, Router PE1 has established the associated bidirectional packet transport LSP.

4. Setting Up the GMPLS VLAN LSP at Router PE1

After successfully establishing the transport LSP, Router PE1 triggers the signaling of the GMPLS VLAN LSP. Router PE1 sends the GMPLS RSVP-TE path message corresponding to the VLAN LSP directly to Router PE2, which is bidirectional in nature and includes the upstream label object.

Router PE2 is not aware of the association between the transport LSP and the VLAN LSP. This association is indicated to Router PE2 by Router PE1.

5. Setting Up the GMPLS VLAN LSP at Router PE2

On receiving the VLAN LSP path message from Router PE1, Router PE2 verifies the availability of the transport LSP. If the transport LSP is not available or the LSP setup is in progress, the VLAN LSP processing is put on hold. When the transport LSP is available, Router PE2 processes the VLAN LSP path message. The ERO object in this path message indicates that the next hop is a strict hop identifying the PE2-to-CE2 Ethernet link. The ERO object can indicate the VLAN ID to be used on the PE2-to-CE2 Ethernet link by Router PE2.

Router PE2 appropriately allocates the VLAN ID to be sent as the upstream label in the VLAN LSP path message to Router CE2, and sends it through an out-of-band control channel.

6. Processing the GMPLS VLAN LSP at Router CE2

On receiving the GMPLS RSVP-TE LSP from Router PE2, Router CE2 validates the availability of VLAN ID for allocation on the PE2-to-CE2 link. Router CE2 then allocates the VLAN ID for this VLAN LSP and sends back a Resv message to Router PE2 with the VLAN ID as the label object in the Resv message.

7. Processing the GMPLS VLAN LSP at Router PE2

On receiving the Resv message from Router CE2, Router PE2 validates that the label object in the Resv message has the same VLAN ID as in the path message. Router PE2 then allocates a 20-bit MPLS label, which is included in the Resv message sent to Router PE1.

Router PE2 then programs the forwarding plane with the entries to provide the Layer 2 service functionality.

NOTE: For all the VLAN IDs that can be allocated as labels on the PE1-to-CE1 and PE2-CE2 Ethernet links, you must manually configure logical interfaces for circuit cross-connect (CCC) purposes on the server-layer edge routers and not for other families, such as IPv4, IPv6, or MPLS.

8. Processing the GMPLS VLAN LSP at Router PE1

On receiving the Resv message for the VLAN LSP from Router PE2, Router PE1 sends a Resv message to Router CE1 with the same VLAN ID it received as the upstream label from Router CE1. Router PE1 programs the forwarding plane with the entries to provide the Layer 2 service functionality as Router PE2.

9. Processing the GMPLS VLAN LSP at Router CE1

On receiving the Resv message from Router PE1, Router CE1 validates that the VLAN ID received in the Resv message matches the VLAN ID in the upstream label in the path message it sent. This completes the setup of the GMPLS VLAN LSP from Router CE1 to Router CE2.

NOTE:

- The GMPLS VLAN LSP setup does not result in the addition of any forwarding plane entries at the client routers, CE1 and CE2. Only the server-layer routers, PE1 and PE2, add the forwarding plane entries for the GMPLS VLAN LSP.
- There is no routing information exchange between the client and the server-layer routers. The client and server-layer routers do not exchange their network topology information with each other.

10. Accounting for Bandwidth of the GMPLS VLAN LSP

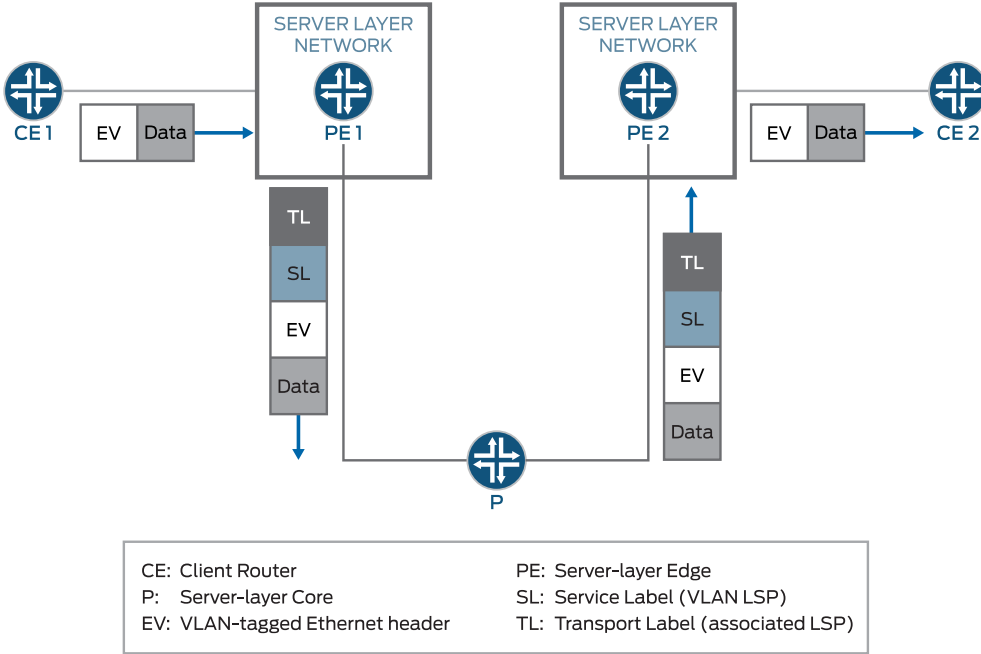

On successfully setting up the GMPLS VLAN LSP, both the client and server-layer routers reduce the amount of available bandwidth on the server-client Ethernet links by the bandwidth amount allocated for the GMPLS VLAN LSP. This bandwidth accounting information is used for admission control purposes when additional GMPLS VLAN LSPs are brought up on the server-client Ethernet links.

11. Using GMPLS VLAN LSP by the Client Routers

After successfully setting up the GMPLS VLAN LSP, the client routers – CE1 and CE2 – need to be manually configured with the VLAN logical interface on top of the server-client Ethernet links with the signaled VLAN ID. This logical interface needs to be configured with the IP address and needs to be included in the IGP protocol. As a result of this configuration, Routers CE1 and CE2 establish IGP adjacency and exchange data traffic over the Layer 2 service established through the GMPLS signaling.

[Figure 108 on page 1390](#) illustrates the data traffic flow of the GMPLS VLAN LSP from Router CE1 to Router CE2 after the LSP setup is complete and the necessary CE1-to-CE2 IGP/MPLS adjacency has been established. The server-layer transport LSP originates from Router PE1, traverses a single server-layer core router, Router P, and reaches Router PE2. The server-layer transport LSP is shown as a penultimate-hop pop LSP, where Router P pops off the transport LSP label, and only the service label is present on the P-to-PE2 link.

Figure 108: Data Traffic Flow of GMPLS VLAN LSP

Topology

In [Figure 109 on page 1390](#), GMPLS RSVP-TE VLAN LSP signaling is used to establish the Layer 2 services between the client routers, Router CE1 and Router CE2. The server routers, Router PE1 and Router PE2, have a GRE tunnel established with each of the directly connected client routers. Routers P1 and P2 are also server routers in the server-layer network.

Figure 109: Configuring GMPLS RSVP-TE VLAN LSP Signaling

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

CE1

```

Configuring the Client Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router CE1:

NOTE: Repeat this procedure for Router CE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router CE1 to Router PE1.

```

[edit interfaces]
user@CE1# set ge-0/0/0 vlan-tagging

```

2. Configure the control VLAN for the ge-0/0/0 interface.

```

[edit interfaces]
user@CE1# set ge-0/0/0 unit 1 vlan-id 1
user@CE1# set ge-0/0/0 unit 1 family inet address 1.1.1.1/30
user@CE1# set ge-0/0/0 unit 1 family mpls

```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 10 vlan-id 10
user@CE1# set ge-0/0/0 unit 10 family inet address 10.10.10.1/24
user@CE1# set ge-0/0/0 unit 10 family mpls
```

4. Configure the GRE tunnel as the controlling interface for Router CE1.

```
[edit interfaces]
user@CE1# set gre unit 0 tunnel source 1.1.1.1
user@CE1# set gre unit 0 tunnel destination 1.1.1.2
user@CE1# set gre unit 0 family inet address 10.35.100.25/30
```

5. Configure the loopback interface of Router CE1.

```
[edit interfaces]
user@CE1# set lo0 unit 0 family inet address 10.255.10.1/32
```

6. Configure the loopback address of Router CE1 as its router ID.

```
[edit routing-options]
user@CE1# set router-id 10.255.10.1
```

7. Enable RSVP on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set rsvp interface all
user@CE1# set rsvp interface fxp0.0 disable
```

8. Configure the RSVP peer interface for Router CE1.

```
[edit protocols]
user@CE1# set rsvp peer-interface PE1
```

9. Disable automatic path computation for label-switched paths (LSPs).

```
[edit protocols]
```

```
user@CE1# set mpls no-cspf
```

10. Configure the LSP to connect Router CE1 to Router CE2.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 from 10.255.10.1
user@CE1# set mpls label-switched-path CE1-to-CE2 to 10.255.10.6
```

11. Configure the CE1-to-CE2 LSP attributes.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes switching-type ethernet-vlan
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes upstream-label vlan-id 10
user@CE1# set mpls label-switched-path CE1-to-CE2 bandwidth 100m
```

12. Configure the CE1-to-CE2 LSP path and path parameters.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 primary path1
user@CE1# set mpls path path1 10.35.1.2 strict
user@CE1# set mpls path path1 10.255.10.5 loose
user@CE1# set mpls path path1 10.36.1.1 strict
```

13. Enable MPLS on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set mpls interface all
user@CE1# set mpls interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@CE1# set link-management te-link link10 local-address 10.35.1.1
user@CE1# set link-management te-link link10 remote-address 10.35.1.2
```

15. Enable setting up of Layer 2 VLAN LSP on the link10 traffic engineering link.

```
[edit protocols]
```

```
user@CE1# set link-management te-link link10 ethernet-vlan
```

16. Configure the Router CE1 interface as the member interface of the link10 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link10 interface ge-0/0/0
```

17. Configure Router PE1 as the Link Management Protocol (LMP) peer for Router CE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer PE1 address 10.255.10.2
user@CE1# set link-management peer PE1 control-channel gre.0
user@CE1# set link-management peer PE1 te-link link10
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces

```

Configuring the Server Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router PE1 to Router CE1.

```

[edit interfaces]
user@PE1# set ge-0/0/0 vlan-tagging
user@PE1# set ge-0/0/0 encapsulation flexible-ethernet-services

```

2. Configure the control VLAN for the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 1 vlan-id 1
user@PE1# set ge-0/0/0 unit 1 family inet address 1.1.1.2/30
user@PE1# set ge-0/0/0 unit 1 family mpls
```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 10 encapsulation vlan-ccc
user@PE1# set ge-0/0/0 unit 10 vlan-id 10
```

4. Configure the interface connecting Router PE1 to the core routers (Router P1 and Router P2).

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 70.70.70.1/30
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 20.20.20.1/30
user@PE1# set ge-0/0/2 unit 0 family mpls
```

5. Configure the GRE tunnel as the controlling interface for Router PE1.

```
[edit interfaces]
user@PE1# set gre unit 0 tunnel source 1.1.1.2
user@PE1# set gre unit 0 tunnel destination 1.1.1.1
user@PE1# set gre unit 0 family inet address 10.35.100.26/30
```

6. Configure the loopback interface of Router PE1.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.10.2/32
```

7. Configure the loopback address of Router PE1 as its router ID.

```
[edit routing-options]
user@PE1# set router-id 10.255.10.2
```

8. Configure an associated bidirectional LSP, and enable unidirectional reverse LSP setup for single-sided provisioned forward LSP.

```
[edit protocols]
user@PE1# set rsdp associated-bidirectional-lsp single-sided-provisioning
```

9. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsdp interface all
user@PE1# set rsdp interface fxp0.0 disable
```

10. Configure the RSVP peer interface for Router PE1, and enable dynamic setup of bidirectional packet LSP for transporting nonpacket GMPLS LSP.

```
[edit protocols]
user@PE1# set rsdp peer-interface CE1 dynamic-bidirectional-transport
```

11. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

12. Configure OSPF with traffic engineering capabilities.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

13. Enable OSPF area 0 on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@PE1# set link-management te-link link1 local-address 10.35.1.2
user@PE1# set link-management te-link link1 remote-address 10.35.1.1
```

15. Enable setting up of a Layer 2 VLAN LSP for a specific range of VLANs on the link1 traffic engineering link.

```
[edit protocols]
user@PE1# set link-management te-link link1 ethernet-vlan vlan-id-range 1-1000
```

16. Configure the Router PE1 interface as the member interface of the link1 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link1 interface ge-0/0/0
```

17. Configure Router CE1 as the LMP peer for Router PE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer CE1 address 10.255.10.1
user@CE1# set link-management peer CE1 control-channel gre.0
user@CE1# set link-management peer CE1 te-link link1
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces

- Verifying End-to-End Connectivity | 1410

Confirm that the configuration is working properly.

Verifying the Traffic Engineering Link Status on the Client Routers

Purpose

Verify the status of the traffic engineering link configured between Router CE1 and Router CE2.

Action

From operational mode, run the **show link-management** and the **show link-management te-link detail** commands.

```
user@CE1> show link-management
```

```
Peer name: PE1, System identifier: 50740
State: Up, Control address: 10.255.10.2
Hello interval: 150, Hello dead interval: 500
  Control-channel      State
  gre.0                Active
TE links:
  link10

TE link name: link10, State: Up
  Local identifier: 65075, Remote identifier: 0, Local address: 10.35.1.1, Remote

```

Name	State	Local ID	Remote ID	Bandwidth	Used
LSP-name					
ge-0/0/0	Up	54183	0	1000Mbps	Yes
CE1-to-CE2					

Meaning

The Link Management Protocol (LMP) peering has been established between the client routers, and the traffic engineering link is up on both Routers CE1 and CE2.

Verifying the RSVP Session Status on the Client Routers

Purpose

Verify the status of the RSVP sessions between Router CE1 and Router CE2.

Action

From operational mode, run the **show rsvp session** command.

```
user@CE1> show rsvp session
```

Ingress RSVP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.255.10.6	10.255.10.1	Up	0	1 FF	-	10	CE1-to-CE2 Bidir

Total 1 displayed, Up 1, Down 0

Egress RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

```
user@CE2> show rsvp session
```

Ingress RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Egress RSVP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.255.10.6	10.255.10.1	Up	0	1 FF	10	-	CE1-to-CE2 Bidir

Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning

The RSVP sessions are established between the ingress router, Router CE1, and the egress router, Router CE2.

Verifying the LSP Status on the Server Router

Purpose

Verify the status of the MPLS LSP on Router PE1.

Action

From operational mode, run the **show mpls lsp** command.

```
user@PE1> show mpls lsp
```

```
Ingress LSP: 1 sessions
To          From          State Rt P    ActivePath    LSPname
10.255.10.5  10.255.10.2    Up    0  *
vlan:0:10:8176:10.255.10.2->10.255.10.5 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
10.255.10.2  10.255.10.5    Up    0  1 FF      3      -
vlan:0:10:8176:10.255.10.2->10.255.10.5:rev
Total 1 displayed, Up 1, Down 0

Transit LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
10.255.10.6  10.255.10.1    Up    0  1 FF      10     299808 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0
```

Meaning

The CE1-to-CE2 LSP is established, and the output displays the LSP attributes.

Verifying the CCC Entries in the MPLS Routing Table of the Server Routers

Purpose

Verify the circuit cross-connect (CCC) interface entries in the MPLS routing table.

Action

From operational mode, run the **show route table mpls.0** and the **show route forwarding-table ccc ccc-interface** commands.

```
user@PE1> show route table mpls.0
```

```
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 1d 22:14:51, metric 1
           Receive
1          *[MPLS/0] 1d 22:14:51, metric 1
           Receive
2          *[MPLS/0] 1d 22:14:51, metric 1
           Receive
13         *[MPLS/0] 1d 22:14:51, metric 1
```

```

                Receive
299824          *[RSVP/7/1] 17:32:07, metric 1
                > via ge-0/0/0.10, Pop
ge-0/0/0.10     *[RSVP/7/1] 17:32:07, metric 1
                > to 20.20.20.2 via ge-0/0/2.0, label-switched-path CE1-to-CE2

```

```
user@PE1> show route forwarding-table ccc ge-0/0/0.10
```

```

Routing table: default.mpls
MPLS:
Destination      Type RtRef Next hop          Type Index   NhRef Netif
ge-0/0/0.10      (CCC) user    0 20.20.20.2      Push 299808, Push 299872(top)
581              2 ge-0/0/2.0

Routing table: __mpls-oam__.mpls
MPLS:
Destination      Type RtRef Next hop          Type Index   NhRef Netif
default          perm    0                      dscd    534     1

```

Meaning

The output displays the CCC interface that is the client-router-facing interface and the next-hop details for that interface.

Verifying End-to-End Connectivity

Purpose

Verify the connectivity between Router CE1 and the remote client router, Router CE2.

Action

From operational mode, run the **ping** command.

```
user@CE1> ping 10.10.10.2
```

```

PING 10.10.10.2 (10.10.10.2): 56 data bytes
64 bytes from 10.10.10.2: icmp_seq=0 ttl=64 time=15.113 ms
64 bytes from 10.10.10.2: icmp_seq=1 ttl=64 time=13.353 ms
64 bytes from 10.10.10.2: icmp_seq=2 ttl=64 time=13.769 ms
64 bytes from 10.10.10.2: icmp_seq=3 ttl=64 time=10.341 ms
64 bytes from 10.10.10.2: icmp_seq=4 ttl=64 time=12.597 ms
^C
--- 10.10.10.2 ping statistics ---

```

```
5 packets transmitted, 5 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 10.341/13.035/15.113/1.575 ms
```

Meaning

The ping from Router CE1 to Router CE2 is successful.

Virtual private networks (VPNs) are private networks that use a public network to connect two or more remote sites. Instead of dedicated connections between networks, VPNs use virtual connections routed (tunneled) through public networks that are typically service provider networks. VPNs are a cost-effective alternative to expensive dedicated lines. The type of VPN is determined by the connections it uses and whether the customer network or the provider network performs the virtual tunneling.

You can configure a router running Junos OS to participate in several types of VPNs. This topic discusses MPLS VPNs.

This topic contains the following sections:

MPLS VPN Topology

There are many ways to set up an MPLS VPN and direct traffic through it. [Figure 110 on page 1417](#) shows a typical MPLS VPN topology.

Figure 110: Typical VPN Topology

There are three primary types of MPLS VPNs: Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. All types of MPLS VPNs share certain components:

- The provider edge (PE) routers in the provider's network connect to the customer edge (CE) routers located at customer sites. PE routers support VPN and MPLS label functionality. Within a single VPN, pairs of PE routers are connected through a virtual tunnel, typically a label-switched path (LSP).
- Provider routers within the core of the provider's network are not connected to any routers at a customer site but are part of the tunnel between pairs of PE routers. Provider routers support LSP functionality as part of the tunnel support, but do not support VPN functionality.
- CE routers are the routers or switches located at the customer site that connect to the provider's network. CE routers are typically IP routers, but they can also be Asynchronous Transfer Mode (ATM), Frame Relay, or Ethernet switches.

All VPN functions are performed by the PE routers. Neither CE routers nor provider routers are required to perform any VPN functions.

MPLS VPN Routing

VPNs tunnel traffic as follows from one customer site to another customer site, using a public network as a transit network, when certain requirements are met:

1. Traffic is forwarded by standard IP forwarding from the CE routers to the PE routers.
2. The PE routers establish an LSP through the provider network.
3. The inbound PE router receives traffic, and it performs a route lookup. The lookup yields an LSP next hop, and the traffic is forwarded along the LSP.
4. The traffic reaches the outbound PE router, and the PE router pops the MPLS label and forwards the traffic with standard IP routing.

VRF Instances

A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The interfaces belong to the routing tables, and the routing protocol parameters control the information in the routing tables. In the case of MPLS VPNs, each VPN has a VPN routing and forwarding (VRF) instance.

A VRF instance consists of one or more routing tables, a derived forwarding table, the interfaces that use the forwarding table, and the policies and routing protocols that determine what goes into the forwarding table. Because each instance is configured for a particular VPN, each VPN has separate tables, rules, and policies that control its operation.

A separate VRF table is created for each VPN that has a connection to a CE router. The VRF table is populated with routes received from directly connected CE sites associated with the VRF instance, and with routes received from other PE routers in the same VPN.

Route Distinguishers

Because a typical transit network is configured to handle more than one VPN, the provider routers are likely to have multiple VRF instances configured. As a result, depending on the origin of the traffic and any filtering rules applied to the traffic, the BGP routing tables can contain multiple routes for a particular destination address. Because BGP requires that exactly one BGP route per destination be imported into the forwarding table, BGP must have a way to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs.

A route distinguisher is a locally unique number that identifies all route information for a particular VPN. Unique numeric identifiers allow BGP to distinguish between routes that are otherwise identical.

Each routing instance that you configure on a PE router must have a unique route distinguisher. There are two possible formats:

- **as-number:number**, where **as-number** is an autonomous system (AS) number (a 2-byte value) in the range 1 through 65,535, and **number** is any 4-byte value. We recommend that you use an Internet Assigned Numbers Authority (IANA)-assigned, nonprivate AS number, preferably the ISP or the customer AS number.
- **ip-address:number**, where **ip-address** is an IP address (a 4-byte value) and **number** is any 2-byte value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a public IP address in your assigned prefix range.

The route target defines which route is part of a VPN. A unique route target helps distinguish between different VPN services on the same router. Each VPN also has a policy that defines how routes are imported into the VRF table on the router. A Layer 2 VPN is configured with import and export policies. A Layer 3 VPN uses a unique route target to distinguish between VPN routes.

The PE router then exports the route in IBGP sessions to the other provider routers. Route export is governed by any routing policy that has been applied to the particular VRF table. To propagate the routes through the provider network, the PE router must also convert the route to VPN format, which includes the route distinguisher.

When the outbound PE router receives the route, it strips off the route distinguisher and advertises the route to the connected CE router, typically through standard BGP IPv4 route advertisements.

MPLS Exceptions on SRX Series Devices

The MPLS implementation on SRX Series device is similar to MPLS implementations on M Series, T Series, and MX Series routers, with the following exception:

- SRX Series devices do not support aggregated Ethernet interfaces. Therefore, aggregated Ethernet interfaces between CE devices and PE routers are not supported for MPLS implementations of Layer 2 VPNs and Layer 2 Circuits on SRX Series devices.

Understanding IPv6 Layer 3 VPNs

The interfaces between the PE and CE routers of a Layer 3 VPN can be configured to carry IP version 6 (IPv6) traffic. IP allows numerous nodes on different networks to interoperate seamlessly. IPv4 is currently used in intranets and private networks, as well as the Internet. IPv6 is the successor to IPv4, and is based for the most part on IPv4.

In the Juniper Networks implementation of IPv6, the service provider implements an MPLS-enabled IPv4 backbone to provide VPN service for IPv6 customers. The PE routers have both IPv4 and IPv6 capabilities. They maintain IPv6 VPN routing and forwarding (VRF) tables for their IPv6 sites and encapsulate IPv6 traffic in MPLS frames that are then sent into the MPLS core network.

IPv6 for Layer 3 VPNs is supported for BGP and for static routes.

IPv6 over Layer 3 VPNs is described in RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*.

Understanding Using MPLS-Based Layer 3 VPNs on Switches

IN THIS SECTION

- [MPLS-Based Layer 3 VPNs | 1420](#)

On the QFX Series switches and on EX4600 switches, you can use MPLS-based Layer 3 virtual private networks (VPNs) to securely connect geographically diverse sites across an MPLS network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

A VPN uses a public telecommunications infrastructure, such as the Internet, to provide remote offices or individual users with secure access to their organization's network. VPNs are designed to provide the same level of performance and security as privately owned or leased networks but without the attendant costs.

This topic describes:

MPLS-Based Layer 3 VPNs

In Junos OS, Layer 3 VPNs are based on RFC 4364, [BGP/MPLS IP Virtual Private Networks](#). RFC 4364 defines a mechanism by which service providers can use their IP backbones to provide VPN services to their customers. A Layer 3 VPN is a set of sites that share common routing information and whose

connectivity is controlled by a collection of policies. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone.

Customer networks, because they are private, can use either public or private addresses, as defined in RFC 1918, [Address Allocation for Private Internets](#). When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the same private addresses used by other network users. BGP/MPLS VPNs solve this problem by adding a VPN identifier prefix to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and on the public Internet. In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only. Two different VPNs can use overlapping addresses. Each route within a VPN is assigned an MPLS label (for example, MPLS-ARCH, MPLS-BGP, or MPLS-ENCAPS). When BGP distributes a VPN route, it also distributes an MPLS label for that route. Before a customer data packet travels across the service provider's backbone, it is encapsulated along with the MPLS label that corresponds to the route within the customer's VPN that is the best match based on the packet's destination address. This MPLS packet is further encapsulated with another MPLS label or with an IP, so that it gets tunneled across the backbone to the egress provider edge (PE) switch. Thus, the backbone core switches do not need to know the VPN routes.

QFX5100 switches also support interprovider VPNs, and carrier-of-carriers VPNs. For more information, see ["Understanding Interprovider and Carrier-of-Carriers VPNs" on page 1647](#)

Configuring a BGP Session for MPLS VPNs (CLI Procedure)

NOTE: This section is valid for Layer 2 VPNs and Layer 3 VPNs, but not Layer 2 circuits.

To configure an IBGP session, perform the following steps on each PE router:

1. Configure BGP.

[edit]

```
user@host# edit protocols bgp group group-name
```

2. Set the BGP type to internal.

```
[edit protocols bgp group group-name]  
user@host# set type internal
```

3. Specify the loopback interface.

```
[edit protocols bgp group group-name]  
user@host# set local-address loopback-interface-ip-address
```

4. Set the Layer 2 or Layer 3 VPN family type to unicast.

```
[edit protocols bgp group group-name]  
user@host# set family family-type unicast
```

Replace *family-type* with **l2vpn** for a Layer 2 VPN or **inet-vpn** for a Layer 3 VPN.

5. Enter the loopback address of the neighboring PE router.

```
[edit protocols bgp]  
user@host# set neighbor ip-address
```

6. Commit the configuration if you are finished configuring the device.

```
[edit]  
user@host# commit
```

Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)

To configure RSVP and OSPF:

1. Configure OSPF with traffic engineering support on the PE routers.

```
[edit]
user@host# edit protocols ospf traffic-engineering shortcuts
```

NOTE: You must configure the IGP at the **[edit protocols]** level, not within the routing instance at the **[edit routing-instances]** level.

2. Enable RSVP on interfaces that participate in the LSP. For PE routers, enable interfaces on the source and destination points. For provider routers, enable interfaces that connect the LSP between the PE routers.

```
[edit]
user@host# edit protocols rsvp interface interface-name
```

3. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring Routing Options for MPLS VPNs (CLI Procedure)

To configure routing options for a VPN:

1. Configure the AS number.

```
[edit]
user@host# set routing-options autonomous-system as-number
```

2. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring a Routing Instance for MPLS VPNs (CLI Procedure)

To configure a VPN routing instance on each PE router:

1. Create the routing instance.

```
[edit]
user@host# edit routing-instances routing-instance-name
```

2. Create a routing instance description. (This text appears in the output of the **show route instance detail** command.)

```
[edit routing-instances routing-instance-name]
user@host# set description "text"
```

3. Specify the instance type, either **l2vpn** for Layer 2 VPNs or **vrf** for Layer 3 VPNs.

```
[edit routing-instances routing-instance-name]
user@host# set instance-type instance-type
```

4. Specify the interface of the remote PE router.

```
[edit routing-instances routing-instance-name]  
user@host# set interface interface-name
```

5. Specify the route distinguisher using one of the following commands:

```
[edit routing-instances routing-instance-name]  
user@host# set route-distinguisher as-number:number  
user@host# set route-distinguisher ip-address:number
```

6. Specify the policy for the Layer 2 VRF table.

```
[edit routing-instances routing-instance-name]  
user@host# set vrf-import import-policy-name vrf-export export-policy-name
```

7. Specify the policy for the Layer 3 VRF table.

```
[edit routing-instances routing-instance-name]  
user@host# set vrf-target target:community-id
```

Where *community-id* is either *as-number:number* or *ip-address:number*.

8. Commit the configuration if you are finished configuring the device.

```
[edit]  
user@host# commit
```

Chained Composite Next Hops for Transit Devices for VPNs

The Juniper Networks PTX Series Packet Transport Routers, MX Series 5G Universal Routing Platforms with MIC and MPC interfaces, T4000 Core Routers, and QFX10000 switches are principally designed to handle large volumes of transit traffic in the core of large networks. Chained composite next hops help to facilitate this capability by allowing the router to process much larger volumes of routes. A chained composite next hop allows the router to direct sets of routes sharing the same destination to a common forwarding next hop, rather than having each route also include the destination. In the event that a network destination is changed, rather than having to update all of the routes sharing that destination with the new information, just the shared forwarding next hop is updated with the new information. The chained composite next hops continue to point to this forwarding next hop which now contains the new destination.

When the next hops for MPLS LSPs are created on the routers, the tag information corresponding to the inner-most MPLS label is extracted into a chained composite next hop. The chained composite next hop is stored in the ingress PFE. The chained composite next hop points to a next hop called the forwarding next hop that resides on the egress PFE. The forwarding next hop contains all of the other information (all of the labels except for the inner-most labels; and the IFA/IP information corresponding to the actual next hop node). Many chained composite next hops can share the same forwarding next hop. Additionally, separating the label from the forwarding next hop and storing it on the ingress PFE (within the chained composite next hop) helps to conserve egress PFE memory by reducing the number of rewrite strings stored on the egress PFE.

The support of chained composite next hops for directly connected Provider Edge (PE) routers varies from one platform to another.

On platforms containing only MPCs, such as PTX Series Packet Transport Routers, the MX80 router, the MX2020 router, and the QFX10000 switches, chained composite next hops are enabled by default for the following MPLS and VPN protocols and applications:

NOTE: Point-to-Multipoint LSPs and Layer 2 VPNs are not supported on the QFX10000 switches.

- Labeled BGP
- Layer 2 VPNs
- Layer 3 VPNs
- LDP
- MPLS
- Point-to-Multipoint LSPs
- RSVP
- Static LSPs

On MX Series 5G Universal Routing Platforms containing both DPC and MPC FPCs, chained composite next hops are disabled by default.

To enable chained composite next hops on the MX Series routers such as: MX80, MX240, MX480, MX960 and MX2020, the chassis must be configured to use the **enhanced-ip** option in network services mode.

On T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default.

To enable chained composite next hops on a T4000 router, the chassis must be configured to use the **enhanced-mode** option in network services mode.

For more information about configuring chassis network services, see the *Junos OS Administration Library*.

Understanding MPLS Layer 2 VPNs

In an MPLS Layer 2 VPN, traffic is forwarded to the provider edge (PE) router in Layer 2 format, carried by MPLS through an label-switched path (LSP) over the service provider network, and then converted back to Layer 2 format at the receiving customer edge (CE) router.

Routing occurs on the customer routers, typically on the CE router. The CE router connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The PE router receiving the traffic sends it across the network to the PE router on the outbound side. The PE routers need no information about the customer's routes or routing topology, and need only to determine the virtual tunnel through which to send the traffic.

Implementing a Layer 2 VPN on the router is similar to implementing a VPN using a Layer 2 technology such as Asynchronous Transfer Mode (ATM) or Frame Relay.

Understanding Ethernet-over-MPLS (L2 Circuit)

IN THIS SECTION

- [Ethernet-over-MPLS in Data Centers | 1428](#)

Ethernet-over-MPLS allows sending Layer 2 (L2) Ethernet frames transparently over MPLS. Ethernet-over-MPLS uses a tunneling mechanism for Ethernet traffic through an MPLS-enabled Layer 3 core. It encapsulates Ethernet protocol data units (PDUs) inside MPLS packets and forwards the packets, using label stacking, across the MPLS network. This technology has applications in service provider, enterprise and data center environments. For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network.

NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) routers. In contrast, each CCC requires a dedicated LSP.

Ethernet-over-MPLS in Data Centers

For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network. These data centers require L2 connectivity between them for the following reasons:

- To replicate the storage over Fiber Channel IP (FCIP). FCIP works only on the same broadcast domain.
- To run a dynamic routing protocol between the sites.
- To support High Availability clusters that interconnect the nodes hosted in the various data centers.

MPLS Layer 2 VPN Configuration Overview

To configure MPLS Layer 2 VPN functionality on a router running Junos OS, you must enable support on the provider edge (PE) router and configure the PE router to distribute routing information to other routers in the VPN, as explained in the following steps. However, because the tunnel information is maintained at both PE routers, neither the provider core routers nor the customer edge (CE) routers need to maintain any VPN information in their configuration databases.

To configure an MPLS Layer 2 VPN:

1. Determine all of the routers that you want to participate in the VPN, and then complete the initial configuration of their interfaces. See *Interfaces User Guide for Security Devices*.
2. For all of the routers in the VPN configuration, update the interface configurations to enable participation in the Layer 2 VPN. As part of the interface configuration, you must configure the MPLS address family for each interface that uses LDP or RSVP. See [“Configuring Interfaces for Layer 2 VPNs \(CLI Procedure\)” on page 1432](#).
3. For all of the routers in the VPN configuration, configure the appropriate protocols.
 - a. MPLS—For PE routers and provider routers, use MPLS to advertise the Layer 2 VPN interfaces that communicate with other PE routers and provider routers.
 - b. BGP and internal BGP (IBGP)—For PE routers, configure a BGP session to enable the routers to exchange information about routes originating and terminating in the VPN. (The PE routers use this information to determine which labels to use for traffic destined to the remote sites. The IBGP session for the VPN runs through the loopback address.) In addition, CE routers require a BGP connection to the PE routers. See [“Configuring a BGP Session for MPLS VPNs \(CLI Procedure\)” on page 1421](#).
 - c. IGP and a signaling protocol—For PE routers, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but you cannot use them for interfaces between PE routers and CE routers.

In addition, configure an IGP such as OSPF or static routes for PE routers to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

See [“Configuring an IGP and the LDP Signaling Protocol \(CLI Procedure\)” on page 1466](#) and [“Configuring an IGP and the RSVP Signaling Protocol \(CLI Procedure\)” on page 1423](#).

4. For all of the routers in the VPN configuration, configure routing options. The only required routing option for VPNs is the AS number. You must specify it on each router involved in the VPN. See [“Configuring Routing Options for MPLS VPNs \(CLI Procedure\)” on page 1423](#).
5. For each PE router in the VPN configuration, configure a routing instance for each VPN. The routing instance should have the same name on each PE router. Each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP distinguish between potentially identical network layer reachable information [NLRI] messages received from different VPNs.) See [“Configuring a Routing Instance for MPLS VPNs \(CLI Procedure\)” on page 1424](#).
6. For each PE router in the VPN configuration, configure a VPN routing policy if you are not using a route target. Within the policy, describe which packets are sent and received across the VPN and specify how routes are imported into and exported from the router's VRF table. Each advertisement must have an associated route target that uniquely identifies the VPN for which the advertisement is valid. If the routing instance uses a policy for accepting and rejecting packets instead of a route target, you must specify the import and export routing policies and the community on each PE router. See [“Configuring a Routing Policy for MPLS Layer 2 VPNs \(CLI Procedure\)” on page 1430](#).

RELATED DOCUMENTATION

[Verifying an MPLS Layer 2 VPN Configuration | 1459](#)

Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure)

These instructions show how to configure a Layer 2 VPN routing policy on the PE routers in the VPN.

After configuring an import routing policy for a Layer 2 VPN, configure an export routing policy for the Layer 2 VPN. Configure this export policy on the PE routers in the VPN. The export routing policy defines how routes are exported from the PE router routing table. An export policy is applied to routes sent to other PE routers in the VPN. The export policy must also evaluate all routes received over the routing protocol session with the CE router. The export policy must also contain a second term for rejecting all other routes.

To configure a Layer 2 VPN routing policy on a PE router:

1. Configure the import routing policy.

```
[edit]
user@host# edit policy-options policy-statement import-policy-name
```

2. Define the import policy's term for accepting packets.

```
[edit edit policy-options policy-statement import-policy-name]
user@host# set term term-name-accept from protocol bgp community community-name
user@host# set term term-name-accept then accept
```

3. Define the import policy's term for rejecting packets.

```
[edit edit policy-options policy-statement import-policy-name]
user@host# set term term-name-reject then reject
```

4. Configure the export routing policy.

```
[edit]
user@host# edit policy-options policy-statement export-policy-name
```

5. Define the export policy's term for accepting packets.

```
[edit policy-options policy-statement export-policy-name]
user@host# set term term-name-accept from community add community-name
user@host# set term term-name-accept then accept
```

6. Define the export policy's term for rejecting packets.

```
[edit policy-options policy-statement export-policy-name]
user@host# set term term-name-reject from community add community-name
user@host# set term term-name-reject then reject
```

7. Define the export policy's community using one of the following commands.

```
[edit policy-options policy-statement export-policy-name]
user@host# community community-name target: as-number
user@host# community community-name target: ip-address:number
```

8. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

[MPLS Layer 3 VPN Configuration Overview | 1471](#)

Configuring Interfaces for Layer 2 VPNs (CLI Procedure)

Configuring the device interfaces that participate in the VPN is similar to configuring them for other uses, with a few requirements for the VPN. Perform the following tasks for each interface involved in the VPN, except Layer 3 loopback interfaces, which do not require other configuration.

To configure an interface for an MPLS VPN:

1. Configure IPv4 address and loopback address on all of the interfaces of the provider edge (PE) and provider (P) devices, excluding the Layer 2 VPN interfaces facing a customer edge (CE) device:

```
[edit interfaces]
user@host# set interface-name unit logical-unit-number family inet address ipv4_address
user@host# set lo0 unit logical-unit-number family inet address ipv4_address primary
```

2. Enable MPLS address family on all the PE and P device interfaces, excluding the loopback interfaces and the CE-facing Layer 2 VPN interfaces.

```
[edit interfaces]
user@host# set interface-name unit logical-unit-number family mpls
```

3. For CE-facing Layer 2 VPN interfaces, enable the reception and transmission of 802.1Q VLAN-tagged frames on the interface.

```
[edit interfaces]
user@host# set interfaces interface-name vlan-tagging encapsulation vlan-ccc unit logical-unit-number
encapsulation vlan-ccc vlan-id vlan-id-number
```

4. Configure the physical and logical link-layer encapsulation type on all the PE devices that communicate with the CE devices on Layer 2 VPNs and Layer 2 circuits.

```
[edit interfaces]
user@host# set interface-name encapsulation encapsulation-type
user@host# set interface-name unit logical-unit-number encapsulation encapsulation-type
```

5. Commit the configuration if you are finished configuring the device.

```
[edit]
user@host# commit
```

Configuring Ethernet over MPLS (L2 Circuit)

IN THIS SECTION

- [Configuring the Local PE Switch for Port-Based Layer 2 Circuit \(Pseudo-wire\) | 1435](#)
- [Configuring the Remote PE Switch for Port-Based Layer 2 Circuit \(Pseudo-wire\) | 1436](#)
- [Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit | 1436](#)
- [Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit | 1437](#)

To implement Ethernet over MPLS, you must configure a Layer 2 circuit on the provider edge (PE) switches. No special configuration is required on the customer edge (CE) switches. The provider switches require MPLS and LDP to be configured on the interfaces that will be receiving and transmitting MPLS packets.

NOTE: A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two PE switches. In contrast, each CCC requires a dedicated LSP.

This topic describes how to configure the PE switches to support Ethernet over MPLS. You must configure interfaces and protocols on both the local PE (PE1) and the remote PE (PE2) switches. The interface configuration varies depending upon whether the Layer 2 circuit is port-based or VLAN-based.

Figure 111 on page 1434 shows an example of a Layer 2 circuit configuration.

Figure 111: Ethernet over MPLS Layer 2 Circuit

NOTE: This topic refers to the local PE switch as PE1 and the remote PE switch as PE2. It also uses interface names rather than variables to help clarify the connections between the switches. The loopback addresses of the switches are configured as follows:

- PE1: 127.1.1.1
- PE2: 127.1.1.2

NOTE: On QFX Series and EX4600 switches, the L2 circuit CE facing interface does not support AE interfaces.

Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

CAUTION: Configure MPLS networks with an MTU (maximum transmission unit) that is at least 12 bytes larger than the largest frame size that will be transported by the LSPs. If the size of a encapsulated packet on the ingress LSR exceeds the LSP MTU, that packet is dropped. If an egress LSR receives a packet on a VC LSP with a length (after the label stack and sequencing control word have been popped) that exceeds the MTU of the destination layer 2 interface, that packet is also dropped.

To configure the local PE switch (PE1) for a port-based layer 2 circuit (pseudo-wire):

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch# set l2circuit neighbor 127.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch# set mpls label-switched-path PE1-to-PE2 to 127.1.1.1
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch# set mpls interface xe-0/0/7
user@switch# set ldp interface lo0.0
```

Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

To configure the remote PE switch (PE2) for a port-based layer 2 circuit:

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

2. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch# set l2circuit neighbor 127.1.1.2 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch# set mpls label-switched-path PE2-to-PE1 to 127.1.1.2
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch# set mpls interface xe-0/0/7
user@switch# set ldp interface lo0.0
```

Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit

To configure the local PE switch (PE1) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch#set l2circuit neighbor 127.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch#set mpls label-switched-path PE1-to-PE2 to 127.1.1.1
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch#set mpls interface xe-0/0/7
user@switch#set ldp interface lo0.0
```

Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit

To configure the remote PE switch (PE2) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch# set l2circuit neighbor 127.1.1.2 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch# set mpls label-switched-path PE2-to-PE1 to 127.1.1.2
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch# set mpls interface xe-0/0/7
user@switch# set ldp interface lo0.0
```

RELATED DOCUMENTATION

Example: Configuring MPLS-Based Layer 2 VPNs

IN THIS SECTION

- [Requirements | 1439](#)
- [Overview and Topology | 1439](#)
- [Configuring the Local PE Routing Device | 1443](#)
- [Configuring the Remote PE Routing Device | 1447](#)
- [Verification | 1450](#)

You can implement an MPLS-based Layer 2 virtual private network (VPN) using Junos OS routing devices to interconnect customer sites with Layer 2 technology. Layer 2 VPNs give customers complete control of their own routing. To support an MPLS-based Layer 2 VPN, you need to add components to the configuration of the two provider edge (PE) routing devices. You do not need to change the configuration of the provider devices.

This example shows how to configure an MPLS-based Layer 2 VPN.

NOTE: You can configure both an MPLS-based Layer 2 VPN and an MPLS-based Layer 3 VPN on the same device. However, you cannot configure the same customer edge interface to support both a Layer 2 VPN and a Layer 3 VPN. The core interfaces and the loopback interfaces are configured in the same way for Layer 2 VPNs and Layer 3 VPNs.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1 or later if you are using EX Series switches
- Two PE routing devices

Before you configure the Layer 2 VPN components, configure the basic components for an MPLS network:

- Configure two PE routing devices. See [“Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\)” on page 95](#).
- Configure one or more provider devices. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 99](#).

NOTE: A Layer 2 VPN requires that the PE routing devices be configured using circuit cross-connect (CCC). The provider routing devices are configured in the same way for MPLS using CCC and for IP over MPLS.

Overview and Topology

A Layer 2 VPN provides complete separation between the provider’s network and the customer’s network—that is, the PE devices and the CE devices do not exchange routing information. Some benefits of a Layer 2 VPN are that it is private, secure, and flexible.

This example shows how to configure Layer 2 VPN components on the local and remote PE devices. This example does not include configuring a provider device, because there are no specific Layer 2 VPN components on the provider devices.

In the basic MPLS configuration of the PE devices using a circuit cross-connect (CCC), the PE devices are configured to use an interior gateway protocol (IGP), such as OSPF or IS-IS, as the routing protocol between the MPLS devices and LDP or RSVP as the signaling protocol. Traffic engineering is enabled. A label-switched path (LSP) is configured within the **[edit protocols]** hierarchy. However, unlike the basic MPLS configuration using a CCC, you do not need to associate the LSP with the customer edge interface. When you are configuring a Layer 2 VPN, you must use BGP signaling. The BGP signaling automates the connections, so manual configuration of the association between the LSP and the customer edge interface is not required.

The following components must be added to the PE routing devices for an MPLS-based Layer 2 VPN:

- BGP group with **family l2vpn signaling**
- Routing instance using instance type **l2vpn**
- The physical layer encapsulation type (**ethernet**) must be specified on the customer edge interface and the encapsulation type must also be specified in the configuration of the routing instance.

Figure 112 on page 1440 illustrates the topology of this MPLS-based Layer 2 VPN.

Figure 112: MPLS-Based Layer 2 VPN

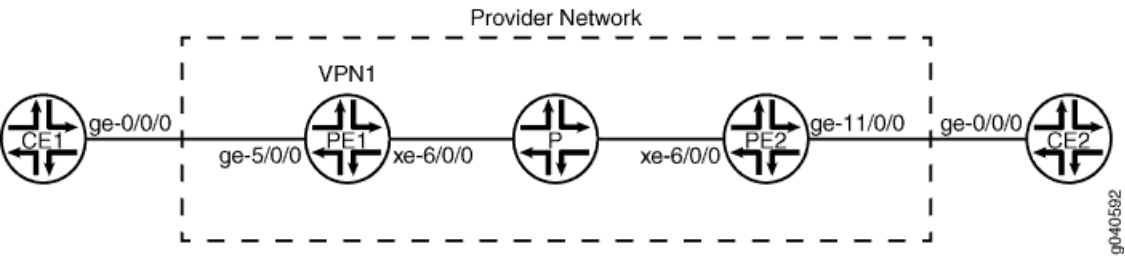

Table 33 on page 1440 shows the settings of the customer edge interface on the local CE device.

Table 33: Local CE Routing Device in the MPLS-Based Layer 2 VPN Topology

Property	Settings	Description
Local CE routing device hardware	Routing device	CE1
Customer edge interface	ge-0/0/0 unit 0 family inet address 10.0.0.2/16	Interface that connects CE1 to PE1.

Table 34 on page 1441 shows the settings of the customer edge interface on the remote CE routing device.

Configuring the Local PE Routing Device

CLI Quick Configuration

To quickly configure the Layer 2 VPN components on the local PE routing device, copy the following commands and paste them into the routing device terminal window:

```
[edit]
set interfaces ge-5/0/0 encapsulation ethernet-ccc
set protocols bgp group ibgp local-address 192.0.2.0 family l2vpn signaling
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 192.0.2.3
set routing-instances vpn1 instance-type l2vpn
set routing-instances vpn1 interface ge-5/0/0
set routing-instances vpn1 route-distinguisher 192.0.2.0:21
set routing-instances vpn1 vrf-target target:21:21
set routing-instances vpn1 protocols l2vpn encapsulation-type ethernet
set routing-instances vpn1 protocols l2vpn interface ge-5/0/0.0 description "BETWEEN PE1 AND CE1"
set routing-instances vpn1 protocols l2vpn site JE-V21 site-identifier 21 interface ge-5/0/0 remote-site-id
26
```

Step-by-Step Procedure

To configure the Layer 2 VPN components on the local PE routing device:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

```
[edit]
user@PE1# set interfaces ge-5/0/0 encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```
[edit protocols bgp]
user@PE1# set group ibgp local-address 192.0.2.0 family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@PE1# set group ibgp type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE routing device as the neighbor's address:

```
[edit protocols bgp]
user@PE1# set group ibgp neighbor 192.0.2.3/24
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@PE1# set vpn1 instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@PE1# set vpn1 interface ge-5/0/0
```

7. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 192.0.2.0:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@PE1# set vpn1 vrf-target target:21:21
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@PE1# set vpn1 protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@PE1# set vpn1 protocols interface ge-5/0/0.0 description "BETWEEN PE1 AND CE1"
```

11. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@PE1# set vpn1 protocols l2vpn site JE-V21 site-identifier 21 remote-site-id 26
```

NOTE: The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured on the other PE routing device.

Results

Display the results of the configuration:

```
user@PE1# show
```

```

            }
        }
    }
}
}
}
}

```

Configuring the Remote PE Routing Device

CLI Quick Configuration

To quickly configure the Layer 2 VPN components on the remote PE routing device, copy the following commands and paste them into the routing device terminal window:

```
[edit]
set interfaces ge-11/0/0 encapsulation ethernet-ccc
set protocols bgp group ibgp local-address 192.0.2.3 family l2vpn signaling
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 192.0.2.0
set routing-instances vpn1 instance-type l2vpn
set routing-instances vpn1 interface ge-11/0/0
set routing-instances vpn1 route-distinguisher 192.0.2.0:21
set routing-instances vpn1 vrf-target target:21:21
set routing-instances vpn1 protocols l2vpn encapsulation-type ethernet
set routing-instances vpn1 protocols l2vpn interface ge-11/0/0.0 description "BETWEEN PE1 AND CE1"
set routing-instances vpn1 protocols l2vpn site T26-VPN1 site-identifier 26 remote-site-id 21
```

Step-by-Step Procedure

To configure the Layer 2 VPN components on the remote PE routing device:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

```
[edit]
user@PE1# set interfaces ge-11/0/0 encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address as the **local-address** and specifying **family l2vpn signaling**:

```
[edit protocols bgp]
user@PE2# set group ibgp local-address 192.0.2.3 family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@PE2# set group ibgp type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE routing device as the neighbor's address:

```
[edit protocols bgp]
user@PE2# set group ibgp neighbor 192.0.2.0
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the **instance-type**:

```
[edit routing-instances]
user@PE2# set vpn1 instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@PE2# set vpn1 interface ge-11/0/0.0
```

7. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

```
[edit routing-instances]
user@PE2# set vpn1 route-distinguisher 192.0.2.0:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@PE2# set vpn1 vrf-target target:21:21
```

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@PE2# set vpn1 protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@PE1# set vpn1 protocols interface ge-11/0/0.0 description "BETWEEN PE1 AND CE1"
```

11. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@PE2# set vpn1 protocols l2vpn site T26-VPN1 site-identifier 26 remote-site-id 21
```

NOTE: The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured on the other PE routing device.

Results

Display the results of the configuration:

user@PE2# **show**

```

Verification

IN THIS SECTION

- [Verifying the Layer 2 VPN Connection | 1451](#)
- [Verifying the Status of MPLS Label-Switched Paths | 1452](#)
- [Verifying BGP Status | 1452](#)
- [Verifying the Status of the RSVP Sessions | 1453](#)
- [Verifying the Routes in the Routing Table | 1454](#)
- [Pinging the Layer 2 VPN Connections | 1455](#)

To confirm that the MPLS-based Layer 2 VPN is working properly, perform these tasks:

Verifying the Layer 2 VPN Connection

Purpose

Verify that the Layer 2 VPN connection is up.

Action

user@PE1> show l2vpn connections

```

Layer-2 VPN connections:

Legend for connection status (St)
EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch     WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down   NP -- interface hardware not present
CM -- control-word mismatch     -> -- only outbound connection is up
CN -- circuit not provisioned    <- -- only inbound connection is up
OR -- out of range              Up -- operational
OL -- no outgoing label         Dn -- down
LD -- local site signaled down  CF -- call admission control failure
RD -- remote site signaled down SC -- local and remote site ID collision
LN -- local site not designated LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status IL -- no incoming label
MM -- MTU mismatch              MI -- Mesh-Group ID not available
BK -- Backup connection         ST -- Standby connection
PF -- Profile parse failure     PB -- Profile busy
RS -- remote site standby       SN -- Static Neighbor

Legend for interface status
Up -- operational
Dn -- down

Instance: vpn1
  Local site: JE-V21 (21)
    connection-site      Type  St      Time last up      # Up trans
    26                   rmt   Up      Apr 16 05:53:21 2010      1
    Remote PE: 192.0.2.3, Negotiated control-word: Yes (Null)
    Incoming label: 800000, Outgoing label: 800001
    Local interface: ge-5/0/0.0, Status: Up, Encapsulation: ETHERNET

```

Meaning

The **St** field in the output shows that the Layer 2 VPN connection to **Remote PE (192.0.2.3)** is up.

Verifying the Status of MPLS Label-Switched Paths

Purpose

Verify that the MPLS label-switched paths (ingress and egress) are up.

Action

user@PE1> **show mpls lsp**

Ingress LSP: 1 sessions

To	From	State	Rt	P	ActivePath	LSPname
192.0.2.3	192.0.2.0	Up	0	*		lsp_to_pe2

Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
192.0.2.0	192.0.2.3	Up	0	1 FF	3	-	lsp_to_pe1

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning

The **State** field in the output shows that the Ingress LSP to **Remote PE (192.0.2.3)** is up, and the Egress LSP from the remote PE routing device to this PE routing device (**192.0.2.0**) is also up.

Verifying BGP Status

Purpose

Verify that BGP is up.

Action

user@PE1> **show bgp summary**

```

Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
bgp.l2vpn.0          1          1          0          0          0          0
Peer              AS      InPkt    OutPkt    OutQ    Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
192.0.2.3           10         33         34         0         1        13:24 Establ

    bgp.l2vpn.0: 1/1/1/0
    vpn2.l2vpn.0: 1/1/1/0

```

Meaning

The output shows that the remote PE routing device (**192.0.2.3**) is listed as the BGP peer and that a protocol session has been established. It also shows the number of packets received from the remote PE routing device (**33**) and the number of packets sent (**34**) to the remote PE routing device.

Verifying the Status of the RSVP Sessions

Purpose

Verify that the RSVP sessions (ingress and egress) are up.

Action

```
user@PE1> show rsvp session
```

```

Ingress RSVP: 1 sessions
To          From          State    Rt  Style  Labelin Labelout LSPname
192.0.2.3    192.0.2.0    Up        0  1 FF      -    462880 lsp_to_pe2
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To          From          State    Rt  Style  Labelin Labelout LSPname
192.0.2.0    192.0.2.3    Up        0  1 FF      3      -    lsp_to_pe1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The output shows that both the ingress RSVP session and the egress RSVP session are up.

Verifying the Routes in the Routing Table

Purpose

On routing device PE 1, use the **show route table** command to verify that the routing table is populated with the Layer 2 VPN routes used to forward the traffic.

Action

user@PE1> **show route table** bgp.l2vpn.0

```
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192:2:27:27/96
    *[BGP/170] 00:13:55, localpref 100, from 192.0.2.3
    AS path: I
    > to 10.2.0.24 via ge-6/0/46.0, label-switched-path lsp_to_pe2
```

user@PE1> **show route table** vpn1.l2vpn.0

```
vpn1.l2vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192:2:27:27/96
    *[BGP/170] 00:14:00, localpref 100, from 192.0.2.3
    AS path: I
    > to 10.2.0.24 via ge-6/0/46.0, label-switched-path lsp_to_pe2

192:2:28:27/96
    *[L2VPN/170/~101] 00:15:55, metric2 1
    Indirect
```

Meaning

The command **show route table bgp.l2vpn.0** displays all Layer 2 VPN routes that have been created on this routing device. The command **show route table vpn1.l2vpn.0** shows the Layer 2 VPN routes that have been created for the routing instance **vpn1**.

Pinging the Layer 2 VPN Connections

Purpose

Verify connectivity.

Action

```
user@PE1> ping mpls l2vpn interface xe-6/0/0.0 reply-mode ip-udp
```

```
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@PE1> ping mpls l2vpn instance vpn1 remote-site-id 26 local-site-id 21 detail
```

```
Request for seq 1, to interface 68, labels <800001, 100176>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 68, labels <800001, 100176>
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 68, labels <800001, 100176>
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 68, labels <800001, 100176>
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 68, labels <800001, 100176>
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Meaning

The output shows that connectivity is established.

Understanding Using MPLS-Based Layer 2 and Layer 3 VPNs on EX Series Switches

IN THIS SECTION

- [MPLS-Based Layer 2 VPNs | 1456](#)
- [Layer 2 Circuits | 1457](#)
- [MPLS-Based Layer 3 VPNs | 1457](#)
- [Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN | 1458](#)

On EX8200 and EX4500 switches, you can use MPLS-based Layer 2 and Layer 3 virtual private networks (VPNs) or MPLS Layer 2 circuits, allowing you to securely connect geographically diverse sites across an MPLS network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

A VPN uses a public telecommunications infrastructure, such as the Internet, to provide remote offices or individual users with secure access to their organization's network. VPNs are designed to provide the same level of performance and security as privately owned or leased networks but without the attendant costs.

This topic describes:

MPLS-Based Layer 2 VPNs

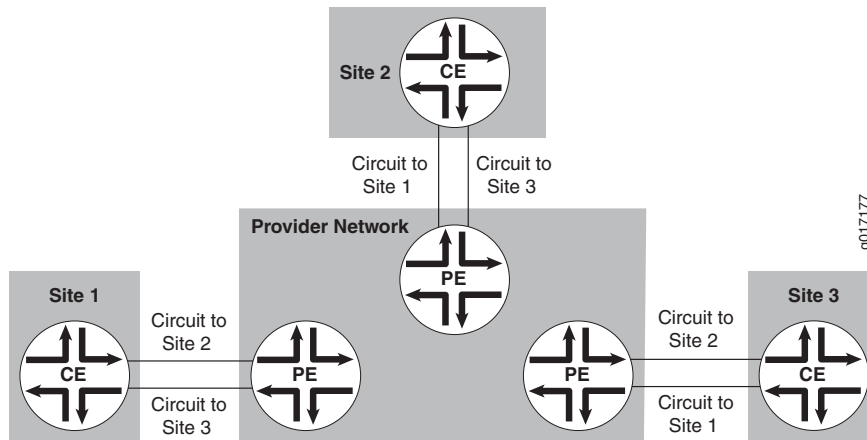

In an MPLS-based Layer 2 VPN, traffic is forwarded by the customer's customer edge (CE) switch (or router) to the service provider's provider edge (PE) switch in a Layer 2 format. It is carried by MPLS over the service provider's network and then converted back to Layer 2 format at the receiving site.

On a Layer 2 VPN, routing occurs on the customer's switches, typically on the CE switch. The CE switch connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The PE switch receiving the traffic sends it across the service provider's network to the PE switch connected to the receiving site. The PE switches do not store or process the customer's routes; the switches must be configured to send data to the appropriate tunnel.

For a Layer 2 VPN, customers must configure their own switches to carry all Layer 3 traffic. The service provider must detect only how much traffic the Layer 2 VPN will need to carry. The service provider's switches carry traffic between the customer's sites using Layer 2 VPN interfaces. The VPN topology is determined by policies configured on the PE switches.

Customers must know only which VPN interfaces connect to which of their own sites. [Figure 113 on page 1457](#) illustrates a full-mesh Layer 2 VPN in which each site has a VPN interface linked to each of the other customer sites. In a full-mesh topology between all three sites, each site requires two logical interfaces (one for each of the other CE routers or switches), although only one physical link is needed to connect each PE switch to each CE router or switch.

Figure 113: Layer 2 VPN Connecting CE Switches

Layer 2 Circuits

A Layer 2 circuit is a point-to-point Layer 2 connection that uses MPLS or another tunneling technology on the service provider's network. A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) switches. In contrast, each CCC requires a dedicated LSP.

The Junos OS implementation of Layer 2 circuits supports only the remote form of a Layer 2 circuit; that is, a connection from a local customer edge (CE) switch to a remote CE switch.

Packets are sent to the remote CE switch by means of an egress virtual private network (VPN) label advertised by the remote PE switch. The VPN label transits over either an RSVP or an LDP LSP (or other type) tunnel to the remote PE switch connected to the remote CE switch. LDP is the signaling protocol used for advertising VPN labels.

Return traffic sent from the remote CE switch to the local CE switch uses an ingress VPN label advertised by the local PE switch.

MPLS-Based Layer 3 VPNs

In a Layer 3 VPN, the routing occurs on the service provider's routers. Therefore, Layer 3 VPNs require more configuration on the part of the service provider, because the service provider's PE routers must store and process the customer's routes.

In the Junos OS, Layer 3 VPNs are based on RFC 4364, [BGP/MPLS IP Virtual Private Networks](#). This RFC defines a mechanism by which service providers can use their IP backbones to provide Layer 3 VPN services to their customers. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone.

VPNs based on RFC 4364 are also known as BGP/MPLS VPNs because BGP is used to distribute VPN routing information across the provider's backbone, and MPLS is used to forward VPN traffic across the backbone to remote VPN sites.

Customer networks, because they are private, can use either public addresses or private addresses, as defined in RFC 1918, [Address Allocation for Private Internets](#). When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the private addresses used by other network users. BGP/MPLS VPNs solve this problem by prefixing a VPN identifier to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and within the public Internet.

In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only. Two different VPNs can use overlapping addresses. Each route within a VPN is assigned an MPLS label (for example, MPLS-ARCH, MPLS-BGP, or MPLS-ENCAPS). When BGP distributes a VPN route, it also distributes an MPLS label for that route. Before a customer data packet travels across the service provider's backbone, it is encapsulated along with the MPLS label that corresponds to the route within the customer's VPN that is the best match based on the packet's destination address. This MPLS packet is further encapsulated with another MPLS label or with an IP, so that it gets tunneled across the backbone to the egress provider edge (PE) switch. Thus, the backbone core switches do not need to know the VPN routes.

Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN

The differences between Layer 2 VPNs and Layer 3 VPNs are summarized in [Table 37 on page 1458](#)

Table 37: Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN

Layer 2 VPN	Layer 3 VPN
Customer sites appear to be on the same LAN even if geographically dispersed.	Service provider's technical expertise ensures efficient site-to-site routing.
	Service providers can provide additional value-added services through network convergence that encompasses voice, video, and data.

Table 37: Comparing an MPLS-Based Layer 2 VPN and an MPLS-Based Layer 3 VPN (*continued*)

Layer 2 VPN	Layer 3 VPN
<p>The service provider does not require information about the customer's network topology, policies, routing information, etc.</p> <p>The customer has complete control over policies and routing.</p>	<p>Customers must share information about their network topology.</p> <p>The service provider determines the policies and routing.</p>
<p>The CE switch forwards traffic to the service provider's PE switch in Layer 2 format.</p>	<p>The customer's CE switch must be configured to use BGP or OSPF to communicate with the service provider's PE switch to carry IP prefixes across the network. Other protocol packets are not supported.</p>

Verifying an MPLS Layer 2 VPN Configuration

Purpose

Verify the connectivity of MPLS Layer 2 VPNs using the **ping mpls** command. This command helps to verify that a VPN has been enabled by testing the integrity of the VPN connection between the PE routers. It does not test the connection between a PE router and CE router.

Action

- To ping an interface configured for the Layer 2 VPN on the PE router, use the following command:

```
ping mpls l2vpn interface interface-name
```

- To ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier to test the integrity of the Layer 2 VPN connection (specified by identifiers) between the two PE routers, use the following command:

```
ping mpls l2vpn instance l2vpn-instance-name local-site-id local-site-id-number remote-site-id remote-site-id-number
```

Configuring an MPLS-Based Layer 2 VPN (CLI Procedure)

You can configure MPLS-based Layer 2 virtual private networks (VPNs) on EX8200 and EX4500 switches. Some benefits of a Layer 2 VPN are that it is private, secure and flexible. To configure Layer 2 VPN functionality in your MPLS network, you must configure Layer 2 VPN components on the local and remote provider edge (PE) switches.

NOTE: This topic shows how to add Layer 2 VPN components to a CCC configured on a simple interface. For information on combining Layer 2 VPN components with a tagged VLAN CCC, see [“Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN \(CLI Procedure\)”](#) on page 1684.

Before you configure the Layer 2 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect \(CLI Procedure\)”](#) on page 95.
- Configure one or more provider switches. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)”](#) on page 99.

NOTE: A Layer 2 VPN requires that the PE switches be configured using a circuit cross-connect (CCC).

Configure the Layer 2 VPN components on both PE switches. This procedure describes how to configure one PE switch. Repeat the procedure to configure the remote PE switch.

To configure Layer 2 VPN components on the PE switch:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

NOTE: The customer edge interface is a simple interface.

```
[edit]
user@switch# set interfaces interface-name encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address of this PE switch as the local address and specifying **family l2vpn signaling**:

```
[edit protocols bgp]
user@switch# set local-address address family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and **type internal**:

```
[edit protocols bgp]
user@switch# set group group-name type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switch# set neighbor address
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@switch# set routing-instance-name instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
user@switch# set routing-instances routing-instance-name interface interface-name
```

7. Configure the routing instance to use a route distinguisher:

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances must have a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

```
user@switch# set routing-instances routing-instance-name route-distinguisher ip-address:number
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name vrf-target community
```

NOTE: If you configure the **community** option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols interface interface-name description text
```

11. Configure the routing instance protocols site:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn site site-name site-identifier
identifier remote-site-id identifier
```

NOTE: The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured on the other PE switch.

Understanding MPLS Layer 2 Circuits

An MPLS Layer 2 circuit is a point-to-point Layer 2 connection that transports traffic by means of MPLS or another tunneling technology on the service provider network. The Layer 2 circuit creates a virtual connection to direct traffic between two customer edge (CE) routers across a service provider network. The main difference between a Layer 2 VPN and a Layer 2 circuit is the method of setting up the virtual connection. As with a leased line, a Layer 2 circuit forwards all packets received from the local interface to the remote interface.

Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router to the local CE router. All Layer 2 circuits using a particular remote PE router neighbor is identified by its IP address and is usually the endpoint destination for the label-switched path (LSP) tunnel transporting the Layer 2 circuit.

Each virtual circuit ID uniquely identifies the Layer 2 circuit among all the Layer 2 circuits to a specific neighbor. The key to identifying a particular Layer 2 circuit on a PE router is the neighbor address and the virtual circuit ID. Based on the virtual circuit ID and the neighbor relationship, an LDP label is bound to an LDP circuit. LDP uses the binding for sending traffic on that Layer 2 circuit to the remote CE router.

[MPLS Layer 2 Circuit Configuration Overview | 1464](#)

MPLS Layer 2 Circuit Configuration Overview

To configure an MPLS Layer 2 circuit:

1. Determine all of the routers that you want to participate in the circuit, and then complete the initial configuration of their interfaces. See the *Interfaces User Guide for Security Devices*.
2. For all of the routers in the circuit configuration, update the interface configurations to enable participation in the Layer 2 circuit.
 - a. On the interface communicating with the other provider edge (PE) router, specify MPLS and IPv4, and include the IP address. For the loopback interface, specify **inet**, and include the IP address. For IPv4, designate the loopback interface as primary so it can receive control packets. (Because it is always operational, the loopback interface is best able to perform the control function.)
 - b. On the PE router interface facing the customer edge (CE) router, specify a circuit cross-connect (CCC) encapsulation type. The type of encapsulation depends on the interface type. For example, an Ethernet interface uses **ethernet-ccc**. (The encapsulation type determines how the packet is constructed for that interface.)
 - c. On the CE router interface that faces the PE router, specify **inet** (for IPv4), and include the IP address. In addition, specify a routing protocol such as Open Shortest Path First (OSPF), which specifies the area and IP address of the router interface.

See [“Configuring Interfaces for Layer 2 VPNs \(CLI Procedure\)” on page 1432](#).

3. For all of the routers in the circuit configuration, configure the appropriate protocols.
 - a. MPLS—For PE routers and provider routers, use MPLS to advertise the Layer 2 circuit interfaces that communicate with other PE routers and provider routers.
 - b. BGP—For PE routers, configure a BGP session.
 - c. IGP and a signaling protocol—For PE routers, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but cannot use them for interfaces between PE routers and CE routers.

In addition, configure an IGP such as OSPF or static routes on the PE routers to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's

loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

See [“Configuring an IGP and the LDP Signaling Protocol \(CLI Procedure\)” on page 1466](#) and [“Configuring an IGP and the RSVP Signaling Protocol \(CLI Procedure\)” on page 1423](#).

4. For all of the routers in the circuit configuration, configure routing options. The only required routing option for circuits is the autonomous system (AS) number. You must specify it on each router involved in the circuit. See [“Configuring Routing Options for MPLS VPNs \(CLI Procedure\)” on page 1423](#).
5. For PE routers, configure Layer 2 circuits on the appropriate interfaces. See [“Configuring an MPLS Layer 2 Circuit \(CLI Procedure\)” on page 1465](#).

Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)

The following instructions show how to configure LDP and OSPF on PE routers and provider routers. Within the task, you specify which interfaces to enable for LDP. Perform this step on each PE router interface and provider router interface that communicates with other PE routers and provider routers. For OSPF, you configure at least one area on at least one of the router's interfaces. (An AS can be divided into multiple areas.) These instructions use the backbone area **0.0.0.0** and show how to enable traffic engineering for Layer 2 VPN circuits.

To configure LDP and OSPF:

1. Enable the ldp protocol.

```
[edit]  
user@host# edit protocols ldp
```

NOTE: You must configure the IGP at the **[protocols]** level of the configuration hierarchy, not within the routing instance at the **[routing-instances]** level of the configuration hierarchy.

2. Specify which interfaces to enable for LDP.

```
[edit protocols ldp]  
user@host# edit interface interface-name
```

3. Configure OSPF for each interface that uses LDP.

```
[edit]  
user@host# edit protocols ospf area 0.0.0.0 interface interface-name
```

4. (Layer 2 VPN circuits only) Enable traffic engineering.

```
[edit protocols ospf]  
user@host# set traffic engineering
```

5. Commit the configuration if you are finished configuring the device.

```
[edit]  
user@host# commit
```

Configure the Layer 2 VPN components on both PE switches. This procedure describes how to configure one PE switch. Repeat the procedure to configure the remote PE switch.

To configure Layer 2 VPN components on the PE switch:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

NOTE: The customer edge interface is a simple interface.

[edit]

```
user@switch# set interfaces interface-name encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address of this PE switch as the local address and specifying family **l2vpn** signaling:

```
[edit protocols bgp]
user@switch# set local-address address family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and **type internal**:

```
[edit protocols bgp]
user@switch# set group group-name type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switch# set neighbor address
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@switch# set routing-instance-name instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
user@switch# set routing-instances routing-instance-name interface interface-name
```

7. Configure the routing instance to use a route distinguisher:

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances must have a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

```
user@switch# set routing-instances routing-instance-name route-distinguisher ip-address:number
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name vrf-target community
```

NOTE: If you configure the **community** option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols interface interface-name description text
```

11. Configure the routing instance protocols site:

```
[edit routing-instances]
user@switch# set routing-instance-name protocols l2vpn site site-name site-identifier
identifier remote-site-id identifier
```

NOTE: The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured on the other PE switch.

[Configuring an MPLS-Based Layer 3 VPN \(CLI Procedure\) | 1512](#)

[Understanding Using MPLS-Based Layer 2 and Layer 3 VPNs on EX Series Switches | 1456](#)

Understanding MPLS Layer 3 VPNs

An MPLS Layer 3 VPN operates at the Layer 3 level of the OSI model, the Network layer. The VPN is composed of a set of sites that are connected over a service provider's existing public Internet backbone. The sites share common routing information and the connectivity of the sites is controlled by a collection of policies.

In an MPLS Layer 3 VPN, routing occurs on the service provider's routers. The provider routers route and forward VPN traffic at the entry and exit points of the transit network. The service provider network must learn the IP addresses of devices sending traffic across the VPN and the routes must be advertised and filtered throughout the provider network. As a result, Layer 3 VPNs require information about customer routes and a more extensive VPN routing and forwarding (VRF) policy configuration than a Layer 2 VPN. This information is used to share and filter routes that originate or terminate in the VPN.

The MPLS Layer 3 VPN requires more processing power on the provider edge (PE) routers than a Layer 2 VPN, because the Layer 3 VPN has larger routing tables for managing network traffic on the customer sites. Route advertisements originate at the customer edge (PE) routers and are shared with the inbound PE routers through standard IP routing protocols, typically BGP. Based on the source address, the PE router filters route advertisements and imports them into the appropriate VRF table.

The provider router uses OSPF and LDP to communicate with the PE routers. For OSPF, the provider router interfaces that communicate with the PE routers are specified, as well as the loopback interface. For the PE routers, the loopback interface is in passive mode, meaning it does not send OSPF packets to perform the control function.

RELATED DOCUMENTATION

[MPLS VPN Overview](#) | 1416

MPLS Layer 3 VPN Configuration Overview

To configure MPLS Layer 3 VPN functionality on a router running Junos OS, you must enable support on the provider edge (PE) router and configure the PE router to distribute routing information to other routers in the VPN, as explained in the following steps. However, because the tunnel information is maintained at both PE routers, neither the provider core routers nor the customer edge (CE) routers need to maintain any VPN information in their configuration databases.

To configure an MPLS Layer 3 VPN:

1. Determine all of the routers that you want to participate in the VPN, and then complete the initial configuration of their interfaces. See the *Junos OS Interfaces Configuration Guide for Security Devices*.
2. For all of the routers in the VPN configuration, update the interface configurations to enable participation in the Layer 3 VPN. As part of the interface configuration, you must configure the MPLS address family for each interface that uses LDP or RSVP. See [“Configuring Interfaces for Layer 2 VPNs \(CLI Procedure\)” on page 1432](#).
3. For all of the routers in the VPN configuration, configure the appropriate protocols.
 - a. MPLS—If you are using RSVP, use MPLS to advertise the Layer 3 VPN interfaces on the PE routers and provider routers that communicate with other PE routers and provider routers.
 - b. BGP, EBGp, and internal BGP (IBGP)—For PE routers, configure a BGP session to enable the routers to exchange information about routes originating and terminating in the VPN. (The PE routers use this information to determine which labels to use for traffic destined to the remote sites. The IBGP session for the VPN runs through the loopback address.) In addition, CE routers require a BGP connection to the PE routers. See [“Configuring a BGP Session for MPLS VPNs \(CLI Procedure\)” on page 1421](#).
 - c. IGP and a signaling protocol—For PE routers and provider, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but cannot use them for interfaces between PE routers and CE routers.

In addition, configure an IGP such as OSPF or static routes on the PE routers in order to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

See [“Configuring an IGP and the LDP Signaling Protocol \(CLI Procedure\)” on page 1466](#) and [“Configuring an IGP and the RSVP Signaling Protocol \(CLI Procedure\)” on page 1423](#).
4. For all of the routers in the VPN configuration, configure routing options. The only required routing option for VPNs is the autonomous system (AS) number. You must specify it on each router involved in the VPN. See [“Configuring Routing Options for MPLS VPNs \(CLI Procedure\)” on page 1423](#).
5. For each PE router in the VPN configuration, configure a routing instance for each VPN. The routing instance should have the same name on each PE router. Each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP

distinguish between potentially identical network layer reachable information [NLR] messages received from different VPNs.) See [“Configuring a Routing Instance for MPLS VPNs \(CLI Procedure\)” on page 1424](#).

6. For CE routers, configure a routing policy. In addition, if you are not using a route target, configure a VPN routing policy for each PE router in the VPN configuration. Within the policy, describe which packets are sent and received across the VPN and specify how routes are imported into and exported from the router's VRF table. Each advertisement must have an associated route target that uniquely identifies the VPN for which the advertisement is valid. See [“Configuring a Routing Policy for MPLS Layer 3 VPNs \(CLI Procedure\)” on page 1473](#).

Example: Configuring MPLS-Based Layer 3 VPNs

IN THIS SECTION

- [Requirements | 1475](#)
- [Overview and Topology | 1475](#)
- [Configuring the Local PE Switch | 1478](#)
- [Configuring the Remote PE Switch | 1482](#)

You can implement an MPLS-based Layer 3 virtual private network (VPN) on QFX switches to interconnect sites for customers who want the service provider to handle all the Layer 3 routing functions. To support an MPLS-based Layer 3 VPN, you need to add components of the Layer 3 VPN to the configuration of the two provider edge (PE) switches. You do not need to change the configuration of the provider switches.

This example shows how to configure an MPLS-based Layer 3 VPN spanning two corporate sites:

Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.3 or later for the QFX Series
- Three QFX switches

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge Switches” on page 83](#).
- Configure one or more provider switches. See [“Configuring MPLS on Provider Switches” on page 88](#).

Overview and Topology

Layer 3 VPNs allow customers to leverage the service provider’s technical expertise to ensure efficient site-to-site routing. The customer’s customer edge (CE) switch uses a routing protocol such as BGP or OSPF to communicate with the service provider’s provider edge (PE) switch to carry IP prefixes across the network. MPLS-based Layer 3 VPNs use only IP over MPLS; other protocol packets are not supported. This example includes two PE switches, PE1 and PE2.

In the basic MPLS configuration of the PE switches using IP over MPLS, the PE switches were configured to use OSPF as the routing protocol between the MPLS switches and RSVP as the signaling protocol. Traffic engineering was enabled. A label-switched path (LSP) was configured.

The following components must be added to the PE switches for an MPLS-based Layer 3 VPN:

- BGP group with **family inet-vpn unicast**
- Routing instance with instance type **vrf**

[Figure 114 on page 1476](#) shows the topology used in this example.

Figure 114: Configuring an MPLS-Based Layer 3 VPN

Table 40 on page 1476 shows the Layer 3 VPN components of the local PE switch.

Table 40: Layer 3 VPN Components of the Local PE Switch

Property	Settings	Description
Local PE switch hardware	QFX switch	PE1

Table 40: Layer 3 VPN Components of the Local PE Switch (*continued*)

Property	Settings	Description
Customer edge interface	ge-5/0/24 unit 0 family inet address 51.51.0.1/16	Connects PE1 to CE1. NOTE: The family inet configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	xe-0/0/6 unit 0 family inet address 60.0.0.60/16 family mpls	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	lo0 unit 0 family inet address 21.21.21.21/32	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	bgp	Added for the Layer 3 VPN configuration.
Routing instance	L3VPN-1	Added for the Layer 3 VPN configuration.

Table 41 on page 1478 shows the Layer 3 VPN components of the remote PE switch.

Table 41: Layer 3 VPN Components of the Remote PE Switch

Property	Settings	Description
Remote PE switch hardware	QFX switch	PE2
Customer edge interface	ge-0/0/14 unit 0 family inet address 11.22.26.14/16	Connects PE2 to CE2. For the Layer 3 VPN configuration, added family mpls . NOTE: The family inet configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	xe-0/0/6 unit 0 family inet address 60.2.0.60/16 family mpls	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	lo0 unit 0 family inet address 22.22.22.22/32	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	bgp	Added for the Layer 3 VPN configuration.
Routing instances	L3VPN-1	Added for the Layer 3 VPN configuration.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the local PE switch, copy the following commands and paste them into the switch terminal window of PE1:

```
[edit]
set protocols bgp local-address 21.21.21.21 family inet-vpn unicast
set protocols bgp group PE1-PE2 type internal
set protocols bgp neighbor 22.22.22.22
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-5/0/24.0
set routing-instances L3VPN-1 protocols ospf interface ge-5/0/24.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label
set routing-options router-id 21.21.21.21
set routing-options autonomous-system 10
```

Step-by-Step Procedure

To configure the Layer 3 VPN components on the local PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

```
[edit protocols bgp]
user@switchPE1# set local-address 21.21.21.21 family inet-vpn unicast
```

2. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@switchPE1# set group PE1-PE2 type internal
```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE1# set neighbor 22.22.22.22
```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 instance-type vrf
```

5. Configure a description for this routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
```

6. Configure the routing instance for the OSPF interface:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 protocols ospf interface ge-5/0/24.0
```

7. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 route-distinguisher 21:21
```

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances require a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-target target:21:21
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Library for Routing Devices*.

9. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-table-label
```

10. Configure the router ID and autonomous system (AS):

NOTE: We recommend that you explicitly configure the router identifier under the **[edit routing-options]** hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
user@switchPE1# set router-id 21.21.21.21 autonomous-system 10
```

Results

Display the results of the configuration:

```
user@switchPE1> show configuration
```

```

                }
            }
        }
    }
}

```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE2:

```
[edit]
set protocols bgp local-address 22.22.22.22 family inet-vpn unicast
set protocols bgp group PE1-PE2 type internal
set protocols bgp neighbor 21.21.21.21
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-0/0/14.0
set routing-instances L3VPN-1 protocols ospf interface ge-0/0/14.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
set routing-options router-id 22.22.22.22
set routing-options autonomous-system 10
```

Step-by-Step Procedure

To configure Layer 3 VPN components on the remote PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

```
[edit protocols bgp]
user@switchPE2# set local-address 22.22.22.22 family inet-vpn unicast
```

2. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@switchPE2# set group PE1-PE2 type internal
```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE2# set neighbor 21.21.21.21
```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 instance-type vrf
```

5. Configure a description for this routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 interface ge-0/0/14.0
```

7. Configure the routing instance for the OSPF interface:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 protocols ospf interface ge-0/0/14.0
```

8. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 route-distinguisher 21:21
```

9. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-target target:21:21
```

10. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-table-label
```

11. Configure the router ID and autonomous system (AS):

```
[edit routing-options]
user@switchPE2# set router-id 22.22.22.22 autonomous-system 10
```

Results

Display the results of the configuration:

```
user@switchPE2> show configuration
```

```

[Configuring MPLS on Provider Switches | 88](#)

Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

IN THIS SECTION

- [Requirements | 1487](#)
- [Overview | 1487](#)
- [Configuration | 1490](#)
- [Verification | 1497](#)

This example shows how to configure Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

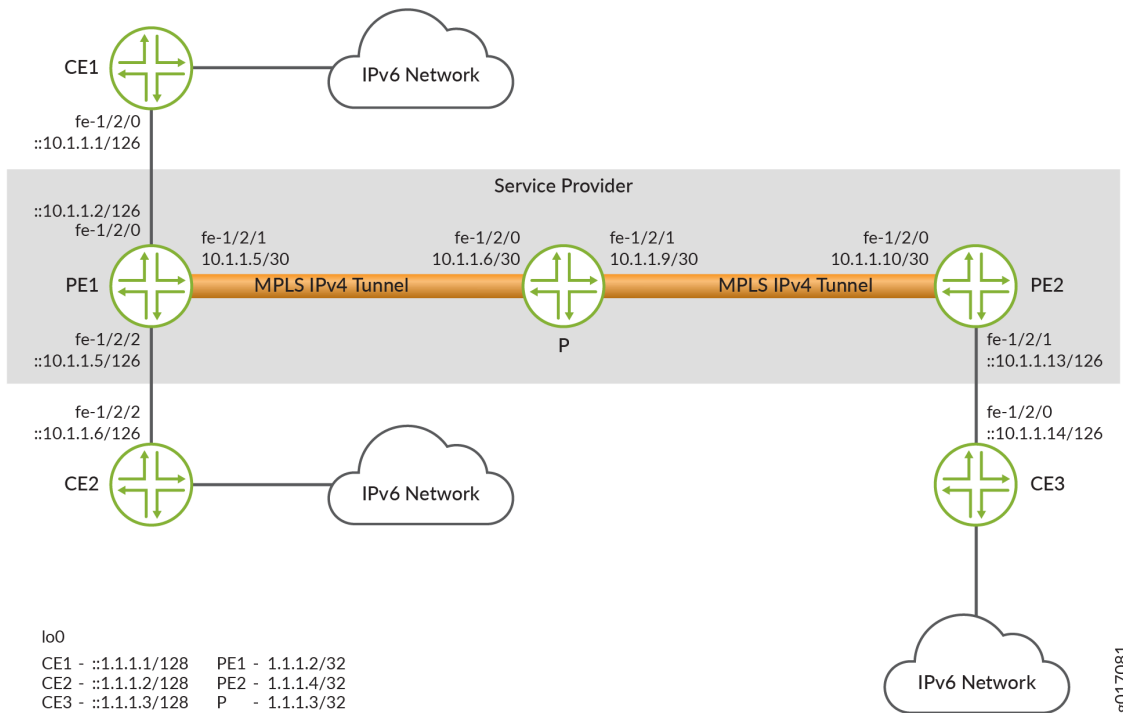

- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at <http://www.ietf.org/>.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In [Figure 17 on page 354](#), PE1 and PE2 are dual-stack BGP routers or switches, meaning they have both IPv4 and IPv6 stacks. The PE devices link the IPv6 networks through the customer edge (CE) routers or switches to the IPv4 core network. The CE devices and the PE devices connect through a link layer that can carry IPv6 traffic. The PE devices use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

Figure 115: IPv6 Networks Linked by MPLS IPv4 Tunnels

The two PE devices are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE devices can learn the IPv6 routes from the CE devices connected to them using MP-BGP or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE device and CE device could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGp, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE devices always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE device is not a Juniper Networks routing or switching platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE devices to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 device in [Figure 17 on page 354](#) receives an IPv6 packet from the CE1 device, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 device, then no labels need to be pushed and the packet is simply sent to the CE2 device. If the destination matches a prefix that was learned from the PE2 device, then the PE1 router pushes two labels onto the packet and sends it to the Provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the **family inet6** statement on all the CE router-facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.
- You enable IPv6 tunneling by including the **ipv6-tunneling** statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

NOTE: BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the inet6.3 routing table.

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the **explicit-null** statement in the BGP configuration.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

set protocols bgp group toPE2 neighbor ::10.1.1.13
set policy-options policy-statement send-v6 from family inet6
set policy-options policy-statement send-v6 from protocol direct
set policy-options policy-statement send-v6 then accept
set routing-options router-id 1.1.1.5
set routing-options autonomous-system 3

```

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```

[edit interfaces]
user@PE1# set xe-0/0/5 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set xe-0/0/5 unit 2 family mpls
user@PE1# set xe-0/0/6 unit 5 family inet address 10.1.1.5/30
user@PE1# set xe-0/0/6 unit 5 family inet6
user@PE1# set xe-0/0/6 unit 5 family mpls
user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32

```

2. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface xe-0/0/5.2
user@PE1# set interface xe-0/0/6.5

```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1
user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6
user@PE1# set group toPE2 neighbor 1.1.1.4
```

4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface xe-0/0/6.5
user@PE1# set interface lo0.2 passive
```

5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set rsvp interface xe-0/0/6.5
```

6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self
user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept
user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```

7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
```

```

user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R1# show interfaces
xe-0/0/5 {
  unit 2 {
    family inet6 {
      address ::10.1.1.2/126;
    }
    family mpls;
  }
}
xe-0/0/6 {
  unit 5 {
    family inet {
      address 10.1.1.5/30;
    }
    family inet6;
    family mpls;
  }
}
lo0 {
  unit 2 {
    family inet {
      address 1.1.1.2/32;
    }
  }
}

```

```

user@R1# show policy-options
policy-statement next-hop-self {
  then {
    next-hop self;
  }
}
policy-statement send-bgp6 {
  from {

```

```

        family inet6;
        protocol bgp;
    }
    then accept;
}
policy-statement send-v6 {
    from {
        family inet6;
        protocol [ bgp direct ];
    }
    then accept;
}

```

```

user@R1# show protocols
mpls {
    ipv6-tunneling;
    interface xe-0/0/5.2;
    interface xe-0/0/6.5;
}
bgp {
    group toCE1 {
        type external;
        local-address ::10.1.1.2;
        family inet6 {
            unicast;
        }
        export send-bgp6;
        peer-as 1;
        neighbor ::10.1.1.1;
    }
    group toPE2 {
        type internal;
        local-address 1.1.1.2;
        family inet6 {
            labeled-unicast {
                explicit-null;
            }
        }
        export [ next-hop-self send-v6 ];
        neighbor 1.1.1.4;
    }
}
ospf {
    area 0.0.0.0 {

```

```

interface xe-0/0/6.5;
interface lo0.2 {
    passive;
}
}
}
}
rsvp {
    interface xe-0/0/6.5;
}

```

```

user@R1# show routing-options
router-id 1.1.1.2;
autonomous-system 2;

```

If you are done configuring the device, enter **commit** from configuration mode.
Configure the other devices in the topology, as shown in [“CLI Quick Configuration” on page 356](#).

Verification

Confirm that the configuration is working properly.

Verifying That the CE Devices Have Connectivity

Purpose

Make sure that the tunnel is operating.

Action

From operational mode, enter the **ping** command.

```
user@CE1> ping ::10.1.1.14
```

```

PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms

```

```
user@CE3> ping ::10.1.1.1
```

```

PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms

```

```
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

Meaning

The IPv6 CE devices can communicate over the core IPv4 network.

RELATED DOCUMENTATION

Example: Configuring MPLS-Based Layer 3 VPNs on EX Series Switches

IN THIS SECTION

- [Requirements | 1499](#)
- [Overview and Topology | 1499](#)
- [Configuring the Local PE Switch | 1502](#)
- [Configuring the Remote PE Switch | 1506](#)
- [Verification | 1510](#)

You can implement an MPLS-based Layer 3 virtual private network (VPN) on EX8200 and EX4500 switches to interconnect sites for customers who want the service provider to handle all the Layer 3 routing functions. To support an MPLS-based Layer 3 VPN, you need to add components of the Layer 3 VPN to the configuration of the two provider edge (PE) switches. You do not need to change the configuration of the provider switches.

NOTE: The core interfaces and the loopback interfaces are configured in the same way for Layer 2 VPNs and Layer 3 VPNs.

This example shows how to configure an MPLS-based Layer 3 VPN spanning two corporate sites:

Requirements

This example uses the following software and hardware components:

- Junos OS Release 11.1 or later for EX Series switches
- Three EX8200 switches

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\)” on page 89](#).
- Configure one or more provider switches. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 99](#).

NOTE: A Layer 3 VPN requires that the PE switches be configured using IP over MPLS.

Overview and Topology

Layer 3 VPNs allow customers to leverage the service provider’s technical expertise to ensure efficient site-to-site routing. The customer’s customer edge (CE) switch uses a routing protocol such as BGP or OSPF to communicate with the service provider’s provider edge (PE) switch to carry IP prefixes across the network. MPLS-based Layer 3 VPNs use only IP over MPLS; other protocol packets are not supported. This example includes two PE switches, PE1 and PE2.

In the basic MPLS configuration of the PE switches using IP over MPLS, the PE switches were configured to use OSPF as the routing protocol between the MPLS switches and RSVP as the signaling protocol. Traffic engineering was enabled. A label-switched path (LSP) was configured.

NOTE: A static path is not configured in this example.

The following components must be added to the PE switches for an MPLS-based Layer 3 VPN:

- BGP group with **family inet-vpn unicast**
- Routing instance with instance type **vrf**

[Figure 116 on page 1500](#) illustrates the topology of this MPLS-based Layer 3 VPN.

Figure 116: MPLS-Based Layer 3 VPN

Table 38 on page 1476 shows the settings of the customer edge interface on the local CE switch.

Table 42: Local CE Switch in the MPLS-Based Layer 3 VPN Topology

Property	Settings	Description
Local CE switch hardware	EX8200 switch	CE1
Customer edge interface	ge-0/0/14 unit 0 family inet address 51.51.0.14/16	Interface that connects CE1 to PE1.

Table 39 on page 1476 shows the settings of the customer edge interface on the remote CE switch.

Table 43: Remote CE Switch in the MPLS-Based Layer 3 VPN Topology

Property	Settings	Description
Remote CE switch hardware	EX8200 switch	CE2
Customer edge interface	ge-0/0/14 unit 0 family inet address 11.22.26.1/16	Interface that connects CE2 to PE2.

Table 40 on page 1476 shows the Layer 3 VPN components of the local PE switch.

Table 44: Layer 3 VPN Components of the Local PE Switch

Property	Settings	Description
Local PE switch hardware	EX8200 switch	PE1

Table 44: Layer 3 VPN Components of the Local PE Switch (*continued*)

Property	Settings	Description
Customer edge interface	ge-5/0/24 unit 0 family inet address 51.51.0.1/16	Connects PE1 to CE1. NOTE: The family inet configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	xe-6/0/0 unit 0 family inet address 60.0.0.60/16 family iso; family mpls	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	lo0 unit 0 family inet address 21.21.21.21/32 family iso address 49.0001.2102.1021.0210.00	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	bgp	Added for the Layer 3 VPN configuration.
Routing instance	L3VPN-1	Added for the Layer 3 VPN configuration.

Table 41 on page 1478 shows the Layer 3 VPN components of the remote PE switch.

Table 45: Layer 3 VPN Components of the Remote PE Switch

Property	Settings	Description
Remote PE switch hardware	EX8200 switch	PE2
Customer edge interface	ge-11/0/14 unit 0 family inet address 11.22.26.14/16 family mpls	Connects PE2 to CE2. For the Layer 3 VPN configuration, added family mpls . NOTE: The family inet configuration should already have been completed as part of the basic MPLS configuration of the PE switch for IP over MPLS. It is included here to show what was specified for that portion of the configuration.
Core interface	xe-6/0/0/ unit 0 family inet address 60.2.0.60/16 family iso family mpls	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	lo0 unit 0 family inet address 22.22.22.22/32 family iso address 49.0001.2202.1022.0220.00	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	bgp	Added for the Layer 3 VPN configuration.
Routing instances	L3VPN-1	Added for the Layer 3 VPN configuration.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the local PE switch, copy the following commands and paste them into the switch terminal window of PE1:

```
[edit]
set protocols bgp group ibgp local-address 21.21.21.21 family inet-vpn unicast
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 22.22.22.22
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-5/0/24.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
set routing-options router-id 21.21.21.21
set routing-options autonomous-system 10;
```

Step-by-Step Procedure

To configure the Layer 3 VPN components on the local PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

```
[edit protocols bgp]
user@switchPE1# set group ibgp local-address 21.21.21.21 family inet-vpn unicast
```

2. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@switchPE1# set group ibgp type internal
```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE1# set group ibgp neighbor 22.22.22.22
```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 instance-type vrf
```

5. Configure a description for this routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
```

6. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 route-distinguisher 21:21
```

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances require a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

7. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-target target:21:21
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

8. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-table-label
```

9. Configure the router ID and autonomous system (AS):

NOTE: We recommend that you explicitly configure the router identifier under the **[edit routing-options]** hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
```

```
user@switchPE1# set router-id 21.21.21.21 autonomous-system 10
```

Results

Display the results of the configuration:

```
user@switchPE1> vrf-table-label
```

```
interfaces {
  ge-5/0/24 {
    unit 0 {
      family inet {
        address 51.51.0.1/16;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 21.21.21.21/32;
      }
    }
  }
  xe-6/0/0 {
    unit 0 {
      family inet {
        address 60.0.0.60/16;
      }
      family iso;
      family mpls;
    }
  }
}
protocols {
  mpls {
    label-switched-path 21-22 {
      from 21.21.21.21;
      to 22.22.22.22;
      no-cspf;
    }
    interface xe-6/0/0.0;
    interface lo0.0;
    bgp {
      group ibgp
      type internal
    }
  }
}
```

```

        local-address 21.21.21.21
        family inet-vpn
        unicast
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ge-5/0/24.0;
            interface lo0.0;
            interface xe-6/0/0.0;
        }
    }
}
routing-instances {
    L3VPN-1 {
        instance-type vrf;
        description "BETWEEN PE1 AND PE2";
        route-distinguisher 21:21;
        vrf-target target:21:21;
        vrf-table-label;
    }
}
routing-options {
    router-id 21.21.21.21;
    autonomous-system 10;
}

```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure the Layer 3 VPN components on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE2:

[edit]

```

set protocols bgp group ibgp local-address 22.22.22.22 family inet-vpn unicast
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 21.21.21.21
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-11/0/14.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
set routing-options router-id 22.22.22.22;

```

```
set routing-options autonomous-system 10;
```

Step-by-Step Procedure

To configure Layer 3 VPN components on the remote PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

```
[edit protocols bgp]
user@switchPE2# set group ibgp local-address 22.22.22.22 family inet-vpn unicast
```

2. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@switchPE2# set group ibgp type internal
```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE2# set group ibgp neighbor 21.21.21.21
```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 instance-type vrf
```

5. Configure a description for this routing instance:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 interface ge-11/0/14.0
```

7. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 route-distinguisher 21:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
```

```
user@switchPE2# set L3VPN-1 vrf-target target:21:21
```

9. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-table-label
```

10. Configure the router ID and autonomous system (AS):

```
[edit routing-options]
user@switchPE2# set router-id 22.22.22.22 autonomous-system 10
```

Results

Display the results of the configuration:

```
user@switchPE2> show configuration
```

```
interfaces {
  ge-11/0/14 {
    unit 0 {
      family inet {
        address 11.22.26.14/16;
      }
    }
  }
  lo0 {

        to 21.21.21.21;
        no-cspf;
    }
    interface xe-6/0/0.0;
    interface lo0.0;
    bgp {
        group ibgp
        type internal
        local-address 21.21.21.21
        family inet-vpn
        unicast
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ge-11/0/14.0;
            interface lo0.0;
            interface xe-6/0/0.0;
        }
    }
}
routing-instances {
    L3VPN-1 {
        instance-type vrf;
        description "BETWEEN PE1 AND PE2";
        route-distinguisher 21:21;
        vrf-target target:21:21;
        vrf-table-label;
    }
}
routing-options {
    router-id 22.22.22.22;
    autonomous-system 10;
}

```

Verification

IN THIS SECTION

- [Verifying Peering and Adjacency | 1510](#)
- [Verifying That the Local CE Switch Can Ping the Local PE Switch | 1510](#)
- [Verifying That the Local PE Switch Can Ping the Local CE Switch | 1511](#)

To confirm that the MPLS-based Layer 3 VPN is working properly, perform these tasks:

Verifying Peering and Adjacency

Purpose

Verify the peering and adjacency along the route from CE1 (the local CE switch or router) to CE2 (the remote CE switch or router), starting with checking the routing protocol adjacency on the local PE switch:

NOTE: Be sure to specify the name of the routing instance.

Action

```
user@switchPE1> show ospf neighbor instance L3VPN-1
```

Address	Interface	State	ID	Pri	Dead
51.51.0.14	ge-5/0/24.0	Full	21.21.21.21	128	38

Meaning

The **Address** field shows the IP address of the customer edge interface that connects CE1 to PE1. The **Interface** field shows the interface name of the customer edge interface that connects PE1 to CE1. For our purposes, the **State** field is the most important. It shows a status of **Full**, indicating that neighboring routing devices are fully adjacent. These adjacencies appear in router-link and network-link advertisements. (The field **Pri** indicates the priority of the neighbor to become the designated router. The field **Dead** indicates the number of seconds until the neighbor becomes unreachable.)

Verifying That the Local CE Switch Can Ping the Local PE Switch

Purpose

Verify that the local CE switch can ping the local PE switch:

Action

```
user@switchCE1> ping 51.51.0.1
```

```
PING 51.51.0.1 (51.51.0.1): 56 data bytes
64 bytes from 51.51.0.1: icmp_seq=0 ttl=64 time=3.461 ms
64 bytes from 51.51.0.1: icmp_seq=1 ttl=64 time=3.543 ms
```

Meaning

This command specified the IP address of the customer edge interface on PE1. The results indicate that CE1 is receiving packets from PE1.

Verifying That the Local PE Switch Can Ping the Local CE Switch

Purpose

Verify that the local PE switch can ping the local CE switch:

Action

```
user@switchPE1> ping 51.51.0.14 routing-instance L3VPN-1
```

```
PING 51.51.0.14 (51.51.0.14): 56 data bytes
64 bytes from 51.51.0.14: icmp_seq=0 ttl=64 time=3.842 ms
64 bytes from 51.51.0.14: icmp_seq=1 ttl=64 time=3.736 ms
```

Meaning

The results indicate a successful connection.

RELATED DOCUMENTATION

[Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\) | 89](#)

[Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\) | 99](#)

Configuring an MPLS-Based Layer 3 VPN (CLI Procedure)

You can configure MPLS-based Layer 3 virtual private networks (VPNs) on EX8200 and EX4500 switches. Layer 3 VPNs leverage the service provider's technical expertise for site-to-site routing.

To configure Layer 3 VPN functionality in your MPLS network, you must enable Layer 3 VPN support on the local and remote provider edge (PE) switches as described in this task.

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge Switches Using IP Over MPLS \(CLI Procedure\)” on page 89](#).
- Configure one or more provider switches. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 99](#).

NOTE: A Layer 3 VPN requires that the PE switches be configured using IP over MPLS.

Configure the Layer 3 VPN components on both PE switches. This procedure describes how to configure one PE switch. Repeat the procedure to configure the remote PE switch.

NOTE: When you configure the remote PE switch, the information specified for the routing instance must be configured the same as the information specified for the routing instance on the local PE switch. You must also specify the same BGP group name. The following statements will have different values on the remote PE switch from those on the local PE switch:

- **local-address**
- **neighbor**

To configure an MPLS-based Layer 3 VPN on the PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:

```
[edit protocols bgp]
user@switch# set local-address address family inet-vpn unicast
```

2. Configure the BGP group, specifying the group name and **type internal**:

```
[edit protocols bgp]
user@switch# set group group-name type internal
```

3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switch# set neighbor address
```

4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:

```
[edit]
user@switch# set routing-instances routing-instance-name instance-type vrf
```

5. Configure a description for this routing instance:

```
[edit]
user@switch# set routing-instances routing-instance-name description text
```

6. Configure the routing instance to use a route distinguisher:

NOTE: Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances must have a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

```
user@switch# set routing-instances routing-instance-name route-distinguisher ip-address:number
```

7. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switch# set routing-instance-name vrf-target community
```

NOTE: If you configure the **community** option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

8. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.

```
[edit routing-instances]
```

```
user@switch# set routing-instance-name vrf-table-label
```

9. (Optional) Configure the routing options:

NOTE: We recommend that you configure the router identifier under the **[edit routing-options]** hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
```

```
user@switch# set router-id ip-address autonomous-system as-number
```

Configuring TCC and Layer 2.5 Switching

IN THIS CHAPTER

- TCC and Layer 2.5 Switching Overview | 1515
- Configuring VLAN TCC Encapsulation | 1516
- Configuring Translation Cross-Connect Interface Switching | 1518

TCC and Layer 2.5 Switching Overview

Translational cross-connect (TCC) allows you to forward traffic between a variety of Layer 2 protocols or circuits. It is similar to its predecessor, CCC. However, while CCC requires the same Layer 2 encapsulations on both sides of a router (such as Point-to-Point Protocol [PPP] or Frame Relay-to-Frame Relay), TCC lets you connect different types of Layer 2 protocols interchangeably. With TCC, combinations such as PPP-to-ATM and Ethernet-to-Frame Relay cross-connections are possible. Also, TCC can be used to create Layer 2.5 VPNs and Layer 2.5 circuits.

Consider a sample topology ([Figure 117 on page 1515](#)) in which you can configure a full-duplex Layer 2.5 translational cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the TCC interface. In this topology, Router B strips all PPP encapsulation data from frames arriving from Router A and adds ATM encapsulation data before the frames are sent to Router C. All Layer 2 negotiations are terminated at the interconnecting router (Router B).

Figure 117: Sample Translation Cross-Connect Topology

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, time-to-live (TTL) decrementing, or protocol handling, is performed. Currently, TCC is supported in IPv4, ISO, and MPLS.

Ethernet TCC is supported on interfaces that carry IPv4 traffic only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC and extended VLAN CCC are not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC and extended VLAN TCC are not supported.

Ethernet Interfaces User Guide for Routing Devices

Configuring VLAN TCC Encapsulation

VLAN TCC encapsulation allows circuits to have different media on either side of the forwarding path. VLAN TCC encapsulation supports TPID 0x8100 only. You must include configuration statements at the logical and physical interface hierarchy levels.

To configure VLAN TCC encapsulation, include the **encapsulation** statement and specify the **vlan-tcc** option:

```
[edit interfaces interface-name unit logical-unit-number]
encapsulation vlan-tcc;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

Additionally, configure the logical interface by including the **proxy** and **remote** statements:

```
proxy {
  inet-address;
}
remote {
  (inet-address | mac-address);
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family tcc]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family tcc]**

The proxy address is the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy.

The remote address is the IP or MAC address of the remote router. The **remote** statement provides ARP capability from the TCC switching router to the Ethernet neighbor. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

When VLAN TCC encapsulation is configured on the logical interface, you also must specify flexible Ethernet services on the physical interface. To specify flexible Ethernet services, include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level and specify the **flexible-ethernet-services** option:

```
[edit interfaces interface-name]  
encapsulation flexible-ethernet-services;
```

Extended VLAN TCC encapsulation supports TPIDs 0x8100 and 0x9901. Extended VLAN TCC is specified at the physical interface level. When configured, all units on that interface must use VLAN TCC encapsulation, and no explicit configuration is needed on logical interfaces.

One-port Gigabit Ethernet, 2-port Gigabit Ethernet, and 4-port Fast Ethernet PICs with VLAN tagging enabled can use VLAN TCC encapsulation. To configure the encapsulation on a physical interface, include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level and specify the **extended-vlan-tcc** option:

```
[edit interfaces interface-name]  
encapsulation extended-vlan-tcc;
```

For VLAN TCC encapsulation, all VLAN IDs from 1 through 1024 are valid. VLAN ID 0 is reserved for tagging the priority of frames.

Extended VLAN TCC is not supported on 4-port Gigabit Ethernet PICs.

[Ethernet Interfaces User Guide for Routing Devices](#)

Configuring Translation Cross-Connect Interface Switching

To configure a full-duplex Layer 2.5 translation cross-connect between two routers (A and C), you can configure a Juniper Networks router (Router B) as the TCC interface. Ethernet TCC encapsulation provides an Ethernet wide area circuit for interconnecting IP traffic. Consider the topology in [Figure 118 on page 1518](#) where the Router A-to-Router B circuit is PPP, and the Router B-to-Router C circuit accepts packets carrying standard TPID values.

Figure 118: Sample Topology of Layer 2.5 Translational Cross-Connect

If traffic flows from Router A to Router C, the Junos OS strips all PPP encapsulation data from incoming packets and adds Ethernet encapsulation data before forwarding the packets. If traffic flows from Router C to Router A, the Junos OS strips all Ethernet encapsulation data from incoming packets and adds PPP encapsulation data before forwarding the packets.

To configure the router as the translational cross-connect interface:

1. In the configuration mode, at the **[edit]** hierarchy level, first configure the interface that is connected to Router A.

```
[edit]
user@host# edit interfaces interface-name
```

2. (Optional) Specify the description of the interface. For example, you could specify the interface name on Router A that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

3. Specify the encapsulation. If the Router A to Router B circuit is PPP, then specify **ppp-tcc** as the encapsulation. If the Router A to Router B circuit is frame relay, specify **frame-relay-tcc**.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

4. In the configuration mode, at the **[edit]** hierarchy level, first configure the interface that is connected to Router C.

```
[edit]
user@host# edit interfaces interface-name
```

5. (Optional) Specify the description of this interface. For example, you could specify the interface name on Router C that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

6. Specify the encapsulation. If the Router B to Router C circuit is Ethernet, then specify **ethernet-tcc** as the encapsulation. If the Router B to Router C circuit is ATM, specify **atm-tcc-vc-mux**.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

7. Specify the IP address or MAC address of the remote router to provide address resolution protocol (ARP) for the TCC router's Ethernet-based neighbor using the **remote** statement. You must specify the statement at the **[edit interfaces interface-name unit unit-number family tcc]** hierarchy level. You can also specify the MAC address of the remote router instead of the IP address. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

```
[edit interfaces interface-name]
user@host# set unit 0 family family remote inet-address ip-address
```

8. Specify the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy using the **proxy** statement. You must specify the statement at the **[edit interfaces interface-name unit unit-number family tcc]** hierarchy level.

```
[edit interfaces interface-name]
user@host# set unit 0 family family proxy inet-address ip-address
```

To verify the TCC connection, use the **show connections** command on TCC router.

CLNS Overview

Connectionless Network Service (CLNS) is a Layer 3 protocol similar to IP version 4 (IPv4) for linking hosts (end systems) with routers (intermediate systems) in an Open Systems Interconnection (OSI) network. CLNS and its related OSI protocols, Intermediate System-to-Intermediate System (IS-IS) and End System-to-Intermediate System (ES-IS), are International Organization for Standardization (ISO) standards.

You can configure devices running Junos OS as provider edge (PE) routers within a CLNS network. CLNS networks can be connected over an IP MPLS network core using Border Gateway Protocol (BGP) and MPLS Layer 3 virtual private networks (VPNs). See RFC 2547, *BGP/MPLS VPNs*.

CLNS uses network service access points (NSAPs), similar to IP addresses found in IPv4, to identify end systems (hosts) and intermediate systems (routers). ES-IS enables the hosts and routers to discover each other. IS-IS is the interior gateway protocol (IGP) that carries ISO CLNS routes through a network.

For more information about CLNS, see the ISO 8473 standards.

| Understanding ES-IS for CLNS 1524 |
| Understanding IS-IS for CLNS 1527 |
| Understanding Static Routes for CLNS 1531 |
| Understanding BGP for CLNS VPNs 1535 |

CLNS Configuration Overview

To configure CLNS:

1. Configure the network interfaces. See the *Junos OS Interfaces Configuration Guide for Security Devices*.
2. If applicable, configure BGP and VPNs. See:
 - [Example: Configuring BGP for CLNS VPNs on page 1535](#)
 - [MPLS Layer 2 VPN Configuration Overview on page 1429](#)
 - [MPLS Layer 3 VPN Configuration Overview on page 1471](#)

3. Configure a VPN routing instance. You typically configure ES-IS, IS-IS, and CLNS static routes using a VPN routing instance. See [“Example: Configuring a VPN Routing Instance for CLNS” on page 1538](#).
4. Configure one or more of the following protocols for CLNS (depending on your network).
 - ES-IS—If a device is a PE router within a CLNS island that contains any end systems, you must configure ES-IS on the device. If a CLNS island does not contain any end systems, you do not need to configure ES-IS on a device. See [“Example: Configuring ES-IS for CLNS” on page 1525](#).

NOTE: ES-IS is enabled only if either ES-IS or IS-IS is configured on the router. ES-IS must not be disabled. If ES-IS is not explicitly configured, the interface sends and receives only intermediate system hello (ISH) messages. If ES-IS is explicitly configured and disabled, the interface does not send or receive ES-IS packets. If ES-IS is explicitly configured and not disabled, the interface sends and receives ISH messages as well as ES-IS packets.

One of the interfaces that is configured for ES-IS must be configured with an ISO address for hello messages. The ISO address family must be configured on an interface to support ES-IS on that interface.

- IS-IS—You can configure IS-IS to exchange CLNS routes within a CLNS island. See [“Example: Configuring IS-IS for CLNS” on page 1528](#).

NOTE: If you have a pure CLNS island—an island that does not contain any IP devices—you must disable IPv4 and IPv6 routing. Also, to export BGP routes into IS-IS, you must configure and apply an export policy.

- Static routes—If some devices in your network do not support IS-IS, you must configure CLNS static routes. You can use static routing with or without IS-IS. You might also consider using static routes if your network is simple. See [“Example: Configuring Static Routes for CLNS When No IGP is Present” on page 1532](#).
- BGP—See [“Example: Configuring BGP for CLNS VPNs” on page 1535](#).

NOTE: Many of the configuration statements used to configure CLNS and routing protocols can be included at different hierarchy levels in the configuration.

RELATED DOCUMENTATION

[Verifying a CLNS VPN Configuration | 1541](#)

Understanding ES-IS for CLNS

End System-to-Intermediate System (ES-IS) is a protocol that resolves Layer 3 ISO network service access points (NSAP) to Layer 2 addresses. ES-IS has an equivalent role as Address Resolution Protocol (ARP) in IP version 4 (IPv4).

ES-IS provides the basic interaction between Connectionless Network Service (CLNS) hosts (end systems) and routers (intermediate systems). ES-IS allows hosts to advertise NSAP addresses to other routers and hosts attached to the network. Those routers can then advertise the address to the rest of the network by using Intermediate System-to-Intermediate System (IS-IS). Routers use ES-IS to advertise their network entity title (NET) to hosts and routers that are attached to that network.

ES-IS routes are exported to Layer 1 IS-IS by default. You can also export ES-IS routes into Layer 2 IS-IS by configuring a routing policy. ES-IS generates and receives end system hello (ESH) hello messages when the protocol is configured on an interface. ES-IS is a resolution protocol that allows a network to be fully ISO integrated at both the network layer and the data layer.

The resolution of Layer 3 ISO NSAPs to Layer 2 subnetwork point of attachments (SNPAs) by ES-IS is equivalent to ARP within an IPv4 network. If a device is a provider edge (PE) router within a CLNS island that contains any end systems, you must configure ES-IS on the device.

For more information about ES-IS, see the ISO 9542 standard.

Example: Configuring ES-IS for CLNS

IN THIS SECTION

- [Requirements | 1525](#)
- [Overview | 1525](#)
- [Configuration | 1525](#)
- [Verification | 1527](#)

This example shows how to create a routing instance and enable ES-IS for CLNS on all interfaces.

Requirements

Before you begin, configure the network interfaces. See *Interfaces User Guide for Security Devices*.

Overview

The configuration instructions in this topic describe how to create a routing-instance called `aaaa`, set the end system configuration timer for the interfaces to 180, and set a preference value to 30 for ES-IS.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa protocols esis interface all end-system-configuration-timer 180
set routing-instances aaaa protocols esis preference 30
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure ES-IS for CLNS:

1. Configure the routing instance.

```
[edit]
user@host# edit routing-instances aaaa
```

2. Enable ES-IS on all interfaces.

```
[edit routing-instances aaaa]
user@host# set protocols esis interface all
```

3. Configure the end system configuration timer.

```
[edit routing-instances aaaa]
user@host# set protocols esis interface all end-system-configuration-timer 180
```

4. Configure the preference value.

```
[edit routing-instances aaaa]
user@host# set protocols esis preference 30
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances
aaaa {
  protocols {
    esis {
      preference 30;
      interface all {
        end-system-configuration-timer 180;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying Routing-Instance for CLNS | 1527](#)
- [Verifying ES-IS for CLNS | 1527](#)

Confirm that the configuration is working properly.

Verifying Routing-Instance for CLNS

Purpose

Verify that the policy options are enabled for the routing instance.

Action

From operational mode, enter the **show routing-instances** command.

Verifying ES-IS for CLNS

Purpose

Verify that ES-IS is enabled.

Action

From operational mode, enter the **show protocols** command.

RELATED DOCUMENTATION

[CLNS Configuration Overview | 1522](#)

[Understanding ES-IS for CLNS | 1524](#)

[Verifying a CLNS VPN Configuration | 1541](#)

Understanding IS-IS for CLNS

IS-IS extensions provide the basic interior gateway protocol (IGP) support for collecting intradomain routing information for Connectionless Network Service (CLNS) destinations within a CLNS network. Routers that learn host addresses through End System-to-Intermediate System (ES-IS) can advertise the addresses to other routers (intermediate systems) by using IS-IS.

For more information about IS-IS, see the ISO 10589 standard.

- [Verification | 1530](#)

This example shows how to create a routing instance and enable IS-IS protocol on all interfaces.

Requirements

Before you begin, configure the network interfaces. See [Interfaces User Guide for Security Devices](#).

Overview

The configuration instructions in this topic describe how to create a routing-instance called `aaaa`, enable IS-IS on all interfaces, and define BGP export policy name (`dist-bgp`), family (ISO), and protocol (BP), and apply the export policy to IS-IS.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter **commit** from configuration mode.

```

set routing-instances aaaa protocols isis clns-routing
set routing-instances aaaa protocols isis interface all
set routing-instances aaaa protocols isis no-ipv4-routing no-ipv6-routing
set policy-options policy-statement dist-bgp from family iso protocol bgp
set policy-options policy-statement dist-bgp then accept
set routing-instances aaaa protocols isis export dist-bgp

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure IS-IS for CLNS:

1. Configure the routing instance.

```

[edit]
user@host# edit routing-instances aaaa

```

2. Enable CLNS routing.

```

[edit routing-instances aaaa]
user@host# set protocols isis clns-routing

```

3. Enable IS-IS on all interfaces.

```

[edit routing-instances aaaa]
user@host# set protocols isis interface all

```

4. (Optional) Disable IPv4 and IPv6 routing to configure a pure CLNS network .

```

[edit routing-instances aaaa]
user@host# set protocols isis no-ipv4-routing no-ipv6-routing

```

5. Define the BGP export policy name, family, and protocol.

```

[edit policy-options]
user@host# set policy-statement dist-bgp from family iso protocol bgp

```

6. Define the action for the export policy.

```
[edit policy-options]
user@host# set policy-statement dist-bgp then accept
```

7. Apply the export policy to IS-IS.

```
[edit routing-instances aaaa]
user@host# set protocols isis export dist-bgp
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances
aaaa {
  protocols {
    isis {
      export dist-bgp;
      no-ipv4-routing;
      no-ipv6-routing;
      clns-routing;
      interface all;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Understanding Static Routes for CLNS

The Connectionless Network Service (CLNS) is an ISO Layer 3 protocol that uses network service access point (NSAP) reachability information instead of IPv4 or IPv6 prefixes.

You can configure static routes to exchange CLNS routes within a CLNS island. A *CLNS island* is typically an IS-IS level 1 area that is part of a single IGP routing domain. An island can contain more than one area. CLNS islands can be connected by VPNs.

RELATED DOCUMENTATION

[Example: Configuring Static Routes for CLNS When No IGP is Present | 1532](#)

Example: Configuring Static Routes for CLNS When No IGP is Present

IN THIS SECTION

- [Requirements | 1532](#)
- [Overview | 1532](#)
- [Configuration | 1532](#)
- [Verification | 1534](#)

This example shows how to configure static routes for CLNS.

Requirements

Before you begin, configure the network interfaces. See *Interfaces User Guide for Security Devices*.

Overview

In this example, you configure static routes for CLNS. In the absence of an interior gateway protocol (IGP) on a certain link, a routing device might need to be configured with static routes for CLNS prefixes to be reachable by way of that link. This might be useful, for example, at an autonomous system (AS) boundary.

When you configure static routes for CLNS, consider the following tasks:

- Specify the **iso.0** routing table option to configure a primary instance CLNS static route.
- Specify the **instance-name.iso.0** routing table option to configure a CLNS static route for a particular routing instance.
- Specify the **route nsap-prefix** statement to configure the destination for the CLNS static route.
- Specify the **next-hop (interface-name | iso-net)** statement to configure the next hop, specified as an ISO network entity title (NET) or interface name.
- Include the **qualified-next-hop (interface-name | iso-net)** statement to configure a secondary backup next hop, specified as an ISO network entity title or interface name.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop
  t1-0/2/2.0
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.0000.0000.0000/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 preference 20
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.0000.0000.0000/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 metric 10
```

Step-by-Step Procedure

To configure static routes for CLNS:

1. Configure the routes.

```
[edit routing-options rib iso.0 static]
user@host# set iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212
user@host# set iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop t1-0/2/2.0
user@host# set iso-route 47.0005.80ff.f800.0000.0000.0000.0000/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 preference 20
user@host# set iso-route 47.0005.80ff.f800.0000.0000.0000.0000/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 metric 10
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show routing-options
rib iso.0 {
  static {
    iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212;
    iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop t1-0/2/2.0;
```

```

iso-route 47.0005.80ff.f800.0000.eee0/152 {
    qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 {
        preference 20;
        metric 10;
    }
}
}
}

```

Verification

Checking the Routing Table

Purpose

Make sure that the expected routes appear in the routing table.

Action

```
user@host> show route table iso.0
```

```

iso.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152
    *[Static/5] 00:00:25
    > via t1-0/2/2.0
47.0005.80ff.f800.0000.eee0/84
    *[Static/20] 00:04:01, metric 10, metric2 10
    > to #75 0.12.0.34.0.56 via fe-0/0/1.0
47.0005.80ff.f800.0000.ffff.ffff/104
    *[Static/5] 00:04:01, metric2 0
    > via t1-0/2/2.0

```

Meaning

The static routes appear in the routing table.

Understanding BGP for CLNS VPNs

BGP extensions allow BGP to carry Connectionless Network Service (CLNS) virtual private network (VPN) network layer reachability information (NLRI) between provider edge (PE) routers. Each CLNS route is encapsulated into a CLNS VPN NLRI and propagated between remote sites in a VPN.

CLNS is a Layer 3 protocol similar to IP version 4 (IPv4). CLNS uses network service access points (NSAPs) to address end systems. This allows for a seamless autonomous system (AS) based on International Organization for Standardization (ISO) NSAPs.

A single routing domain consisting of ISO NSAP devices are considered to be CLNS islands. CLNS islands are connected together by VPNs.

You can configure BGP to exchange ISO CLNS routes between PE routers connecting various CLNS islands in a VPN using multiprotocol BGP extensions. These extensions are the ISO VPN NLRIs.

Each CLNS network island is treated as a separate VPN routing and forwarding instance (VRF) instance on the PE router.

You can configure CLNS on the global level, group level, and neighbor level.

- [Configuration | 1536](#)
- [Verification | 1537](#)

This example shows how to create a BGP group for CLNS VPNs, define the BGP peer neighbor address for the group, and define the family.

Requirements

Before you begin, configure the network interfaces. See the *Interfaces User Guide for Security Devices*.

Overview

In this example, you create the BGP group called pedge-pedge, define the BGP peer neighbor address for the group as 10.255.245.215, and define the BGP family.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols bgp group pedge-pedge neighbor 10.255.245.213
set protocols bgp family iso-vpn unicast
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure BGP for CLNS VPNs:

1. Configure the BGP group and define the BGP peer neighbor address.

```
[edit protocols bgp]
user@host# set group pedge-pedge neighbor 10.255.245.213
```

2. Define the family.

```
[edit protocols bgp]
user@host# set family iso-vpn unicast
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

Verifying the Neighbor Status

Purpose

Display information about the BGP peer.

Action

From operational mode, run the **show bgp neighbor 10.255.245.213** command. Look for **iso-vpn-unicast** in the output.

```
user@host> show bgp neighbor 10.255.245.213
```

Example: Configuring a VPN Routing Instance for CLNS

IN THIS SECTION

- [Requirements | 1538](#)
- [Overview | 1538](#)
- [Configuration | 1539](#)
- [Verification | 1540](#)

This example shows how to create a CLNS routing instance and set the instance type for Layer 3 VPNs.

Requirements

Before you begin, configure the network interfaces. See *Interfaces User Guide for Security Devices*.

Overview

The following example shows how to create a CLNS routing instance called `aaaa` and set the instance type to VRF for Layer 3 VPNs. Within the example, you specify that the `lo0.1` interface, `e1-2/0/0.0` interface, and `t1-3/0/0.0` interface all belong to the routing instance. The route distinguisher is set as `10.255.245.1:1` and the policy for the Layer 3 VRF table is set as `target:11111:1`.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa instance-type vrf
set routing-instances aaaa interface lo0.1
set routing-instances aaaa interface ge-0/0/3
set routing-instances aaaa interface ge-0/0/2
set routing-instances aaaa route-distinguisher 10.255.245.1:1
set routing-instances aaaa vrf-target target:1111:1
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a VPN routing instance:

1. Create the routing instance.

```
[edit]
user@host# edit routing-instances aaaa
```

2. Specify the routing instance type.

```
[edit routing-instances aaaa]
user@host# set instance-type vrf
```

3. Specify the interfaces that belong to the routing instance.

```
[edit routing-instances aaaa]
user@host# set interface lo0.1
user@host# set interface ge-0/0/3
user@host# set interface ge-0/0/2
```

4. Specify the route distinguisher.

```
[edit routing-instances aaaa]
user@host# set route-distinguisher 10.255.245.1:1
```

5. Specify the policy for the Layer 3 VRF table.

```
[edit routing-instances aaaa]
user@host# set vrf-target target:11111:1
```

6. Enable family ISO on the interfaces edit interfaces interface-name unit-id.

```
[edit routing-instances aaaa]
user@host# set family ISO
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit ]
user@host# show routing-instances
instance-type vrf;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
interface lo0.1;
route-distinguisher 10.255.245.1:1;
vrf-target target:11111:1;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying the Configured CLNS Routing Instance

Purpose

Confirm that the configuration is working properly.

Verify that the CLNS routing instance is configured.

Action

From operational mode, enter the **show routing-instances** command.

VPLS Overview

IN THIS SECTION

- [Sample VPLS Topology | 1546](#)
- [VPLS on PE Routers | 1547](#)
- [Using an Ethernet Switch as the VPLS CE Device | 1549](#)
- [VPLS Exceptions on SRX Series Devices | 1549](#)

Virtual private LAN service (VPLS) is an Ethernet-based point-to-multipoint Layer 2 VPN. It allows you to connect geographically dispersed Ethernet LAN sites to each other across an MPLS backbone. For customers who implement VPLS, all sites appear to be in the same Ethernet LAN even though traffic travels across the service provider's network.

VPLS, in its implementation and configuration, has much in common with an MPLS Layer 2 VPN. In a VPLS topology, a packet originating within a customer's network is sent first to a customer edge (CE) device (for example, a router or Ethernet switch). It is then sent to a provider edge (PE) router within the service provider's network. The packet traverses the service provider's network over an MPLS label-switched path (LSP). It arrives at the egress PE router, which then forwards the traffic to the CE device at the destination customer site.

The difference is that for VPLS, packets can traverse the service provider's network in point-to-multipoint fashion, meaning that a packet originating from a CE device can be broadcast to all the PE routers participating in a VPLS routing instance. In contrast, a Layer 2 VPN forwards packets in point-to-point fashion only. The paths carrying VPLS traffic between each PE router participating in a routing instance are signaled using BGP.

NOTE: The RSVP automatic mesh feature with multiple RSVP neighbors on a single LAN is not supported on SRX Series devices because RSVP runs on WAN links in a service provider network. Most of these WAN interfaces are point-to-point and are rarely seen in LAN networks.

This topic contains the following sections:

Sample VPLS Topology

[Figure 119 on page 1547](#) shows a basic VPLS topology.

Figure 119: Basic VPLS Topology

In this sample, the PE routers use the same autonomous system (AS). Within the AS, routing information is communicated through an interior gateway protocol (IGP). Outside the AS, routing information is shared with other ASs through BGP. The PE routers must use the same signaling protocols to communicate.

VPLS on PE Routers

Within a VPLS configuration, a device running Junos OS can act as a PE router. Junos OS passes the VPLS traffic through the following ports and PIMs on the Juniper Networks device to CE routers in the VPLS network:

- Built-in Ethernet ports on front panel
- Gigabit Ethernet uPIMs
- Gigabit Ethernet ePIMs

- Fast Ethernet PIMs
- Fast Ethernet ePIMs

NOTE: Ports on uPIMs and ePIMs must be in routing mode before you can configure the corresponding interfaces for VPLS.

Because a VPLS carries Ethernet traffic across a service provider network, it must mimic an Ethernet network in some ways. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, it forwards the packet to the appropriate PE router or CE device. If it does not, it broadcasts the packet to all other PE routers and CE devices that are members of that VPLS routing instance. In both cases, the CE device receiving the packet must be different from the one sending the packet.

When a PE router receives a packet from another PE router, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, the PE router either forwards the packet or drops it depending on whether the destination is a local or remote CE device:

- If the destination is a local CE device, the PE router forwards the packet to it.
- If the destination is a remote CE device (connected to another PE router), the PE router discards the packet.

If the PE router cannot determine the destination of the VPLS packet, it floods the packet to all attached CE devices. [Figure 120 on page 1548](#) illustrates this process.

Figure 120: Flooding a Packet with an Unknown Destination

A VPLS interface can be directly connected to an Ethernet switch. Layer 2 information gathered by an Ethernet switch, for example, MAC addresses and interface ports, is included in the VPLS routing instance table.

An MPLS label-switched interface (LSI) label is used as the inner label for VPLS. This label maps to a VPLS routing instance on the ingress PE router. On the egress PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

One restriction on flooding behavior in VPLS is that traffic received from remote PE routers is never forwarded to other PE routers. This restriction helps prevent loops in the core network. However, if a CE Ethernet switch has two or more connections to the same PE router, you must enable the Spanning Tree Protocol (STP) on the CE switch to prevent loops.

NOTE: Under certain circumstances, VPLS PE routers might duplicate an Internet Control Message Protocol (ICMP) reply from a CE device when a PE router has to flood an ICMP request because the destination MAC address has not yet been learned. The duplicate ICMP reply can be triggered when a CE device with promiscuous mode enabled is connected to a PE router. The PE router automatically floods the promiscuous mode enabled CE device, which then returns the ICMP request to the VPLS PE routers. The VPLS PE routers consider the ICMP request to be new and flood the request again, creating a duplicate ping reply.

Using an Ethernet Switch as the VPLS CE Device

For VPLS configurations, the CE device does not necessarily need to be a router. You can link the PE routers directly to Ethernet switches. However, be aware of the following configuration issues:

- When you configure VPLS routing instances and establish two or more connections between a CE Ethernet switch and a PE router, you must enable the Spanning Tree Protocol (STP) on the switch to prevent loops.
- Junos OS allows standard bridge protocol data unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

VPLS Exceptions on SRX Series Devices

The VPLS implementation on SRX Series device is similar to VPLS implementations on M Series, T Series, and MX Series routers, with the following exceptions:

- SRX Series devices do not support aggregated Ethernet interfaces. Therefore, aggregated Ethernet interfaces between CE devices and PE routers, and aggregated Ethernet interfaces between PE devices and PE routers are not supported for VPLS routing instances on SRX Series devices.
- VPLS multihoming, which allows connecting a CE device to multiple PE routers to provide redundant connectivity, is not supported on SRX Series devices.
- SRX Series devices do not support BGP mesh groups.
- SRX Series devices support only the following encapsulation types on VPLS interfaces that face CE devices: extended VLAN VPLS, Ethernet VPLS, and VLAN VPLS. Ethernet VPLS over ATM LLC encapsulation is not supported.
- Virtual ports are generated dynamically on a Tunnel Services PIC on some Juniper Networks routing platforms. SRX Series devices do not support Tunnel Services modules or virtual ports.
- The VPLS implementation on SRX Series devices does not support dual-tagged frames. Therefore, VLAN rewrite operations are not supported on dual-tagged frames. VLAN rewrite operations such as pop-pop, pop-swap, push-push, swap-push, and swap-swap, which are supported on M Series and T Series routing platforms, are not supported on SRX Series devices.

VPLS Configuration Overview

To configure VPLS functionality, you must enable VPLS support on the provider edge (PE) routers. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the customer edge (CE) devices, as explained in the steps that follow.

NOTE: Many configuration procedures for VPLS are identical to the procedures for Layer 2 and Layer 3 VPNs.

To configure VPLS:

1. Determine which uPIM and ePIM ports correspond to the interfaces that will carry the VPLS traffic and enable routing mode on those ports.
2. Configure the interfaces that will carry the VPLS traffic between the PE router and CE devices. On the PE router interfaces that are facing the CE devices, specify a VPLS encapsulation type. The type of encapsulation depends on the interface type. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
3. Create a VPLS routing instance on each PE router that is participating in the VPLS. For each VPLS routing instance, specify which interfaces will carry the VPLS traffic between the PE and CE devices. On the CE device interface that faces the PE router, you must specify inet (for IPv4), and include the IP address. Additionally, each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP identify overlapping network layer reachability information (NLRI) messages from different VPNs.) See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).
4. Configure routing options on the PE router. See [“Example: Configuring Routing Options on the VPLS PE Router” on page 1630](#).
5. Configure MPLS LSPs between the PE routers. See [“Example: Configuring MPLS on the VPLS PE Router” on page 1585](#).
6. Configure RSVP on the PE routers. Enable RSVP for all connections that participate in the MPLS LSP. See [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#).
7. Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See [“Example: Configuring BGP on the VPLS PE Router” on page 1628](#).
8. Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
9. Configure VLAN encapsulation. See [“Example: Configuring VPLS VLAN Encapsulation on Gigabit Ethernet Interfaces” on page 1637](#), [“Example: Configuring VPLS VLAN Encapsulation” on page 1633](#), and [“Example: Configuring Extended VLAN VPLS Encapsulation” on page 1639](#).

Migrating from FEC128 LDP-VPLS to EVPN Overview

IN THIS SECTION

- [Technology Overview and Benefits | 1552](#)
- [FEC128 LDP-VPLS to EVPN Migration | 1553](#)
- [Sample Configuration for LDP-VPLS to EVPN Migration | 1555](#)

For service providers with virtual private LAN service (VPLS) networks and Ethernet VPN (EVPN) networks, there is a need to interconnect these networks. Prior to Junos OS Release 17.3, a logical tunnel interface on the interconnection point of the VPLS and EVPN routing instances was used for this purpose. In this case, the provider edge (PE) devices in each network were unaware of the PE devices in the other technology network. Starting in Junos OS Release 17.3, a solution is introduced for enabling staged migration from FEC128 LDP-VPLS toward EVPN on a site-by-site basis for every VPN routing instance. In this solution, the PE devices running EVPN and VPLS for the same VPN routing instance and single-homed segments can coexist. During migration, there is minimal impact to the customer edge (CE) device-to-CE device traffic forwarding for affected customers.

The following sections describe the migration from LDP-VPLS to EVPN:

Technology Overview and Benefits

Virtual private LAN service (VPLS) is an Ethernet-based point-to-multipoint Layer 2 VPN. This technology allows you to connect geographically dispersed data center LANs to each other across an MPLS backbone while maintaining Layer 2 connectivity. The high availability features defined in VPLS standards (such as LER dual homing) and topology autodiscovery features using BGP signaling make VPLS scalable and easy

to deploy. Because VPLS uses MPLS as its core, it provides low latency variation and statistically bound low convergence times within the MPLS network.

Ethernet VPN (EVPN), on the other hand, is a combined Layer 2 and Layer 3 VPN solution that is more scalable, resilient, and efficient than current technologies. It provides several benefits including greater network efficiency, reliability, scalability, virtual machine (VM) mobility, and policy control for service providers and enterprises.

Although VPLS is a widely deployed Layer 2 VPN technology, service provider networks migrate to EVPN because of the scaling benefits and ease of deployment. Some of the benefits of EVPN include:

- Control plane traffic is distributed with BGP and the broadcast and multicast traffic is sent using a shared multicast tree or with ingress replication.
- Control plane learning is used for MAC and IP addresses instead of data plane learning. MAC address learning requires the flooding of unknown unicast and ARP frames, whereas IP address learning does not require any flooding.
- Route reflector is used to reduce a full mesh of BGP sessions among PE devices to a single BGP session between a PE device and the route reflector.
- Autodiscovery with BGP is used to discover PE devices participating in a given VPN, PE devices participating in a given redundancy group, tunnel encapsulation types, multicast tunnel type, and multicast members.
- All-active multihoming is used. This allows a given CE device to have multiple links to multiple PE devices, and traffic traversing to-and-from that CE device fully utilizes all of these links (Ethernet segment).
- When a link between a CE device and a PE device fails, the PE devices for that EVPN instance (EVI) are notified of the failure with the withdrawal of a single EVPN route. This allows those PE devices to remove the withdrawing PE device as a next hop for every MAC address associated with the failed link (mass withdrawal).

FEC128 LDP-VPLS to EVPN Migration

Some service providers want to preserve their investments in VPLS. This leads to the need to connect the old VPLS networks to new networks that run EVPN. For this purpose, logical tunnel interfaces on the interconnection point of the VPLS and EVPN routing instances were used. However, all the other PE devices belonged either to the VPLS network or to the EVPN network and were unaware of the other technology.

Starting in Junos OS Release 17.3, EVPN can be introduced into an existing VPLS network in a staged manner, with minimal impact to VPLS services. On a VPLS PE device, some customers can be moved to EVPN, while other customers continue to use VPLS pseudowires. Other PE devices can be entirely VPLS and switching customers on other PE devices to EVPN. This solution provides support for the seamless migration Internet draft (expires January ,2018), *(PBB-)EVPN Seamless Integration with (PBB-)VPLS*.

The seamless migration from FEC128 LDP-VPLS to EVPN solution supports the following functionality:

- Allow for staged migration toward EVPN on a site-by-site basis per VPN instance. For instance, new EVPN sites to be provisioned on EVPN PE devices.
- Allow for the coexistence of PE devices running both EVPN and VPLS for the same VPN instance and single-homed segments.

In the LDP-VPLS to EVPN migration, the PE device where some customers have been migrated to EVPN while other customers are being served using VPLS is called a super PE device. As super PE devices discover other super PE devices within a routing instance, they use EVPN forwarding to communicate with other super PE devices and VPLS pseudowires to PE devices running VPLS. The PE device with no EVPN awareness, and running only VPLS for all the customers, is called a VPLS PE device.

The CE device connected to a super PE can reach CE devices connected to EVPN-only PE devices or VPLS-only PE devices, but CE devices connected to EVPN-only PE devices cannot reach CE devices connected to VPLS-only PE devices.

Because the migration from LDP-VPLS to EVPN is supported on a per-routing instance basis, and if the routing instance is serving multiple customers on a PE device, all are migrated together. EVPN is responsible for setting up data forwarding between the PE devices upgraded to EVPN, while VPLS continues to set up data forwarding to PE devices that run VPLS. There should be zero impact for customers that still use VPLS pseudowire on all the PE devices.

NOTE:

The following features are not supported with the LDP-VPLS to EVPN migration:

- Migration from FEC129 VPLS to EVPN.
- Migration from BGP-VPLS to EVPN.
- Migration of VPLS virtual switch to EVPN virtual switch.
- Migration of VPLS routing instance to EVPN virtual switch.
- Migration of VPLS routing instance or PBB-VPLS to PBB-EVPN.
- Seamless migration from EVPN back to VPLS.
- Enhancing EVPN to support the set of tools or statements and commands that VPLS supports.
- Active-active and active-standby multihoming. The migration to EVPN is supported only on single-homed deployments.
- Spanning all-active across EVPN and VPLS PE devices does not work, because the all-active multihoming feature is not supported on VPLS.
- Connecting EVPN-only PE devices with VPLS-only PE devices through super PE devices.
- IPv6, logical systems, multichassis support, and SNMP, because they are currently not supported on EVPN.

Sample Configuration for LDP-VPLS to EVPN Migration

IN THIS SECTION

- [LDP-VPLS Configuration | 1555](#)
- [EVPN Migration Configuration | 1557](#)

The following sections provide the sample configuration required for performing the LDP-VPLS to EVPN migration.

LDP-VPLS Configuration

A typical static LDP-VPLS routing instance configuration is as follows:

```
user@host# show routing-instance foo
```

```

instance-type vpls;
vlan-id 100; (not needed for VLAN bundle service)
interface ge-2/0/0.590;
interface ae500.590;
routing-interface irb.0;
forwarding-options {
    family vpls {
        filter {
            input UNKNOWN-UNICAST;
        }
    }
}
protocols {
    vpls {
        control-word;
        encapsulation-type ethernet-vlan;
        enable-mac-move-action;
        mac-table-size {
            100000;
            packet-action drop;
        }
        mac-table-aging-time ;
        interface-mac-limit {
            100000;
            packet-action drop;
        }
        no-tunnel-services; (use label-switched interfaces)
        vpls-id 245015;
        mtu 1552;
        ignore-mtu-mismatch;
        mac-flush {
            any-spoke;
        }
        no-vlan-id-validate;
        neighbor 192.168.252.64 {
            psn-tunnel-endpoint 10.0.0.31;
            pseudowire-status-tlv;
            revert-time 60;
            backup-neighbor 192.168.252.65 {
                psn-tunnel-endpoint 10.0.0.32;
                hot-standby;
            }
        }
    }
    mesh-group Spoke { (access label-switched interface toward spoke)

```

```

local-switching;
neighbor 192.168.252.66 {
    psn-tunnel-endpoint 10.0.0.41;
    pseudowire-status-tlv;
}
neighbor 192.168.252.67 {
    psn-tunnel-endpoint 10.0.0.42;
    pseudowire-status-tlv;
}
}
connectivity-type permanent;
}

```

```

user@host# show interfaces ge-2/0/0.590
encapsulation vlan-vpls;
vlan-id 590;
output-vlan-map {
    swap;
    tag-protocol-id 0x8100;
    inner-vlan-id 590;
}
family vpls {
    filter {
        input-list [ listA ];
        output-list listB;
    }
}

```

EVPN Migration Configuration

To perform the FEC128 LDP-VPLS to EVPN migration, do the following:

1. On the backup Routing Engine, load Junos OS Release 17.3R1.
2. Perform in-service software upgrade (ISSU) to acquire mastership. Ensure that the VPLS unified ISSU does not have any impact on the VPLS forwarding.
3. Identify routing instances (customers) that need to be migrated to EVPN.
4. Enable EVPN in a single routing instance.
 - Change routing instance type to **evpn**, and include the **evpn** statement at the **[edit routing-instances routing-instance-name protocols]** hierarchy level, and also include the **vpls** statement at the same hierarchy to support VPLS commands.

For example:

```
[edit routing-instances routing-instance-name]
instance-type evpn;
interface ge-2/0/0.590;
interface ae500.590;
routing-interface irb.0;
route-distinguisher 1.1.1.1:50; (add for LDP-VPLS)
vrf-target target:100:100; (add for LDP-VPLS)
forwarding-options {
  family vpls {
    filter {
      input UNKNOWN-UNICAST;
    }
  }
}
protocols {
  vpls { (supports all existing VPLS commands)
}
```

5. Enable family EVPN signaling in BGP.

For example:

```
protocols {
  bgp {
    local-as 102;
    group 2mx {
      type internal;
      local-address 81.1.1.1;
      family evpn {
        signaling;
      }
    }
    neighbor 81.2.2.2;
    neighbor 81.9.9.9;
  }
}
```

After the configuration for the EVPN migration is committed, the routing protocol process and the Layer 2 address learning process start building the EVPN state to reflect interfaces, bridge domains, peers and routes. The locally learnt MAC addresses are synchronized by the Layer 2 address learning process in the instance.vpls.0 to the routing protocol process. When a local MAC ages out in the instance.vpls.0, the routing protocol process is informed by the Layer 2 address learning process.

When an EVPN peer is learnt, the routing protocol process sends a new message to the Layer 2 address learning process to remove the peer's label-switched interface or virtual tunnel logical interface from the VE mesh group and disables MAC-learning on it. The EVPN IM next-hop is then added to the VE mesh group. The EVPN behavior in the routing protocol process of learning MAC addresses over BGP and informing Layer 2 address learning process of the MPLS next hop is maintained.

The VPLS statements and commands continue to apply to the VPLS pseudowires between the PE devices and the MAC addresses learnt over them. The EVPN statements and commands apply to PE devices running EVPN.

Reverting to VPLS

If the EVPN migration runs into issues, you can revert back to VPLS until the issue is understood. The routing instance is reverted from a super PE to a VPLS PE in a non-catastrophic manner by enabling the following configuration:

```
[edit routing-instances routing-instance-name]
user@host# set instance-type vpls
user@host# delete protocols evpn
user@host# delete route-distinguisher (if running LDP-VPLS)
user@host# delete vrf-target (if running LDP-VPLS)
```

On reverting the EVPN migration to VPLS, the following happens:

1. The EVPN state information is deleted.
2. There is a trigger for withdrawal of EVPN control plane routes.
3. The routing protocol process sends a new message to the Layer 2 address learning process with the label-switched interface or the virtual tunnel logical interface for the routing instance and peer.
4. The label-switched or virtual tunnel interface adds the new message to the flood group and MAC learning is enabled.
5. The egress IM next hop is deleted by the routing protocols process, prompting the Layer 2 address learning process to remove it from the flood group.
6. Remote MAC addresses are learned again over the label-switched interface or virtual tunnel logical interface.

LDP-VPLS to EVPN Migration and Other Features

Table 46 on page 1560 describes the functionality of some of the related features, such as multihoming and integrated routing and bridging (IRB) with the LDP-VPLS to EVPN migration.

Table 46: EVPN Migration and Other Features Support

Feature	Supported Functionality in EVPN Migration
MAC move	<p>MAC moves are supported between VPLS-only PE device and super PE devices.</p> <p>When a MAC address moves from a VPLS-only PE device to a super PE device, it is learned over BGP, and the routing protocol process informs the Layer 2 address learning process of the EVPN next hop to be updated in the foo.vpls.0 routing table.</p> <p>When a MAC address moves from a super PE device to a VPLS-only PE device, it is learned in the Packet Forwarding Engine on the label-switched interface or virtual tunnel interface. The Layer 3 address learning process updates it to VPLS or the label-switched interface next hop.</p> <p>When the type 2 route is withdrawn by EVPN BGP, the MAC address is not deleted from the forwarding table, so there is no loss of data.</p> <p>The forwarding MAC table is shared by VPLS and EVPN. Some attributes, such as mac-table-size and mac-table-aging-time could be configured under both EVPN and VPLS. When there is a conflict, the values under EVPN take precedence.</p>
IRB	<p>No changes needed in IRB.</p> <p>On a super PE device, EVPN populates the /32 host routes learned over MAC+IP type 2 routes from EVPN peers in a Layer 3 virtual routing and forwarding, while VPLS IRB forwarding using subnet routes works on sites still running VPLS.</p>

Table 46: EVPN Migration and Other Features Support *(continued)*

Feature	Supported Functionality in EVPN Migration
Hierarchical VPLS	<p>In an H-VPLS network with hub-and-spoke PE devices, when the hub PE device is migrated to EVPN, local MAC addresses learned over the access label-switched or virtual tunnel interface need to be advertised to BGP, so that the other EVPN-only PE devices or super PE devices can reach them.</p> <p>Take the following into consideration when migrating an H-VPLS network to EVPN:</p> <ul style="list-style-type: none">• Hubs typically have local switching enabled as interspoke traffic is forwarded through the hub. If spokes alone are migrated to EVPN and spokes have Layer 3 or MPLS reachability to each other, the label-switched or virtual tunnel interface to the hub and EVPN next hop (remote spoke) is present in the VPLS edge (VE) floodgroup. This results in two copies of broadcast, unknown unicast, and multicast (BUM) traffic received by the remote spoke. One option to avoid this behavior is to migrate the hubs to EVPN too.• EVPN is not aware of hierarchy. All peers are considered core-facing. Once hubs and spokes are migrated to EVPN, split horizon prevents the BUM traffic from being forwarded to other core-facing PE devices.
ESI configuration	Ethernet segment identifier (ESI) is configured at the physical interface or port level.

Understanding VPLS Interfaces

IN THIS SECTION

- [Interface Name | 1562](#)
- [Encapsulation Type | 1562](#)
- [Flexible VLAN Tagging | 1562](#)
- [VLAN Rewrite | 1563](#)

For each VPLS routing instance on a PE router, you specify which interfaces are to be used to carry VPLS traffic between the PE and CE devices.

This topic contains the following sections:

Interface Name

Specify both the physical and logical portions of the interface name, in the following format:

physical.logical

For example, in ge-1/2/1.2, ge-1/0/1 is the physical portion of the interface name and 2 is the logical portion. If you do not specify the logical portion of the interface name, 0 is set by default. A logical interface can be associated with only one routing instance.

Encapsulation Type

The physical link-layer encapsulation type for a VPLS interface can be one of the following:

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol Identifier (TPID) values.
- **extended-vlan-vpls**—Use extended virtual LAN (VLAN) VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. All VLAN IDs from 1 through 1023 are valid for VPLS VLANs on Fast Ethernet interfaces, and all VLAN IDs from 1 through 4094 are valid for VPLS VLANs on Gigabit Ethernet interfaces.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. You must configure this encapsulation type on both the physical interface and the logical interface. VLAN IDs 1 through 511 are reserved for normal Ethernet VLANs, IDs 512 through 1023 are reserved for VPLS VLANs on Fast Ethernet interfaces, and IDs 512 through 4094 are reserved for VPLS VLANs on Gigabit Ethernet interfaces.
- **flexible-ethernet-services**—Use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. This encapsulation type allows you to configure any combination of route, TCC, CCC, and VPLS encapsulations on a single physical port. Aggregated Ethernet bundles cannot use this encapsulation type.

For flexible Ethernet services encapsulation, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

Flexible VLAN Tagging

For untagged packets to be accepted on an 802.1Q VLAN-tagged port, specify the native VLAN ID with the flexible VLAN tagging option. (No other flexible VLAN tagging features are supported.)

VLAN Rewrite

You can rewrite VLAN tags on VPLS interfaces. Rewriting VLAN tags allows you to use an additional (outer) VLAN tag to differentiate between CE devices that share a VLAN ID.

You can configure rewrite operations to stack (push), remove (pop), or rewrite (swap) tags on single-tagged frames. If a port is not configured for VLAN tagging, rewrite operations are not supported on any logical interface on that port.

You can configure the following VLAN rewrite operations:

- **pop**—Remove a VLAN tag from the top of the VLAN tag stack. The outer VLAN tag of the frame is removed.
- **push**—Add a new VLAN tag to the top of the VLAN stack. An outer VLAN tag is pushed in front of the existing VLAN tag.
- **swap**—Replace the VLAN tag at the top of the VLAN tag stack with a user-specified VLAN tag value.

You perform VLAN rewrite operations by applying input and output VLAN maps at the ingress and egress, respectively, of the interface. For incoming frames, use the `input-vlan-map`; for outgoing frames, use the `output-vlan-map`.

The VPLS implementation on SRX Series devices does not support dual-tagged frames. Therefore, VLAN rewrite operations are not supported on dual-tagged frames. VLAN rewrite operations such as pop-pop, pop-swap, push-push, swap-push, and swap-swap, which are supported on M Series and T Series routing platforms, are not supported on SRX Series devices.

- [Overview | 1564](#)
- [Configuration | 1564](#)
- [Verification | 1565](#)

This example shows how to configure routing interfaces on the VPLS PE router.

Requirements

Before you begin, see *Understanding Selective Stateless Packet-Based Services* .

Overview

In this example, you configure the PE1 router loopback interface and the interface to the PE2 router ge-2/0/1.

Configuration

Step-by-Step Procedure

To configure the routing interface on the VPLS PE router:

1. Configure the loopback interface.

```
[edit]
user@host# set interfaces lo0 unit 0 family inet address 10.255.7.168/32 primary
```

2. Configure the IP address on the MPLS core interface.

```
[edit]
user@host# set interfaces ge-3/0/2 unit 0 family inet address 100.1.1.1/30
```

3. Configure the MPLS family.

```
[edit]
user@host# set interfaces ge-3/0/2 unit 0 family mpls
```

4. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces** command.

[Understanding VPLS Interfaces | 1561](#)

Example: Configuring the Interface to the VPLS CE Device

IN THIS SECTION

- [Requirements | 1565](#)
- [Overview | 1566](#)
- [Configuration | 1566](#)
- [Verification | 1566](#)

This example shows how to configure the router interface that is connected to the CE device to include VPLS encapsulation.

Requirements

Before you begin, see *Understanding Selective Stateless Packet-Based Services* .

Overview

In this example, you configure the router interface ge-1/2/1 that is connected to the CE device to include VPLS encapsulation.

Configuration

Step-by-Step Procedure

To configure the interface to the VPLS CE device:

1. Configure VPLS encapsulation for the interface facing the CE router.

```
[edit]
user@host# set interfaces ge-1/2/1 encapsulation ethernet-vpls
```

2. Configure the interface for the VPLS family group.

```
[edit]
user@host# set interfaces ge-1/2/1 unit 0 family vpls
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces ge-1/2/1** command.

VPLS Filters and Policers Overview

This feature permits users to configure both firewall filters and policers for virtual private LAN service (VPLS). Firewall filters enable you to filter packets based on their components and perform an action on packets that match the filter. Policers enable you to limit the amount of traffic that passes into or out of an interface.

This feature can be enabled by configuring VPLS filters, policers, and accounting through various CLI commands. VPLS filters and policers act on a Layer 2 frame that includes the media access control (MAC) header (after any VLAN rewrite or other rules are applied), but that does not include the cyclical redundancy check (CRC) field.

NOTE: You can apply VPLS filters and policers on the PE routers only to customer-facing (PE-CE) interfaces.

RELATED DOCUMENTATION

[Example: Configuring VPLS Policers | 1571](#)

[Example: Configuring VPLS Filters | 1567](#)

Example: Configuring VPLS Filters

IN THIS SECTION

- [Requirements | 1568](#)
- [Overview | 1568](#)
- [Configuration | 1568](#)
- [Verification | 1570](#)

This example shows how to configure VPLS filters.

Requirements

Before you begin:

- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).
- Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
- Configure RSVP-TE on the PE routers. See [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#).

Overview

This example describes how to configure filtering and accounting for VPLS.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your device to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device.

Configuration

CLI Quick Configuration

To quickly configure VPLS filters, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall family vpls filter blue term term1 from interface ge-3/0/0.512
set firewall family vpls filter blue term term1 from interface fe-5/0/0.512
set firewall family vpls filter blue term term1 then count count1
set firewall family vpls filter blue accounting-profile fw_profile
set accounting-options file fw_acc size 500k
set accounting-options file fw_acc transfer-interval 5
```

```

set accounting-options filter-profile fw_profile file fw_acc
set accounting-options filter-profile fw_profile interval 1
set accounting-options filter-profile fw_profile counters count1
set interfaces ge-0/0/1 unit 512 family vpls filter input blue

```

Step-by-Step Procedure

To configure filters for VPLS:

1. Configure a filter with a GE interface as the match condition and count as the action.

```

[edit ]

Example: Configuring VPLS Policers

IN THIS SECTION

- [Requirements | 1571](#)
- [Overview | 1571](#)
- [Configuration | 1572](#)
- [Verification | 1573](#)

This example shows how to configure VPLS policers.

Requirements

Before you begin:

- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).
- Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
- Configure RSVP-TE on the PE routers. See [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#).

Overview

This example describes how to configure policing and apply it on the interface for VPLS.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your device to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device.

Configuration

CLI Quick Configuration

To quickly configure VPLS policers, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall policer police2 if-exceeding bandwidth-percent 10
set firewall policer police2 if-exceeding burst-size-limit 1500
set firewall policer police2 then discard
set interfaces ge-0/0/1 unit 512 family vpls policer input police2
```

Step-by-Step Procedure

To configure filters for VPLS:

1. Configure bandwidth percentage.

```
[edit ]
user@host# set firewall policer police2 if-exceeding bandwidth-percent 10
```

2. Configure the burst size limit.

```
[edit ]
user@host# set firewall policer police2 if-exceeding burst-size-limit 1500
```

3. Configure the terminal action on the packet.

```
[edit ]
user@host# set firewall policer police2 then discard
```

4. Apply the policer to the interface.

```
[edit ]
user@host# set interfaces ge-0/0/1 unit 512 family vpls policer input police2
```

5. If you are done configuring the device, commit the configuration.

```
[edit ]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show firewall** command.

Understanding VPLS Routing Instances

IN THIS SECTION

- [BGP Signaling | 1574](#)
- [VPLS Routing Table | 1575](#)
- [Trace Options | 1576](#)

To configure VPLS functionality, you must enable VPLS support on the PE router. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the CE devices.

You create a VPLS routing instance on each PE router that is participating in the VPLS. The routing instance has the same name on each PE router. To configure the VPLS routing instance, you specify the following:

- **Route distinguisher**—Helps BGP distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPLS instances. Each routing instance that you configure on a PE router must have a unique route distinguisher.
- **Route target**—Defines which route is part of a VPLS. A unique route target helps distinguish between different VPLS services on the same router.
- **Site name**—Provides unique name for the VPLS site.
- **Site identifier**—Provides unique numerical identifier for the VPLS site.

- Site range—Specifies total number of sites in the VPLS. The site range must be greater than the site identifier.
- Interface to the CE router—Specifies the physical interface to the CE router that carries VPLS traffic. The interface must be configured for a VPLS encapsulation type.

NOTE: In addition to the VPLS routing instance, you must configure MPLS label-switched paths (LSPs) between the PE routers, internal BGP (IBGP) sessions between the PE routers, and an interior gateway protocol (IGP) on the PE routers.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your router to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the router performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the router.

This topic contains the following sections:

BGP Signaling

BGP is used to signal the paths between each of the PE routers participating in the VPLS routing instance. These paths carry VPLS traffic across the service provider's network between the VPLS sites.

NOTE: LDP signaling is not supported for the VPLS routing instance.

To configure BGP signaling, you specify the following:

- VPLS site name and site identifier—When you configure BGP signaling for the VPLS routing instance, you must specify each VPLS site that has a connection to the router. For each VPLS site, you must configure a site name and site identifier (a numerical identifier between 1 to 65,534 that uniquely identifies the VPLS site).
- Site range—When you enable BGP signaling for the VPLS routing instance, you need to configure a site range. The site range specifies the total number of sites in the VPLS.

NOTE: The site range value must be greater than the largest site identifier.

- **Site preference**—You can specify the preference value advertised for a particular VPLS site. The site preference value is encoded in the BGP local preference attribute. When a PE router receives multiple advertisements with the same VPLS edge (VE) device identifier, the advertisement with the highest local preference value is preferred.

VPLS Routing Table

The VPLS routing table contains MAC addresses and interface information for both physical and virtual ports. You can configure the following characteristics for the table:

- **Table size**—You can modify the size of the VPLS MAC address table. The default table size is 512 MAC addresses; the minimum is 16 addresses, and the maximum is 65,536 addresses.

If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

The interfaces affected include all of the interfaces within the VPLS routing instance, including the local interfaces and the LSI interfaces.

- **Timeout interval**—You can modify the timeout interval for the VPLS table. The default timeout interval is 300 seconds; the minimum is 10 seconds, and the maximum is 1,000,000 seconds. We recommend you configure longer values for small, stable VPLS networks and shorter values for large, dynamic VPLS networks. If the VPLS table does not receive any updates during the timeout interval, the router waits one additional interval before automatically clearing the MAC address entries from the VPLS table.
- **Number of addresses learned from an interface**—You can configure a limit on the number of MAC addresses learned by a VPLS routing instance by setting the MAC table size. The default is 512 addresses; the minimum is 16, and the maximum is 65,536 addresses. If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

Because this limit applies to each VPLS routing instance, the MAC addresses of a single interface can consume all the available space in the table, preventing the routing instance from acquiring addresses from other interfaces. You can limit the number of MAC addresses learned from all interfaces configured for a VPLS routing instance, as well as limit the number of MAC addresses learned from a specific interface.

The MAC limit configured for an individual interface overrides the limit configured for all interfaces for the VPLS routing instance. Also, the table limit can override the limits configured for the interfaces.

The MAC address limit applies only to interfaces to CE devices.

Trace Options

The following trace flags display operations associated with VPLS:

- **all**—All VPLS tracing options
- **connections**—VPLS connections (events and state changes)
- **error**—Error conditions
- **nlri**—VPLS advertisements received or sent using BGP
- **route**—Trace-routing information
- **topology**—VPLS topology changes caused by reconsideration or advertisements received from other PE routers using BGP

Example: Configuring the VPLS Routing Instance

IN THIS SECTION

- [Requirements | 1577](#)
- [Overview | 1577](#)
- [Configuration | 1577](#)
- [Verification | 1579](#)

This example shows how to create a VPLS routing instance on each PE router that is participating in the VPLS.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services*.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).

Overview

This example describes how to create a VPLS routing instance; configure VPLS site identifier, site range, no tunnel services option, route distinguisher, and route target for the VPLS routing instance; and specify the VPLS interface to the CE router.

NOTE: You must specify no tunnel services in the VPLS routing instance configuration, because SRX Series devices do not support tunnel serial PICs.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances green instance-type vpls
set routing-instances green protocols vpls site-range 10 site R3 site-identifier 2
set routing-instances green protocols vpls no-tunnel-services
set routing-instances green route-distinguisher 10.255.7.1:1
set routing-instances green vrf-target target:11111:1
set routing-instances green instance-type vpls interface ge-1/2/1.0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a VPLS routing instance:

1. Configure the routing instance of type VPLS.

```
[edit]
user@host# edit routing-instances green
```

2. Enable the VPLS instance type.

```
[edit routing-instances green]
user@host# set instance-type vpls
```

3. Configure the VPLS site identifier and range for the VPLS routing instance.

```
[edit routing-instances green protocols vpls]
user@host# set site-range 10 site R3 site-identifier 2
```

4. Configure the no-tunnel-services option for the VPLS routing instance.

```
[edit routing-instances green protocols vpls]
user@host# set no-tunnel-services
```

5. Configure the route distinguisher.

```
[edit routing-instances green]
user@host# set route-distinguisher 10.255.7.1:1
```

6. Configure the route target.

```
[edit routing-instances green]
user@host# set vrf-target target:11111:1
```

7. Specify the VPLS interface to the CE router.

```
[edit routing-instances green]
user@host# set instance-type vpls interface ge-1/2/1.0
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances green** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances green
instance-type vpls;
interface ge-1/2/1.0;
route-distinguisher 10.255.7.1:1;
vrf-target target:11111:1;
protocols {
  vpls {
    site-range 10;
    no-tunnel-services;
    site R3 {
      site-identifier 2;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying VPLS Routing Instance Is Configured | 1579](#)
- [Verifying VPLS Routing Attributes Are Configured | 1579](#)

Confirm that the configuration is working properly.

Verifying VPLS Routing Instance Is Configured

Purpose

Verify that the VPLS routing instance is configured.

Action

From operational mode, enter the **show routing-instances** command.

Verifying VPLS Routing Attributes Are Configured

Purpose

Verify that attributes such as VPLS site identifier, site range, no tunnel services option, route distinguisher, and route target for the VPLS routing instance are configured.

Action

From operational mode, enter the **show routing-instances green protocols vpls** command.

Example: Configuring Automatic Site Identifiers for VPLS

This example shows how to configure automatic site identifiers for VPLS sites.

Requirements

Before you begin, see information on selective stateless packet-based services in *Interfaces User Guide for Security Devices*.

Overview

When you enable automatic site identifiers, the Junos OS automatically assigns site identifiers to VPLS sites. In this example, you configure a routing instance called `vpls` instance and enable automatic site identifiers for VPLS.

NOTE: Site identifiers for VPLS sites can be different for different routing instances.

Configuration

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure automatic site identifiers:

1. Configure the routing instance of type VPLS.

[edit]

```
user@host#set routing-instances vpls-instance
```

2. Enable automatic site identifiers.

```
[edit routing-instances vpls-instance]
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id collision-detect-time 10
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id new-site-wait-time 20
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id reclaim-wait-time minimum
5 maximum 20
user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id startup-wait-time 5
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show vpls connections** command.

Example: Configuring OSPF on the VPLS PE Router

IN THIS SECTION

- [Requirements | 1582](#)
- [Overview | 1582](#)
- [Configuration | 1582](#)
- [Verification | 1583](#)

This example shows how to configure OSPF on the VPLS PE router.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services*.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).

Overview

The PE routers exchange routing information using an IGP such as OSPF. In this example, you configure OSPF area 0.0.0.0 on the VPLS PE router and traffic engineering for OSPF.

Configuration

Step-by-Step Procedure

To configure OSPF on the VPLS PE router:

1. Configure the OSPF area on the VPLS PE router.

```
[edit]
user@host# set protocols ospf area 0.0.0.0 interface t1-1/0/1.0
user@host# set protocols ospf area 0.0.0.0 interface lo0.0
```

2. Configure traffic engineering for OSPF.

```
[edit]
user@host# set protocols ospf traffic-engineering
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

[VPLS Configuration Overview | 1550](#)

[VPLS Overview | 1546](#)

Example: Configuring VPLS over GRE with IPsec VPNs

IN THIS SECTION

- [Requirements | 1589](#)
- [Overview | 1589](#)
- [Configuration | 1594](#)
- [Verification | 1609](#)

This example demonstrates a network scenario consisting of a central office and one branch office that will use VPLS, MPLS, GRE, and IPsec to create secure Ethernet connectivity over a Layer 3 network. This configuration can be expanded to add many other branch sites.

Requirements

Before you begin:

- Ensure that a layer 3 network is in place for all branch offices and that there is an ingress (head-end) device at the central office configured to terminate the VPNs from each branch office.
- Obtain IDP licenses for each SRX Series device. IDP is used to reassemble GRE packets that might become fragmented.

Overview

Junos OS can selectively choose whether traffic is processed by the flow engine or packet engine using the selective stateless packet-based feature. This feature allows you to combine flow and packet-based services in a single device. In this example, we describe a deployment scenario that uses this feature to deploy large-scale VPLS over GRE. This enables SRX devices to securely transport Ethernet traffic over Layer 3 networks when used in conjunction with IPsec.

In this scenario you configure a central office ingress (head-end) using an SRX650 device and one branch office using an SRX240 device. This setup is accomplished by carrying MPLS pseudowires over GRE, which in turn, is encapsulated in IPsec in order to guarantee data integrity and confidentiality. By default, SRX Series devices use secure flow forwarding. Because VPLS services are provided in packet-mode only, the configuration requires the GRE tunnel to be terminated in a packet-mode routing instance (the default routing instance).

NOTE: You can also use an MX Series device as the ingress (head-end) device, which is mentioned later in this topic.

To better understand this configuration, we will discuss two scenarios. The first scenario uses pseudowires to allow the creation of point-to-point circuits between two endpoints carried over the MPLS network. If we leave the signaling protocols aside (that is, there are a few ways to provision the pseudowires), these connections are just point-to-point connections. Using this approach provides an end-to-end wire between sites. This is beneficial from a traffic processing point of view because the gateways do not need to do MAC address learning, they simply forward anything they receive to the pseudowire. Because of this, it may be difficult to deploy this setup when trying to provide connectivity to multiple branch offices.

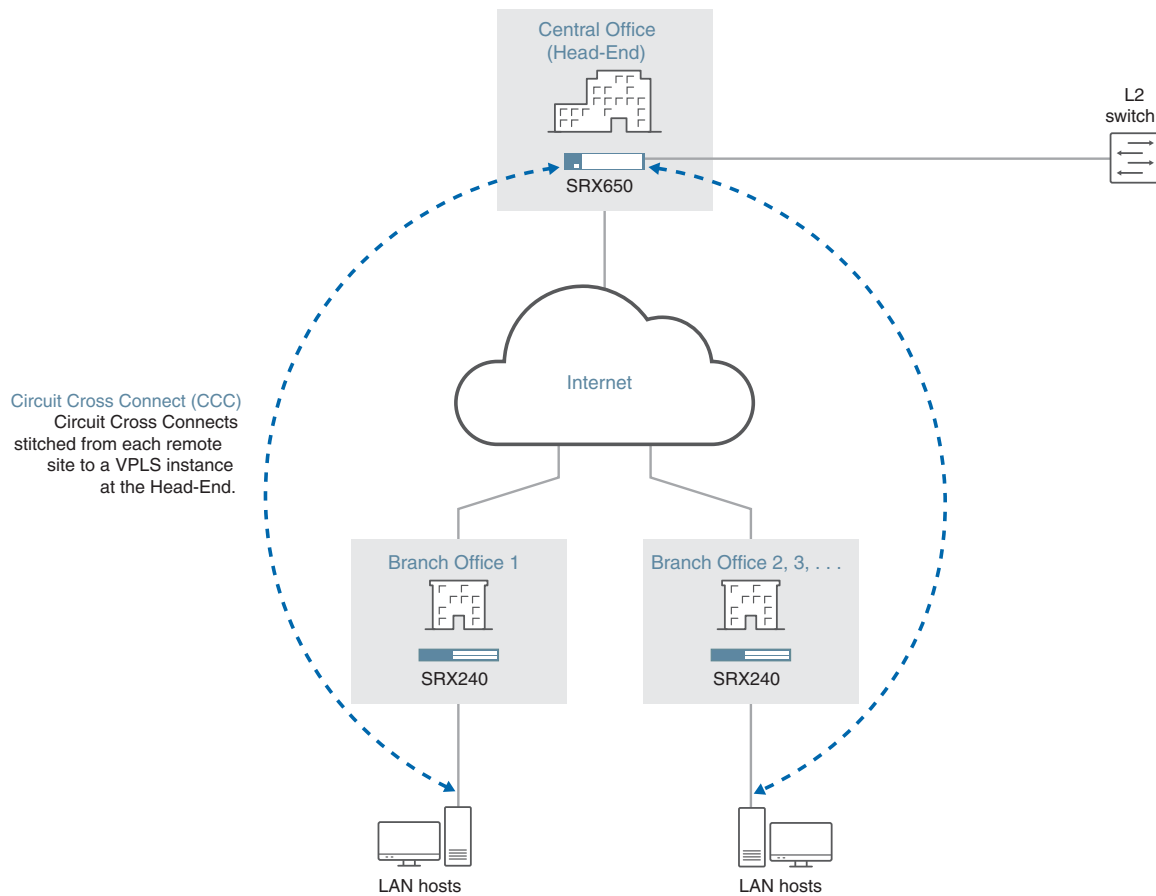

The second scenario could use VPLS to provide a Layer 2 network abstraction. With VPLS, endpoints are expected to negotiate LSPs and pseudowires with every other endpoint (that is, they are fully meshed).

When a node receives an Ethernet frame from one of its LAN interfaces the source MAC address is learned, if it's not already known, and flooded using every pseudowire connecting to all other branch nodes. However, if the destination has been previously learned, then the frame is sent to the appropriate destination. When an Ethernet frame is received through one of the pseudowires (that is, from the MPLS network), source MAC address learning is performed. The next time a frame is sent to that MAC it does not need to be flooded and the frame is flooded to every single LAN interface in the node, but not over the pseudowires. In other words, the network acts as a distributed Layer 2 switch providing any-to-any Ethernet connectivity between the devices connected to the different nodes in the network.

While the advantages of this second scenario is evident (any-to-any connectivity, automated provisioning, and simple abstraction), it comes at the cost of complexity. Every PE node has to perform Layer 2 learning and flooding of traffic, which can cause problems when either multiple broadcast/multicast or frames to unknown MAC addresses are used. As an example, if you had a topology with a thousand branch offices, each office that receives a broadcast packet must replicate it 999 times, encapsulate each copy in GRE and IPsec and forward the resulting traffic. Additionally, because each node performs Layer 2 learning, there are limitations in the maximum number of MAC addresses that each node can learn, limiting the total number of nodes in the domain.

In this example, we use a hybrid approach to these two scenarios. We use a circuit cross connect (CCC) at each branch office stitched to a VPLS instance at central office (ingress). This solution makes sense if most of the traffic flows from the branch offices to central office, and the branch-to-branch office traffic is always forwarded through the hub. The use of CCCs at branch offices combined with VPLS stitching at the central office provides a scalable way to deploy large hub-and-spoke topologies where Ethernet must be transported over an IP network (with or without encryption). At the expense of configuration complexity, it is possible to use SRX Series devices to terminate such connections, providing a scalable and cost-effective way to deploy small-to-large networks where Ethernet traffic is carried transparently using lower cost IP connections. [Figure 121 on page 1591](#) shows this topology.

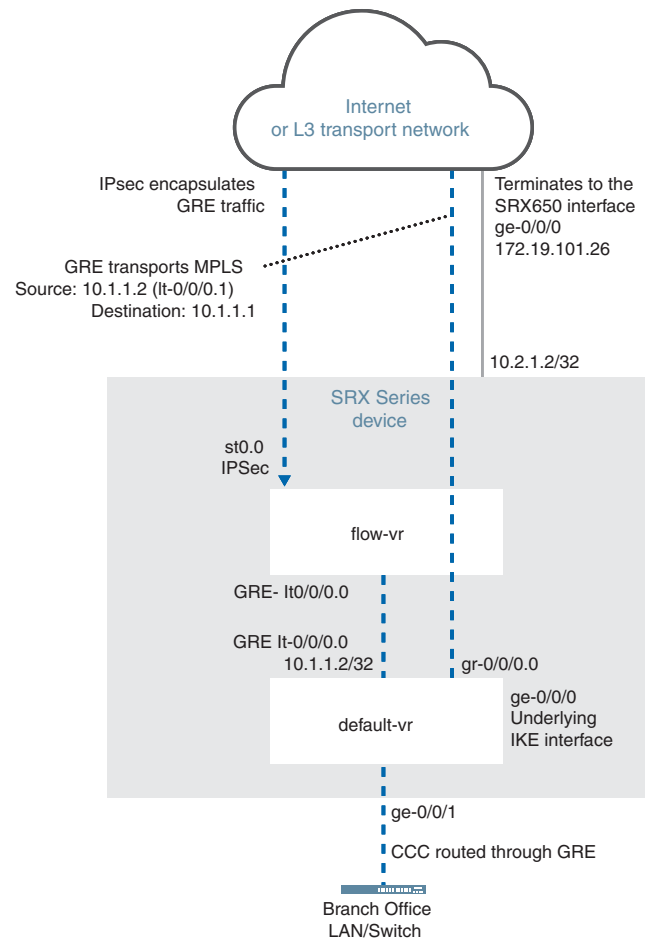

Figure 121: VPLS Deployment Scenario

9031178

In this deployment, VPLS services are provided only in packet mode and must be configured in the default routing instance. Unfortunately, IPsec is only provided in flow mode. Hence, a flow-mode routing-instance is used that provides both GRE reassembly and IPsec termination. While the GRE termination is done in the default routing instance, a flow-mode routing instance is connected between the default routing instance and the Internet (or whatever Layer 3 network is used as a transport), and it terminates the IPsec tunnel towards the ingress device. Because it is likely that a single public IP address is available, the Internet-facing Interface is connected to the default routing instance and is used to terminate IKE; however, the tunnel interface (st0) is bound to the flow-mode routing instance. See [Figure 122 on page 1592](#).

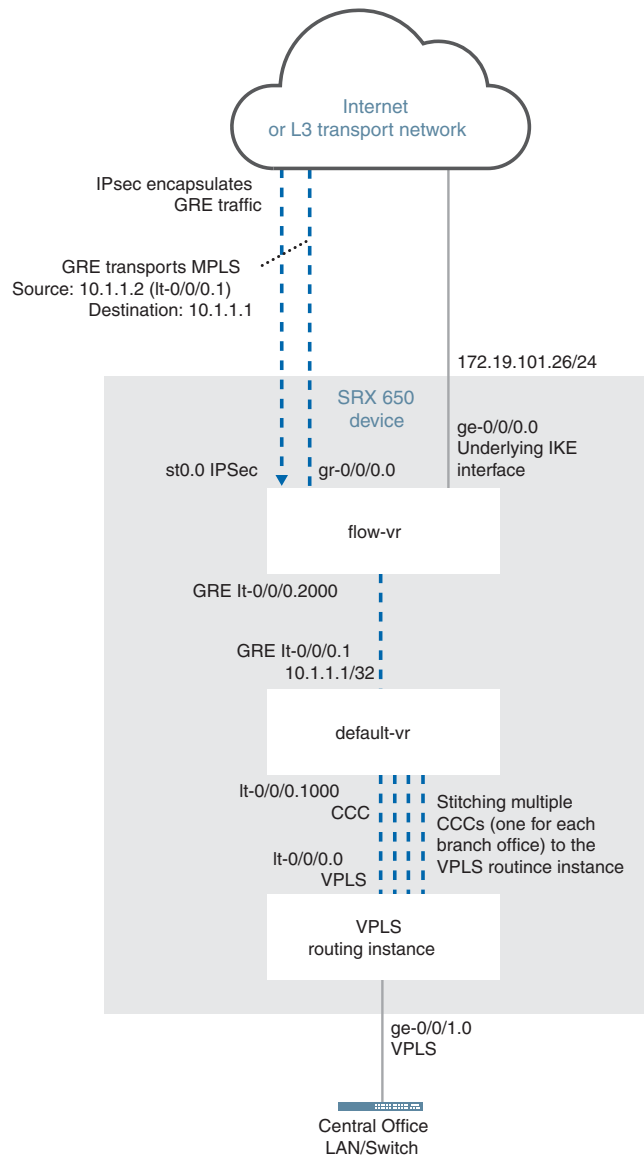

Figure 122: Branch Office Circuit Cross Connect Termination

When configuring the central office SRX650, the first thing you do is terminate the IPsec tunnels, GRE, and CCC connections. Because a SRX Series device is used as the ingress (head-end), the configuration to terminate the CCC circuits is identical to the one used at each branch office, with the exception that instead of one tunnel, multiple tunnels (and pseudowires) are terminated.

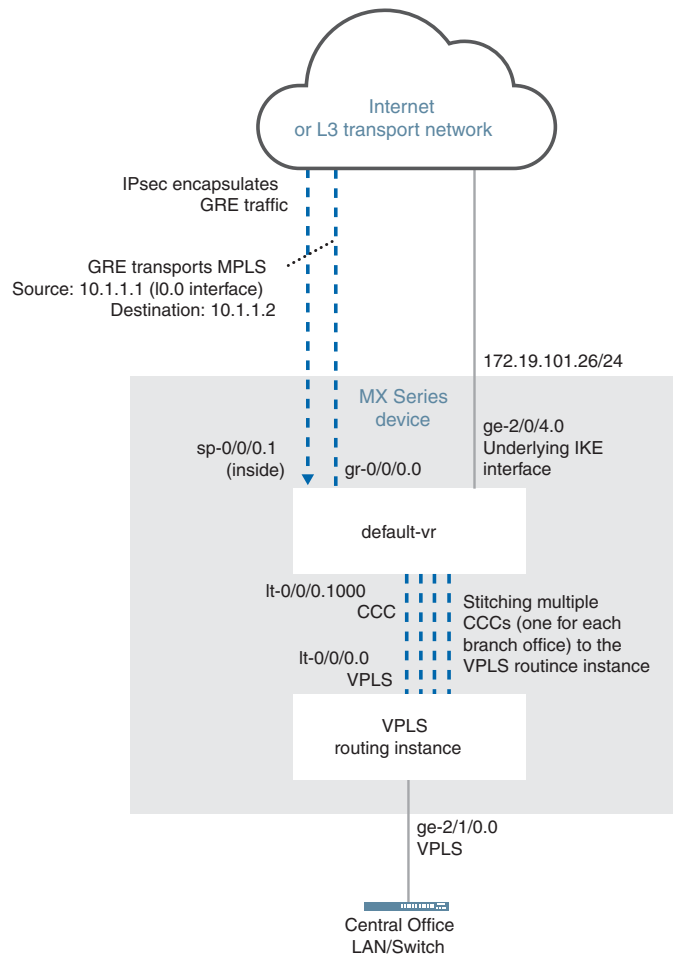

The pseudowires are stitched to a VPLS routing instance using logical tunnel (lt) interfaces. It is possible to use an lt interface unit to terminate a CCC connection and connect this unit to a different unit that is part of a VPLS routing instance. The overall result is as if the pseudowires were terminated directly in the VPLS routing instance. [Figure 123 on page 1593](#) illustrates this configuration.

Figure 123: Central Office Ingress (Head-End) Configuration with an SRX Series Device

You can also use an MX Series device as the central office ingress (head-end) to terminate all branch office connections. The differences in the configuration are due to the way IPsec is configured and the fact that on MX Series devices IDP is not required to reassemble the GRE packets; MX Series devices natively support GRE reassembly. With this configuration, you still use lt interfaces to stitch the CCCs between the remote branch offices and the VPLS routing instance as shown in [Figure 124 on page 1594](#).

Figure 124: Central Office Ingress (Head-End) Configuration with an MX Series Device

Configuration

IN THIS SECTION

- [Configuring the SRX240 Device at the Branch Office | 1595](#)
- [Configuring the SRX650 Device at the Central Office | 1601](#)

In this example, we use SRX Series devices and the branch and ingress (head-end) sites will typically be connected to the Internet by Frame-Relay/T1-E1/xDSL/T3/E3 or even Ethernet. A provider MPLS network is not required.

Configuring the SRX240 Device at the Branch Office

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces gr-0/0/0 description "GRE tunnel to SRX650"

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the SRX240 at the branch office:

1. Configure a GRE tunnel to the central office.

```

[edit interfaces]
user@host# set gr-0/0/0 description "GRE tunnel to SRX650"
user@host# set gr-0/0/0 unit 0 clear-dont-fragment-bit
user@host# set gr-0/0/0 unit 0 tunnel source 10.1.1.2
user@host# set gr-0/0/0 unit 0 tunnel destination 10.1.1.1
user@host# set gr-0/0/0 unit 0 tunnel allow-fragmentation
user@host# set gr-0/0/0 unit 0 family inet mtu 2000
user@host# set gr-0/0/0 unit 0 family inet filter input inet-packet-mode
user@host# set gr-0/0/0 unit 0 family mpls mtu 1900
user@host# set gr-0/0/0 unit 0 family mpls filter input mpls-packet-mode

```

2. Create a logical interface that connects to the default routing instance.

```

[edit interfaces]
user@host# set lt-0/0/0 unit 0 encapsulation frame-relay
user@host# set lt-0/0/0 unit 0 dlci 16
user@host# set lt-0/0/0 unit 0 peer-unit 1
user@host# set lt-0/0/0 unit 0 family inet
user@host# set lt-0/0/0 unit 0 description "Flow-vr Instance"

```

3. Connect the logical tunnel interface to the flow mode virtual router.

```

[edit interfaces]
user@host# set lt-0/0/0 unit 1 encapsulation frame-relay
user@host# set lt-0/0/0 unit 1 dlci 16
user@host# set lt-0/0/0 unit 1 peer-unit 0
user@host# set lt-0/0/0 unit 1 family inet filter input inet-packet-mode
user@host# set lt-0/0/0 unit 1 family inet address 10.1.1.2/32

```

4. Connect the CCC interface to the branch LAN.

```
[edit interfaces]
user@host# set ge-0/0/1 encapsulation ethernet-ccc
user@host# set ge-0/0/1 unit 0 description "CCC Interface to customer LAN"
user@host# set ge-0/0/1 unit 0 family ccc filter input ccc-packet-mode
```

5. Configure the interface bound to the default virtual router.

```
[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 172.19.101.45/24
```

6. Set the loopback interface to terminate the CCC connection.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.2.1.2/32
```

7. Bind the IPsec tunnel interface to the flow-mode virtual router.

```
[edit interfaces]
user@host# set st0 unit 0 family inet
```

8. Set a static route address, which will be the default gateway to the Internet.

```
[edit routing-options]
user@host# set static route 0.0.0.0/0 next-hop 172.19.101.1
```

9. Set a static route for the remote GRE tunnel endpoint.

```
[edit routing-options]
user@host# set static route 10.1.1.1/32 next-hop lt-0/0/0.1
```

10. Set a static route for the loopback interface of the SRX650 ingress (head-end) device.

```
[edit routing-options]
user@host# set static route 10.2.1.1/32 next-hop gr-0/0/0.0
```

11. Configure MPLS and the CCC using LDP as the label protocol.

```
[edit]
user@host# set routing-options router-id 10.2.1.2
user@host# set protocols mpls interface gr-0/0/0.0
user@host# set protocols ldp interface gr-0/0/0.0
user@host# set protocols ldp interface lo0.0
user@host# set protocols l2circuit neighbor 10.2.1.1 interface ge-0/0/1.0 virtual-circuit-id 1
```

12. Configure the IPsec tunnel.

NOTE: The underlying IKE interface is not in the same routing instance as the tunnel interface.

```
[edit security]
user@host# set ike policy SRX650 mode main
user@host# set ike policy SRX650 proposal-set standard
user@host# set ike policy SRX650 pre-shared-key ascii-text "$ABC123"
user@host# set ike gateway SRX650 ike-policy SRX650
user@host# set ike gateway SRX650 address 172.19.101.26
user@host# set ike gateway SRX650 external-interface ge-0/0/0.0
user@host# set ipsec policy SRX650 proposal-set standard
user@host# set ipsec vpn SRX650 bind-interface st0.0
user@host# set ipsec vpn SRX650 ike gateway SRX650
user@host# set ipsec vpn SRX650 ike ipsec-policy SRX650
user@host# set ipsec vpn SRX650 establish-tunnels immediately
```

13. Configure security zones.

NOTE: In a production environment, host-inbound traffic should be restricted to only allow the necessary protocols and services.

```
[edit security]
user@host# set zones security-zone untrust host-inbound-traffic system-services all
user@host# set zones security-zone untrust host-inbound-traffic protocols all
user@host# set zones security-zone untrust interfaces gr-0/0/0.0
user@host# set zones security-zone untrust interfaces lo0.0
user@host# set zones security-zone untrust interfaces lt-0/0/0.1
user@host# set zones security-zone untrust interfaces ge-0/0/0.0
```

```

user@host# set zones security-zone vpn host-inbound-traffic system-services all
user@host# set zones security-zone vpn host-inbound-traffic protocols all
user@host# set zones security-zone vpn interfaces st0.0
user@host# set zones security-zone trust-flow host-inbound-traffic system-services all
user@host# set zones security-zone trust-flow host-inbound-traffic protocols all
user@host# set zones security-zone trust-flow interfaces lt-0/0/0.0

```

14. Configure IDP.

```

[edit security]
user@host# set policies from-zone trust-flow to-zone vpn policy gre match source-address any
user@host# set policies from-zone trust-flow to-zone vpn policy gre match destination-address any
user@host# set policies from-zone trust-flow to-zone vpn policy gre match application junos-gre
user@host# set policies from-zone trust-flow to-zone vpn policy gre then permit application-services idp
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-all match application junos-gre
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-all then action ignore-connection
user@host# set idp active-policy gre-reassembly

```

15. Configure packet-mode filters.

```

[edit firewall]
user@host# set family inet filter inet-packet-mode term control-traffic from protocol tcp
user@host# set family inet filter inet-packet-mode term control-traffic from port 22
user@host# set family inet filter inet-packet-mode term control-traffic from port 80
user@host# set family inet filter inet-packet-mode term control-traffic from port 8080
user@host# set family inet filter inet-packet-mode term control-traffic then accept
user@host# set family inet filter inet-packet-mode term packet-mode then packet-mode
user@host# set family inet filter inet-packet-mode term packet-mode then accept
user@host# set family mpls filter mpls-packet-mode term packet-mode then packet-mode
user@host# set family mpls filter mpls-packet-mode term packet-mode then accept
user@host# set family ccc filter ccc-packet-mode term all then packet-mode
user@host# set family ccc filter ccc-packet-mode term all then accept

```

16. Configure the flow-mode virtual router.

```

[edit routing-instances]
user@host# set flow-vr instance-type virtual-router
user@host# set flow-vr interface lt-0/0/0.0
user@host# set flow-vr interface st0.0
user@host# set flow-vr routing-options static route 10.1.1.1/32 next-hop st0.0
user@host# set flow-vr routing-options static route 10.1.1.2/32 next-hop lt-0/0/0.0

```

17. Disable syn check and sequence check to bypass LDP session from syn check and sequence check.

```
[edit ]
user@host# set security flow tcp-session no-syn-check
user@host# set security flow tcp-session no-sequence-check
```

18. Enable syn check and sequence check at the policy level.

```
[edit ]
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy all then permit
    tcp-options syn-check-required
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy all then permit
    tcp-options sequence-check-required
user@host# set security policies apply-groups test
```

Results

From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the SRX650 Device at the Central Office

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the ingress (head-end) SRX650 device at the central office:

1. Configure the interface bound to the default virtual router.

```
[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 172.19.101.26/24
```

2. Create the GRE tunnel from the SRX650 to the SRX240 device.

NOTE: As the network expands to include multiple branch offices, you will need to add a similar GRE tunnel configuration on the SRX650 device (head-end) along with a corresponding IPsec configuration to connect to each additional SRX device (SRX240).

```
[edit interfaces]
user@host# set gr-0/0/0 unit 0 clear-dont-fragment-bit
user@host# set gr-0/0/0 unit 0 tunnel source 10.1.1.1
user@host# set gr-0/0/0 unit 0 tunnel destination 10.1.1.2
user@host# set gr-0/0/0 unit 0 tunnel allow-fragmentation
user@host# set gr-0/0/0 unit 0 family inet mtu 1500
user@host# set gr-0/0/0 unit 0 family inet filter input inet-packet-mode
user@host# set gr-0/0/0 unit 0 family mpls filter input mpls-packet-mode
```

3. Configure a logical tunnel interface to stitch the CCC connection to the VPLS instance.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 0 description "VPLS hub port - Interconnect for CCC to SRX240"
user@host# set lt-0/0/0 unit 0 encapsulation ethernet-vpls
user@host# set lt-0/0/0 unit 0 peer-unit 1000
```

4. Set unit 1000 to terminate the CCC connection.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 1000 description "Stitch to VPLS for CCC to SRX240"
user@host# set lt-0/0/0 unit 1000 encapsulation ethernet-ccc
user@host# set lt-0/0/0 unit 1000 peer-unit 0
user@host# set lt-0/0/0 unit 1000 family ccc filter input ccc-packet-mode
```

5. Configure the logical tunnel interface.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 2000 encapsulation frame-relay
```

```

user@host# set lt-0/0/0 unit 2000 dlci 1
user@host# set lt-0/0/0 unit 2000 peer-unit 2001
user@host# set lt-0/0/0 unit 2000 family inet

```

6. Bind the logical tunnel interface to the default virtual router.

```

[edit interfaces]
user@host# set lt-0/0/0 unit 2001 encapsulation frame-relay
user@host# set lt-0/0/0 unit 2001 dlci 1
user@host# set lt-0/0/0 unit 2001 peer-unit 2000
user@host# set lt-0/0/0 unit 2001 family inet filter input inet-packet-mode
user@host# set lt-0/0/0 unit 2001 family inet address 10.1.1.1/32

```

7. Set the interface to the central office LAN network.

```

[edit interfaces]
user@host# set ge-0/0/1 unit 0
user@host# set ge-0/0/1 encapsulation ethernet-vpls

```

8. Set the loopback interface to terminate the CCC connections to each SRX device.

```

[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.2.1.1/32

```

9. Bind the IPsec interface to the flow-mode virtual router.

```

[edit interfaces]
user@host# set st0 unit 0 family inet

```

10. Set a static route for the remote GRE tunnel endpoint.

```

[edit routing-options]
user@host# set static route 10.1.1.2/32 next-hop lt-0/0/0.2001

```

11. Set a static route for the loopback interface of the SRX device.

```

[edit]
user@host# set routing-options static route 10.2.1.2/32 next-hop gr-0/0/0.0

```

12. Configure MPLS and CCC using LDP as the label protocol.

```
[edit protocols]
user@host# set mpls interface gr-0/0/0.0
user@host# set ldp interface gr-0/0/0.0
user@host# set ldp interface lo0.0
user@host# set l2circuit neighbor 10.2.1.2 interface lt-0/0/0.1000 virtual-circuit-id 1
```

13. Configure the IPsec tunnel.

NOTE: The underlying IKE interface is not in the same routing instance as the tunnel interface.

```
[edit security]
user@host# set ike policy SRX mode main
user@host# set ike policy SRX proposal-set standard
user@host# set ike policy SRX pre-shared-key ascii-text "$ABC123"
user@host# set ike gateway SRX240-1 ike-policy SRX
user@host# set ike gateway SRX240-1 address 172.19.101.45
user@host# set ike gateway SRX240-1 external-interface ge-0/0/0.0
user@host# set ipsec policy SRX proposal-set standard
user@host# set ipsec vpn SRX240-1 bind-interface st0.0
user@host# set ipsec vpn SRX240-1 ike gateway SRX240-1
user@host# set ipsec vpn SRX240-1 ike ipsec-policy SRX
user@host# set ipsec vpn SRX240-1 establish-tunnels immediately
```

14. Configure security zones.

NOTE: In a production environment, restrict host-inbound traffic to only the necessary protocols and services.

```
[edit security]
user@host# set zones security-zone untrust host-inbound-traffic system-services all
user@host# set zones security-zone untrust host-inbound-traffic protocols all
user@host# set zones security-zone untrust interfaces lo0.0
user@host# set zones security-zone untrust interfaces lt-0/0/0.2001
user@host# set zones security-zone untrust interfaces gr-0/0/0.0
```

```

user@host# set zones security-zone untrust interfaces ge-0/0/0.0
user@host# set zones security-zone vpn host-inbound-traffic system-services all
user@host# set zones security-zone vpn host-inbound-traffic protocols all
user@host# set zones security-zone vpn interfaces st0.0
user@host# set zones security-zone trust-flow host-inbound-traffic system-services all
user@host# set zones security-zone trust-flow host-inbound-traffic protocols all
user@host# set zones security-zone trust-flow interfaces lt-0/0/0.2000

```

15. Configure IDP.

```

[edit security]
user@host# set policies from-zone trust-flow to-zone vpn policy GRE match source-address any
user@host# set policies from-zone trust-flow to-zone vpn policy GRE match destination-address any
user@host# set policies from-zone trust-flow to-zone vpn policy GRE match application junos-gre
user@host# set policies from-zone trust-flow to-zone vpn policy GRE then permit application-services idp
user@host# set policies from-zone vpn to-zone trust-flow policy GRE match source-address any
user@host# set policies from-zone vpn to-zone trust-flow policy GRE match destination-address any
user@host# set policies from-zone vpn to-zone trust-flow policy GRE match application junos-gre
user@host# set policies from-zone vpn to-zone trust-flow policy GRE then permit application-services idp
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-gre match application junos-gre
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-gre then action ignore-connection
user@host# set idp active-policy gre-reassembly

```

16. Configure packet-mode filters.

```

[edit firewall]
user@host# set family inet filter inet-packet-mode term control-traffic from protocol tcp
user@host# set family inet filter inet-packet-mode term control-traffic from port 22
user@host# set family inet filter inet-packet-mode term control-traffic from port 80
user@host# set family inet filter inet-packet-mode term control-traffic from port 8080
user@host# set family inet filter inet-packet-mode term control-traffic then accept
user@host# set family inet filter inet-packet-mode term packet-mode then packet-mode
user@host# set family inet filter inet-packet-mode term packet-mode then accept
user@host# set family mpls filter mpls-packet-mode term packet-mode then packet-mode
user@host# set family mpls filter mpls-packet-mode term packet-mode then accept
user@host# set family ccc filter ccc-packet-mode term all then packet-mode
user@host# set family ccc filter ccc-packet-mode term all then accept

```

17. Configure the flow-mode virtual router.

```

[edit routing-instances]

```

```

user@host# set flow-vr instance-type virtual-router
user@host# set flow-vr interface lt-0/0/0.2000
user@host# set flow-vr interface st0.0
user@host# set flow-vr routing-options static route 10.1.1.1/32 next-hop lt-0/0/0.2000
user@host# set flow-vr routing-options static route 10.1.1.2/32 next-hop st0.0

```

18. Configure the VPLS instance.

```

[edit routing-instances]
user@host# set vpls-hub instance-type vpls
user@host# set vpls-hub interface lt-0/0/0.0
user@host# set vpls-hub interface ge-0/0/1.0

```

19. Disable syn check and sequence check to bypass LDP session from syn check and sequence check.

```

[edit ]
user@host# set security flow tcp-session no-syn-check
user@host# set security flow tcp-session no-sequence-check

```

20. Enable syn check and sequence check at the policy level.

```

[edit ]
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy all then permit
    tcp-options syn-check-required
user@host# set groups test security policies from-zone trust-flow to-zone vpn policy all then permit
    tcp-options sequence-check-required
user@host# set security policies apply-groups test

```

Results

From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying Interfaces | 1609](#)
- [Verifying an IPsec tunnel | 1609](#)
- [Verifying GRE | 1609](#)
- [Verifying the CCC/L2 circuit. | 1609](#)
- [Verifying that LDP sessions are working. | 1610](#)

Confirm that the configuration is working properly.

Verifying Interfaces

Purpose

Verify that the interfaces are configured properly on each device in the VPLS network.

Action

From configuration mode, enter **show interfaces** and verify that the IP addressing is correct for each interface, including logical tunnel (lt), loopback (lo), GRE (gr), IPsec tunnel st0, and GE interfaces.

Verifying an IPsec tunnel

Purpose

Verify that an IPsec tunnel is working.

Action

From operational mode, enter the **show security ipsec security associations** and the **show security ipsec statistics** command.

Verifying GRE

Purpose

Verify that GRE is working.

Action

From operational mode, enter the **show security flow session protocol gre** command. You can also do a ping between loopback addresses.

Verifying the CCC/L2 circuit.

Purpose

Verify that the CCC/L2 circuit is working.

Action

From operational mode, enter the **show connections** command.

Verifying that LDP sessions are working.

Purpose

Verify that LDP sessions are being created between devices.

Action

From operational mode, enter the **show interfaces gr-0/0/0 detail** command.

[MPLS Overview | 8](#)

Example: Configuring VPLS with BGP Signaling

IN THIS SECTION

- [Requirements | 1610](#)
- [Overview | 1611](#)
- [Configuration | 1612](#)
- [Verification | 1625](#)

This example shows how to configure VPLS with BGP signaling between two devices.

Requirements

Before you begin, see *Understanding Selective Stateless Packet-Based Services* .

Overview

This example shows a minimum configuration for PE devices and CE devices to create a VPLS network with BGP signaling. The topology consists of two PE devices and two CE devices. In this example, you configure a VPLS routing instance vpls-instance between two PE devices, PE1 and PE2. You also configure the CE1 and CE2 devices that use Ethernet-based interfaces to connect VLAN 600 to their local PE devices. On the CE1 device, configure the Fast Ethernet interface that connects to the PE1 device. The VLAN identifier and IP address must match those of the CE2 device.

Figure 125 on page 1611 shows the topology used in this example.

Figure 125: Configuring VPLS with BGP Signaling

Configuration

Configuring the CE1 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family inet address 10.11.3.1/24
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Enable VLAN tagging on the VPLS interface.

```
[edit interfaces fe-0/0/3]
user@host# set vlan-tagging
```

2. Configure the VLAN ID on the logical interface.

```
[edit interfaces fe-0/0/3 unit 0]
user@host# set vlan-id 600
```

3. Configure the VPLS family on the logical interface.

```
[edit interfaces fe-0/0/3 unit 0]
```

```
user@host# set family inet address 10.11.3.1/24
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
fe-0/0/3 {
  vlan-tagging;
  unit 0 {
    vlan-id 600;
    family inet {
      address 10.11.3.1/24;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the PE1 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system host-name PE1
set interfaces fe-0/0/3 description "CE1 on PE1"
set interfaces fe-0/0/3 vlan-tagging

set routing-instances vpls-instance instance-type vpls
set routing-instances vpls-instance interface fe-0/0/3.0
set routing-instances vpls-instance route-distinguisher 172.28.1.2:1
set routing-instances vpls-instance vrf-target target:65512:1
set routing-instances vpls-instance protocols vpls site-range 10
set routing-instances vpls-instance protocols vpls no-tunnel-services site site10 automatic-site-id

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure PE1:

1. Configure the hostname for the PE1 device.

```

[edit ]
user@host# set system host-name PE1

```

2. Configure VPLS VLAN encapsulation on the VPLS PE1 device.

```

[edit interfaces]
user@host# set fe-0/0/3 description "CE1 on PE1"
user@host# set fe-0/0/3 vlan-tagging
user@host# set fe-0/0/3 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 vlan-id 600
user@host# set fe-0/0/3 unit 0 family vpls

```

3. Configure the routing interface on the VPLS PE1 device.

```

[edit interfaces]
user@host# set fe-0/0/5 vlan-tagging
user@host# set fe-0/0/5 unit 37 vlan-id 37

```

```

user@host# set fe-0/0/5 unit 37 family inet address 172.28.2.133/30
user@host# set fe-0/0/5 unit 37 family mpls
user@host# set lo0 unit 0 family inet address 172.28.1.2/32

```

NOTE: For this example, it is optional to configure VLAN tagging. Remove the VLAN tagging configuration on the physical interfaces if you do not plan to configure VLAN tagging.

4. Configure the routing options on the VPLS PE1 device.

```

[edit routing-options]
user@host# set router-id 172.28.1.2
user@host# set autonomous-system 65512

```

5. Configure RSVP on the VPLS PE1 device.

```

[edit protocols]
user@host# set rsvp interface fe-0/0/5.37

```

6. Configure MPLS on the VPLS PE1 device.

```

[edit protocols]
user@host# set mpls label-switched-path pe1-to-pe2 to 172.28.1.1
user@host# set mpls interface fe-0/0/5.37
user@host# set mpls interface lo0.0

```

7. Configure BGP on the VPLS PE1 device.

```

[edit protocols]
user@host# set bgp group vpls-peering type internal
user@host# set bgp group vpls-peering local-address 172.28.1.2
user@host# set bgp group vpls-peering family l2vpn signaling
user@host# set bgp group vpls-peering neighbor 172.28.1.1

```

8. (Optional) Configure OSPF on the VPLS PE1 device.

NOTE: For this example, it is optional to configure OFPF. You must configure OSPF only in cases where two PE devices are not connected directly.

```
[edit protocols]
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
user@host# set ospf area 0.0.0.0 interface fe-0/0/5.37
```

9. Create a VPLS routing instance.

```
[edit ]
user@host# set routing-instances vpls-instance
```

10. Configure a VPLS routing instance.

```
[edit routing-instances vpls-instance]
user@host# set description "Routing instance from VPLS routing"
user@host# set instance-type vpls
user@host# set interface fe-0/0/3.0
user@host# set route-distinguisher 172.28.1.2:1
user@host# set vrf-target target:65512:1
user@host# set protocols vpls site-range 10
user@host# set protocols vpls no-tunnel-services site site10 automatic-site-id
```

Results

From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system
host-name PE1;
```

```
[edit]
user@host# show interfaces
fe-0/0/5 {
  vlan-tagging;

    vrf-target target:65512:1;
    protocols {
        vpls {
            site-range 10;
            no-tunnel-services;
            site site10 {
                automatic-site-id;
            }
        }
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the PE2 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set system host-name PE2
set interfaces fe-0/0/3 description "CE2 on PE2"
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family vpls
set interfaces fe-0/0/5 vlan-tagging
set interfaces fe-0/0/5 unit 37 vlan-id 37
set interfaces fe-0/0/5 unit 37 family inet address 172.28.2.133/30
set interfaces fe-0/0/5 unit 37 family mpls
set interfaces lo0 unit 0 family inet address 172.28.1.1/32
set routing-options router-id 172.28.1.1
set routing-options autonomous-system 65512
set protocols rsvp interface fe-0/0/5.37
set protocols mpls label-switched-path pe2-to-pe1 to 172.28.1.2
set protocols mpls interface fe-0/0/5.37
set protocols mpls interface lo0.0
set protocols bgp group vpls-peering type internal
set protocols bgp group vpls-peering local-address 172.28.1.1
set protocols bgp group vpls-peering family l2vpn signaling
set protocols bgp group vpls-peering neighbor 172.28.1.2
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-0/0/5.37
set routing-instances vpls-instance description "Routing instance for VPLS routing"
set routing-instances vpls-instance instance-type vpls
set routing-instances vpls-instance interface fe-0/0/3.0
set routing-instances vpls-instance route-distinguisher 172.28.1.1:1
set routing-instances vpls-instance vrf-target target:65512:1
set routing-instances vpls-instance protocols vpls site-range 10
set routing-instances vpls-instance protocols vpls no-tunnel-services site site11 automatic-site-id

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure PE2:

1. Configure the hostname for the device.

```

[edit ]
user@host# set system host-name PE2

```

2. Configure VPLS VLAN encapsulation on the VPLS PE2 device.

```
[edit interfaces]
user@host# set fe-0/0/3 description "CE2 on PE2"
user@host# set fe-0/0/3 vlan-tagging
user@host# set fe-0/0/3 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 vlan-id 600
user@host# set fe-0/0/3 unit 0 family vpls
```

3. Configure the routing interface on the VPLS PE2 device.

```
[edit interfaces]
user@host# set fe-0/0/5 vlan-tagging
user@host# set fe-0/0/5 unit 37 vlan-id 37
user@host# set fe-0/0/5 unit 37 family inet address 172.28.2.133/30
user@host# set fe-0/0/5 unit 37 family mpls
user@host# set lo0 unit 0 family inet address 172.28.1.1/32
```

NOTE: For this example, it is optional to configure VLAN tagging. Remove the VLAN tagging configuration on the physical interfaces if you do not plan to configure VLAN tagging.

4. Configure the routing options on the VPLS PE2 device.

```
[edit routing-options]
user@host# set router-id 172.28.1.1
user@host# set autonomous-system 65512
```

5. Configure RSVP on the VPLS PE2 device.

```
[edit protocols]
user@host# set rsvp interface fe-0/0/5.37
```

6. Configure MPLS on the VPLS PE2 device.

```
[edit protocols]
user@host# set mpls label-switched-path pe2-to-pe1 to 172.28.1.2
user@host# set mpls interface fe-0/0/5.37
```

```
user@host# set mpls interface lo0.0
```

7. Configure BGP on the VPLS PE2 device.

```
[edit protocols]
user@host# set bgp group vpls-peering type internal
user@host# set bgp group vpls-peering local-address 172.28.1.1
user@host# set bgp group vpls-peering family l2vpn signaling
user@host# set bgp group vpls-peering neighbor 172.28.1.2
```

8. (Optional) Configure OSPF on the VPLS PE2 device.

NOTE: For this example, it is optional to configure OSPF. You must configure OSPF only in cases where two PE devices are not connected directly.

```
[edit protocols]
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
user@host# set ospf area 0.0.0.0 interface fe-0/0/5.37
```

9. Create a VPLS routing instance.

```
[edit ]
user@host# set routing-instances vpls-instance
```

10. Configure a VPLS routing instance.

```
[edit routing-instances vpls-instance]
user@host# set description "Routing instance for VPLS routing"
user@host# set instance-type vpls
user@host# set interface fe-0/0/3.0
user@host# set route-distinguisher 172.28.1.1:1
user@host# set vrf-target target:65512:1
user@host# set protocols vpls site-range 10
user@host# set protocols vpls no-tunnel-services site site11 automatic-site-id
```

Results

From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system
host-name PE2;
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the CE2 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family inet address 10.11.3.2/24

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Enable VLAN tagging on the VPLS interface.

```

[edit interfaces fe-0/0/3]
user@host# set vlan-tagging

```

2. Configure the VLAN ID on the logical interface.

```

[edit interfaces fe-0/0/3 unit 0]
user@host# set vlan-id 600

```

3. Configure the VPLS family on the logical interface.

```

[edit interfaces fe-0/0/3 unit 0]
user@host# set family inet address 10.11.3.2/24

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
fe-0/0/3 {  
  vlan-tagging;  
  unit 0 {  
    vlan-id 600;  
    family inet {  
      address 10.11.3.2/24;  
    }  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: If VLAN trunking is not needed between the CE devices, remove the configuration on VLAN tagging on the interfaces connecting the CE and PE devices. Also, use ethernet-VPLS-encapsulation instead of vlan-vpls on the CE facing interfaces of the PE devices.

Verification

IN THIS SECTION

Confirm that the configuration is working properly.

Verifying Interfaces

Purpose

Verify that the interfaces are configured correctly.

Action

From operational mode, enter the **show interfaces terse** command.

Verifying Routing Information

Purpose

Verify that the routing information is configured correctly.

Action

From operational mode, enter the following commands:

- **show route forwarding-table family mpls**
- **show route forwarding-table family vpls (destination | extensive | matching | table)**
- **show route instance (detail)**

Verifying VPLS Information

Purpose

Verify that the VPLS is configured correctly.

Action

From operational mode, enter the following commands:

- **show system statistics vpls**
- **show vpls connections**
- **show vpls statistics**

Verifying Automatic Site Identifier Generation

Purpose

Verify that the automatic site identifier has been generated.

Action

From operational mode, enter the **show vpls connections** command.

```

Example: Configuring BGP on the VPLS PE Router

IN THIS SECTION

- [Requirements | 1628](#)
- [Overview | 1628](#)
- [Configuration | 1629](#)
- [Verification | 1629](#)

This example shows how to configure BGP on the VPLS PE router.

Requirements

Before you begin:

- See *Understanding Selective Stateless Packet-Based Services* .
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).
- Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
- Configure RSVP-TE. See [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#). Then configure MPLS LSPs on the PE routers. See [“Example: Configuring MPLS on the VPLS PE Router” on page 1585](#). Alternatively, configure LDP on the PE routers. See [“Example: Configuring LDP on the VPLS PE Router” on page 1587](#).
- Configure routing options on the PE router. See [“Example: Configuring Routing Options on the VPLS PE Router” on page 1630](#).

Overview

In this example, you configure an internal BGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. The PE routers use this information to determine which labels to use for traffic destined for remote sites.

NOTE: On all SRX Series devices, BGP-based virtual private LAN service (VPLS) works on child ports and physical interfaces, but not over aggregated Ethernet (ae) interfaces.

Configuration

Step-by-Step Procedure

To configure BGP on the VPLS PE router:

1. Configure the BGP internal group on the VPLS PE router.

```
[edit ]
user@host# set protocols bgp group ibgp type internal local-address 10.255.7.168 neighbor 10.255.7.164
```

2. Configure the BGP family L2vpn and specify NLRI signaling.

```
[edit ]
user@host# set protocols bgp family L2 VPN signaling
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

Example: Configuring Routing Options on the VPLS PE Router

IN THIS SECTION

- Requirements | 1630
- Overview | 1630
- Configuration | 1630
- Verification | 1631

This example shows how to configure the routing options on the VPLS PE router.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services*.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).
- Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
- Configure RSVP-TE, see [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#) and then MPLS LSPs on the PE routers, see [“Example: Configuring MPLS on the VPLS PE Router” on page 1585](#). Alternatively configure LDP on the PE routers, see [“Example: Configuring LDP on the VPLS PE Router” on page 1587](#).

Overview

This example describes how to specify the router ID and the AS number for each router involved in the VPLS. In this example, the routers PE1 and PE2 use the same AS number (100).

Configuration

Step-by-Step Procedure

To configure the routing options on the VPLS PE router:

1. Configure the router ID on the VPLS PE router.

```
[edit]
user@host# set routing-options router-id 10.255.7.168
```

2. Configure the AS number on the VPLS PE router.

```
[edit]
user@host# set routing-options autonomous-system 100
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show routing-options** command.

RELATED DOCUMENTATION

[VPLS Configuration Overview | 1550](#)

[VPLS Overview | 1546](#)

Understanding VPLS VLAN Encapsulation

Gigabit Ethernet IQ, Gigabit Ethernet PIMs with small form-factor pluggable optics (SFPs), SRX Series devices with Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces with VLAN tagging enabled can use flexible Ethernet services, VLAN virtual private LAN service (VPLS) encapsulation.

NOTE: VLAN encapsulation is not supported on SRX100 devices because there is no Gigabit Ethernet port.

Aggregated Ethernet interfaces configured for VPLS can use Ethernet VPLS or VLAN VPLS.

To configure the encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface, include the **encapsulation** statement at the **[edit interfaces interface-name]** hierarchy level, specifying **vlan-ccc** or **vlan-vpls**:

```
[edit interfaces interface-name] encapsulation (vlan-ccc | vlan-vpls);
```

To configure the encapsulation on an aggregated Ethernet interface, include the encapsulation statement at the **[edit interfaces interface-name]** hierarchy level, specifying **ethernet-vpls** or **vlan-vpls**:

```
[edit interfaces interface-name] encapsulation (ethernet-vpls | vlan-vpls);
```

Ethernet interfaces in VLAN mode can have multiple logical interfaces. In CCC and VPLS modes, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for CCC or VPLS VLANs. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for CCC or VPLS VLANs.

RELATED DOCUMENTATION

[Example: Configuring Extended VLAN VPLS Encapsulation | 1639](#)

[Example: Configuring VPLS VLAN Encapsulation | 1633](#)

[VPLS Overview | 1546](#)

Understanding VPLS VLAN Encapsulation on a Logical Interface

You can configure a logical interface with VLAN VPLS encapsulation by using the following methods:

- Configure the physical interface with the same encapsulation and set VLAN ID of 512 or higher.
- Configure the physical interface with flexible Ethernet services encapsulation. If you configure flexible Ethernet services encapsulation, the VLAN ID restriction is removed.

Ethernet interfaces in VLAN mode can have multiple logical interfaces. In VPLS mode, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for VPLS VLAN. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for VPLS VLAN.

For encapsulation type **flexible-ethernet-services**, all VLAN IDs are valid.

- Configure routing options on the PE router. See [“Example: Configuring Routing Options on the VPLS PE Router” on page 1630](#).
- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See [“Example: Configuring BGP on the VPLS PE Router” on page 1628](#).

Overview

This example describes how to enable VLAN tagging on VPLS interface ge-3/0/6, configure the encapsulation type on the physical and logical interfaces, and configure the VPLS family on the logical interface.

NOTE: Perform the following CLI quick configuration and procedures on all of the PE interfaces (CE facing).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-3/0/6 vlan-tagging
set interfaces ge-3/0/6 encapsulation vlan-vpls
set interfaces ge-3/0/6 unit 0 encapsulation vlan-vpls
set interfaces ge-3/0/6 unit 0 vlan-id 512
set interfaces ge-3/0/6 unit 0 family vpls
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure VPLS VLAN encapsulation:

1. Enable VLAN tagging on the VPLS interface.

```
[edit interfaces ge-3/0/6]
user@host# set vlan-tagging
```

2. Configure the encapsulation type on the physical interface.

```
[edit interfaces ge-3/0/6]  
user@host# set interfaces ge-3/0/6 encapsulation vlan-vpls
```

3. Configure the encapsulation type on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]  
user@host# set encapsulation vlan-vpls
```

4. Configure the VLAN ID on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]  
user@host# set vlan-id 512
```

5. Configure the family VPLS on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]  
user@host# set family vpls
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces ge-3/0/6** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]  
user@host# show interfaces ge-3/0/6  
vlan-tagging;  
encapsulation vlan-vpls;  
unit 0 {  
    encapsulation vlan-vpls;  
    vlan-id 512;  
    family vpls;  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Example: Configuring VPLS VLAN Encapsulation on Gigabit Ethernet Interfaces

IN THIS SECTION

- Requirements | 1637
- Overview | 1638
- Configuration | 1638
- Verification | 1638

This example shows how to configure the VPLS VLAN encapsulation on either a Gigabit Ethernet IQ or Gigabit Ethernet physical interface.

Requirements

Before you begin:

- Before you begin, see *Understanding Selective Stateless Packet-Based Services*.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See [“Example: Configuring Routing Interfaces on the VPLS PE Router” on page 1564](#) and [“Example: Configuring the Interface to the VPLS CE Device” on page 1565](#).
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See [“Example: Configuring the VPLS Routing Instance” on page 1576](#).
- Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
- Configure RSVP-TE, see [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#) and then MPLS LSPs on the PE routers, see [“Example: Configuring MPLS on the VPLS PE Router” on page 1585](#). Alternatively configure LDP on the PE routers, see [“Example: Configuring LDP on the VPLS PE Router” on page 1587](#).
- Configure routing options on the PE router. See [“Example: Configuring Routing Options on the VPLS PE Router” on page 1630](#).
- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See [“Example: Configuring BGP on the VPLS PE Router” on page 1628](#).

Overview

This example describes how to configure Ethernet VPLS encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface and enable the VPLS family on the interface.

Configuration

Step-by-Step Procedure

To configure VPLS VLAN encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface:

1. Configure the ethernet-vpls encapsulation on the interface.

```
[edit ]
user@host# set interfaces ge-3/0/6 encapsulation ethernet-vpls
```

2. Enable the VPLS family on the interface.

```
[edit ]
user@host# set interfaces ge-3/0/6 unit 0 family vpls
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces** command.

- Configure an IGP on the PE routers to exchange routing information. See [“Example: Configuring OSPF on the VPLS PE Router” on page 1581](#).
- Configure RSVP-TE, see [“Example: Configuring RSVP on the VPLS PE Router” on page 1583](#) and then MPLS LSPs on the PE routers, see [“Example: Configuring MPLS on the VPLS PE Router” on page 1585](#). Alternatively configure LDP on the PE routers, see [“Example: Configuring LDP on the VPLS PE Router” on page 1587](#).
- Configure routing options on the PE router. See [“Example: Configuring Routing Options on the VPLS PE Router” on page 1630](#).
- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See [“Example: Configuring BGP on the VPLS PE Router” on page 1628](#).

Overview

This example describes how to enable VLAN tagging on the VPLS interface ge-3/0/6, configure the extended-vlan-vpls type on the physical and logical interfaces, and configure the VPLS family on the logical interface.

NOTE: Perform the following CLI quick configurations and procedures on all PE interfaces (CE facing).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-3/0/6 vlan-tagging
set interfaces ge-3/0/6 encapsulation extended-vlan-vpls
set interfaces ge-3/0/6 unit 0 vlan-id 100
set interfaces ge-3/0/6 unit 0 family vpls
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure extended VPLS VLAN encapsulation:

1. Enable VLAN tagging on the VPLS interface as it will receive tagged packets from CE.

```
[edit interfaces ge-3/0/6]
user@host# set vlan-tagging
```

2. Configure the encapsulation type on the physical interface.

```
[edit interfaces ge-3/0/6]
user@host# set interfaces ge-3/0/6 encapsulation vlan-vpls
```

3. Configure the VLAN ID on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]
user@host# set encapsulation vlan-vpls vlan-id 100
```

4. Configure the VPLS family on the logical interface.

```
[edit interfaces ge-3/0/6 unit 0]
user@host# set family vpls
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces ge-3/0/6** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces ge-3/0/6
vlan-tagging;
encapsulation extended-vlan-vpls;
unit 0 {
    encapsulation vlan-vpls;
    vlan-id 100;
    family vpls;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

- [Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit \(CLI Procedure\) | 1689](#)

CCC Overview

Circuit cross-connect (CCC) allows you to configure transparent connections between two circuits, where a circuit can be a Frame Relay data-link connection identifier (DLCI), an Asynchronous Transfer Mode (ATM) virtual circuit (VC), a Point-to-Point Protocol (PPP) interface, a Cisco High-Level Data Link Control (HDLC) interface, or an MPLS label-switched path (LSP). Using CCC, packets from the source circuit are delivered to the destination circuit with, at most, the Layer 2 address being changed. No other processing—such as header checksums, time-to-live (TTL) decrementing, or protocol processing—is done.

NOTE: The QFX10000 Series switches do not support ATM virtual circuits.

CCC circuits fall into two categories: logical interfaces, which include DLCIs, VCs, virtual local area network (VLAN) IDs, PPP and Cisco HDLC interfaces, and LSPs. The two circuit categories provide three types of cross-connect:

- Layer 2 switching—Cross-connects between logical interfaces provide what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.
- MPLS tunneling—Cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit.
- LSP stitching—Cross-connects between LSPs provide a way to “stitch” together two label-switched paths, including paths that fall in two different traffic engineering database areas.

For Layer 2 switching and MPLS tunneling, the cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first. For LSP stitching, the cross-connect is unidirectional.

You can police (control) the amount of traffic flowing over CCC circuits. For more information, see the *Junos OS VPNs Library for Routing Devices*.

It is also possible to use the **ping** command to check the integrity of CCC LSPs. See [“Pinging CCC LSPs” on page 524](#) for more information.

Understanding Carrier-of-Carriers VPNs

IN THIS SECTION

- [Internet Service Provider as the Customer | 1646](#)
- [VPN Service Provider as the Customer | 1646](#)

The customer of a VPN service provider might be a service provider for the end customer. The following are the two main types of carrier-of-carriers VPNs (as described in RFC 4364):

- [“Internet Service Provider as the Customer” on page 1646](#)—The VPN customer is an ISP that uses the VPN service provider’s network to connect its geographically disparate regional networks. The customer does not have to configure MPLS within its regional networks.
- [“VPN Service Provider as the Customer” on page 1646](#)—The VPN customer is itself a VPN service provider offering VPN service to its customers. The carrier-of-carriers VPN service customer relies on the backbone VPN service provider for inter-site connectivity. The customer VPN service provider is required to run MPLS within its regional networks.

[Figure 126 on page 1645](#) illustrates the network architecture used for a carrier-of-carriers VPN service.

Figure 126: Carrier-of-Carriers VPN Architecture

8017197

This topic covers the following:

Internet Service Provider as the Customer

In this type of carrier-of-carriers VPN configuration, ISP A configures its network to provide Internet service to ISP B. ISP B provides the connection to the customer wanting Internet service, but the actual Internet service is provided by ISP A.

This type of carrier-of-carriers VPN configuration has the following characteristics:

- The carrier-of-carriers VPN service customer (ISP B) does not need to configure MPLS on its network.
- The carrier-of-carriers VPN service provider (ISP A) must configure MPLS on its network.
- MPLS must also be configured on the CE routers and PE routers connected together in the carrier-of-carriers VPN service customer's and carrier-of-carriers VPN service provider's networks.

VPN Service Provider as the Customer

A VPN service provider can have customers that are themselves VPN service providers. In this type of configuration, also called a hierarchical or recursive VPN, the customer VPN service provider's VPN-IPv4 routes are considered external routes, and the backbone VPN service provider does not import them into its VRF table. The backbone VPN service provider imports only the customer VPN service provider's internal routes into its VRF table.

The similarities and differences between interprovider and carrier-of-carriers VPNs are shown in [Table 47 on page 1646](#).

Table 47: Comparison of Interprovider and Carrier-of-Carriers VPNs

Feature	ISP Customer	VPN Service Provider Customer
Customer edge device	AS border router	PE router
IBGP sessions	Carry IPv4 routes	Carry external VPN-IPv4 routes with associated labels
Forwarding within the customer network	MPLS is optional	MPLS is required

Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

Release History Table

Release	Description
17.1R1	Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

Interprovider VPNs

Understanding Interprovider and Carrier-of-Carriers VPNs

All interprovider and carrier-of-carriers VPNs share the following characteristics:

- Each interprovider or carrier-of-carriers VPN customer must distinguish between internal and external customer routes.
- Internal customer routes must be maintained by the VPN service provider in its PE routers.
- External customer routes are carried only by the customer's routing platforms, not by the VPN service provider's routing platforms.

The key difference between interprovider and carrier-of-carriers VPNs is whether the customer sites belong to the same AS or to separate ASs:

- *Interprovider VPNs*—The customer sites belong to different ASs. You need to configure EBGp to exchange the customer's external routes.
- [“Understanding Carrier-of-Carriers VPNs” on page 1644](#)—The customer sites belong to the same AS. You need to configure IBGP to exchange the customer's external routes.

In general, each service provider in a VPN hierarchy is required to maintain its own internal routes in its P routers, and the internal routes of its customers in its PE routers. By recursively applying this rule, it is possible to create a hierarchy of VPNs.

The following are definitions of the types of PE routers specific to interprovider and carrier-of-carriers VPNs:

- The AS border router is located at the AS border and handles traffic leaving and entering the AS.
- The end PE router is the PE router in the customer VPN; it is connected to the CE router at the end customer's site.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 circuit on the switch to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on Provider Switches” on page 88](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the `vlan-ccc` encapsulation, you cannot configure the associated logical interfaces with the `inet` family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 circuit:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
```

```

user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address

```

4. Enable the MPLS protocol with CSPF disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```

[edit protocols]
user@switch# set mpls no-cspf

```

5. Configure the customer edge interface as a Layer 2 circuit from the local PE switch to the other PE switch:

```

[edit protocols]
user@switch# set l2circuit neighbor address interface interface-name virtual-circuit-id identifier

```

TIP: Use the switch address of the other switch as the neighbor address.

6. Configure MPLS on the core interfaces:

```

[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name

```

7. Configure LDP on the loopback interface and the core interfaces:

```

[edit protocols]
user@switch# set ldp interface lo0.0
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name

```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use VLAN CCC encapsulation:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit **0**. The logical unit number must be **1** or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-id vlan-id
```

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: For EX Series switches, you must use the same type of switch for the other PE switch.
h.

VLAN CCC Encapsulation on Transport Side of Pseudowire Client Logical Interfaces Overview

Currently, Junos OS does not allow the same VLAN ID to be configured on more than one logical interface under the same pseudowire client physical interface. To support **vlan-ccc** encapsulation on transport pseudowire service (PS) interface on the provider edge (PE) device, this restriction is removed and you can configure the same VLAN ID on more than one logical interface.

The primary reason to configure **vlan-ccc** on the transport PS interface is interoperability with the existing access and aggregate devices in the network. Currently, Junos OS supports **ethernet-ccc** encapsulation on the transport PS interface. Typically, while establishing a pseudowire connection, the access device initiates a VLAN-based pseudowire (also known as VLAN-tagged mode), and a PE router signals the Ethernet mode VLAN back to the access device. For this type of pseudowire connection to be established, you can use the **ignore-encapsulation-mismatch** statement. However, the Junos OS device (access device) might not support the **ignore-encapsulation-mismatch** statement and, as a result, the pseudowire connection is not formed. When the **ignore-encapsulation-mismatch** statement is not supported on the access device, you can configure **vlan-ccc** between the nodes to form a pseudowire connection.

The forwarding data path is not changed with the new **vlan-ccc** encapsulation on the transport PS interface and the behavior similar to that when the **ethernet-ccc** encapsulation is configured on the transport PS interface. The transport PS interface either encapsulates or de-encapsulate the outer Layer 2 header and MPLS headers on the transmitted or received packets on the WAN port. Inner Ethernet or VLAN headers of the packet are handled on pseudowire client service logical interfaces. You must configure pseudowire client service logical interfaces with appropriate VLAN IDs or VLAN tags.

The following sections provides details, along with a sample configuration, about pseudowire configuration from both access and aggregation nodes.

Pseudowire Configuration from Access Node

These pseudowires are set up using VLANs from the access node for customer devices attached to the Layer 2 circuit configured on access and PE routers with customer VLANs (C-VLANs). The ingress traffic (from the access node side) on the PE router is single VLAN tagged (inner Ethernet header), and thus the service logical interfaces must be configured with the same VLAN IDs corresponding to the C-VLAN IDs attached to the access node.

[Figure 127 on page 1652](#) provides the details of a transport PS interface from an access node (access node).

Figure 127: Pseudowire Client Transport Logical Interface from Access Node

The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an access node:

```

interfaces {
  ps0 {
    anchor-point lt-3;
    unit 0 {
      encapsulation VLAN-ccc;
      VLAN ID 100;
    }
    unit 1 {
      VLAN ID 100;
      family inet;
    }
  }
}

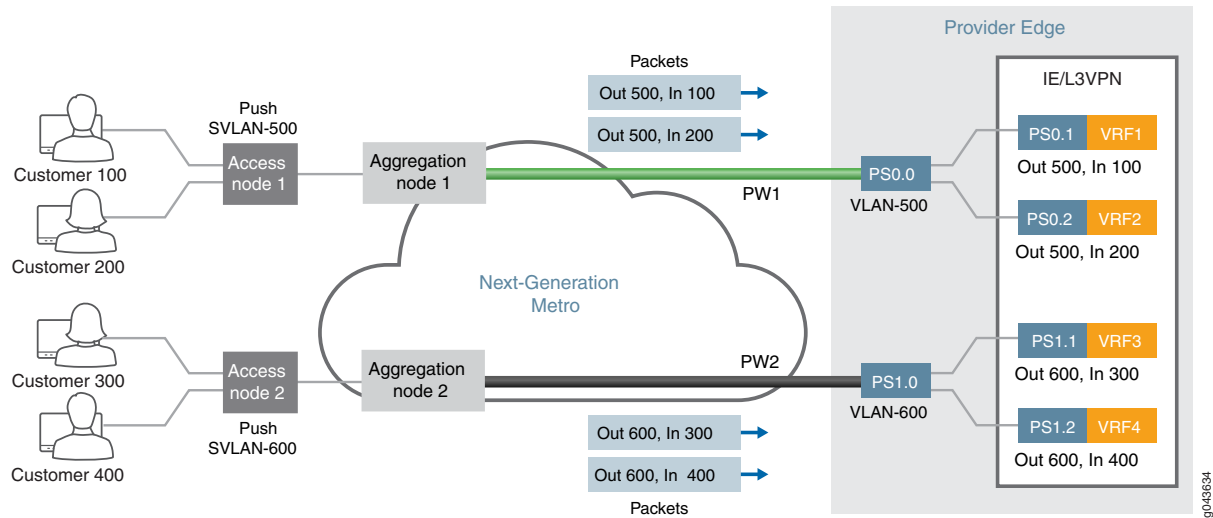

```

Pseudowire Configuration from Aggregation Node

In this case, the aggregation node processes a stacked VLAN (also known as Q-in-Q). The pseudowire originates from aggregation node and terminates on a PE router. The aggregation node pushes the service VLAN (S-VLAN) tag, and the PE router is expected to operate on two VLAN tags—the outer VLAN tag corresponds to an S-VLAN and the inner VLAN tag corresponds to a C-VLAN. The VLAN ID configured on the transport PS interface at the PE router must match the VLAN tag of the S-VLAN. On the pseudowire client service logical interface, the outer VLAN tag must be configured to match the S-VLAN and the inner VLAN tag must be configured to match the C-VLAN.

[Figure 128 on page 1653](#) provides the details of a transport PS interface from an aggregation node.

Figure 128: Pseudowire Client Transport Logical Interface from Aggregation Node

The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an aggregation node:

```

interfaces {
  ps0 {
    anchor-point lt-3;
    unit 0 {
      encapsulation VLAN-ccc;
      VLAN ID 500;
    }
    unit 1 {
      VLAN tags {
        outer 500;
        inner 100;
      }
    }
    unit 2 {
      VLAN tags {
        outer 500;
        inner 200;
      }
    }
  }
}

```

RELATED DOCUMENTATION

Anchor Redundancy Pseudowire Subscriber Logical Interfaces Overview

Pseudowire Subscriber Logical Interfaces Overview

Transmitting Nonstandard BPDUs

CCC protocol (and Layer 2 Circuit and Layer 2 VPN) configurations can transmit nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment. This is the default behavior on all supported PICs and requires no additional configuration.

The following PICs are supported on M320 and T Series routers:

- 1-port Gigabit Ethernet PIC
- 2-port Gigabit Ethernet PIC
- 4-port Gigabit Ethernet PIC
- 10-port Gigabit Ethernet PIC

TCC Overview

Translational cross-connect (TCC) is a switching concept that enables you to establish interconnections between a variety of Layer 2 protocols or circuits. It is similar to CCC. However, whereas CCC requires the same Layer 2 encapsulations on each side of a Juniper Networks router (such as PPP-to-PPP or Frame Relay-to-Frame Relay), TCC enables you to connect different types of Layer 2 protocols interchangeably. When you use TCC, combinations such as PPP-to-ATM (see [Figure 129 on page 1654](#)) and Ethernet-to-Frame Relay connections are possible.

Figure 129: TCC Example

The Layer 2 circuits and encapsulation types that can be interconnected by TCC are:

- Ethernet
- Extended VLANs
- PPP

- HDLC
- ATM
- Frame Relay

TCC works by removing the Layer 2 header when frames enter the router and adding a different Layer 2 header on the frames before they leave the router. In [Figure 129 on page 1654](#), the PPP encapsulation is stripped from the frames arriving at Router B, and the ATM encapsulation is added before the frames are sent to Router C.

Note that all control traffic is terminated at the interconnecting router (Router B). Examples of traffic controllers include the Link Control Protocol (LCP) and the Network Control Protocol (NCP) for PPP, keepalives for HDLC, and Local Management Interface (LMI) for Frame Relay.

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, TTL decrementing, or protocol handling is performed. TCC is supported for IPv4 only.

Address Resolution Protocol (ARP) packet policing on TCC Ethernet interfaces is effective for releases 10.4 and onwards.

You can configure TCC for interface switching and for Layer 2 VPNs. For more information about using TCC for virtual private networks (VPNs), see the *Junos OS VPNs Library for Routing Devices*.

Configuring Layer 2 Switching Cross-Connects Using CCC

IN THIS SECTION

- [Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects | 1656](#)
- [Configuring the CCC Connection for Layer 2 Switching Cross-Connects | 1661](#)
- [Configuring MPLS for Layer 2 Switching Cross-Connects | 1662](#)
- [Example: Configuring a Layer 2 Switching Cross-Connect | 1662](#)
- [Configuring Layer 2 Switching Cross-Connect on ACX5440 | 1664](#)

Layer 2 switching cross-connects join logical interfaces to form what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.

Figure 130 on page 1656 illustrates a Layer 2 switching cross-connect. In this topology, Router A and Router C have Frame Relay connections to Router B, which is a Juniper Networks router. Circuit cross-connect (CCC) allows you to configure Router B to act as a Frame Relay (Layer 2) switch.

To configure Router B to act as a Frame Relay switch, you configure a circuit from Router A to Router C that passes through Router B, effectively configuring Router B as a Frame Relay switch with respect to these routers. This configuration allows Router B to transparently switch packets (frames) between Router A and Router C without regard to the packets' contents or the Layer 3 protocols. The only processing that Router B performs is to translate DLCI 600 to 750.

Figure 130: Layer 2 Switching Cross-Connect

If the Router A-to-Router B and Router B-to-Router C circuits were PPP, for example, the Link Control Protocol and Network Control Protocol exchanges occur between Router A and Router C. These messages are handled transparently by Router B, allowing Router A and Router C to use various PPP options (such as header or address compression and authentication) that Router B might not support. Similarly, Router A and Router C exchange keepalives, providing circuit-to-circuit connectivity status.

You can configure Layer 2 switching cross-connects on PPP, Cisco HDLC, Frame Relay, Ethernet, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

To configure Layer 2 switching cross-connects, you must configure the following on the router that is acting as the switch (Router B in Figure 130 on page 1656):

Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects

IN THIS SECTION

- [Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects | 1657](#)
- [Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects | 1657](#)
- [Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects | 1658](#)
- [Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects | 1659](#)
- [Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects | 1660](#)
- [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects | 1661](#)

To configure Layer 2 switching cross-connects, configure the CCC encapsulation on the router that is acting as the switch (Router B in [Figure 130 on page 1656](#)).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the **family** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

For instructions for configuring the encapsulation for Layer 2 switching cross-connects, see the following sections:

Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects

For ATM circuits, specify the encapsulation when configuring the virtual circuit (VC). Configure each VC as a circuit or a regular logical interface by including the following statements:

```
at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    encapsulation encapsulation-type;
    point-to-point; # Default interface type
    vci vpi-identifier.vci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects

For Ethernet circuits, specify **ethernet-ccc** in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must also configure a logical interface (unit 0).

Ethernet interfaces with standard Tag Protocol Identifier (TPID) tagging can use Ethernet CCC encapsulation. On M Series Multiservice Edge Routers, except the M320, one-port Gigabit Ethernet, two-port Gigabit Ethernet, four-port Gigabit Ethernet, and four-port Fast Ethernet PICs can use Ethernet CCC encapsulation. On T Series Core Routers and M320 routers, one-port Gigabit Ethernet and two-port Gigabit Ethernet PICs installed in FPC2 can use Ethernet CCC encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.

```
fe-fpc/pic/port {
```

```
encapsulation ethernet-ccc;
unit 0;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects

An Ethernet virtual LAN (VLAN) circuit can be configured using either the **vlan-ccc** or **extended-vlan-ccc** encapsulation. If you configure the **extended-vlan-ccc** encapsulation on the physical interface, you cannot configure the **inet** family on the logical interfaces. Only the **ccc** family is allowed. If you configure the **vlan-ccc** encapsulation on the physical interface, both the **inet** and **ccc** families are supported on the logical interfaces. Ethernet interfaces in VLAN mode can have multiple logical interfaces.

For encapsulation type **vlan-ccc**, VLAN IDs from 512 through 4094 are reserved for CCC VLANs. For the **extended-vlan-ccc** encapsulation type, all VLAN IDs 1 and higher are valid. VLAN ID 0 is reserved for tagging the priority of frames.

NOTE: Some vendors use the proprietary TPIDs 0x9100 and 0x9901 to encapsulate a VLAN-tagged packet into a VLAN-CCC tunnel to interconnect a geographically separated metro Ethernet network. By configuring the **extended-vlan-ccc** encapsulation type, a Juniper Networks router can accept all three TPIDs (0x8100, 0x9100, and 0x9901).

Configure an Ethernet VLAN circuit with the **vlan-ccc** encapsulation as follows:

```
interfaces {
  type-fpc/pic/port {
    vlan-tagging;
    encapsulation vlan-ccc;
    unit logical-unit-number {
      encapsulation vlan-ccc;
      vlan-id vlan-id;
    }
  }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]

- [edit logical-systems *logical-system-name* interfaces]

Configure an Ethernet VLAN circuit with the **extended-vlan-ccc** encapsulation statement as follows:

```
interfaces {
  type-fpc/pic/port {
    vlan-tagging;
    encapsulation extended-vlan-ccc;
    unit logical-unit-number {
      vlan-id vlan-id;
      family ccc;
    }
  }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Whether you configure the encapsulation as **vlan-ccc** or **extended-vlan-ccc**, you must enable VLAN tagging by including the **vlan-tagging** statement.

Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects

You can configure aggregated Ethernet interfaces for CCC connections and for Layer 2 virtual private networks (VPNs).

Aggregated Ethernet interfaces configured with VLAN tagging can be configured with multiple logical interfaces. The only encapsulation available for aggregated Ethernet logical interfaces is **vlan-ccc**. When you configure the **vlan-id** statement, you are limited to VLAN IDs 512 through 4094.

Aggregated Ethernet interfaces configured without VLAN tagging can be configured only with the **ethernet-ccc** encapsulation. All untagged Ethernet packets received are forwarded based on the CCC parameters.

To configure aggregated Ethernet interfaces for CCC connections, include the **ae0** statement at the [edit interfaces] hierarchy level:

```
[edit interfaces]
ae0 {
  encapsulation (ethernet-ccc | extended-vlan-ccc | vlan-ccc);
  vlan-tagging;
  aggregated-ether-options {
    minimum-links links;
    link-speed speed;
```

```

    }
    unit logical-unit-number {
        encapsulation vlan-ccc;
        vlan-id identifier;
        family ccc;
    }
}

```

Be aware of the following limitations when configuring CCC connections over aggregated Ethernet interfaces:

- If you configured load balancing between child links, be aware that a different hash key is used to distribute packets among the child links. Standard aggregated interfaces have family inet configured. An IP version 4 (IPv4) hash key (based on the Layer 3 information) is used to distribute packets among the child links. A CCC connection over an aggregated Ethernet interface has family ccc configured instead. Instead of an IPv4 hash key, an MPLS hash key (based on the destination media access control [MAC] address) is used to distributed packets among the child links.
- The extended-vlan-ccc encapsulation is not supported on the 12-port Fast Ethernet PIC and the 48-port Fast Ethernet PIC.
- The Junos OS does not support the Link Aggregation Control Protocol (LACP) when an aggregated interface is configured as a VLAN (with vlan-ccc encapsulation). LACP can be configured only when the aggregated interface is configured with the ethernet-ccc encapsulation.

For more information about how to configure aggregated Ethernet interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects

For Frame Relay circuits, specify the encapsulation when configuring the DLCI. Configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be from 1 through 511. For CCC interfaces, it must be from 512 through 4094.

```

interfaces {
    type-fpc/pic/port {
        unit logical-unit-number {
            dlcid dlcid-identifier;
            encapsulation encapsulation-type;
            point-to-point; # Default interface type
        }
    }
}

```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects

For PPP and Cisco HDLC circuits, specify the encapsulation in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must configure a logical interface (unit 0).

```
interfaces type-fpc/pic/port {
  encapsulation encapsulation-type;
  unit 0;
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces *type-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *type-fpc/pic/port*]

Configuring the CCC Connection for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, define the connection between the two circuits by including the **interface-switch** statement. You configure this connection on the router that is acting as the switch (Router B in [Figure 130 on page 1656](#)). The connection joins the interface that comes from the circuit's source to the interface that leads to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

```
interface-switch connection-name {
  interface interface-name.unit-number;
  interface interface-name.unit-number;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Configuring MPLS for Layer 2 Switching Cross-Connects

For Layer 2 switching cross-connects to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
  interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

Example: Configuring a Layer 2 Switching Cross-Connect

Configure a full-duplex Layer 2 switching cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the virtual switch. See the topology in [Figure 131 on page 1662](#) and [Figure 132 on page 1663](#).

Configuring Layer 2 Switching Cross-Connect on ACX5440

Starting in Junos OS Release 19.3R1, you can leverage the hardware support available for cross-connects on the ACX5448 device with the Layer 2 local switching functionality using certain models. With this support, you can provide the EVP and Ethernet Virtual Private Line (EVPL) services..

Local-switching with the following forwarding models are supported:

- VLAN-CCC (logical interface-level local-switching) without any map.
- VLAN-CCC (logical interface-level local-switching) with the following vlan-maps:
 - Push 0x8100.pushVLAN (QinQ type)
 - Swap 0x8100.swapVLAN
- Aggregated Ethernet (AE) static interfaces.

- AE interfaces with LACP, load-balance all active mode.
- Local-switching end-interface support for AE or LAG interface (one non-AE interface and other AE interface).
- Local-switching both interface as AE or LAG interfaces.

To enable Layer 2 local switching on the ACX5448 device, you can use the existing configuration statements for Layer 2 circuits. For example,

```
[edit protocols l2circuit]
local-switching {
  interface interface1 {
    end-interface interface3;
    ignore-encapsulation-mismatch;
    ignore-mtu-mismatch;
  }
}
```

Release History Table

Release	Description
19.3R1	Starting in Junos OS Release 19.3R1, you can leverage the hardware support available for cross-connects on the ACX5448 device with the Layer 2 local switching functionality using certain models. With this support, you can provide the EVP and Ethernet Virtual Private Line (EVPL) services.

Configuring MPLS LSP Tunnel Cross-Connects Using CCC

IN THIS SECTION

- [Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects | 1667](#)
- [Configuring the CCC Connection for LSP Tunnel Cross-Connects | 1669](#)
- [Example: Configuring an LSP Tunnel Cross-Connect | 1669](#)

MPLS tunnel cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit. The topology in [Figure 133 on page 1666](#) illustrates an MPLS LSP tunnel cross-connect. In this topology, two separate networks, in this case ATM access networks, are connected through an IP backbone. CCC allows you to establish an LSP tunnel between the two domains. With LSP tunneling, you tunnel the ATM traffic from one network across a SONET backbone to the second network by using an MPLS LSP.

Figure 133: MPLS Tunnel Cross-Connect

When traffic from Router A (VC 234) reaches Router B, it is encapsulated and placed into an LSP, which is sent through the backbone to Router C. At Router C, the label is removed, and the packets are placed onto the ATM permanent virtual circuit (PVC) (VC 591) and sent to Router D. Similarly, traffic from Router D (VC 591) is sent over an LSP to Router B, then placed on VC 234 to Router A.

You can configure LSP tunnel cross-connect on PPP, Cisco HDLC, Frame Relay, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

When you use MPLS tunnel cross-connects to support IS-IS, you must ensure that the LSP's maximum transmission unit (MTU) can, at a minimum, accommodate a 1492-octet IS-IS protocol data unit (PDU) in addition to the link-level overhead associated with the technology being connected.

For the tunnel cross-connects to work, the IS-IS frame size on the edge routers (Routers A and D in [Figure 134 on page 1669](#)) must be smaller than the LSP's MTU.

NOTE: Frame size values do not include the frame check sequence (FCS) or delimiting flags.

To determine the LSP MTU required to support IS-IS, use the following calculation:

IS-IS MTU (minimum 1492, default 1497) + frame overhead + 4 (MPLS shim header) = Minimum LSP MTU

The framing overhead varies based on the encapsulation being used. The following lists the IS-IS encapsulation overhead values for various encapsulations:

- ATM
 - AAL5 multiplex—8 bytes (RFC 1483)

- VC multiplex—0 bytes
- Frame Relay
 - Multiprotocol—2 bytes (RFCs 1490 and 2427)
 - VC multiplex—0 bytes
- HDLC—4 bytes
- PPP—4 bytes
- VLAN—21 bytes (802.3/LLC)

For IS-IS to work over VLAN-CCC, the LSP's MTU must be at least 1513 bytes (or 1518 for 1497-byte PDUs). If you increase the size of a Fast Ethernet MTU above the default of 1500 bytes, you might need to explicitly configure jumbo frames on intervening equipment.

To modify the MTU, include the **mtu** statement when configuring the logical interface family at the **[edit interfaces interface-name unit logical-unit-number encapsulation family]** hierarchy level. For more information about setting the MTU, see the *Junos OS Network Interfaces Library for Routing Devices*.

To configure an LSP tunnel cross-connect, you must configure the following on the interdomain router (Router B in [Figure 134 on page 1669](#)):

Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, you must configure the CCC encapsulation on the ingress and egress routers (Router B and Router C, respectively, in [Figure 134 on page 1669](#)).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the **family** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level.

For PPP or Cisco HDLC circuits, include the **encapsulation** statement to configure the entire physical device. For these circuits to work, you must configure logical unit 0 on the interface.

```
type-fpc/pic/port {
  encapsulation (ppp-ccc | cisco-hdlc-ccc);
  unit 0;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems logical-system-name interfaces]**

For ATM circuits, specify the encapsulation when configuring the VC by including the following statements. For each VC, you configure whether it is a circuit or a regular logical interface.

```
at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    point-to-point; # Default interface type
    encapsulation atm-ccc-vc-mux;
    vci vpi-identifier.vci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For Frame Relay circuits, include the following statements to specify the encapsulation when configuring the DLCI. For each DLCI, you configure whether it is a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range 1 through 511. For CCC interfaces, it must be in the range 512 through 1022.

```
type-fpc/pic/port {
  encapsulation frame-relay-ccc;
  unit logical-unit-number {
    point-to-point; # default interface type
    encapsulation frame-relay-ccc;
    dlci dlci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For more information about the **encapsulation** statement, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring the CCC Connection for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, include the **remote-interface-switch** statement to define the connection between the two circuits on the ingress and egress routers (Router B and Router C, respectively, in [Figure 134 on page 1669](#)). The connection joins the interface or LSP that comes from the circuit's source to the interface or LSP that leads to the circuit's destination. When you specify the interface name, include the logical portion of the name, which corresponds to the logical unit number. For the cross-connect to be bidirectional, you must configure cross-connects on two routers.

```
remote-interface-switch connection-name {
  interface interface-name.unit-number;
  transmit-lsp label-switched-path;
  receive-lsp label-switched-path;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Example: Configuring an LSP Tunnel Cross-Connect

Configure a full-duplex MPLS LSP tunnel cross-connect from Router A to Router D, passing through Router B and Router C. See the topology in [Figure 134 on page 1669](#).

Figure 134: Example Topology of MPLS LSP Tunnel Cross-Connect

On Router B:

```
[edit]
interfaces {
  at-7/1/1 {
    atm-options {
      vpi 1 maximum-vcs 600;
    }
    unit 1 {
```

```

        point-to-point; # default interface type
        encapsulation atm-ccc-vc-mux;
        vci 1.234;
    }
}
}
protocols {
    connections {
        remote-interface-switch router-b-to-router-c {
            interface at-7/1/1.1;
            transmit-lsp lsp1;
            receive-lsp lsp2;
        }
    }
}

```

On Router C:

```

[edit]
interfaces {
    at-3/0/0 {
        atm-options {
            vpi 2 maximum-vcs 600;
        }
        unit 2 {
            point-to-point; # default interface type
            encapsulation atm-ccc-vc-mux;
            vci 2.591;
        }
    }
}
protocols {
    connections {
        remote-interface-switch router-b-to-router-c {
            interface at-3/0/0.2;
            transmit-lsp lsp2;
            receive-lsp lsp1;
        }
    }
}

```

Configuring TCC

IN THIS SECTION

- [Configuring the Encapsulation for Layer 2 Switching TCCs | 1671](#)
- [Configuring the Connection for Layer 2 Switching TCCs | 1675](#)
- [Configuring MPLS for Layer 2 Switching TCCs | 1676](#)

This section describes how to configure translational cross-connect (TCC).

To configure TCC, you must perform the following tasks on the router that is acting as the switch:

Configuring the Encapsulation for Layer 2 Switching TCCs

IN THIS SECTION

- [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs | 1672](#)
- [Configuring ATM Encapsulation for Layer 2 Switching TCCs | 1672](#)
- [Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs | 1672](#)
- [Configuring Ethernet Encapsulation for Layer 2 Switching TCCs | 1673](#)
- [Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs | 1674](#)
- [Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations | 1675](#)

To configure a Layer 2 switching TCC, specify the TCC encapsulation on the desired interfaces of the router that is acting as the switch.

NOTE: You cannot configure standard protocol families on TCC or CCC interfaces. Only the CCC family is allowed on CCC interfaces, and only the TCC family is allowed on TCC interfaces.

For Ethernet circuits and Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 1675](#).

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs

For PPP and Cisco HDLC circuits, configure the encapsulation type for the entire physical device by specifying the appropriate value for the **encapsulation** statement. For these circuits to work, you must also configure the logical interface **unit 0**.

```
encapsulation (ppp-tcc | cisco-hdlc-tcc);
unit 0{...}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

Configuring ATM Encapsulation for Layer 2 Switching TCCs

For ATM circuits, configure the encapsulation type by specifying the appropriate value for the **encapsulation** statement in the virtual circuit (VC) configuration. Specify whether each VC is a circuit or a regular logical interface.

```
atm-options {
  vpi vpi-identifier maximum-vcs maximum-vcs;
}
unit logical-unit-number {
  encapsulation (atm-tcc-vc-mux | atm-tcc-snap);
  point-to-point;
  vci vpi-identifier.vci-identifier;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *at-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *at-fpc/pic/port*]

Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs

For Frame Relay circuits, configure the encapsulation type by specifying the value **frame-relay-tcc** for the **encapsulation** statement when configuring the data-link connection identifier (DLCI). You configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range from 1 through 511, but for TCC and CCC interfaces it must be in the range from 512 through 1022.

```
encapsulation frame-relay-tcc;
unit logical-unit-number {
  dlci dlci-identifier;
  encapsulation frame-relay-tcc;
```

```
point-to-point;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

Configuring Ethernet Encapsulation for Layer 2 Switching TCCs

For Ethernet TCC circuits, configuring the encapsulation type for the entire physical device by specifying the value **ethernet-tcc** for the **encapsulation** statement.

You must also specify static values for a remote address and a proxy address at the [edit interfaces *interface-name* unit *unit-number* family *tcc*] or [edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family *tcc*] hierarchy level.

The remote address is associated with the TCC switching router's Ethernet neighbor; in the **remote** statement you must specify both the IP address and the media access control (MAC) address of the Ethernet neighbor. The proxy address is associated with the TCC router's other neighbor connected by the unlike link; in the **proxy** statement you must specify the IP address of the non-Ethernet neighbor.

You can configure Ethernet TCC encapsulation for the interfaces on 1-port Gigabit Ethernet, 2-port Gigabit Ethernet, 4-port Fast Ethernet, and 4-port Gigabit Ethernet PICs.

```
encapsulation ethernet-tcc;
unit logical-unit-number {
  family tcc {
    proxy {
      inet-address ip-address;
    }
    remote {
      inet-address ip-address;
      mac-address mac-address;
    }
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces (fe | ge)-*fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces (fe | ge)-*fpc/pic/port*]

NOTE: For Ethernet circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 1675](#).

Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs

For Ethernet extended VLAN circuits, configure the encapsulation type for the entire physical device by specifying the value **extended-vlan-tcc** for the **encapsulation** statement.

You must also enable VLAN tagging. Ethernet interfaces in VLAN mode can have multiple logical interfaces. With encapsulation type **extended-vlan-tcc**, all VLAN IDs from 0 through 4094 are valid, up to a maximum of 1024 VLANs. As with Ethernet circuits, you must also specify a proxy address and a remote address at the **[edit interfaces *interface-name* unit *logical-unit-number* family tcc]** or **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family tcc]** hierarchy level (see [“Configuring Ethernet Encapsulation for Layer 2 Switching TCCs” on page 1673](#)).

```
encapsulation extended-vlan-tcc;
vlan-tagging;
unit logical-unit-number {
    vlan-id identifier;
    family tcc;
    proxy {
        inet-address ip-address;
    }
    remote {
        inet-address ip-address;
        mac-address mac-address;
    }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces *interface-name*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name*]**

NOTE: For Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 1675](#).

Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations

For Ethernet and Ethernet extended VLAN circuits with TCC encapsulation, you must also configure ARP. Because TCC simply removes one Layer 2 header and adds another, the default form of dynamic ARP is not supported; you must configure static ARP.

Because remote and proxy addresses are specified on the router performing TCC switching, you must apply the static ARP statement to the Ethernet-type interfaces of the routers that connect to the TCC-switched router. The **arp** statement must specify the IP address and the MAC address of the remotely connected neighbor by use of the unlike Layer 2 protocol on the far side of the TCC switching router.

```
arp ip-address mac mac-address;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]

Configuring the Connection for Layer 2 Switching TCCs

You must configure the connection between the two circuits of the Layer 2 switching TCC on the router acting as the switch. The connection joins the interface coming from the circuit's source to the interface leading to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted from the second interface, and those received on the second interface are transmitted from the first.

To configure a connection for a local interface switch, include the following statements:

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
lsp-switch connection-name {
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

To configure a connection for a remote interface switch, include the following statements:

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Configuring MPLS for Layer 2 Switching TCCs

For a Layer 2 switching TCC to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
    interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

NOTE: MPLS LSP link protection does not support TCC.

RELATED DOCUMENTATION

[TCC Overview | 1654](#)
[Configuring TCC Encapsulation for Layer 2 VPNs and Layer 2 Circuits](#)

CCC and TCC Graceful Restart

CCC and TCC graceful restart allows Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the PE routers and P routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

[Figure 135 on page 1677](#) illustrates how graceful restart might work on a CCC connection between two CE routers.

Figure 135: Remote Interface Switch Connecting Two CE Routers Using CCC

PE Router A is the ingress for the transmit LSP from PE Router A to PE Router B and the egress for the receive LSP from PE Router B to PE Router A. With RSVP graceful restart enabled on all the PE and P routers, the following occurs when PE router A restarts:

- PE Router A preserves the forwarding state associated with the CCC routes (those from CCC to MPLS and from MPLS to CCC).
- Traffic flows without disruption from CE router to CE router.
- After the restart, PE Router A preserves the label for the LSP for which PE Router A is the egress (the receive LSP, for example). The transmit LSP from PE Router A to PE Router B can derive new label mappings, but should not cause any traffic disruption.

Configuring CCC and TCC Graceful Restart

To enable CCC and TCC graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

The **graceful-restart** statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

CCC and TCC graceful restart depend on RSVP graceful restart. If you disable RSVP graceful restart, CCC and TCC graceful restart will not work. For more information about RSVP graceful restart, see [“RSVP Graceful Restart” on page 881](#) and [“Configuring RSVP Graceful Restart” on page 883](#).

Configuring an MPLS-Based VLAN CCC Using the Connection Method (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based connection using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 99](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the `vlan-ccc` encapsulation, you cannot configure the associated logical interfaces with the `inet` family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based connections:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
```

```

user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address

```

4. Enable the MPLS protocol with **cspf** disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```

[edit protocols]
user@switch# set mpls no-cspf

```

5. Enable VLAN tagging on the customer edge interface of the local PE switch:

```

[edit]
user@switch# set interfaces interface-name vlan-tagging

```

6. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```

[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc

```

7. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit **0**.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```

[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-id

```

8. Define the label switched path (LSP):

```

[edit protocols]
user@switch# set mpls label-switched-path lsp-name from address
user@switch# set mpls label-switched-path lsp-name to address

```

TIP: You will need to use the specified LSP name again when configuring the CCC.

9. Configure the connection between the two circuits in the CCC connection

```
[edit protocols]
user@switch# set connections remote-interface-switch interface-switch interface local-interface
user@switch# set connections remote-interface-switch interface-switch transmit-lsp destination-lsp
user@switch# set connections remote-interface-switch interface-switch receive-lsp source-lsp
```

Configuring CCC Switching for Point-to-Multipoint LSPs

IN THIS SECTION

- [Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers | 1682](#)
- [Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers | 1682](#)
- [Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers | 1683](#)

You can configure circuit cross-connect (CCC) between two circuits to switch traffic from interfaces to point-to-multipoint LSPs. This feature is useful for handling multicast or broadcast traffic (for example, a digital video stream).

To configure CCC switching for point-to-multipoint LSPs, you do the following:

- On the ingress provider edge (PE) router, you configure CCC to switch traffic from an incoming interface to a point-to-multipoint LSP.
- On the egress PE, you configure CCC to switch traffic from an incoming point-to-multipoint LSP to an outgoing interface.

The CCC connection for point-to-multipoint LSPs is unidirectional.

For more information about point-to-multipoint LSPs, see [“Point-to-Multipoint LSPs Overview” on page 691](#).

To configure a CCC connection for a point-to-multipoint LSP, complete the steps in the following sections:

Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers

To configure the ingress PE router with a CCC switch for a point-to-multipoint LSP, include the **p2mp-transmit-switch** statement:

```
p2mp-transmit-switch switch-name {
    input-interface input-interface-name.unit-number;
    transmit-p2mp-lsp transmitting-lsp;
}
```

You can include the **p2mp-transmit-switch** statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

switch-name specifies the name of the ingress CCC switch.

input-interface *input-interface-name.unit-number* specifies the name of the ingress interface.

transmit-p2mp-lsp *transmitting-lsp* specifies the name of the transmitting point-to-multipoint LSP.

Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers

In addition to configuring an incoming CCC interface to a point-to-multipoint LSP on an ingress PE router, you can also configure CCC to switch traffic on an incoming CCC interface to one or more outgoing CCC interfaces by configuring output interfaces as local receivers.

To configure output interfaces, include the **output-interface** statement at the [edit protocols connections **p2mp-transmit-switch** *p2mp-transmit-switch-name*] hierarchy level.

```
[edit protocols connections]
p2mp-transmit-switch pc-ccc {
    input-interface fe-1/3/1.0;
    transmit-p2mp-lsp myp2mp;
    output-interface [fe-1/3/2.0 fe-1/3/3.0];
}
```

You can configure one or more output interfaces as local receivers on the ingress PE router using this statement.

Use the **show connections p2mp-transmit-switch** (*extensive* | *history* | *status*), **show route ccc** *<interface-name>* (*detail* | *extensive*), and **show route forwarding-table ccc** *<interface-name>* (*detail* | *extensive*) commands to view details of the local receiving interfaces on the ingress PE router.

Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers

To configure the CCC switch for a point-to-multipoint LSP on the egress PE router, include the **p2mp-receive-switch** statement.

```
p2mp-receive-switch switch-name {
    output-interface [ output-interface-name.unit-number ];
    receive-p2mp-lsp receptive-lsp;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

switch-name specifies the name of the egress CCC switch.

output-interface [*output-interface-name.unit-number*] specifies the name of one or more egress interfaces.

receive-p2mp-lsp *receptive-lsp* specifies the name of the receptive point-to-multipoint LSP.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 virtual private network (VPN) using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on EX8200 and EX4500 Provider Switches \(CLI Procedure\)” on page 99](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the `vlan-ccc` encapsulation, you cannot configure the associated logical interfaces with the `inet` family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 VPN:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
```

```

user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address

```

4. Enable the MPLS protocol with **cspf** disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```

[edit protocols]
user@switch# set mpls no-cspf

```

5. Define the label switched path (LSP):

```

[edit protocols]
user@switch# set mpls label-switched-path lsp_name to address

```

TIP: You will need to use the specified LSP name again when configuring the CCC.

6. Configure MPLS on the core interfaces:

```

[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name

```

7. Configure RSVP on the loopback interface and the core interfaces:

```

[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name

```

8. Configure **family mpls** on the logical units of the core interfaces:

```

[edit]

```

```

user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls

```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```

[edit]
user@switch# set interfaces interface-name vlan-tagging

```

10. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```

[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc

```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit **0**. The logical unit number must be **1** or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```

[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-id vlan-id

```

12. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```

[edit protocols bgp]
user@switchPE1# set local-address address family l2vpn signaling

```

13. Configure the BGP group, specifying the group name and type:

```

[edit protocols bgp]
user@switchPE1# set group ibgp type internal

```

14. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
user@switchPE1# set neighbor address
```

15. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name instance-type l2vpn
```

16. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name interface interface-name
```

17. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name route-distinguisher address
```

18. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name vrf-target community
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

19. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn encapsulation-type ethernet-vlan
```

20. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols interface interface-name description description
```

21. Configure the routing-instance protocols site:

```
[edit routing-instances]
```

```
user@switchPE1# set routing-instance-name protocols l2vpn site site-name site-identifier identifier  
remote-site-id identifier
```

NOTE: The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured on the other PE switch.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: You must use the same type of switch for the other PE switch. You cannot use an EX8200 as one PE switch and use an EX3200 or EX4200 as the other PE switch.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 circuit on the switch to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on Provider Switches” on page 88](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the `vlan-ccc` encapsulation, you cannot configure the associated logical interfaces with the `inet` family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 circuit:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
```

```

user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address

```

4. Enable the MPLS protocol with CSPF disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```

[edit protocols]
user@switch# set mpls no-cspf

```

5. Configure the customer edge interface as a Layer 2 circuit from the local PE switch to the other PE switch:

```

[edit protocols]
user@switch# set l2circuit neighbor address interface interface-name virtual-circuit-id identifier

```

TIP: Use the switch address of the other switch as the neighbor address.

6. Configure MPLS on the core interfaces:

```

[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name

```

7. Configure LDP on the loopback interface and the core interfaces:

```

[edit protocols]
user@switch# set ldp interface lo0.0
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name

```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use VLAN CCC encapsulation:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit **0**. The logical unit number must be **1** or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-id vlan-id
```

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: For EX Series switches, you must use the same type of switch for the other PE switch.

Introduction to Path Computation Element Protocol (PCEP)

IN THIS CHAPTER

- [PCEP Overview](#) | 1695

PCEP Overview

A Path Computation Element (PCE) is an entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE. The Path Computation Element Protocol (PCEP) enables communications between a PCC and a PCE, or between two PCEs (defined in RFC 5440).

PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain traffic engineered LSPs (TE LSPs). It provides a mechanism for a PCE to perform path computation for a PCC's external LSPs. The PCEP interactions include LSP status reports sent by the PCC to the PCE, and PCE updates for the external LSPs.

[Figure 136 on page 1696](#) illustrates the role of PCEP in the client-side implementation of a stateful PCE architecture in an MPLS RSVP-TE enabled network.

Figure 136: PCEP Session

A TCP-based PCEP session connects a PCC to an external PCE. The PCC initiates the PCEP session and stays connected to the PCE for the duration of the PCEP session. During the PCEP session, the PCC requests LSP parameters from the stateful PCE. On receiving one or more LSP parameters from the PCE, the PCC re-signals the TE LSP. When the PCEP session is terminated, the underlying TCP connection is closed immediately, and the PCC attempts to re-establish the PCEP session.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between a PCC and a stateful PCE—When an active stateful PCE connection is detected, a PCC tries to delegate all LSPs to this PCE in a procedure called LSP state synchronization. PCEP enables synchronization of the PCC LSP state to the PCE.
- Delegation of control over LSP tunnels to a stateful PCE—An active stateful PCE controls one or more LSP attributes for computing paths, such as bandwidth, path (ERO), and priority (setup and hold). PCEP enables such delegation of LSPs for path computation.
- Stateful PCE control of timing and sequence of path computations within and across PCEP sessions—An active stateful PCE modifies one or more LSP attributes, such as bandwidth, path (ERO), and priority (setup and hold). PCEP communicates these new LSP attributes from the PCE to the PCC, after which the PCC re-signals the LSP in the specified path.

Understanding MPLS RSVP-TE

Traffic engineering (TE) deals with performance optimization of operational networks, mainly mapping traffic flows onto an existing physical topology. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

For traffic engineering in large, dense networks, MPLS capabilities can be implemented because they potentially provide most of the functionality available from an overlay model, in an integrated manner, and at a lower cost than the currently competing alternatives. The primary reason for implementing MPLS traffic engineering is to control paths along which traffic flows through a network. The main advantage of implementing MPLS traffic engineering is that it provides a combination of the traffic engineering capabilities of ATM, along with the class-of-service (CoS) differentiation of IP.

In an MPLS network, data plane information is forwarded using label switching. A packet arriving on a provider edge (PE) router from the customer edge (CE) router has labels applied to it, and it is then forwarded to the egress PE router. The labels are removed at the egress router and it is then forwarded out to the appropriate destination as an IP packet. The label-switching routers (LSRs) in the MPLS domain use label distribution protocols to communicate the meaning of labels used to forward traffic between and through the LSRs. RSVP-TE is one such label distribution protocol that enables an LSR peer to learn about the label mappings of other peers.

When both MPLS and RSVP are enabled on a router, MPLS becomes a client of RSVP. The primary purpose of the Junos OS RSVP software is to support dynamic signaling within label-switched paths (LSPs). RSVP reserves resources, such as for IP unicast and multicast flows, and requests quality-of-service (QoS) parameters for applications. The protocol is extended in MPLS traffic engineering to enable RSVP to set up LSPs that can be used for traffic engineering in MPLS networks.

When MPLS and RSVP are combined, labels are associated with RSVP flows. Once an LSP is established, the traffic through the path is defined by the label applied at the ingress node of the LSP. The mapping of label to traffic is accomplished using different criteria. The set of packets that are assigned the same label value by a specific node belong to the same forwarding equivalence class (FEC), and effectively define the RSVP flow. When traffic is mapped onto an LSP in this way, the LSP is called an LSP tunnel.

LSP tunnels are a way to establish unidirectional label-switched paths. RSVP-TE builds on the RSVP core protocol by defining new objects and modifying existing objects used in the PATH and RESV objects for LSP establishment. The new objects—LABEL-REQUEST object (LRO), RECORD-ROUTE object (RRO), LABEL object, and EXPLICIT-ROUTE object (ERO)—are optional with respect to the RSVP protocol, except for the LRO and LABEL objects, which are both mandatory for establishing LSP tunnels.

In general, RSVP-TE establishes a label-switched path that ensures frame delivery from ingress to egress router. However, with the new traffic engineering capabilities, the following functions are supported in an MPLS domain:

- Possibility to establish a label-switched path using either a full or partial explicit route (RFC 3209).
- Constraint-based LSP establishment over links that fulfill requirements, such as bandwidth and link properties.
- Endpoint control, which is associated with establishing and managing LSP tunnels at the ingress and egress routers.
- Link management, which manages link resources to do resource-aware routing of traffic engineering LSPs and to program MPLS labels.
- MPLS fast reroute (FRR), which manages the LSPs that need protection and assigns backup tunnel information to these LSPs.

Current MPLS RSVP-TE Limitations

Although the RSVP extensions for traffic engineering enable better network utilization and meet requirements of classes of traffic, today's MPLS RSVP-TE protocol suite has several issues inherent to its distributed nature. This causes a number of issues during contention for bisection capacity, especially within an LSP priority class where a subset of LSPs share common setup and hold priority values. The limitations of RSVP-TE include:

- Lack of visibility of individual per-LSP, per-device bandwidth demands—The ingress routers in an MPLS RSVP-TE network establish LSPs without having a global view of the bandwidth demand on the network. Information about network resource utilization is only available as total reserved capacity by traffic class on a per interface basis. Individual LSP state is available locally on each label edge router (LER) for its own LSPs only. As a result, a number of issues related to demand pattern arise, particularly within a common setup and hold priority.
- Asynchronous and independent nature of RSVP signaling—In RSVP-TE, the constraints for path establishment are controlled by an administrator. As such, bandwidth reserved for an LSP tunnel is set by the administrator and does not automatically imply any limit on the traffic sent over the tunnel. Therefore, bandwidth available on a traffic engineering link is the bandwidth configured for the link, excluding the sum of all reservations made on the link. Thus, the unsignaled demands on an LSP tunnel lead to service degradation of the LSP requiring excess bandwidth, as well as the other LSPs that comply with the bandwidth requirements of the traffic engineering link.

- LSPs established based on dynamic or explicit path options in the order of preference—The ingress routers in an MPLS RSVP-TE network establish LSPs for demands based on the order of arrival. Because the ingress routers do not have a global view of the bandwidth demand on the network, using the order of preference to establish LSPs can cause traffic to be dropped or LSPs not being established at all when there is an excess of bandwidth demand.

As an example, [Figure 137 on page 1700](#) is configured with MPLS RSVP-TE, in which A and G are the label edge routers (LERs). These ingress routers establish LSPs independently based on the order of demands and have no knowledge or control over each other's LSPs. Routers B, C, and D are intermediate or transit routers that connect to the egress routers E and F.

Figure 137: Example MPLS Traffic Engineering

The ingress routers establish LSPs based on the order in which the demands arrive. If Router G receives two demands of capacity 5 each for G-F, then G signals two LSPs – LSP1 and LSP2 – through G-B-D-F. In the same way, when Router A receives the third demand of capacity 10 for A-E, then it signals an LSP, LSP3, through A-B-C-E. However, if the demand on the A-E LSP increases from 10 to 15, Router A cannot signal LSP3 using the same (A-B-C-E) path, because the B-C link has a lower capacity.

Router A should have signaled the increased demand on LSP3 using the A-B-D-C-E path. Since LSP1 and LSP2 have utilized the B-D link based on the order of demands received, LSP3 is not signaled.

Thus, although adequate max-flow bandwidth is available for all the LSPs, LSP3 is subject to potentially prolonged service degradation. This is due to Router A's lack of global demand visibility and the lack of systemic coordination in demand placement by the ingress routers A and G.

Use of an External Path Computing Entity

As a solution to the current limitations found in the MPLS RSVP-TE path computation, an external path computing entity with a global view of per-LSP, per-device demand in the network independent of available capacity is required.

Currently, only online and real-time constraint-based routing path computation is provided in an MPLS RSVP-TE network. Each router performs constraint-based routing calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status. The MPLS RSVP-TE tunnels are set up using the CLI. An operator configures the TE LSP, which is then signaled by the ingress router.

In addition to the existing traffic engineering capabilities, the MPLS RSVP-TE functionality is extended to include an external path computing entity, called the Path Computation Element (PCE). The PCE computes the path for the TE LSPs of ingress routers that have been configured for external control. The ingress router that connects to a PCE is called a Path Computation Client (PCC). The PCC is configured with the Path Computation Client Protocol (PCEP) to facilitate external path computing by a PCE.

For more information, see [“Components of External Path Computing” on page 1701](#).

To enable external path computing for a PCC's TE LSPs, include the **lsp-external-controller pccd** statement at the **[edit mpls]** and **[edit mpls lsp lsp-name]** hierarchy levels.

Components of External Path Computing

IN THIS SECTION

- [Path Computation Element | 1701](#)
- [Path Computation Client | 1703](#)
- [Path Computation Element Protocol | 1703](#)

The components that make up an external path computing system are:

Path Computation Element

A Path Computation Element (PCE) can be any entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. However, a PCE can compute the path for only those TE LSPs of a PCC that have been configured for external control.

A PCE can either be stateful or stateless.

- **Stateful PCE**—A stateful PCE maintains strict synchronization between the PCE and network states (in terms of topology and resource information), along with the set of computed paths and reserved resources in use in the network. In other words, a stateful PCE utilizes information from the traffic engineering database as well as information about existing paths (for example, TE LSPs) in the network when processing new requests from the PCC.

A stateful PCE is of two types:

- **Passive stateful PCE**—Maintains synchronization with the PCC and learns the PCC LSP states to better optimize path calculations, but does not have control over them.
- **Active stateful PCE**—Actively modifies the PCC LSPs, in addition to learning about the PCC LSP states.

NOTE: In a redundant configuration with main and backup active stateful PCEs, the backup active stateful PCE cannot modify the attributes of delegated LSPs until it becomes the main PCE at the time of a failover. There is no preempting of PCEs in the case of a switchover. The main PCE is backed by a backup PCE, and when the main PCE goes down, the backup PCE assumes the role of the main PCE and remains the main PCE even after the PCE that was previously the main PCE is operational again.

A stateful PCE provides the following functions:

- Offers offline LSP path computation.
- Triggers LSP re-route when there is a need to re-optimize the network.
- Changes LSP bandwidth when there is an increase in bandwidth demand from an application.
- Modifies other LSP attributes on the router, such as ERO, setup priority, and hold priority.

A PCE has a global view of the bandwidth demand in the network and maintains a traffic-engineered database to perform path computations. It performs statistics collection from all the routers in the MPLS domain using SNMP and NETCONF. This provides a mechanism for offline control of the PCC's TE LSPs. Although an offline LSP path computation system can be embedded in a network controller, the PCE acts like a full-fledged network controller that provides control over the PCC's TE LSPs, in addition to computing paths.

Although a stateful PCE allows for optimal path computation and increased path computation success, it requires reliable state synchronization mechanisms, with potentially significant control plane overhead and the maintenance of a large amount of data in terms of states, as in the case of a full mesh of TE LSPs.

- **Stateless PCE**—A stateless PCE does not remember any computed path, and each set of requests is processed independently of each other (RFC 5440).

Path Computation Client

A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE.

A PCC can connect to a maximum of 10 PCEs at one time. The PCC to PCE connection can be a configured static route or a TCP connection that establishes reachability. The PCC assigns each connected PCE a priority number. It sends a message to all the connected PCEs with information about its current LSPs, in a process called LSP state synchronization. For the TE LSPs that have external control enabled, the PCC delegates those LSPs to the main PCE. The PCC elects, as the main PCE, a PCE with the lowest priority number, or the PCE that it connects to first in the absence of a priority number.

The PCC re-signals an LSP based on the computed path it receives from a PCE. When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

Path Computation Element Protocol

The Path Computation Element Protocol (PCEP) is used for communication between PCC and PCE (as well as between two PCEs) (RFC 5440). PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain TE LSPs. The PCEP interactions include PCC messages, as well as notifications of specific states related to the use of a PCE in the context of MPLS RSVP-TE. When PCEP is used for PCE-to-PCE communication, the requesting PCE assumes the role of a PCC.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between PCC and a stateful PCE.
- Delegation of control over LSP tunnels to a stateful PCE.

Interaction Between a PCE and a PCC Using PCEP

[Figure 138 on page 1704](#) illustrates the relationship between a PCE, PCC, and the role of PCEP in the context of MPLS RSVP-TE.

Figure 138: PCC and RSVP-TE

The PCE to PCC communication is enabled by the TCP-based PCEP. The PCC initiates the PCEP session and stays connected to a PCE for the duration of the PCEP session.

NOTE: Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440. To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce pce-id]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains key-chain]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce pce-id]** hierarchy level.

The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session, thereby securing the PCEP communication between the devices, which might be subject to attacks and can disrupt services on the network.

For more information on securing PCEP sessions using MD5 authentication, see [“TCP-MD5 Authentication for PCEP Sessions” on page 1714](#).

Once the PCEP session is established, the PCC performs the following tasks:

1. LSP state synchronization—The PCC sends information about all the LSPs (local and external) to all connected PCEs. For external LSPs, the PCC sends information about any configuration change, RRO change, state change, and so on, to the PCE.

For PCE-initiated LSPs, there is no LSP configuration present on the PCC. The PCE initiating the LSP sends the LSP parameters to the PCC that has indicated its capability of supporting PCE-initiated LSPs.

NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

2. LSP delegation—After the LSP state information is synchronized, the PCC then delegates the external LSPs to one PCE, which is the main active stateful PCE. Only the main PCE can set parameters for the external LSP. The parameters that the main PCE modifies include bandwidth, path (ERO), and priority (setup and hold). The parameters specified in the local configuration are overridden by the parameters that are set by the main PCE.

NOTE: When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

In the case of PCE-initiated LSPs, the PCC creates the LSP using the parameters received from the PCE. The PCC assigns the PCE-initiated LSP a unique LSP-ID, and automatically delegates the LSP to the PCE. A PCC cannot revoke the delegation for the PCE-initiated LSPs for an active PCEP session.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs – **delegation cleanup timeout** and **lsp cleanup timer** – to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE, by sending a create request for the LSP.

Control over PCE-initiated LSPs reverts to the PCC at the expiration of the **delegation cleanup timeout**. When the **delegation cleanup timeout** expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated LSPs, the PCC delegates these LSPs to the PCE and the **lsp cleanup timer** timer is stopped.

A PCE may return the delegation of the PCE-initiated LSP to the PCC to allow LSP transfer between PCEs. This triggers the **lsp cleanup timer** for the PCE-initiated LSP. The PCC waits for the LSP cleanup timer to expire before removing the non-delegated PCE-initiated LSPs from the failed PCE.

When the **lsp cleanup timer** expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

3. LSP signaling—On receiving one or more LSP parameters from the main active stateful PCE, the PCC re-signals the TE LSP based on the PCE provided path. If the PCC fails to set up the LSP, it notifies the PCE of the setup failure and waits for the main PCE to provide new parameters for that LSP, and then re-signals it.

When the PCE specifies a path that is incomplete or has loose hops where only the path endpoints are specified, the PCC does not perform local constraint-based routing to find out the complete set of hops. Instead, the PCC provides RSVP with the PCE provided path, as it is, for signaling, and the path gets set up using IGP hop-by-hop routing.

Considering the topology used in [Figure 137 on page 1700](#), [Figure 139 on page 1707](#) illustrates the partial client-side PCE implementation in the MPLS RSVP-TE enabled network. The ingress routers A and G are the PCCs that are configured to connect to the external stateful PCE through a TCP connection.

The PCE has a global view of the bandwidth demand in the network and performs external path computations after looking up the traffic engineering database. The active stateful PCE then modifies one or more LSP attributes and sends an update to the PCC. The PCC uses the parameters it receives from the PCE to re-signal the LSP.

Figure 139: Example PCE for MPLS RSVP-TE

This way, the stateful PCE provides a cooperative operation of distributed functionality used to address specific challenges of a shortest interdomain constrained path computation. It eliminates congestion scenarios in which traffic streams are inefficiently mapped onto available resources, causing overutilization of some subsets of network resources, while other resources remain underutilized.

LSP Behavior with External Computing

IN THIS SECTION

- LSP Types | 1707
- LSP Control Mode | 1708

LSP Types

In a client-side PCE implementation, there are three types of TE LSPs:

- CLI-controlled LSPs—The LSPs that do not have the **lsp-external-controller pccd** statement configured are called CLI-controlled LSPs. Although these LSPs are under local control, the PCC updates the connected PCEs with information about the CLI-controlled LSPs during the initial LSP synchronization process. After the initial LSP synchronization, the PCC informs the PCE of any new and deleted LSPs as well.

- PCE-controlled LSPs—The LSPs that have the **lsp-external-controller pccd** statement configured are called PCE-controlled LSPs. The PCC delegates the PCC-initiated LSPs to the main PCE for external path computation.

The PCC informs the PCE about the configured parameters of a PCE-controlled LSP, such as bandwidth, ERO, and priorities. It also informs the PCE about the actual values used for these parameters to set up the LSP including the RRO, when available.

The PCC sends such LSP status reports to the PCE only when a reconfiguration has occurred or when there is a change in the ERO, RRO, or status of the PCE-controlled LSPs under external control.

There are two types of parameters that come from the CLI configuration of an LSP for a PCE:

- Parameters that are not overridden by a PCE, and that are applied immediately.
- Parameters that are overridden by a PCE. These parameters include bandwidth, path, and priority (setup and hold values). When the control mode switches from external to local, the CLI-configured values for these parameters are applied at the next opportunity to re-signal the LSP. The values are not applied immediately.
- Externally-provisioned LSPs (or PCE-initiated LSPs)—The LSPs that have the **lsp-provisioning** statement configured are called PCE-initiated LSPs. A PCE-initiated LSP is dynamically created by an external PCE; as a result, there is no LSP configuration present on the PCC. The PCC creates the PCE-initiated LSP using the parameters provided by the PCE, and automatically delegates the LSP to the PCE.

NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

The CLI-controlled LSPs, PCE-controlled LSPs, and PCE-initiated LSPs can coexist on a PCC.

The CLI-controlled LSPs and PCE-controlled LSPs can coexist on a PCC.

LSP Control Mode

In a client-side PCE implementation, there are two types of control modes for a PCC-controlled LSP:

- External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP.
- Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control.

A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

For more information about CLI-controlled LSPs and PCE-controlled LSPs, see [“LSP Types” on page 1707](#).

Configuration Statements Supported for External Computing

Table 48 on page 1709 lists the MPLS and existing LSP configuration statements that apply to a PCE-controlled LSP.

Table 48: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements can be configured along with the PCE configuration. However, they take effect only when the local configuration is in use. During PCE control, these configuration statements remain inactive.	<ul style="list-style-type: none"> • admin-group • auto-bandwidth • hop-limit • least-fill • most-fill • random 	<ul style="list-style-type: none"> • admin-group • admin-groups • admin-group-extended • hop-limit • no-cspf • smart-optimize-timer
<p>These configuration statements can be configured along with the PCE configuration, but are overridden by the PCE-controlled LSP attributes. However, when the local configuration is in use, the configured values for these configuration statements are applied.</p> <p>NOTE: Changes to the local configuration using the CLI while the LSP is under the control of a stateful PCE do not have any effect on the LSP. These changes come into effect only when the local configuration is applied.</p>	<ul style="list-style-type: none"> • bandwidth • primary • priority 	<ul style="list-style-type: none"> • priority
These configuration statements cannot be configured along with the PCE configuration.	<ul style="list-style-type: none"> • p2mp • template 	<ul style="list-style-type: none"> • p2mp-lsp-next-hop

The rest of the LSP configuration statements are applicable in the same way as for existing LSPs. On configuring any of the above configuration statements for a PCE-controlled LSP, an MPLS log message is generated to indicate when the configured parameters take effect.

PCE-Controlled LSP Protection

The protection paths, including fast reroute and bypass LSPs, are locally computed by the PCC using constraint-based routing. A stateful PCE specifies the primary path (ERO) only. A PCE can also trigger a non-standby secondary path, even if the local configuration does not have a non-standby secondary path for LSP protection.

PCE-Controlled LSP ERO

For PCE-controlled LSPs (PCC-delegated LSPs and PCE-initiated LSPs), only a full-blown Explicit Route Object (ERO) object has to be sent from the PCE to the PCC; otherwise the PCC rejects the PCUpdate or PCCreate message for that PCEP session.

Starting in Junos OS Release 17.2, in addition to **external cspf**, two new path computation types are introduced for the PCE-controlled LSPs: **local cspf** and **no cspf**.

- **local cspf**—A PCC uses the **local cspf** computation type only when the PCE sends in a Juniper Vendor TLV (enterprise number: 0x0a4c) of type 5.
- **no cspf**—Neither the PCE nor the PCC performs a constrained path calculation. The endpoints and constraints are given to the RSVP module for setting up the LSP with the IGP path.

A PCC uses **no cspf** computation type in the following cases:

- When the PCE sends **local cspf** TLV, and when the Junos OS configuration or matching template for this LSP included **no-cspf** in the PCC-delegated LSP.
- When the PCE sends **local cspf** TLV, and when the Junos OS configuration template for this LSP included **no-cspf** in the PCE-initiated LSP.
- When the PCE does not send **local cspf** TLV with an empty ERO or loose ERO (with loose bit set in the ERO object).

With these new computation types, a PCC can accept an ERO object either as a loose ERO, or as an empty ERO. An external path computing entity that is not capable of computing a path can modify parameters such as bandwidth and color, based on the analytics. In such cases, an empty ERO object or loose ERO is used and the path to be taken is decided by the PCC.

PCE-Controlled Point-to-Multipoint RSVP-TE LSPs

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well. For a PCE, the point-to-multipoint LSP is similar to that of RSVP point-to-multipoint LSP, where the point-to-multipoint LSP is treated as collection of point-to-point LSPs grouped under a point-to-multipoint identifier.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce pce-name]** or **[edit protocols pcep pce-group group-id]** hierarchy levels. After the point-to-multipoint report capability is configured on a PCC, the PCC advertises this capability to the PCE. If the PCE advertises the same point-to-multipoint report capability in return, then the PCC reports the complete point-to-multipoint LSP tree to the PCE for LSP state synchronization.

A PCC with the point-to-multipoint TE LSP capability supports reporting of point-to-multipoint TE LSPs for stateful PCEs, point-to-multipoint update, and LSP database supporting point-to-multipoint LSP name as key. However, the following features and functions are not supported for Junos OS Release 15.1F6 and 16.1:

- Static point-to-multipoint LSPs
- PCE-delegated and PCE-initiated point-to-multipoint LSPs
- Auto-bandwidth
- TE++
- PCE request and reply message
- Creation of point-to-multipoint LSPs using templates
- Configuring forward entry on the PCE-initiated point-to-multipoint LSPs
- Configuring forward entry on the router pointing to a provisioned LSP.

PCE-Initiated Point-to-Point LSPs

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

By default, a PCC rejects the request for provisioning PCE-initiated point-to-point LSPs from a PCE. To enable support of PCE-initiated LSPs on the PCC, include the *lsp-provisioning* statement at the **[edit protocols pcep pce pce-id]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

A PCC indicates its capability of supporting PCE-initiated point-to-point LSPs while establishing the Path Computation Element Protocol (PCEP) session with the PCE. A PCE selects a PCC with this capability to initiate an LSP. The PCE provides the PCC with the PCE-initiated LSP parameters. On receiving the PCE-initiated point-to-point LSP parameters, the PCC sets up the LSP, assigns an LSP ID, and automatically delegates the LSP to the PCE.

When the PCE initiating the LSP does not provide the PCE-initiated point-to-point LSP parameters, the PCC uses the default parameters. An optional LSP template may also be configured to specify values for the PCE-initiated point-to-point LSP when the LSP parameters are not provided by the PCE. To configure an LSP template for PCE-initiated point-to-point LSPs on the PCC, include the [label-switched-path-template](#) statement at the **[edit protocols mpls lsp-external-controller lsp-external-controller]** hierarchy level.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs—**delegation cleanup timeout** and **lsp cleanup timer**—to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE.

A PCE may return the delegation of the PCE-initiated point-to-point LSP to the PCC to allow LSP transfer between PCEs. Control over PCE-initiated LSPs reverts to the PCC at the expiration of the delegation cleanup timeout. When the delegation cleanup timeout expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated point-to-point LSPs, the PCC delegates these LSPs to the PCE and the LSP cleanup timer is stopped.

The PCC waits for the LSP cleanup timer to expire before deleting the non-delegated PCE-initiated point-to-point LSPs from the failed PCE. When the LSP cleanup timer expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

PCE-Initiated Bypass LSP

IN THIS SECTION

- [Understanding PCE-Initiated Bypass LSPs | 1712](#)
- [Benefits of PCE-Initiated Bypass LSP | 1713](#)
- [Behavior of PCE-Initiated Bypass LSPs During PCEP Session Failure | 1713](#)

Understanding PCE-Initiated Bypass LSPs

There can be traffic outages at the time of a link or node failure because the backup protection paths in the network do not have sufficient bandwidth to handle traffic. In such networks, although a PCE may be used to compute all the paths, to optimize network performance, the local protection paths also need to be controlled through the PCE.

Junos OS Release 19.2R1 and later releases provide partial support for the Internet draft draft-cbrt-pce-stateful-local-protection-01 (expires December 2018), *PCEP Extensions for RSVP-TE Local-Protection with PCE-Stateful*, where the PCEP functionality is extended to allow a stateful PCE to initiate, provision, and manage bypass LSPs for a protected interface. Multiple bypass LSPs with bandwidth reservation can be initiated by the PCE to protect a link or node. The bandwidth on the bypass LSP is expected to be smaller than the total bandwidth of the primary LSPs that it might protect.

The existing bypass selection mechanism, that prefers manual bypass LSPs (if available) over dynamic bypass LSPs, is extended to prefer PCE-provisioned bypass LSPs (if available) over dynamic bypass LSPs.

The PCE-provisioned bypass LSPs have a higher preference over dynamic bypass LSPs, but are less preferred over manual bypass LSPs.

The set of operations that are used to perform on any operational bypass LSPs, such as **clear rsvp session**, can also be performed on the PCE-initiated bypass LSPs. You can use commands, such as **show path-computation-client status extensive** and **show path-computation-client lsp** to view PCE-initiated bypass LSP statistics.

With the support of PCE-initiated bypass LSP, you can:

- Create a RSVP bypass LSP through PCEP from an external controller, where the bypass LSP:
 - can be for link or node protection.
 - must have a non-zero bandwidth.
 - must have a specified strict ERO.
- Update the bandwidth and ERO for an existing PCE-created bypass LSP.
- Oversubscribe the bypass LSP bandwidth for admission control of primary LSPs. This must be a per-bypass parameter, and should allow updating the subscription per bypass LSP.

Benefits of PCE-Initiated Bypass LSP

The PCE-initiated bypass LSPs provide the following benefits:

- Better control over traffic after a failure and more deterministic path computation of protection paths.
- Meet complex constraints and diversity requirements, such as maintaining diverse paths for LSPs, as well as their local protection paths.
- Ensure links are not overloaded during failure events.

Behavior of PCE-Initiated Bypass LSPs During PCEP Session Failure

At the time of a PCEP session failure, the PCE-initiated bypass LSPs become orphan until the expiration of the state timeout timer. The PCE-initiated bypass LSPs get cleaned up on the expiration of the state timeout timer. To obtain control of a PCE-initiated bypass LSP (after PCEP session fails), a PCE (either the primary PCE, or any secondary PCE) sends a PCInitiate message before the expiration of the state timeout timer.

PCE-Initiated Point-to-Multipoint LSPs

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

For more information, see [“Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs” on page 1771.](#)

Auto-Bandwidth and PCE-Controlled LSP

Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs. In earlier releases, the auto-bandwidth option did not apply to PCE-controlled LSPs, although LSPs under the control of auto-bandwidth and constraint-based routing could coexist with PCE-controlled LSPs. The statistics collection for auto-bandwidth was taking effect only when the control mode of a PCE-controlled LSP changes from external to local. This was happening in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

TCP-MD5 Authentication for PCEP Sessions

A stateful PCE server automates the creation of traffic engineering paths across the network, increasing network utilization and enabling a customized programmable networking experience with the use of PCEP communication with a PCC. A PCC sends LSP reports to a PCE server, and the PCE updates or provisions LSPs back to the PCC. The data sent over a PCEP session is crucial for a PCE server to perform external path computing. As a result, an attack on the PCEP communication can disrupt network services. If altered PCEP messages are sent to a PCC, inappropriate LSPs can be set up. Similarly, if altered PCEP messages are sent to a PCE, an incorrect view of the network is learned by the PCE.

Considering the significance of the PCEP communication between a PCE and PCC in executing the PCE functionalities effectively, Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440. This feature protects the communication between a PCE and PCC over a PCEP session, which might be subject to an attack, and can disrupt network services.

To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce pce-id]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains key-chain]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce pce-id]** hierarchy level.

The following configuration is executed on the PCC to establish a secure PCEP session with a PCE:

- Using MD5 authentication key:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key key
```

- Using predefined authentication keychain:

```
[edit protocols pcep pce pce-id]
```

```

user@PCC# set authentication-key-chain key-chain
user@PCC# set authentication-algorithm md5

```

For secure PCEP sessions to be established successfully, the MD5 authentication should be configured with the pre-shared authentication key on both the PCE server and the PCC. The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session.

NOTE:

- Junos OS Release 16.1 supports only TCP-MD5 authentication for PCEP sessions, without extending support for TLS and TCP-AO, such as protection against eavesdropping, tampering, and message forgery.
- Initial application of security mechanism to a PCEP session causes the session to reset.
- If MD5 is misconfigured or not configured on one side of the PCEP session, the session does not get established. Verify that the configurations on the PCC and PCE are matching.
- This feature does not provide support for any session authentication mechanism.
- To view the authentication keychain used by the PCEP session, use the **show path-computation-client status** and **show protocols pcep** command outputs.
- Use the **show system statistics tcp | match auth** command to view the number of packets that get dropped by TCP because of authentication errors.
- Operation of the keychain can be verified by using the **show security keychain detail** command output.

Impact of Client-Side PCE Implementation on Network Performance

The maintenance of a stateful database can be non-trivial. In a single centralized PCE environment, a stateful PCE simply needs to remember all the TE LSPs that the PCE has computed, the TE LSPs that were actually set up (if this can be known), and when the TE LSPs were torn down. However, these requirements cause substantial control protocol overhead in terms of state, network usage and processing, and optimizing links globally across the network. Thus, the concerns of a stateful PCE implementation include:

- Any reliable synchronization mechanism results in significant control plane overhead. PCEs might synchronize state by communicating with each other, but when TE LSPs are set up using distributed computation performed among several PCEs, the problems of synchronization and race condition avoidance become larger and more complex.
- Out-of-band traffic engineering database synchronization can be complex with multiple PCEs set up in a distributed PCE computation model, and can be prone to race conditions, scalability concerns, and so on.

- Path calculations incorporating total network state is highly complex, even if the PCE has detailed information on all paths, priorities, and layers.

In spite of the above concerns, the partial client-side implementation of the stateful PCE is extremely effective in large traffic engineering systems. It provides rapid convergence and significant benefits in terms of optimal resource usage, by providing the requirement for global visibility of a TE LSP state and for ordered control of path reservations across devices within the system being controlled.

Release History Table

Release	Description
17.2R1	Starting in Junos OS Release 17.2, in addition to external cspf , two new path computation types are introduced for the PCE-controlled LSPs: local cspf and no cspf .
16.1	Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440.
16.1	Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440.
14.2R4	Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs.

Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE

IN THIS SECTION

- [Requirements | 1717](#)
- [Overview | 1718](#)
- [Configuration | 1720](#)
- [Verification | 1727](#)

This example shows how to enable external path computing by a Path Computation Element (PCE) for traffic engineered label-switched paths (TE LSPs) on a Path Computation Client (PCC). It also shows how to configure the Path Computation Element Protocol (PCEP) on the PCC to enable PCE to PCC communication.

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series routers, M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Transport Router, one of which is configured as a PCC.
- A TCP connection to an external stateful PCE from the PCC.
- Junos OS Release 12.3 or later running on the PCC along with the JSDN add-on package.

NOTE: The JSDN add-on package is required to be installed along with the core Junos OS installation package.

Before you begin:

1. Configure the device interfaces.
2. Configure MPLS and RSVP-TE.
3. Configure IS-IS or any other IGP protocol.

Overview

Starting with Junos OS Release 12.3, the MPLS RSVP-TE functionality is extended to provide a partial client-side implementation of the stateful PCE architecture (draft-ietf-pce-stateful-pce) on a PCC.

NOTE: The partial client-side implementation of the stateful PCE architecture is based on version 2 of Internet draft draft-ietf-pce-stateful-pce. Starting with Junos OS Release 16.1, this implementation is upgraded to support version 7, as defined in Internet draft draft-ietf-pce-stateful-pce-07. Releases prior to 16.1 support the older version of the PCE draft, causing interoperability issues between a PCC running a previous release and a stateful PCE server that adheres to Internet draft draft-ietf-pce-stateful-pce-07.

To enable external path computing by a PCE, include the **lsp-external-controller** statement on the PCC at the **[edit mpls]** and **[edit mpls lsp *lsp-name*]** hierarchy levels.

```
lsp-external-controller pccd;
```

An LSP configured with the **lsp-external-controller** statement is referred to as a PCE-controlled LSP and is under the external control of a PCE by default. An active stateful PCE can override the parameters set from the CLI, such as bandwidth, path (ERO), and priority, for such PCE-controlled LSPs of the PCC.

To enable PCE to PCC communication, configure PCEP on the PCC at the **[edit protocols]** hierarchy level.

```
pcep { ... }
```

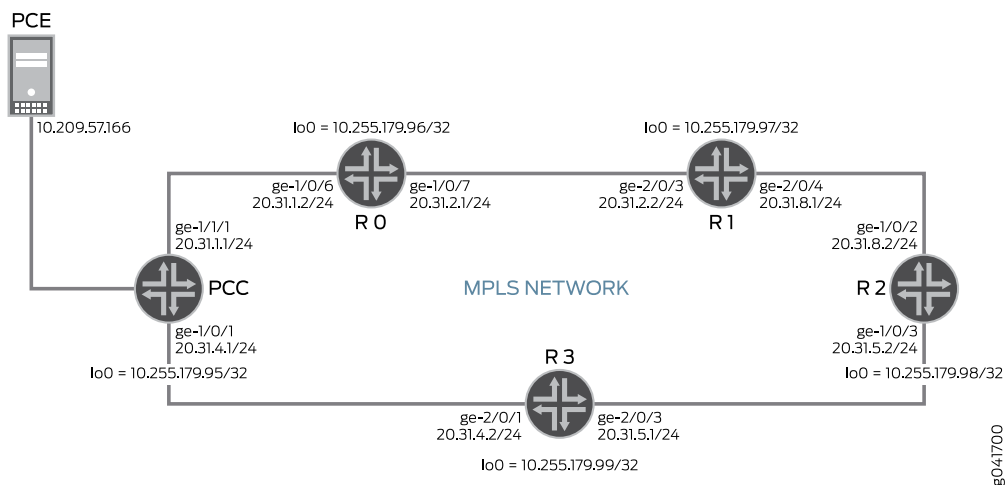

When configuring PCEP on a PCC, be aware of the following considerations:

- The JSDN add-on package is required to be installed along with the core Junos OS installation package.
- Junos OS Release 12.3 supports only stateful PCEs.
- A PCC can connect to a maximum of 10 stateful PCEs. At any given point in time, there can be only one main PCE (the PCE with the lowest priority value, or the PCE that connects to the PCC first in the absence of a PCE priority) to which the PCC delegates LSPs for path computation.
- For Junos OS Release 12.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-controlled LSPs.
- The auto-bandwidth option is turned off for PCE-controlled LSPs, although LSPs under the control of auto-bandwidth and constraint-based routing can coexist with PCE-controlled LSPs.
- PCE-controlled LSPs can be referred to by other CLI configurations, such as `lsp-nexthop` to routes, forwarding adjacencies, CCC connections, and logical tunnels.

- PCE-controlled LSPs do not support GRES.
- PCE-controlled LSPs under logical-systems are not supported.
- PCE-controlled LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- PCE-controlled LSPs cannot have secondary paths without a primary path.
- PCE-controlled LSPs depend on external path computation, which impacts overall setup time, reroutes, and make-before-break features.
- Setup time and convergence time (reroute, MBB) for existing LSPs is the same as in previous releases, in the absence of PCE-controlled LSPs. However, a small impact is seen in the presence of PCE-controlled LSPs.
- ERO computation time is expected to be significantly higher than local-CSPF.

Topology

Figure 140: Configuring PCEP for MPLS RSVP-TE

In this example, PCC is the ingress router that connects to the external active stateful PCE.

The external LSPs of Router PCC are computed as follows:

1. Router PCC receives the LSP tunnel configuration that was set up using the CLI. Assuming that the received configuration is enabled with external path computing, Router PCC becomes aware that some of the LSP attributes – bandwidth, path, and priority – are under the control of the stateful PCE and delegates the LSP to the PCE.

In this example, the external LSP is called **PCC-to-R2** and it is being set up from Router PCC to Router R2. The CLI-configured ERO for **PCC-to-R2** is PCC-R0-R1-R2. The bandwidth for **PCC-to-R2** is 10m, and both the setup and hold priority values are 4.

2. Router PCC tries to retrieve the PCE-controlled LSP attributes. To do this, Router PCC sends out a PCRpt message to the stateful PCE stating that the LSP has been configured. The PCRpt message communicates the status of the LSP and contains the local configuration parameters of the LSP.
3. The stateful PCE modifies one or more of the delegated LSP attributes and sends the new LSP parameters to Router PCC through the PCUpd message.
4. On receiving the new LSP parameters, Router PCC sets up a new LSP and re-signals it using the PCE-provided path.

In this example, the PCE-provided ERO for **PCC-to-R2** is PCC-R3-R2. The bandwidth for **PCC-to-R2** is 8m, and both the setup and hold priority values are 3.

5. Router PCC sends a PCRpt with the new RRO to the stateful PCE.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

```
set interfaces ge-1/0/1 unit 0 family inet address 20.31.4.1/24

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PCC:

NOTE: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```

[edit interfaces]
user@PCC# set ge-1/0/1 unit 0 family inet address 20.31.4.1/24
user@PCC# set ge-1/0/1 unit 0 family iso
user@PCC# set ge-1/0/1 unit 0 family mpls
user@PCC# set ge-1/1/1 unit 0 family inet address 20.31.1.1/24
user@PCC# set ge-1/1/1 unit 0 family iso
user@PCC# set ge-1/1/1 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 10.255.179.95/32

```

2. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

3. Configure the label-switched path (LSP) from Router PCC to Router R2 and enable external control of LSPs by the PCE.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
user@PCC# set mpls label-switched-path PCC-to-R2 to 10.255.179.98/32
user@PCC# set mpls label-switched-path PCC-to-R2 bandwidth 10m
user@PCC# set protocols mpls label-switched-path PCC-to-R2 priority 4 4
user@PCC# set protocols mpls label-switched-path PCC-to-R2 primary to-R2-path
user@PCC# set protocols mpls label-switched-path PCC-to-R2 lsp-external-controller pccd
```

4. Configure the LSP from Router PCC to Router R2, which has local control and is overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path to-R2-path 20.31.1.2/30 strict
user@PCC# set mpls path to-R2-path 20.31.2.2/30 strict
```

5. Enable MPLS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Configure IS-IS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis interface all
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0
```

7. Define the PCE that Router PCC connects to, and configure the IP address of the PCE.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-ipv4-address 10.209.57.166
```

8. Configure the destination port for Router PCC that connects to a PCE using the TCP-based PCEP.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-port 4189
```

9. Configure the PCE type.

```
[edit protocols]
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-1/0/1 {
  unit 0 {
    family inet {
      address 20.31.4.1/24;
    }
    family iso;
    family mpls;
  }
}
ge-1/1/1 {
  unit 0 {
    family inet {
      address 20.31.1.1/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
```

```

unit 0 {
    family inet {
        address 10.255.179.95/32;
    }
}

```

user@PCC# **show protocols**

```

rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    lsp-external-controller pccd;
    label-switched-path PCC-to-R2 {
        to 10.255.179.98;
        bandwidth 10m;
        priority 4 4;
        primary to-R2-path;
        lsp-external-controller pccd;
    }
    path to-R2-path {
        20.31.1.2 strict;
        20.31.2.2 strict;
    }
    interface all;
    interface fxp0.0 {
        disable;
    }
}
isis {
    level 1 disable;
    interface all;
    interface fxp0.0 {
        disable;
    }
    interface lo0.0;
}
pcep {
    pce pce1 {
        destination-ipv4-address 10.209.57.166;
        destination-port 4189;
    }
}

```

```

    pce-type active stateful;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the PCEP Session Status | 1727](#)
- [Verifying the PCE-Controlled LSP Status When LSP Control Is External | 1728](#)
- [Verifying the PCE-Controlled LSP Status When LSP Control Is Local | 1730](#)

Confirm that the configuration is working properly.

Verifying the PCEP Session Status

Purpose

Verify the PCEP session status between the PCE and Router PCC when the PCE status is up.

Action

From operational mode, run the **show path-computation-client active-pce** command.

user@PCC> show path-computation-client active-pce

```

PCE pce1
General
  IP address           : 10.209.57.166
  Priority              : 0
  PCE status           : PCE_STATE_UP
  Session type         : PCE_TYPE_STATEFULACTIVE
  PCE-mastership       : main

Counters
  PCReqs               Total: 0           last 5min: 0           last hour: 0

Errors			
PCErr-recv			
PCErr-sent			
PCE-PCC-NTFS			
PCC-PCE-NTFS			

Meaning

The output displays information about the current active stateful PCE that Router PCC is connected to. The **PCE status** output field indicates the current status of the PCEP session between the PCE and Router PCC.

For **pce1**, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established between the PCEP peers.

The statistics of **PCRpts** indicate the number of messages sent by Router PCC to the PCE to report the current status of LSPs. The **PCUpdates** statistics indicate the number of messages received by Router PCC from the PCE. The **PCUpdates** messages include the PCE modified parameters for the PCE-controlled LSPs.

Verifying the PCE-Controlled LSP Status When LSP Control Is External

Purpose

Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP is under external control.

Action

From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

user@PCC> show mpls lsp name PCC-to-R2 extensive

```
Ingress LSP: 1 sessions

Meaning

In the output, the **LSPTYPE** and **LSP Control Status** output fields show that the LSP is externally controlled. The output also shows a log of the PCEP messages sent between Router PCC and the PCE.

The PCEP session between the PCE and Router PCC is up, and Router PCC receives the following PCE-controlled LSP parameters:

- ERO (path)—20.31.4.2 and 20.31.5.2
- Bandwidth—8Mbps
- Priorities—3 3 (setup and hold values)

Verifying the PCE-Controlled LSP Status When LSP Control Is Local

Purpose

Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP control becomes local.

Action

From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

user@PCC> show mpls lsp name PCC-to-R2 extensive

```

Ingress LSP: 1 sessions

```

Meaning

In the output, the **LSP Control Status** output field shows that the LSP is under local control. Although the PCE-controlled LSP is under local control, Router PCC continues to use the PCE-provided parameters, until the next opportunity to re-signal the LSP.

The output now displays the LSP parameters that were configured using the CLI along with the PCE-provided parameters used to establish the LSP as the actual values in use.

- Bandwidth—10Mbps (ActualBandwidth: 8Mbps)
- Priorities—4 4 (ActualPriorities 3 3)

On the trigger to re-signal the LSP, Router PCC uses the local configuration parameters to establish the PCE-controlled LSP.

[Support of the Path Computation Element Protocol for RSVP-TE Overview | 1697](#)

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

IN THIS SECTION

- [Requirements | 1735](#)
- [Overview | 1735](#)
- [Configuration | 1737](#)
- [Verification | 1742](#)

This example shows how to configure the Path Computation Client (PCC) with the capability of supporting Path Computation Element (PCE)-initiated traffic-engineered point-to-point label-switched paths (LSPs).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- A TCP connection to two external stateful PCEs from the ingress router (PCC).
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE (RSVP-Traffic Engineering).
- Configure OSPF or any other IGP protocol.

Overview

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

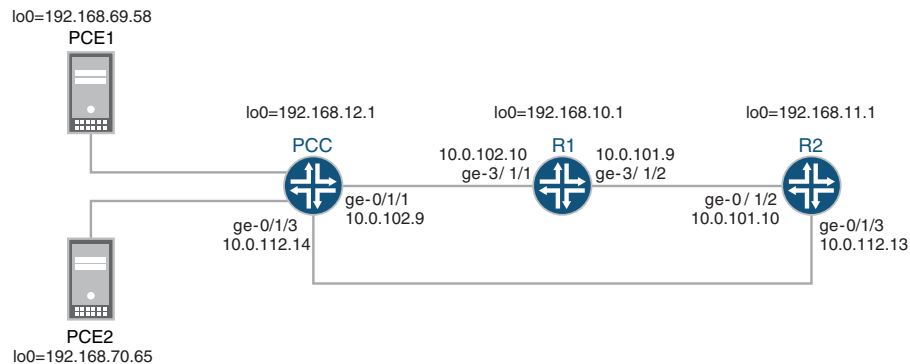

When configuring the support of PCE-initiated point-to-point LSPs for a PCC, be aware of the following considerations:

- Junos OS Release 13.3 supports only stateful PCEs.
- For Junos OS Release 13.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-initiated LSPs.
- PCE-initiated LSPs do not support graceful Routing Engine switchover (GRES).
- PCE-initiated LSPs under logical systems are not supported.
- PCE-initiated LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- RSVP-TE for unnumbered links is not supported. PCE-initiated LSPs support only numbered links.
- The PCE initiating a segment routing LSP can use the binding segment ID (SID) labels associated with non-colored segment routing LSPs to provision the PCE-initiated segment routing LSP paths.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to a PCE through a PCEP session. These non-colored segment routing LSPs may have binding SID labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

Topology

Figure 141: Example PCE-Initiated Point-to-Point LSP for MPLS RSVP-TE

In this example, PCC is the ingress router that connects to two external stateful PCEs: PCE1 and PCE2.

When there is a new demand, the active stateful PCE dynamically initiates an LSP to meet the requirement. Since PCC is configured with the capability of supporting the PCE-initiated LSP, path computation on PCC is performed as follows:

1. A PCE sends a PCCreate message to the PCC to initiate and provision an LSP. The PCC sets up the PCE-initiated LSP using the parameters received from the PCE, and automatically delegates the PCE-initiated LSP to the PCE that initiated it.

In this example, PCE1 is the active stateful PCE that initiates and provisions the PCE-initiated LSP on PCC. On receiving the PCE-initiated LSP parameters, PCC sets up the LSP and automatically delegates the PCE-initiated LSP to PCE1.

2. When the PCEP session between PCC and PCE1 is terminated, PCC starts two timers for the PCE1-initiated LSP: delegation cleanup timeout and the LSP cleanup timer. During this time, PCE1 or PCE2 can acquire control of the PCE-initiated LSP.
3. If PCE2 acquires control over the PCE-initiated LSP before the expiration of the LSP cleanup timer, PCC delegates the PCE-initiated LSP to PCE2, and the LSP cleanup timer and the delegation cleanup timeout are stopped.

4. If the delegation cleanup timeout expired, and neither PCE1 nor PCE2 acquired control over the PCE-initiated LSP, PCC takes local control of the non-delegated PCE-initiated LSP until the expiration of the LSP cleanup timer.
5. After the expiration of the LSP cleanup timer, PCC deletes the PCE-initiated LSP provisioned by PCE1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

NOTE: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```
[edit interfaces]
user@PCC# set ge-0/1/1 unit 0 family inet address 10.0.102.9/24
user@PCC# set ge-0/1/1 unit 0 family iso
user@PCC# set ge-0/1/1 unit 0 family mpls
user@PCC# set ge-0/1/3 unit 0 family inet address 10.0.112.14/24
user@PCC# set ge-0/1/3 unit 0 family iso
user@PCC# set ge-0/1/3 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 192.168.12.1/32
```

2. Enable RSVP on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

3. Enable external control of LSPs by the PCEs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
```

4. Enable MPLS on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure OSPF on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
user@PCC# set ospf area 0.0.0.0 interface all
user@PCC# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PCC# set ospf interface lo0.0
```

6. Define the PCE group and enable support of PCE-initiated LSPs for the PCE group.

```
[edit protocols]
user@PCC# set protocols pcep pce-group PCEGROUP pce-type active
user@PCC# set protocols pcep pce-group PCEGROUP pce-type stateful
user@PCC# set protocols pcep pce-group PCEGROUP lsp-provisioning
user@PCC# set protocols pcep pce-group PCEGROUP lsp-cleanup-timer 30
```

7. Define the PCEs that connect to the PCC.

```
[edit protocols]
user@PCC# set pcep pce PCE1 destination-ipv4-address 192.168.69.58
user@PCC# set pcep pce PCE1 destination-port 4189
user@PCC# set pcep pce PCE1 pce-group PCEGROUP
user@PCC# set pcep pce PCE2 destination-ipv4-address 192.168.70.65
user@PCC# set pcep pce PCE2 destination-port 4189
user@PCC# set pcep pce PCE2 pce-group PCEGROUP
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/1/1 {
  unit 0 {
    family inet {
      address 10.0.102.9/24;
    }
    family iso;
    family mpls;
  }
}
```

```

}
ge-0/1/3 {
  unit 0 {
    family inet {
      address 10.0.112.14/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.12.1/32;
    }
  }
}
}

```

user@PCC# **show protocols**

```

rsvp {
  interface all;
}
interface fxp0.0 {
  disable;
}
}
mpls {
  lsp-external-controller pccd;
  interface all;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface all;
    interface fxp0.0 {
      disable;
    }
  }
}
pce-group PCEGROUP {
  pce-type active stateful;
}

```

```
lsp-provisioning;
lsp-cleanup-timer 30;
}
pce PCE1 {
  destination-ipv4-address 192.168.69.58;
  destination-port 4189;
  pce-group PCEGROUP;
}
pce PCE2 {
  destination-ipv4-address 192.168.70.65;
  destination-port 4189;
  pce-group PCEGROUP;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying PCC Status | 1742](#)
- [Verifying PCE1 Status | 1743](#)
- [Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned | 1745](#)

Confirm that the configuration is working properly.

Verifying PCC Status

Purpose

Verify the PCEP session status and LSP summary between the PCC and the connected PCEs.

Action

From operational mode, run the **show path-computation-client status** command.

```
user@PCC# show path-computation-client status
```

Session	Type	Provisioning	Status
PCE1	Stateful Active	On	Up
PCE2	Stateful Active	On	Up

```

LSP Summary
  Total number of LSPs      : 1
  Static LSPs               : 0
  Externally controlled LSPs : 0
  Externally provisioned LSPs : 1/16000 (current/limit)
  Orphaned LSPs            : 0

PCE1 (main)
  Delegated                 : 1
  Externally provisioned    : 1
PCE2
  Delegated                 : 0
  Externally provisioned    : 0

```

Meaning

The output displays the status of the PCEP session between the active stateful PCEs and the PCC. It also displays information about the different types of LSPs on the PCC, and the number of LSPs provisioned by the connected PCEs and delegated to them.

PCE1 is the main active PCE and has one PCE-initiated LSP that has been automatically delegated to it by the PCC.

Verifying PCE1 Status

Purpose

Verify the status of the main active stateful PCE.

Action

From operational mode, run the **show path-computation-client active-pce detail** command.

```
user@PCC# show path-computation-client active-pce
```

```

Meaning

The output displays information about the current active stateful PCE to which the PCC is connected. The **PCE status** output field indicates the current status of the PCEP session between a PCE and PCC.

For PCE1, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established with the PCC.

Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned

Purpose

Verify the status of the PCE-initiated LSP.

Action

From operational mode, run the **show mpls lsp externally-provisioned detail** command.

```
user@PCC# show mpls lsp externally-provisioned detail
```

```
Ingress LSP: 1 sessions

    Bandwidth: 8Mbps
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 3)
    10.0.102.10 S 10.0.101.9 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node
    10=SoftPreempt 20=Node-ID):
    10.0.102.10 S 10.0.101.9 S
```

Meaning

In the output, the **LSPTYPE** output field shows that the LSP is externally provisioned.

The PCEP session between PCC and PCE1 is up, and the PCC receives the following PCE-initiated LSP parameters:

- ERO (path)—10.0.102.10 and 10.0.101.9
- Bandwidth—8 Mbps
- Priority—7 0 (setup and hold values)

Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

You can configure a Path Computation Client (PCC) with the capability of supporting dynamically created label switched paths (LSPs) from a centralized external path computing entity. A stateful Path Computaiton Element (PCE) can be used to perform external path computation and generate dynamic LSPs when there is an increase in demand.

A PCC creates the PCE-initiated point-to-point LSP using the PCE-provided LSP parameters, or parameters from a pre-configured LSP template when the PCE does not provision the LSP, and automatically delegates the PCE-initiated point-to-point LSP to the respective PCE. As a result, for PCE-initiated LSPs, there is no need for a locally configured LSP on the PCC.

A CLI-controlled LSP, PCE-controlled LSP, and PCE-initiated LSP can coexist with each other on a PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

To configure PCC to support PCE-initiated point-to-point LSPs, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@PCC# edit protocols pcep
```

2. Specify the number of messages per minute that the PCC can receive at maximum.

```
[edit protocols pcep]
user@PCC# set message-rate-limit messages-per-minute
```

- Specify the number of externally provisioned label switched paths (LSPs) over all connected PCEs that the PCC can accept at maximum.

```
[edit protocols pcep]
user@PCC# set max-provisioned-lsps max-count
```

- Specify the unique user defined ID for the connected PCE to configure the PCE parameters.

```
[edit protocols pcep]
user@PCC# edit pce pce-id
```

- Specify the amount of time (in seconds) that the PCC must wait before returning control of LSPs to the routing protocol process after a PCEP session is disconnected.

```
[edit protocols pcep pce pce-id]
user@PCC# set delegation-cleanup-timeout seconds
```

- Specify the IPv4 address of the PCE to connect with.

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-ipv4-address ipv4-address
```

- Specify the TCP port number that the PCE is using

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-port port-number
```

The value can range from 1 through 65535 and the default value is 4189.

- Specify the amount of time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-cleanup-timer seconds
```

- Configure the PCC to accept SPs that are externally provisioned by connected PCEs. By default, the PCC rejects PCE-initiated LSPs.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-provisioning
```

10. Specify the number of unknown messages per minute that the PCC can receive at maximum after which the PCEP session is closed.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-messages messages-per-minute
```

The value can range from 1 through 16384, and the default value is 0 (disabled or no limit).

11. Specify the number of unknown requests per minute that the PCC can receive at maximum after which the PCEP session is terminated.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-requests requests-per-minute
```

The value can range from 0 through 16384, and the default value is 5. A value of 0 disables this statement.

12. Configure the PCE type.

```
[edit protocols pcep pce pce-id]
user@PCC# set pce-type active stateful
```

13. Specify the amount of time (in seconds) that the PCC must wait for a reply before resending a request.

```
[edit protocols pcep pce pce-id]
user@PCC# set request-timer seconds
```

The value can range from 0 through 65535 seconds.

14. Verify and commit the configuration.

```
user@PCC# show
user@PCC# commit
```

Sample Output

```
[edit]
user@PCC# edit protocols pcep

[edit protocols pcep]
user@PCC# set message-rate-limit 50

[edit protocols pcep]
user@PCC# set max-provisioned-lsps 16000

[edit protocols pcep]
user@PCC# edit pce PCE

[edit protocols pcep pce PCE]
user@PCC# set delegation-cleanup-timeout 20

[edit protocols pcep pce PCE]
user@PCC# set destination-ipv4-address 192.168.69.58

[edit protocols pcep pce PCE]
user@PCC# set destination-port 4189

[edit protocols pcep pce PCE]
user@PCC# set lsp-cleanup-timer 50

[edit protocols pcep pce PCE]
user@PCC# set lsp-provisioning

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-messages 5

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-requests 5

[edit protocols pcep pce PCE]
user@PCC# set request-timer 50

[edit protocols pcep pce PCE]
user@PCC# up

[edit protocols pcep]
user@PCC# show
message-rate-limit 50;
max-provisioned-lsps 16000;
```

```
pce PCE {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    lsp-provisioning;
    lsp-cleanup-timer 50;
    request-timer 50;
    max-unknown-requests 5;
    max-unknown-messages 5;
    delegation-cleanup-timeout 20;
}

[edit protocols pcep]
user@PCC# commit
commit complete
```

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Controlled Point-to-Multipoint LSPs

IN THIS SECTION

- [Requirements | 1751](#)
- [Overview | 1751](#)
- [Configuration | 1752](#)
- [Verification | 1766](#)

This example shows how to configure the Path Computation Client (PCC) with the capability of reporting point-to-multipoint traffic engineered label-switched paths (TE LSPs) to a Path Computation Element (PCE).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- One virtual machine configured with Virtual Route Reflector (VRR) feature.
- A TCP connection to an external stateful PCE from the VRR.
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

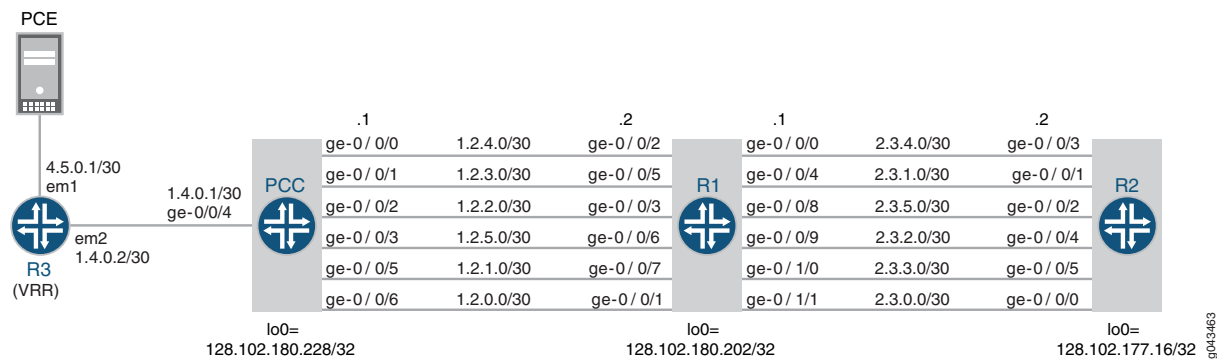

Overview

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce *pce-name*]** or **[edit protocols pcep pce-group *group-id*]** hierarchy levels.

Topology

Figure 142: Example PCE-Controlled Point-to-Multipoint LSPs

In this example, PCC is the ingress router, Router R1 is the transit router, and Router R2 is the egress router. PCC is connected to a Virtual Route Reflector (VRR) that is connected to a PCE. There are many point-to-multipoint interfaces between PCC, Router R1, and Router R2.

The reporting of point-to-multipoint LSPs is executed as follows:

1. If Router PCC is configured with point-to-point and point-to-multipoint LSPs without the support for point-to-multipoint reporting capability, only the point-to-point LSPs are reported to the connected PCE. By default, a PCC does not support point-to-multipoint LSP reporting capability.
2. When Router PCC is configured with point-to-multipoint LSP reporting capability, PCC first advertises this capability to PCE through a report message.
3. By default, a PCE provides support for point-to-multipoint LSP capability. On receiving the PCC's advertisement for point-to-multipoint LSP capability, the PCE in return advertises its capability to the PCC.
4. On receiving the PCE's advertisement of the point-to-multipoint capability, PCC reports all branches of point-to-multipoint LSPs to the PCE using the update message.
5. Once all the LSPs are reported to the PCE, LSP state is synchronized between the PCE and PCC.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

1. Configure the interfaces of Router PCC. To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```
[edit interfaces]
user@PCC# set ge-0/0/0 unit 0 family inet address 1.2.4.1/30
user@PCC# set ge-0/0/0 unit 0 family mpls
user@PCC# set ge-0/0/1 unit 0 family inet address 1.2.3.1/30
user@PCC# set ge-0/0/1 unit 0 family mpls
user@PCC# set ge-0/0/2 unit 0 family inet address 1.2.2.1/30
user@PCC# set ge-0/0/2 unit 0 family mpls
user@PCC# set ge-0/0/3 unit 0 family inet address 1.2.5.1/30
user@PCC# set ge-0/0/3 unit 0 family mpls
user@PCC# set ge-0/0/4 unit 0 family inet address 1.4.0.1/30
user@PCC# set ge-0/0/4 unit 0 family mpls
user@PCC# set ge-0/0/5 unit 0 family inet address 1.2.1.1/30
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set ge-0/0/6 unit 0 family inet address 1.2.0.1/30
user@PCC# set ge-0/0/6 unit 0 family mpls
```

2. Configure the autonomous system number for Router PCC.

```
[edit routing-options]
user@PCC# set autonomous-system 100
```

3. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure a dynamic LSP and disable automatic path computation for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp_template_no_cspf template
user@PCC# set mpls label-switched-path lsp_template_no_cspf no-cspf
```

6. Configure point-to-multipoint LSPs and define external path computing entity for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp1-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc lsp-external-controller pccd
```

7. Enable external path computing for the MPLS LSPs and assign a template for externally provisioned LSPs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pcc_delegated_no_cspf_*
    label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pce_initiated_no_ero_no_cspf_*
    label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pce_initiated_loose_ero_no_cspf_*
    label-switched-path-template lsp_template_no_cspf
```

8. Configure the LSPs that have local control and are overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path loose-path 1.2.3.2 loose
user@PCC# set mpls path strict-path 1.2.3.2 strict
user@PCC# set mpls path strict-path 2.3.3.2 strict
user@PCC# set mpls path path-B
user@PCC# set mpls path path-C
```

9. Configure MPLS administrative group policies for constrained-path LSP computation.

```
[edit protocols]
user@PCC# set mpls admin-groups violet 1
user@PCC# set mpls admin-groups indigo 2
user@PCC# set mpls admin-groups blue 3
user@PCC# set mpls admin-groups green 4
user@PCC# set mpls admin-groups yellow 5
user@PCC# set mpls admin-groups orange 6
```

10. Assign the configured administrative group policies to Router PCC interfaces.

```
[edit protocols]
user@PCC# set mpls interface ge-0/0/6.0 admin-group violet
user@PCC# set mpls interface ge-0/0/5.0 admin-group indigo
```

```

user@PCC# set mpls interface ge-0/0/2.0 admin-group blue
user@PCC# set mpls interface ge-0/0/1.0 admin-group green
user@PCC# set mpls interface ge-0/0/0.0 admin-group yellow
user@PCC# set mpls interface ge-0/0/3.0 admin-group orange

```

11. Configure a traffic engineering database (TED) import policy.

```

[edit protocols]
user@PCC# set mpls traffic-engineering database import policy TE

```

12. Configure a BGP internal group.

```

[edit protocols]
user@PCC# set bgp group northstar type internal
user@PCC# set bgp group northstar local-address 128.102.180.228
user@PCC# set bgp group northstar neighbor 128.102.180.215

```

13. Configure traffic engineering for BGP and assign the export policy.

```

[edit protocols]
user@PCC# set bgp group northstar family traffic-engineering unicast
user@PCC# set bgp group northstar export TE

```

14. Configure OSPF area 0 on all the point-to-multipoint interfaces of Router PCC.

```

[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface lo0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/3.0

```

15. Configure OSPF area 0 on the point-to-point interface of Router PCC.

```

[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/4.0 interface-type p2p

```

16. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
```

17. Define the PCE that Router PCC connects to, and configure the the PCE parameters.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 10.102.180.228
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.246
user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 lsp-cleanup-timer 0
user@PCC# set pcep pce pce1 delegation-cleanup-timeout 60
```

18. Configure Router PCC to enable point-to-multipoint LSP capability for external path computing.

```
[edit protocols]
set pcep pce pce1 p2mp-lsp-report-capability
```

19. Configure the traffic engineering policy.

```
[edit policy-options]
user@PCC# set policy-statement TE term 1 from family traffic-engineering
user@PCC# set policy-statement TE term 1 then accept
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces

Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs

IN THIS SECTION

- [Benefits of PCE-Initiated Point-to-Multipoint LSPs | 1772](#)
- [Signaling of PCE-Initiated Point-to-Multipoint LSPs | 1772](#)
- [Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure | 1772](#)
- [Configuring PCE-Initiated Point-to-Multipoint LSP Capability | 1773](#)
- [Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs | 1773](#)
- [Mapping PCE-initiated Point-To-Multipoint LSPs to MVPN | 1773](#)

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

Benefits of PCE-Initiated Point-to-Multipoint LSPs

Meets the requirements of point-to-multipoint traffic engineering LSP placement in response to application demands through dynamic creation and tear down of point-to-multipoint LSPs, thereby creating a dynamic network that is centrally controlled and deployed.

Signaling of PCE-Initiated Point-to-Multipoint LSPs

The signaling of PCE-initiated point-to-multipoint LSPs is as follows:

- **When a new branch is added (Grafting)**—Only the new branch sub-LSP is signaled and does not result in re-signaling of the entire point-to-multipoint tree.

If any topology changes occurred before provisioning of the new sub-LSP, then the Path Computation Server (PCS) re-computes the entire point-to-multipoint tree and updates the point-to-multipoint LSP using a PC update message.

- **When a branch is deleted (Pruning)**—The deleted branch sub-LSP is torn down and does not result in re-signaling of the entire point-to-multipoint tree.
- **When a branch sub-LSP parameter is changed**—Change in sub-LSP parameters, such as Explicit Route Object (ERO), bandwidth, or priority, can happen either because of optimization, or on user request. If there is a re-signaling request for a sub-LSP, the entire point-to-multipoint tree is re-signaled, and then the switchover to the new instance happens once the new instances of all the branches are up.
- **When a branch sub-LSP path fails**—An error is reported to the PCS for the failed branch sub-LSP. On receiving the new ERO from the PCS, the entire point-to-multipoint tree is re-signaled along with the failed branch sub-LSP, and the switchover to the new instance happens in a make-before-break (MBB) fashion.

Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure

When a PCEP session fails, the PCE-initiated point-to-multipoint LSPs are orphaned until the expiration of the **state timeout** timer. After the **state timeout** timer expires, the PCE-initiated LSPs are cleaned up.

To obtain control of a PCE-initiated point-to-multipoint LSP after a PCEP session failure, the primary or secondary PCE sends a **PCInitiate** message before the **state timeout** timer expires.

Configuring PCE-Initiated Point-to-Multipoint LSP Capability

By default, the creation and provisioning of point-to-multipoint LSPs by a PCE is not supported on a PCC. To enable this capability, include the **p2mp-lsp-init-capability** and **p2mp-lsp-update-capability** statements at the **[edit protocols pcep pce pce-name]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

The **p2mp-lsp-init-capability** statement provides the capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. The **p2mp-lsp-update-capability** statement provides the capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE.

Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs

The following features are supported with PCE-initiated point-to-multipoint LSPs:

- Partial compliance with the Internet draft draft-ietf-pce-stateful-pce-p2mp (expires October 2018), *Path Computation Element (PCE) Protocol Extensions for Stateful PCE usage for Point-to-Multipoint Traffic Engineering Label Switched Paths*.

The following features are not supported with PCE-initiated point-to-multipoint LSPs:

- Delegation of point-to-multipoint locally controlled LSP.
- LSP control delegation.
- Interior gateway protocol (IGP) extension for PCE discovery within an IGP routing domain.
- Request/response messaging.
- Direct movement of branch sub-LSP from one point-to-multipoint tree to another.

The same can be achieved by deleting a branch sub-LSP from the first point-to-multipoint tree and re-adding it to another after the **PCReport** message indicates LSP removal from the device.

- IPv6 is not supported.
- SERO based signalling is not supported.
- Empty-ERO feature is not supported.
- Link protection is not supported.

Mapping PCE-initiated Point-To-Multipoint LSPs to MVPN

You can associate a single or range of MVPN multicast flows (S,G) to a dynamically created PCE-initiated point-to-multipoint label-switched path (LSP). You can specify only selective types of flows for this feature to work. This includes:

- Route distinguisher (RD) which is mapped to the MVPN routing-instance.

- (S,G) which is the source of a multicast packet and destination multicast group address. This is used to filter incoming traffic for mapping it to the tunnel.
- Point-to-multipoint LSP that is used to send traffic that matches the above-mentioned flow specification.

For more details, see Internet draft draft-ietf-pce-pcep-flowspec-05 (expires February 16, 2020) *PCEP Extension for Flow Specification*.

The current implementation of this feature does not implement the following sections of the draft:

- Section 3.1.2—Advertising PCE capabilities in IGP
- Section 3.2—PCReq and PCRep message
- Section 7—Most of the flow specifications, except route distinguisher and IPv4 multicast flow specifications, are not supported.

To enable the mapping of PCE-initiated point-to-multipoint LSPs to MVPN:

- Include the **pce_traffic_steering** statement at the [edit protocols pcep pce pce-id] hierarchy level to indicate the support for flow specification capability (also called traffic steering) by the PCC.
- Include the **external-controller** statement at the [edit routing-instances routing-instance-name provider-tunnel] hierarchy level.

The presence of **external-controller** in the provider-tunnel configuration for MVPN indicates that the point-to-multipoint LSP and (S,G) for this MVPN instance can be provided by the external controller. This enables the external controller to dynamically configure (S,G) and point-to-multipoint LSP for MVPN.

Take the following into consideration for mapping of PCE-initiated point-to-multipoint LSPs to MVPN:

- If you do not enable the **external-controller pccd** statement for a particular MVPN instance, then the PCCD process does not configure (S,G) dynamically.
- If you disable the **external-controller pccd** configuration from the CLI, then the dynamically learned multicast flows (S,G) for that particular MVPN instance is deleted and reported to the external controller.
- When (S,G) is already configured from the CLI, the PCC cannot configure (S,G) dynamically as local configuration has a higher priority.
- If any particular (S,G) is learned from the external controller dynamically and then you configure the same (S,G) for the same MVPN instance, then the dynamically learned (S,G) is deleted and reported to the external controller through the PCC.
- If the routing protocol process reboots, then the PCCD process reconfigures all the (S,G) again.
- If the PCCD process reboots, then MVPN reports all PCCD configured (S,G) to the external controller.
- If user enables **external-controller pccd** for a particular MVPN instance, then MVPN requests the PCCD process to configure (S,G), if any present.
- If there are major configuration changes to a particular MVPN instance, then MVPN requests the PCCD process to reconfigure all (S,G) for that particular MVPN instance.

- All flow specifications associated with any PCE-initiated point-to-multipoint LSP must have the same RD. During PC initiation if all flow specifications do not have the same RD, then the PC initiate message is dropped with an error.
- You can associate a point-to-multipoint LSP only with selective type of flow specifications, otherwise the PC initiate message is dropped with an error.
- During PC update if all flow specifications do not have same the RD either due to a new flow specification addition, or due to existing flow specification update, then the PCC drops the update message.
- During PC update if all flow specifications do not meet the selective condition either due to new flow specification addition, or due to existing flow specifications update, then the PCC drops the update message.
- Behavior for mapping of PCE-initiated point-to-multipoint LSP with MVPN routing-instance and mapping of static (locally configured) point-to-multipoint LSP with MVPN instance is the same at user level.
- A flow specification ID can be associated with only one point-to-multipoint LSP. To associate the same RD and (S,G) to multiple point-to-multipoint LSPs, you can add multiple flow specifications with different IDs and same RD & (S,G).
- For PCEP-mapped dynamic (S,G), the threshold value is always the default value of 0.
- There is no limit on the number of flow specifications mapped to a single PCE-initiated point-to-multipoint LSP.
- The current implementation of this feature does not support:
 - Reporting of forwarding states that are associated with the point-to-multipoint LSP.
 - Inclusive provider tunnel dynamic configuration
 - Mapping for MVPN ingress replication tunnel
 - Programmable routing protocol process (prpd)
 - Reporting of CLI configured point-to-multipoint LSP which is mapped to MVPN multicast flows (S,G).

Release History Table

Release	Description
19.4R1	You can associate a single or range of MVPN multicast flows (S,G) to a dynamically created PCE-initiated point-to-multipoint label-switched path (LSP).

The traffic engineering (TE) capabilities of Source Packet Routing in Networking (SPRING) are supported in the Path Computation Element Protocol (PCEP) implementation of Junos OS. With this support, the advantages of SPRING are extended to the label-switched paths (LSPs) initiated by a Path Computation Element (PCE), augmenting the benefits of external path computing in an MPLS network. This topic describes the PCEP implementation for SPRING-TE LSPs.

SPRING for Traffic Engineering

Traditionally, RSVP has been used to address traffic engineering problems. RSVP-TE is an extension to RSVP that allows MPLS labels to be generated for prefixes, and at the same time uses the resource reservation capabilities to reserve specific LSPs through the network. Currently, the Junos OS

implementation of PCEP uses RSVP-TE. Starting in Junos OS Release 17.2, the PCEP implementation is extended to support SPRING-TE as well.

SPRING can operate over an IPv4 or IPv6 data plane, and supports equal-cost multipath (ECMP). With the IGP extensions built into it, SPRING integrates with the rich multiservice capabilities of MPLS, including Layer 3 VPN (L3VPN), Virtual Private Wire Service (VPWS), Virtual Private LAN Service (VPLS), and Ethernet VPN (EVPN).

Some of the high-level components of the SPRING-TE solution are:

- Use of an IGP for advertising link characteristics. This is similar to RSVP-TE.
- Use of CSPF on the ingress device or the PCE.
- Use of an IGP for advertising labels for links.

With SPRING, the ingress device constructs an LSP by stacking the labels of the links that it wants to traverse. The per-link IGP advertisement is combined with label stacking to create source routed LSPs on the ingress, so the transit devices are not aware of the end-to-end LSPs. As a result, there is no per-LSP signaling in SPRING-TE, and the ability to stack per-neighbor labels contributes to the control plane scaling property. This enables creation of LSPs between edge nodes without placing any per-LSP memory requirements on the transit devices. However, the label stacking feature of SPRING-TE results in the management of a large number of labels, which might be difficult for some platforms to support.

Junos OS Implementation of PCEP for SPRING-TE LSPs

IN THIS SECTION

- [SPRING-TE Module | 1779](#)
- [Traffic Engineering Database | 1779](#)
- [PCEP Interaction | 1779](#)

The Junos OS implementation of SPRING-TE LSPs for PCEP allows creation of tunnel routes for SPRING-TE LSPs, and using the tunnel routes for placing IP traffic or services. The SPRING-TE LSPs are created by the PCE using the adjacency and node segments.

Junos OS SPRING-TE LSPs cannot be longer than six hops. The PCE computes the path of the SPRING-TE LSP, and provisions the LSP on the Path Computation Client (PCC) using PCEP segment routing (SR) extensions. The PCEP SR extensions are parsed and a tunnel is created on the PCC. Like any other tunnel route, IP traffic and services can be resolved over the tunnel.

The Junos OS implementation of PCEP for SPRING-TE LSPs includes the following components:

SPRING-TE Module

SPRING-TE LSPs are created on the PCC, making the tunnel routes available in the inet.3 routing table. The PCC selects the outgoing interface based on the first network access identifier (NAI) in the source Explicit Route Object (S-ERO). If the PCC receives an S-ERO that does not have labels in it, it rejects the S-ERO. SPRING-TE creates tunnel routes that have their own preference value.

If the path has more than five labels, then the path is unviable. So, any S-ERO that carries more than six hops is rejected. When there are multiple LSPs to the same destination with the same metric, the PCC creates an equal-cost multipath (ECMP) route.

Junos OS supports S-EROs that contain the first hop as a strict hop; there is no support on the PCC to select the outgoing interface based on a loose hop node segment ID. However, the remaining hops can be loose. No specific processing is done for the S-EROs that are beyond the first hop, other than to simply use the label for next-hop creation.

Traffic Engineering Database

After a PCE has provisioned a SPRING-TE LSP for the PCC, a few things can change, such as:

- The label used by a path can change.
- The label used by a path can be withdrawn.
- One of the interfaces traversed by the LSP can go down, which is detected by monitoring IGP advertisements.

The PCC does not react to any of the above changes. The PCC waits for the PCE to process the event, and either re-program the LSP or bring down the LSP, as appropriate. However, when the directly attached interface of a SPRING-TE LSP goes down, that SPRING-TE LSP is not used for tunnel route creation.

PCEP Interaction

The Junos OS implementation of PCEP provides support to process received provisioning type S-ERO objects on the PCC. If the PCC loses connection with the PCE, the SPRING-TE LSPs remain up for 300 seconds, and then get purged out. If the PCE supplies parameters, such as setup priority, that do not apply to SR, the PCC ignores them.

The PCEP interaction with SPRING-TE LSPs is based on the Internet drafts—*draft-ietf-pce-lsp-setup-type-03.txt* and *draft-ietf-pce-segment-routing-06.txt*. The PCEP draft compliance is as follows:

- Support the PCE capability type, length, and value TLV. The maximum service identifier (SID) is set to 5 by default. The **max-sid-depth** statement can be used to control the maximum SID depth advertised.
- Path setup TLV is supported.
- ERO is supported, but loose hop expansion is not supported.
- Only IPv4 node IDs and adjacencies are supported. IPv6 or unnumbered adjacencies are not supported.
- Because the maximum SID depth is always set to five, the metric object is also set to five.

NOTE: The S-ERO objects that do not carry labels are rejected.

Configuration of PCEP for SPRING-TE

Enabling SPRING for PCEP

To enable SPRING for PCEP, you need to configure MPLS and SPRING-TE.

NOTE: PCEP for RSVP-TE cannot be disabled when PCEP for SPRING-TE is enabled.

To enable PCEP for SPRING-TE LSPs, the following configuration must be executed:

1. Enable external path computing capabilities for MPLS. This configuration is required for PCEP for RSVP-TE as well.

```
[edit protocols]
user@host# set mpls lsp-external-controller
```

2. Configure SPRING-TE with external path computing capabilities.

```
[edit protocols]
user@host# set spring-traffic-engineering lsp-external-controller pccd
```

3. Enable SPRING on a PCE.

```
[edit protocols]
user@host# set pcep pce pce1 spring-capability
```

Configuring Maximum SID Depth

The maximum SID depth value for SPRING-TE is set to five by default. The following configuration can be used to control the maximum SID depth that is advertised:

```
[edit protocols]
user@host# set pcep pce pce1 max-sid-depth 5
```

Configuring Preference Value for SPRING-TE

The default preference value of SPRING-TE is eight.

```
[edit protocols]
user@host# set spring-te preference preference-value
```

Configuring SPRING-TE Logging

The following configuration is used to control logging for SPRING-TE LSPs:

```
[edit protocols]
user@host# set spring-te traceoptions file file-name size file-size
user@host# set spring-te traceoptions flag [controller | state | route | general | interface | all]
```

Viewing SPRING-TE LSPs

The **show spring-te lsp** command displays the SPRING-TE LSPs on the device.

```
show spring-te lsp name lsp-name
```

```
show spring-te lsp extensive
```

Limitations and Unsupported Features for PCEP SPRING-TE

The support of SPRING for PCEP does not add any additional performance burden on the system; however, the PCEP SPRING-TE implementation has the following limitations:

- A SPRING-TE LSP is not locally protected on the PCC. When the LSP is over six hops, no other service is provided on the LSP other than to carry plain IP.
- Graceful Routing Engine switchover (GRES) and unified ISSU in-service software upgrade are not supported.
- Nonstop active routing (NSR) is not supported.
- IPv6 is not supported.
- Logical systems are not supported.

Example: Configuring Path Computation Element Protocol for SPRING-TE LSPs

IN THIS SECTION

- [Requirements | 1782](#)
- [Overview | 1782](#)
- [Configuration | 1783](#)
- [Verification | 1791](#)

This example shows how to configure Path Computation Element Protocol (PCEP) for traffic engineered label-switched paths (LSPs) of Source Packet Routing in Networking (SPRING). The advantages of SPRING are leveraged with the benefits of external path computing for efficient traffic engineering.

Requirements

This example uses the following hardware and software components:

- Four MX Series 5G Universal Routing Platforms, where the ingress router is the Path Computation Client (PCC).
- A TCP connection to an external stateful Path Computation Element (PCE) from the PCC.
- Junos OS Release 17.2 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS.
- Configure IS-IS.

Overview

Starting in Junos OS Release 17.2, the traffic engineering capabilities of Source Packet Routing in Networking (SPRING) are supported in PCEP sessions for the LSPs initiated by a PCE. Tunnel routes are created in the inet.3 routing table of the PCC corresponding to the SPRING-TE LSPs. Similar to any other tunnel route, the SPRING-TE tunnel routes can be used for resolving indirect next hops for plain IP and service traffic. The SPRING-TE LSPs are created by the PCE for the adjacency and node segments.

The SPRING-TE LSPs can be a maximum of six hops long. The PCE computes the path of the SPRING-TE LSP, and provisions the LSP on the Path Computation Client (PCC) using PCEP segment routing (SR) extensions. Tunnel routes are created in the inet.3 routing table of the PCC corresponding to the SPRING-TE LSPs. Similar to any other tunnel route, the SPRING-TE tunnel routes can be used for resolving indirect next hops for plain IP and service traffic.

To configure SPRING-TE for PCEP:

- Enable external path computing for MPLS and SPRING-TE at the **[edit protocols]** hierarchy level.
- Enable spring capability for the PCE at the **[edit protocols pcep pce pce]** hierarchy level.

Topology

Figure 143 on page 1783 illustrates a sample network topology that has PCE as the external path computing entity, and the PCC as the ingress router that connects to the PCE. Routers R1, R2, and R3 are the other routers in the network. The PCC is enabled with SPRING-TE capability for the PCEP sessions. A static route is configured on the PCC to Router R3 to verify the use of SPRING-TE tunnel routes when routing traffic for the static route.

Figure 143: PCEP for SPRING-TE LSPs

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure PCC:

1. Configure the interfaces of the PCC.

```
[edit interfaces]
user@PCC# set ge-0/0/5 unit 0 family inet address 172.16.0.1/16
user@PCC# set ge-0/0/5 unit 0 family iso
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 127.0.0.4/8 primary
user@PCC# set lo0 unit 0 family iso address 49.0011.0110.0000.0101.00
user@PCC# set lo0 unit 0 family mpls
```

2. Configure the router ID and assign an autonomous system number for the PCC.

```
[edit routing-options]
user@PCC# set router-id 127.0.0.4
user@PCC# set autonomous-system 11
```

3. Configure a static route from the PCC to Router R3.

The static route is created for verification purpose only and does not affect the feature functionality.

```
[edit routing-options]
user@PCC# set static route 100.1.1.1/32 next-hop 127.0.0.3
```

4. Configure RSVP on all the interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface fxp0.0 disable
user@PCC# set rsvp interface all
```

5. Configure MPLS on all the interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Enable external path computing capability for the PCC.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
```

7. Configure IS-IS level 2 on all the interfaces of the PCC, excluding the management and loopback interfaces.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis level 2 wide-metrics-only
user@PCC# set isis interface all point-to-point
user@PCC# set isis interface all level 2 metric 10
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0 passive
```

8. Configure Segment routing global block (SRGB) attributes for SPRING.

```
[edit protocols]
user@PCC# set isis source-packet-routing srgb start-label 800000
user@PCC# set isis source-packet-routing srgb index-range 4000
user@PCC# set isis source-packet-routing node-segment ipv4-index 101
user@PCC# set isis source-packet-routing node-segment ipv6-index 11
```

9. Configure SPRING with external path computing capability.

```
[edit protocols]
user@PCC# set spring-traffic-engineering lsp-external-controller pccd
```

10. Configure the PCE parameters and enable provisioning of LSP by the PCE and SPRING capability.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 127.0.0.4
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.232
user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 spring-capability
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PCC# show interfaces
ge-0/0/5 {
  unit 0 {
    family inet {
      address 172.16.0.1/16;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 127.0.0.4/8 {
        primary;
      }
    }
    family iso {
      address 49.0011.0110.0000.0101.00;
    }
    family mpls;
  }
}

```

```

user@PCC# show routing-options
static {
  route 100.1.1.1/32 next-hop 127.0.0.3;
}

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying IS-IS Adjacency and Labels | 1791](#)
- [Verifying the Traffic Engineering Database | 1800](#)
- [Verifying SPRING-TE LSPs | 1804](#)
- [Verifying Tunnel Route Creation | 1806](#)
- [Verifying Forwarding Table Entries | 1808](#)
- [Verifying Use of Tunnel Routes for Static Route Forwarding | 1810](#)

Confirm that the configuration is working properly.

Verifying IS-IS Adjacency and Labels

Purpose

Verify the IS-IS adjacency and label assignments for interfaces and nodes on the PCC.

Action

From operational mode, run the **show isis adjacency extensive**, **show isis database extensive**, and **show isis overview** commands.

```
user@PCC> show isis adjacency extensive
```

```
R1

Meaning

The IS-IS adjacency between the PCC and PCE and the PCC and Router R1 is up and operational. The output also displays the label assignments for the adjacent and node segments.

Verifying the Traffic Engineering Database

Purpose

Verify the traffic engineering database entries on the PCC.

Action

From operational mode, run the **show ted database extensive** command.

user@PCC# **show ted database extensive**

```

Meaning

The traffic engineering database includes entries advertised from Routers R1, R2, and R3, which the PCE uses for external path computing for the PCC.

Verifying *SPRING-TE LSPs*

Purpose

Verify the creation of *SPRING-TE LSP* on the PCC.

Action

From operational mode, run the **show path-computation-client lsp** and **show spring-traffic-engineering lsp detail** commands.

```
user@PCC> show path-computation-client lsp
```

- [Example: Configuring Static Segment Routing Label Switched Path | 1836](#)

The segment routing architecture enables the ingress devices in a core network to steer traffic through explicit paths. You can configure these paths using segment lists to define the paths that the incoming traffic should take. The incoming traffic may be labeled or IP traffic, causing the forwarding operation at the ingress device to be either a label swap, or a destination-based lookup.

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Introduction to Segment Routing LSPs

Segment routing leverages the source routing paradigm. A device steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress device to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack.

Segment routing LSPs can either be dynamic or static in nature.

Dynamic segment routing LSPs—When a segment routing LSP is created either by an external controller and downloaded to an ingress device through Path Computation Element Protocol (PCEP) extensions, or from a BGP segment routing policy through BGP segment routing extensions, the LSP is dynamically provisioned. The segment list of the dynamic segment routing LSP is contained in the PCEP Explicit Route Object (ERO), or the BGP segment routing policy of the LSP.

Static segment routing LSPs—When a segment routing LSP is created on the ingress device through local configuration, the LSP is statically provisioned.

A static segment routing LSP can further be classified as colored and non-colored LSPs based on the configuration of the **color** statement at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level.

For example:

```
[edit protocols]
  source-packet-routing {
    source-routing-path lsp_name {
      to destination_address;
      color color_value;
      binding-sid binding-label;
      primary segment_list_1_name weight weight;
      ...
      primary segment_list_n_name weight weight;
      secondary segment_list_n_name;
      sr-preference sr_preference_value;
    }
  }
```

Here, each primary and secondary statement refers to a segment list.

```
[edit protocols]
  source-packet-routing {
    segment-list segment_list_name {
      hop_1_name label sid_label;
      ...
      hop_n_name label sid_label;
    }
  }
```

Benefits of using Segment Routing LSPs

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

Colored Static Segment Routing LSP

IN THIS SECTION

- [Understanding Colored Static Segment Routing LSPs | 1814](#)
- [Segment List of Colored Segment Routing LSPs | 1814](#)

A static segment routing LSP configured with the **color** statement is called a colored LSP.

Understanding Colored Static Segment Routing LSPs

Similar to a BGP segment routing policy, the ingress route of the colored LSP is installed in the **inetcolor.0** or **inet6color.0** routing tables, with **destination-ip-address, color** as key for mapping IP traffic.

A static colored segment routing LSP may have a binding SID, for which a route is installed in the **mpls.0** routing table. This binding SID label is used to map labeled traffic to the segment routing LSP. The gateways of the route are derived from the segment list configurations under the primary and secondary paths.

Segment List of Colored Segment Routing LSPs

The colored static segment routing LSPs already provide support for first hop label mode of resolving an LSP. However, first hop IP mode is not supported for colored segment routing LSPs. Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops. If this requirement is not met, the commit is blocked.

Non-Colored Static Segment Routing LSP

IN THIS SECTION

- [Understanding Non-Colored Segment Routing LSPs | 1814](#)
- [Segment List of Non-Colored Segment Routing LSPs | 1815](#)

A static segment routing LSP that is configured without the **color** statement is a non-colored LSP. Similar to PCEP segment routing tunnels, the ingress route is installed in the **inet.3** or **inet6.3** routing tables.

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

Understanding Non-Colored Segment Routing LSPs

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the **inet.3** routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol

(PCEP) session. These non-colored segment routing LSPs may have binding service identifier (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may specify a metric at `[edit protocols source-packet-routing source-routing-path lsp-name]` for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route. Each path, either primary or secondary, of each segment routing LSP is considered as a gateway candidate, if the path is functional and the segment routing LSP has the best preference of all these segment routing LSPs. However, the maximum number of gateways that the next-hop can hold cannot exceed the RPD multi-path limit, which is 128 by default. Extra paths are pruned, firstly secondary paths and then primary paths. A given segment list may be referred multiple times as primary or secondary paths by these segment routing LSPs. In this case, there are multiple gateways, each having a unique segment routing LSP tunnel ID. These gateways are distinct, although they have identical outgoing label stack and interface. A non-colored segment routing LSP and a colored segment routing LSP may also have the same destination address. However, they correspond to different destination addresses for ingress routes, as the colored segment routing LSP's destination address is constructed with both its destination address and color.

NOTE: In the case where a static non-colored segment routing LSP and a PCEP-created segment routing LSP co-exist and have the same address that contributes to the same ingress route, if they also have the same preference. Otherwise, the segment routing LSP with the best preference is installed for the route.

Segment List of Non-Colored Segment Routing LSPs

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. The number of SID labels in the segment list should not exceed the maximum segment list limit. You can configure the maximum segment list limit at the `[edit protocols source-packet-routing]` hierarchy level.

Prior to Junos OS Release 19.1R1, for a non-colored static segment routing LSP to be usable, the first hop of the segment list had to be an IP address of an outgoing interface and the second to *n*th hops could be

SID labels. Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.

For the first-hop label mode to take effect, you must include the **inherit-label-nexthops** statement globally or individually for a segment list, and the first hop of the segment list must include both IP address and label. If the first hop includes only IP address, the **inherit-label-nexthops** statement does not have any effect.

You can configure **inherit-label-nexthops** at any one of the following hierarchies. The **inherit-label-nexthops** statement takes effect only if the segment list first hop includes both IP address and label.

- **Segment list level**—At the `[edit protocols source-packet-routing segment-list segment-list-name]` hierarchy level.
- **Globally**—At the `[edit protocols source-packet-routing]` hierarchy level.

When the **inherit-label-nexthops** statement is configured globally, it takes precedence over the segment-list level configuration, and the **inherit-label-nexthops** configuration is applied to all the segment lists. When the **inherit-label-nexthops** statement is not configured globally, only segment lists with both labels and IP address present in the first hop, and configured with **inherit-label-nexthops** statement are resolved using SID labels.

For dynamic non-colored static LSPs, that is the PCEP-driven segment routing LSPs, the **inherit-label-nexthops** statement must be enabled globally, as the segment-level configuration is not applied.

[Table 16 on page 637](#) describes the mode of segment routing LSP resolution based on the first hop specification.

Table 49: Non-Colored Static LSP Resolution Based on First Hop Specification

First Hop Specification	Mode of LSP Resolution
IP address only For example: <pre> segment-list path-1 { hop-1 ip-address 172.0.12.2; hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	The segment list is resolved using the IP address.

Table 49: Non-Colored Static LSP Resolution Based on First Hop Specification (*continued*)

First Hop Specification	Mode of LSP Resolution
<p>SID only</p> <p>For example:</p> <pre>segment-list path-2 { hop-1 label 1000011; hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	<p>The segment list is resolved using SID labels.</p>
<p>IP address and SID (without the inherit-label-nexthops configuration)</p> <p>For example:</p> <pre>segment-list path-3 { hop1 { label 801006; ip-address 172.24.1.2; } hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	<p>By default, the segment list is resolved using IP address.</p>
<p>IP address and SID (with the inherit-label-nexthops configuration)</p> <p>For example:</p> <pre>segment-list path-3 { inherit-label-nexthops; hop1 { label 801006; ip-address 172.24.1.2; } hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	<p>The segment list is resolved using SID labels.</p>

You can use the **show route *ip-address* protocol spring-te active-path table inet.3** command to view the non-colored segment routing traffic-engineered LSPs having multiple segment lists installed in the inet.3 routing table.

For example:

user@host> **show route 7.7.7.7 protocol spring-te active-path table inet.3**

```
inet.3: 42 destinations, 59 routes (41 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

7.7.7.7/32      *[SPRING-TE/8] 00:01:25, metric 1, metric2 0
                > to 11.1.1.2 via et-0/0/0.1, Push 801007
                  to 21.1.1.2 via et-0/0/2.1, Push 801007
                  to 11.102.1.2 via et-0/0/0.2, Push 801007, Push 801002(top)

                  to 21.202.1.2 via et-0/0/2.2, Push 801007, Push 801005(top)

                  to 11.103.1.2 via et-0/0/0.3, Push 801007, Push 801003(top)

                  to 21.203.1.2 via et-0/0/2.3, Push 801007, Push 801006(top)

                  to 11.104.1.2 via et-0/0/0.4, Push 801007, Push 801003, Push
801002(top)
                  to 21.204.1.2 via et-0/0/2.4, Push 801007, Push 801006, Push
801005(top)
```

NOTE:

The first hop type of segment lists of a static segment routing LSP can cause a commit to fail, if:

- Different segment lists of a tunnel have different first hop resolution types. This is applicable to both colored and non-colored static segment routing LSPs. However, this does not apply for PCEP-driven LSPs; a system log message is generated for the mismatch in the first hop resolution type at the time of computing the path.

For example:

```
segment-list path-1 {
  hop-1 ip-address 172.0.12.2;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
segment-list path-2 {
  hop-1 label 1000011;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
source-routing-path lsp1 {
  to 172.10.10.1;
  primary {
    path-1;
    path-2;
  }
}
```

The commit of tunnel *lsp1* fails, as path-1 is of IP address mode and path-2 is of label mode.

- The binding SID is enabled for the static non-colored LSP whose segment list type is SID label.

For example:

```
segment-list path-3 {
  hop-1 label 1000011;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
source-routing-path lsp1 {
```

```

to 172.10.10.1;
binding-sid 333;
primary {
    path-3;
}
}

```

Configuring binding SID over label segment list is supported only for colored static LSPs and not for no-colored static LSPs.

Static Segment Routing LSP Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique service identifier (SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. The adjacency SID label can be dynamically allocated, which is the default behavior, or be allocated from a local static label pool (SRLB). A route for the SID label is then installed in the mpls.0 table.

Junos OS allows static segment routing LSPs by configuring the **segment** statement at the **[edit protocols mpls static-label-switched-path static-label-switched-path]** hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the **static-label-range static-label-range** statement at the **[edit protocols mpls label-range]** hierarchy level.

Static Segment Routing LSP Limitations

- Junos OS currently has a limitation that the next hop cannot be built to push more than the maximum segment list depth labels. So, a segment list with more than the maximum SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than the maximum limit, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed the maximum segment list depth. You can configure the maximum segment list limit at **[edit protocols source-packet-routing]** hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to the maximum SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label.
- The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring **no-ingress** statement at **[edit protocols source-packet-routing source-routing-path lsp-name]** hierarchy level.

- A maximum of 8 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- If any segment-list is configured with more labels than the maximum segment list depth, the configuration commit check fails with an error.

Dynamic Creation of Segment Routing LSPs

IN THIS SECTION

- [Configuring Dynamic Segment Routing LSP Template | 1822](#)
- [Resolving Dynamic Segment Routing LSPs | 1823](#)
- [Considerations for Configuring Dynamic Creation of Segment Routing LSPs | 1827](#)
- [Services Supported over Dynamic Segment Routing LSPs | 1827](#)
- [Behavior With Multiple Tunnel Sources in Segment Routing | 1828](#)
- [Dynamic Segment Routing LSPs Limitations | 1828](#)

In segment routing networks that have each provider edge (PE) device connected to every other PE device, a large amount of configuration is required for setting up the segment routing label-switched paths (LSPs), although only a few segment routing traffic-engineered (SR-TE) paths may be used. You can enable BGP-triggered dynamic creation of these LSPs to reduce the amount of configuration in such deployments.

Configuring Dynamic Segment Routing LSP Template

To configure the template for enabling dynamic creation of segment routing LSPs, you must include the [spring-te](#) statement at the `[edit routing-options dynamic-tunnels]` hierarchy.

- The following is a sample configuration for color dynamic segment routing LSP template:

```
[edit routing-options]
dynamic-tunnels {
  <dynamic-tunnel-name> {
    spring-te {
      source-routing-path-template {
        <template-name1> color [c1 c2];
        <template-name2> color [c3];
        <template-name3> color-any;
      }
      destination-networks {
        <dest1>;
        <dest2>;
      }
    }
  }
}
```

```

    }
  }
}

```

- The following is a sample configuration for non-color dynamic segment routing LSP template:

```

dynamic-tunnels {
  <dynamic-tunnel-name> {
    spring-te {
      source-routing-path-template {
        <template-name1>;
      }
      destination-networks {
        <dest1>;
        <dest2>;
      }
    }
  }
}

```

Resolving Dynamic Segment Routing LSPs

IN THIS SECTION

- [Resolving Colored Dynamic Segment Routing LSP | 1823](#)
- [Resolving Uncolored Dynamic Segment Routing LSPs | 1824](#)
- [Dynamic Segment Routing LSP Sample Configuration | 1824](#)

Resolving Colored Dynamic Segment Routing LSP

When the BGP prefixes are assigned with color community, they initially get resolved over the catch-all-route-for-that-particular-color policy, and in turn, the SR-TE template on which the BGP prefix should be resolved onto is identified. The destinations SID is then derived from the BGP payload prefix next-hop attribute. For example, if the next hop of the BGP payload prefix is an IP address that belongs to Device A, then the node-SID of Device A is taken and a corresponding label is prepared and pushed to the bottom of the stack. The BGP payload prefix is resolved in a color-only mode, where the node-SID of Device A is at the bottom of the final label stack, and the SR-TE path labels are on top.

The final LSP template name is a combination of prefix, color, and tunnel name; for example, **<prefix>:<color>:dt-srte-<tunnel-name>**. The color in the LSP name is displayed in hexadecimal format, and the format of the tunnel name is similar to that of RSVP-triggered tunnel LSP names.

To successfully resolve a colored destination network, the color should have a valid template mapping, either to a specific color, or through the **color-any** template. Without a valid mapping, the tunnel is not created and the BGP route requesting for resolution remains unresolved.

Resolving Uncolored Dynamic Segment Routing LSPs

The catch-all routes for non-colored LSPs are added to the inet.3 routing table. The non-colored tunnel destination must be configured in a different **spring-te** configuration with only one template name in the mapping list. This template name is used for all the tunnel routes matching any of the destination networks configured under the same **spring-te** configuration. These tunnels are similar to RSVP tunnels in functionality.

The final LSP template name is a combination of prefix and tunnel name; for example, **<prefix>:dt-srte-<tunnel-name>**.

Dynamic Segment Routing LSP Sample Configuration

IN THIS SECTION

- [Colored Dynamic Segment Routing LSPs | 1824](#)
- [Non-Colored Dynamic Segment Routing LSPs | 1825](#)
- [Unresolved Dynamic Segment Routing LSP | 1826](#)

The dynamic segment routing LSP template always carries a partial path. The last hop node SID is derived automatically at the tunnel creation time depending on the protocol next-hop address (PNH) node SID. The same template can be used by multiple tunnels to different destinations. In such cases, the partial path remains the same, and only the last hop changes depending on the PNH. Dynamic segment routing LSP templates are not common to a single tunnel, as a result a full path cannot be carried on it. You can use a segment list if a full path is to be used.

Colored Dynamic Segment Routing LSPs

Sample configuration for colored dynamic segment routing LSPs:

```
protocols source-packet-routing {
  source-routing-path-template sr_lsp1 {
    primary sr_sl1
    primary sr_sl2 weight 2
    sr-preference 180;
  }
}
dynamic-tunnels tunnel1 {
  spring-te {
    source-routing-path-template {
```

```

        sr_lsp1 color [ 123 124 125 ];
        sr_lsp2 color-any
    }
    destination-networks {
        22.33.44.0/24;
    }
}
}
}

```

For the above-mentioned sample configuration, the route entries are as follows:

inetcolor.0 tunnel route: 22.33.44.0-0/24 --> RT_NH_TUNNEL

inetcolor6.0 tunnel route: ffff::22.33.44.0-0/120 --> RT_NH_TUNNEL

BGP prefix to tunnel mapping:

R1(prefix) -> 22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

R1(prefix) -> ffff::22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

R1(prefix) -> ffff::22.33.44.55-124(PNH) LSP tunnel name = 22.33.44.55:7c:dt-srte-tunnel1

inetcolor.0 tunnel route:

22.33.44.55-101/64 --> <next-hop>

22.33.44.55-124/64 --> <next-hop>

inetcolor6.0 tunnel route:

ffff::22.33.44.55-101/160 --> <next-hop>

ffff::22.33.44.55-124/160 --> <next-hop>

Non-Colored Dynamic Segment Routing LSPs

Sample configuration for non-colored dynamic segment routing LSPs:

```

protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels {
    tunnel1 {
        spring-te {
            source-routing-path-template {

```

```

        sr_lsp1 color [ 101 ];
    }
    destination-networks {
        22.33.44.0/24;
    }
}
}
tunnel2 {
    spring-te {
        source-routing-path-template {
            sr_lsp1;
        }
        destination-networks {
            22.33.44.0/24;
        }
    }
}
}
}

```

For the above-mentioned sample configuration, the route entries are as follows:

inet.3 tunnel route: 22.33.44.0/24 --> RT_NH_TUNNEL

inet6.3 tunnel route: ffff::22.33.44.0/120 --> RT_NH_TUNNEL

BGP prefix to tunnel mapping:

R1(prefix) -> 22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2

R1(prefix) -> ffff::22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2

inet.3 tunnel route: 22.33.44.55/32 --> <next-hop>

inet6.3 tunnel route: ffff::22.33.44.55/128 --> <next-hop>

Unresolved Dynamic Segment Routing LSP

Sample configuration for unresolved dynamic segment routing LSPs:

```

protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels tunnel1 {
    spring-te {

```

```

source-routing-path-template {
    sr_lsp1 color [120 121 122 123];
}
destination-networks {
    22.33.44.0/24;
    1.1.1.0/24;
}
}
}

```

For the above-mentioned sample configuration, the route entries are as follows:

inetcolor.0 tunnel route: 22.33.44.0 - 0/24 --> RT_NH_TUNNEL 1.1.1.0 - 0 /24 --> RT_NH_TUNNEL

inetcolor6.0 tunnel route: ffff::22.33.44.0 - 0/120 --> RT_NH_TUNNEL ffff::1.1.1.0 - 0 /24 --> RT_NH_TUNNEL

BGP prefix to tunnel mapping: R1(prefix) -> 22.33.44.55-124(PNH) Tunnel will not be created. (Template not found for the color).

Considerations for Configuring Dynamic Creation of Segment Routing LSPs

When configuring the dynamic creation of segment routing LSPs, take the following into consideration:

- A template can be assigned with a color object. When the dynamic tunnel **spring-te** configuration includes a template with a color object, you must configure all other templates with color objects as well. All destinations are assumed to be colored within that configuration.
- A template can have a list of colors defined on it, or can be configured with the **color-any** option. Both these options can coexist in the same **spring-te** configuration. In such cases, templates assigned with specific colors have a higher preference.
- In a **spring-te** configuration, only one template can be defined with the **color-any** option.
- The color-to-template mapping is done on a one-to-one basis. One color cannot map to multiple templates.
- The template name should be configured in the **spring-te** statement under the **[edit protocols]** hierarchy, and should have the **primary** option enabled.
- Colored and non-colored destinations cannot co-exist in the same **spring-te** configuration.
- You cannot configure same destination networks, with or without color, under different **spring-te** configuration statements.
- In non-colored **spring-te** configuration, only one template can be configured without color object.

Services Supported over Dynamic Segment Routing LSPs

The following services are supported over colored dynamic segment routing LSPs:

- Layer 3 VPN

- BGP EVPN
- Export policy services

The following services are supported over non-colored dynamic segment routing LSPs:

- Layer 3 VPN
- Layer 2 VPN
- Multipath configurations

Behavior With Multiple Tunnel Sources in Segment Routing

When two sources download routes to the same destination from segment routing (for example static and dynamic sourced tunnels), then the segment routing preference is used for choosing the active route entry. A higher value has greater preference. In case the preference remains the same, then the tunnel source is used to determine the route entry.

Dynamic Segment Routing LSPs Limitations

The dynamic SR-TE LSPs do not support the following features and functionalities:

- IPv6 segment routing tunnels.
- Static tunnels.
- 6PE is not supported.
- Distributed CSPF.
- sBFD and LDP tunnelling is not supported for dynamic SR-TE LSPs and in a template.
- Install and B-SID routes in a template.

Color-Based Mapping of VPN Services

IN THIS SECTION

- [VPN Service Coloring | 1829](#)
- [Specifying VPN Service Mapping Mode | 1832](#)
- [Color-IP Protocol Next Hop Resolution | 1833](#)
- [Fallback to IP Protocol Next Hop Resolution | 1834](#)
- [Supported and Unsupported Features for Color-Based Mapping of VPN Services | 1834](#)

You can specify color as a protocol next hop constraint (in addition to the IPv4 or IPv6 address) for resolving transport tunnels over static colored and BGP segment routing traffic-engineered (SRTE) LSPs. This is called the color-IP protocol next hop resolution, where you are required to configure a resolution-map

and apply to the VPN services. With this feature, you can enable color-based traffic steering of Layer 2 and Layer 3 VPN services.

Junos OS supports colored SRTE LSPs associated with a single color. The color-based mapping of VPN services feature is supported on static colored LSPs and BGP SRTE LSPs.

VPN Service Coloring

IN THIS SECTION

- [Egress Color Assignment | 1829](#)
- [Ingress Color Assignment | 1831](#)

In general, a VPN service may be assigned a color on the egress router where the VPN NLRI is advertised, or on an ingress router where the VPN NLRI is received and processed.

You can assign a color to the VPN services at different levels:

- Per routing instance.
- Per BGP group.
- Per BGP neighbor.
- Per prefix.

Once you assign a color, the color is attached to a VPN service in the form of BGP color extended community.

You can assign multiple colors to a VPN service, referred to as multi-color VPN services. In such cases, the last color attached is considered as the color of the VPN service, and all other colors are ignored.

Multiple colors are assigned by egress and/or ingress devices through multiple policies in the following order:

- BGP export policy on the egress device.
- BGP import policy on the ingress device.
- VRF import policy on the ingress device.

The two modes of VPN service coloring are:

Egress Color Assignment

In this mode, the egress device (that is, the advertiser of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it in the VPN service's

routing-instance **vrf-export**, group export, or group neighbor export at the **[edit protocols bgp]** hierarchy level. The VPN NLRI is advertised by BGP with the specified color extended community.

For example:

```
[edit routing-options]
community red-comm {
  members color:0:50;
}
```

```
[edit policy-options]
policy-statement pol-color {
  term t1 {
    from {
      [any match conditions];
    }
    then {
      community add red-comm;
      accept;
    }
  }
}
```

```
[edit routing-instances]
vpn-X {
  ...
  vrf-export pol-color ...;
}
```

Or

NOTE: When you apply the routing policy as an export policy of a BGP group or BGP neighbor, you must include the **vpn-apply-export** statement at the BGP, BGP group, or BGP neighbor level in order for the policy to take an effect on the VPN NLRI.

```
[edit protocols bgp]
group PEs {
  ...
  neighbor PE-A {
    export pol-color ...;
```

```

        vpn-apply-export;
    }
}

```

The routing policies are applied to Layer 3 VPN prefix NLRIs, Layer 2 VPN NLRIs, and EVPN NLRIs. The color extended community is inherited by all the VPN routes, imported, and installed in the target VRFs on one or multiple ingress devices.

Ingress Color Assignment

In this mode, the ingress device (that is, the receiver of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it to the VPN service's routing-instance **vrf-import**, group import, or group neighbor import at the **[edit protocols bgp]** hierarchy level. All the VPN routes matching the routing policy is attached with the specified color extended community.

For example:

```

[edit routing-options]
community red-comm {
    members color:0:50;
}

```

```

[edit policy-options]
policy-statement pol-color {
    term t1 {
        from {
            [any match conditions];
        }
        then {
            community add red-comm;
            accept;
        }
    }
}

```

```

[edit routing-instances]
vpn-Y {
    ...
    vrf-import pol-color ...;
}

```

Or

```
[edit protocols bgp]
group PEs {
  ...
  neighbor PE-B {
    import pol-color ...;
  }
}
```

Specifying VPN Service Mapping Mode

To specify flexible VPN service mapping modes, you must define a policy using the **resolution-map** statement, and refer the policy in a VPN service's routing-instance **vrf-import**, group import, or group neighbor import at the **[edit protocols bgp]** hierarchy level. All the VPN routes matching the routing policy are attached with the specified resolution-map.

For example:

```
[edit policy-options]
resolution-map map-A {
  <mode-1>;
  <mode-2>;
  ...
}
policy-statement pol-resolution {
  term t1 {
    from {
      [any match conditions];
    }
    then {
      resolution-map map-A;
      accept;
    }
  }
}
```

You can apply import policy to the VPN service's routing-instance.

```
[edit routing-instances]
vpn-Y {
  ...
  vrf-import pol-resolution ...;
}
```

You can also apply the import policy to a BGP group or BGP neighbor.

```
[edit protocols bgp]
group PEs {
  ...
  neighbor PE-B {
    import pol-resolution ...;
  }
}
```

NOTE: Each VPN service mapping mode should have a unique name defined in the resolution-map. Only a single entry of IP-color is supported in the resolution-map, where the VPN route(s) are resolved using a colored-IP protocol next hop in the form of **ip-address:color**.

Color-IP Protocol Next Hop Resolution

The protocol next hop resolution process is enhanced to support colored-IP protocol next hop resolution. For a colored VPN service, the protocol next hop resolution process takes a color and a resolution-map, builds a colored-IP protocol next hop in the form of *IP-address:color*, and resolves the protocol next hop in the inet6color.0 routing table.

You must configure a policy to support multipath resolution of colored Layer 2 VPN, Layer 3 VPN, or EVPN services over colored LSPs. The policy must then be applied with the relevant RIB table as the resolver import policy.

For example:

```
[edit policy-options]
policy-statement mpath {
  then multipath-resolve;
}
```

```
[edit routing-options]
resolution {
  rib bgp.l3vpn.0 {
    inetcolor-import mpath;
  }
}
resolution {
  rib bgp.l3vpn-inet6.0 {
    inet6color-import mpath;
  }
}
```

```

resolution {
    rib bgp.l2vpn.0 {
        inetcolor-import mpath;
    }
}
resolution {
    rib mpls.0 {
        inetcolor-import mpath;
    }
}
resolution {
    rib bgp.evpn.0 {
        inetcolor-import mpath;
    }
}

```

Fallback to IP Protocol Next Hop Resolution

If a colored VPN service does not have a resolution-map applied to it, the VPN service ignores its color and falls back to the IP protocol next hop resolution. Conversely, if a non-colored VPN service has a resolution-map applied to it, the resolution-map is ignored, and the VPN service uses the IP protocol next hop resolution.

The fallback is a simple process from colored SRTE LSPs to LDP LSPs, by using a RIB group for LDP to install routes in inet{6}color.0 routing tables. A longest prefix match for a colored-IP protocol next hop ensures that if a colored SRTE LSP route does not exist, an LDP route with a matching IP address should be returned.

Supported and Unsupported Features for Color-Based Mapping of VPN Services

The following features and functionality are supported with color-based mapping of VPN services:

- BGP Layer 3 VPN
- BGP Layer 2 VPN (Kompella Layer 2 VPN)
- BGP EVPN
- Resolution-map with a single IP-color option.
- Colored IPv4 and IPv6 protocol next hop resolution.
- Routing information base (also known as routing table) group based fallback to LDP LSP in inetcolor.0 routing table.
- Colored SRTE LSP.
- Virtual platforms.

- 64-bit Junos OS.
- Logical systems.

The following features and functionality are not supported with color-based mapping of VPN services:

- Colored MPLS LSPs, such as RSVP, LDP, BGP-LU, static.
- Layer 2 circuit
- FEC-129 BGP auto-discovered and LDP-signaled Layer 2 VPN.
- VPLS
- MVPN
- IPv4 and IPv6 using resolution-map.
- BGP labeled unicast.

Tunnel Templates for PCE-Initiated Segment Routing LSPs

You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.

When a PCE-Initiated segment routing LSP is being created, the LSP is checked against policy statements (if any) and if there is a match, the policy applies the configured template for that LSP. The template configuration is inherited only if it is not provided by the LSP source (PCEP); for example, metric.

To configure a template:

1. Include the [source-routing-path-template](#) statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure the additional BFD and LDP tunneling parameters here.
2. Include the [source-routing-path-template-map](#) statement at the **[edit protocols source-packet-routing]** hierarchy level to list the policy statements against which the PCE-initiated LSP should be checked.
3. Define a policy to list the LSPs on which the template should be applied.

The **from** statement can include either the LSP name or LSP regular expression using the **lsp** and **lsp-regex** match conditions. These options are mutually exclusive, so you can specify only one option at a given point in time.

The **then** statement must include the **sr-te-template** option with an accept action. This applies the template to the PCE-initiated LSP.

Take the following into consideration when configuring a template for PCE-initiated LSPs:

- Template configuration is not applicable to statically configured segment routing LSPs, or any other client's segment routing LSP.
- PCEP-provided configuration has precedence over template configuration.

- PCEP LSP does not inherit template segment-list configuration.

Example: Configuring Static Segment Routing Label Switched Path

IN THIS SECTION

- [Requirements | 1836](#)
- [Overview | 1836](#)
- [Configuration | 1837](#)
- [Verification | 1850](#)

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

Overview

Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the **segment-list** statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure segment routing tunnel by configuring the **source-routing-path** statement at **[edit protocols source-packet-routing]** hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5 . Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring Device PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5

set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5

set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRI in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
```

```
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 55.1.12.1/24;
    }
    family mpls {
      maximum-labels 5;
    }
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 55.1.13.1/24;
    }

Configuring Device PE2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls

set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

user@PE2# **show interfaces**

```
ge-0/0/0 {
  unit 0 {
    family inet {
      address 55.1.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 55.1.23.2/24;
    }
    family mpls;
  }
}
```

user@PE2# **show protocols**

```
mpls {
  static-label-switched-path adj-23 {
    segment {
      1000123;
      next-hop 55.1.23.3;
      pop;
    }
  }
  static-label-switched-path adj-21 {
    segment {
      1000221;
      next-hop 55.1.12.1;
      pop;
    }
  }
  interface ge-0/0/0.0;
  interface ge-0/0/1.0;
  label-range {
    static-label-range 1000000 1000999;
  }
}
ospf {
  area 0.0.0.0 {
    interface ge-0/0/0.0;
    interface ge-0/0/1.0;
```

```
}
}
```

Verification

IN THIS SECTION

- Verifying Route Entry of Routing Table inet.3 of Router PE1 | 1850
- Verifying Route Table Entries of Routing Table mpls.0 of Router PE1 | 1851
- Verifying SPRING Traffic Engineered LSP of Router PE1 | 1851
- Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1 | 1852
- Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2 | 1853
- Verifying the Status of Static MPLS LSP Segments of Router PE2 | 1854

Confirm that the configuration is working properly.

Verifying Route Entry of Routing Table inet.3 of Router PE1

Purpose

Verify the route entry of routing table inet.3 of router PE1.

Action

From operational mode, enter the **show route table inet.3** command.

```
user@PE1> show route table inet.3
```

```
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32    *[SPRING-TE/8] 03:09:26, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)

                    to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134,
                    Push 1000123(top)
```

Meaning

The output displays the ingress routes of segment routing tunnels.

Verifying Route Table Entries of Routing Table mpls.0 of Router PE1

Purpose

Verify the route entries of routing table mpls.0

Action

From operational mode, enter the **show route table mpls.0** command.

user@PE1> **show route table mpls.0**

```
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 03:25:52, metric 1
            Receive
1          *[MPLS/0] 03:25:52, metric 1
            Receive
2          *[MPLS/0] 03:25:52, metric 1
            Receive
13         *[MPLS/0] 03:25:52, metric 1
            Receive
16         *[VPN/0] 03:25:52
            > via lsi.0 (VRF1), Pop
1000999    *[SPRING-TE/8] 03:04:03, metric 1
            > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)

            to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134,
            Push 1000123(top)
```

Meaning

The output displays the SID labels of segment routing tunnels.

Verifying SPRING Traffic Engineered LSP of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress routers.

Action

From operational mode, enter the **show spring-traffic-engineering overview** command.

user@PE1> **show spring-traffic-engineering overview**

```

Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
    < Not configured >

```

Meaning

The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress router.

Action

From operational mode, enter the **show spring-traffic-engineering lsp detail** command.

```
user@PE1# show spring-traffic-engineering lsp detail
```

```

Name: lsp-15
To: 192.168.146.181
State: Up
  Path: sl-15-primary
  Outgoing interface: ge-0/0/1.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 3
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.13.3
      SID type: None
    Hop 2 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000134
    Hop 3 (Strict):
      NAI: None
      SID type: 20-bit label, Value: 1000145
  Path: sl-15-backup
  Outgoing interface: ge-0/0/0.0
  BFD status: N/A (Up: 0, Down: 0)
  SR-ERO hop count: 4
    Hop 1 (Strict):
      NAI: IPv4 Adjacency ID, 0.0.0.0 -> 10.10.12.2
      SID type: None

```

```

Hop 2 (Strict):
  NAI: None
  SID type: 20-bit label, Value: 1000123
Hop 3 (Strict):
  NAI: None
  SID type: 20-bit label, Value: 1000134
Hop 4 (Strict):
  NAI: None
  SID type: 20-bit label, Value: 1000145

Total displayed LSPs: 1 (Up: 1, Down: 0)

```

Meaning

The output displays details of SPRING traffic engineered LSPs on the ingress router

Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2

Purpose

Verify the routing table entries of routing table mpls.0 of router PE2.

Action

From operational mode, enter the **show route table mpls.0** command.

```
user@PE2> show route table mpls.0
```

```

mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 03:22:29, metric 1
            Receive
1          *[MPLS/0] 03:22:29, metric 1
            Receive
2          *[MPLS/0] 03:22:29, metric 1
            Receive
13         *[MPLS/0] 03:22:29, metric 1
            Receive
1000123    *[MPLS/6] 03:22:29, metric 1
            > to 10.10.23.3 via ge-0/0/1.0, Pop
1000123(S=0) *[MPLS/6] 03:22:29, metric 1
            > to 10.10.23.3 via ge-0/0/1.0, Pop
1000221    *[MPLS/6] 03:22:29, metric 1
            > to 10.10.12.1 via ge-0/0/0.0, Pop

```

```
1000221(S=0)          *[MPLS/6] 03:22:29, metric 1
                      > to 10.10.12.1 via ge-0/0/0.0, Pop
```

Verifying the Status of Static MPLS LSP Segments of Router PE2

Purpose

Verify the status of MPLS LSP segments of router PE2.

Action

From operational mode, enter the **show mpls static-lsp** command.

```
user@PE2> show mpls static-lsp
```

```
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname                SID-label    State
adj-21                 1000221      Up
adj-23                 1000123      Up
Total 2, displayed 2, Up 2, Down 0
```

Meaning

The output displays the status of static MPLS LSP segments of router PE2.

Release History Table

Release	Description
19.4R1	You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.
19.1R1	Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops.
19.1R1	Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.

Verify MPLS Interfaces

Purpose

If the MPLS protocol is not configured correctly on the routers in your network, the interfaces are not able to perform MPLS switching.

NOTE: For a labeled route to be resolved over an interface, **family mpls** must be configured at the **[edit interfaces]** hierarchy level for the route to be successfully resolved. When the interface is not configured with **family mpls**, labelled routes do not get resolved.

Action

To verify MPLS interfaces, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls interface
```

Sample Output 1

The following sample output is for all routers in the network shown in [“MPLS Network Topology” on page 2217](#).

```
user@R1> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
```

```
user@R2> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
so-0/0/3.0     Up         <none>
```

```
user@R3> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
```

```
so-0/0/1.0      Up      <none>
so-0/0/2.0      Up      <none>
so-0/0/3.0      Up      <none>
```

user@R4> **show mpls interface**

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>
so-0/0/3.0	Up	<none>

user@R5> **show mpls interface**

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>

user@R6> **show mpls interface**

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>
so-0/0/3.0	Up	<none>

Sample Output 2

user@R6> **show mpls interface**

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/3.0	Up	<none>

so-0/0/2.0 is missing

Sample Output 3

```
user@host> show mpls interface
MPLS not configured
```

Meaning

Sample Output 1 shows that all MPLS interfaces on all routers in the network are enabled (**Up**) and can perform MPLS switching. If you fail to configure the correct interface at the **[edit protocols mpls]** hierarchy level or include the **family mpls** statement at the **[edit interfaces type-fpc/pic/port unit number]** hierarchy level, the interface cannot perform MPLS switching, and does not appear in the output for the **show mpls interface** command.

Administrative groups are not configured on any of the interfaces shown in the example network in “[MPLS Network Topology](#)” on page 2217. However, if they were, the output would indicate which affinity class bits are enabled on the router.

Sample Output 2 shows that interface **so-0/0/2.0** is missing and therefore might be incorrectly configured. For example, the interface might not be included at the **[edit protocols mpls]** hierarchy level, or the **family mpls** statement might not be included at the **[edit interfaces type-fpc/pic/port unit number]** hierarchy level. If the interface is configured correctly, RSVP might not have signaled over this interface yet. For more information on determining which interface is incorrectly configured, see “[Verify Protocol Families](#)” on page 2222.

Sample Output 3 shows that the MPLS protocol is not configured at the **[edit protocols mpls]** hierarchy level.

Verify the MPLS Configuration

Purpose

After you have checked the transit and ingress routers, use the **traceroute** command to verify the BGP next hop, and used the **ping** command to verify the active path, you can check for problems with the MPLS configuration at the **[edit protocols mpls]** and **[edit interfaces]** hierarchy levels.

NOTE: For a labeled route to be resolved over an interface, **family mpls** must be configured at the **[edit interfaces]** hierarchy level for the route to be successfully resolved. When the interface is not configured with **family mpls**, labelled routes do not get resolved.

Action

To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show configuration protocols mpls
user@host> show configuration interfaces
```

Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured
```

Sample Output 2

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/1 {
    unit 0 {
        family inet {
            address 10.1.46.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.26.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/3 {
    unit 0 {
        family inet {
            address 10.1.36.2/30;
        }
        family iso;
        family mpls;
    }
}
fxp0 {
    unit 0 {
        family inet {
            address 192.168.70.148/21;
        }
    }
}
```

```
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.0.0.6/32;
        address 127.0.0.1/32;
      }
      family iso {
        address 49.0003.1000.0000.0006.00;
      }
    }
  }
}
```

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the **[edit protocols mpls]** hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

Checklist for Checking the MPLS Layer

Problem

Description: This checklist provides the steps and commands for checking the Multiprotocol Label Switching (MPLS) layer of the layered MPLS model. The checklist provides links to an overview of the MPLS layer and more detailed information about the commands used to investigate the problem.

[Table 50 on page 1871](#) provides commands for checking the MPLS layer.

Solution

Table 50: Checklist for Checking the MPLS Layer

Tasks	Command or Action
“Checking the MPLS Layer” on page 1872	
1. Verify the LSP on page 1874	show mpls lsp show mpls lsp extensive show mpls lsp name <i>name</i> show mpls lsp name <i>name</i> extensive

Table 50: Checklist for Checking the MPLS Layer (*continued*)

Tasks	Command or Action
2. Verify the LSP Route on the Transit Router on page 1878	<code>show route table mpls.0</code>
3. Verify the LSP Route on the Ingress Router on page 1880	<code>show route <i>destination</i></code>
4. Verify MPLS Labels with the traceroute Command on page 1882	<code>traceroute <i>hostname</i></code>
5. Verify MPLS Labels with the ping Command on page 1883	On the ingress router: <code>ping mpls rsvp <i>lsp-name</i> detail</code>
6. Verify the MPLS Configuration on page 1868	<code>show configuration protocols mpls</code> <code>show configuration interfaces</code>
7. Take Appropriate Action on page 1888	The following sequence of commands addresses the specific problem described in this topic: <code>edit</code> <code>edit protocols mpls</code> <code>[edit protocols mpls]</code> <code>show</code> <code>activate interface so-0/0/3.0</code> <code>show</code> <code>commit</code>
8. Verify the LSP Again on page 1889	<code>show mpls lsp extensive</code>

Checking the MPLS Layer

Purpose

After you have configured the label-switched path (LSP), issued the `show mpls lsp` command, and determined that there is an error, you might find that the error is not in the physical, data link, Internet Protocol (IP), interior gateway protocol (IGP), or Resource Reservation Protocol (RSVP) layers. Continue investigating the problem at the MPLS layer of the network.

[Figure 145 on page 1873](#) illustrates the MPLS layer of the layered MPLS model.

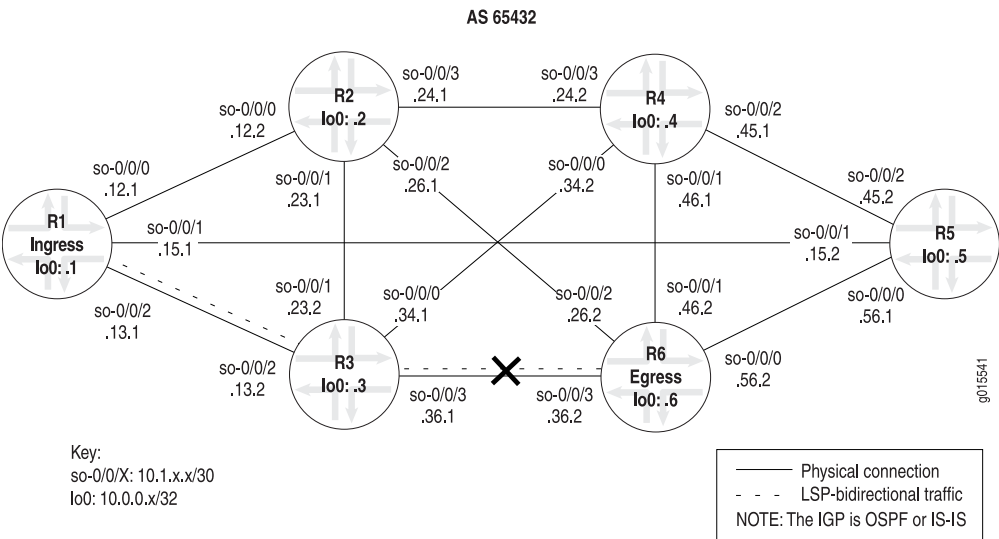

Figure 145: Checking the MPLS Layer

BGP Layer	traceroute <i>host-name</i> show bgp summary show configuration protocols bgp show route <i>destination-prefix</i> detail show route receive protocol bgp <i>neighbor-address</i>
MPLS Layer	show mpls lsp show mpls lsp extensive show route table mpls.0 show route <i>address</i> traceroute <i>address</i> ping mpls rsvp <i>lsp-name</i> detail
RSVP Layer	show rsvp session show rsvp neighbor show rsvp interface
↩ IGP and IP Layers Functioning ↪	
OSPF Layer show ospf neighbor show configuration protocols ospf show ospf interface	IS-IS Layer show isis adjacency show configuration protocols isis show isis interface
IP Layer show ospf neighbor extensive show interfaces terse	IP Layer show isis adjacency extensive show interfaces terse
Data Link Layer	show interfaces extensive "JUNOS Interfaces Operations Guide"
Physical Layer	show interfaces show interfaces terse ping <i>host</i>

With the MPLS layer, you check whether the LSP is up and functioning correctly. If the network is not functioning at this layer, the LSP does not work as configured.

Figure 146 on page 1873 illustrates the MPLS network used in this topic.

Figure 146: MPLS Network Broken at the MPLS Layer

The network shown in [Figure 146 on page 1873](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the reverse LSP is down without a path from **R6** to **R1**.

The cross shown in [Figure 146 on page 1873](#) indicates where the LSP is broken. Some possible reasons the LSP is broken might include an incorrectly configured MPLS protocol, or interfaces that are incorrectly configured for MPLS.

In the network shown in [Figure 146 on page 1873](#), a configuration error on egress router **R6** prevents the LSP from traversing the network as expected.

To check the MPLS layer, follow these steps:

1. [Verify the LSP | 1874](#)
2. [Verify the LSP Route on the Transit Router | 1878](#)
3. [Verify the LSP Route on the Ingress Router | 1880](#)
4. [Verify MPLS Labels with the traceroute Command | 1882](#)
5. [Verify MPLS Labels with the ping Command | 1883](#)
6. [Verify the MPLS Configuration | 1885](#)
7. [Take Appropriate Action | 1888](#)
8. [Verify the LSP Again | 1889](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```

user@R1> show mpls lsp

```

Meaning

Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-to-R1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only one LSP is configured in the example network in [Figure 146 on page 1873](#). However, in a large network with many LSPs configured, the results would be quite different between the two commands.

Verify the LSP Route on the Transit Router

Purpose

If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

Action

To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

Sample Output 1

```
user@R3> show route table mpls.0
```

```

mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
1          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
2          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive

```

Sample Output 2

user@R3> show route table mpls.0

```

mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
1          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
2          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
100864     *[RSVP/7] 00:07:23, metric 1
            > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0) *[RSVP/7] 00:07:23, metric 1
            > via so-0/0/2.0, label-switched-path R6-to-R1
100880     *[RSVP/7] 00:07:01, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0) *[RSVP/7] 00:07:01, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6

```

Meaning

Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see [“Checklist for Verifying LSP Use” on page 2090](#).

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries represent two routes. There are two entries per route

because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

Verify the LSP Route on the Ingress Router

Purpose

Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

Action

To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

Sample Output 1

```
user@R1> show route 10.0.0.6
```

```
inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.6/32      *[IS-IS/18] 6d 01:41:37, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0
```

```
user@R6> show route 10.0.0.1
```

```
inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32      *[IS-IS/18] 5d 01:01:38, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0
```

Sample Output 2

user@R1> show route 10.0.0.6

```
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.6/32      *[IS-IS/18] 6d 02:13:42, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0
```

```
inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.6/32      *[RSVP/7] 00:08:07, metric 20
                  > via so-0/0/2.0, label-switched-path R1-to-R6
```

user@R6> show route 10.0.0.1

```
inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.1/32      *[IS-IS/18] 5d 01:34:03, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0
```

```
inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.1/32      *[RSVP/7] 00:10:39, metric 20
                  > via so-0/0/3.0, label-switched-path R6-to-R1
```

Meaning

Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router.

BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in [Figure 146 on page 1873](#).

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

Verify MPLS Labels with the traceroute Command

Purpose

Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the **traceroute** command as a debugging tool to determine whether the LSP is being used to forward traffic.

Action

To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

Sample Output 2

```
user@R1> traceroute 100.100.6.1
to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
```

```

1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
    MPLS Label=100912 CoS=0 TTL=1 S=1
2  10.1.36.2 (10.1.36.2)  0.577 ms !N  0.597 ms !N  0.546 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
1  10.1.36.1 (10.1.36.1)  0.802 ms  0.716 ms  0.688 ms
    MPLS Label=100896 CoS=0 TTL=1 S=1
2  10.1.13.1 (10.1.13.1)  0.570 ms !N  0.568 ms !N  0.546 ms !N

```

Meaning

Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in [Figure 146 on page 1873](#)) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

Verify MPLS Labels with the ping Command

Purpose

When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

Action

To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

Sample Output 1

```

user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

```

```
user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.
```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.15.2 (10.1.15.2)  0.708 ms  0.613 ms  0.576 ms
 2  10.0.0.6 (10.0.0.6)  0.763 ms  0.708 ms  0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 69, label 100880
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 69, label 100880
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 69, label 100880
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

user@R6> ping mpls rsvp R6-to-R1 detail
Request for seq 1, to interface 70, label 100864
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 70, label 100864
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 70, label 100864
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 70, label 100864
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 70, label 100864
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Meaning

Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

Verify the MPLS Configuration

Purpose

After you have checked the transit and ingress routers, use the **traceroute** command to verify the BGP next hop, and used the **ping** command to verify the active path, you can check for problems with the MPLS configuration at the **[edit protocols mpls]** and **[edit interfaces]** hierarchy levels.

NOTE: For a labeled route to be resolved over an interface, **family mpls** must be configured at the **[edit interfaces]** hierarchy level for the route to be successfully resolved. When the interface is not configured with **family mpls**, labelled routes do not get resolved.

Action

To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show configuration protocols mpls
user@host> show configuration interfaces
```

Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
```

```

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured

```

Sample Output 2

```

user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/1 {
    unit 0 {
        family inet {
            address 10.1.46.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/2 {

```

```

    unit 0 {
        family inet {
            address 10.1.26.2/30;
        }
        family iso;
        family mpls;
    }
}
so-0/0/3 {
    unit 0 {
        family inet {
            address 10.1.36.2/30;
        }
        family iso;
        family mpls;
    }
}
fxp0 {
    unit 0 {
        family inet {
            address 192.168.70.148/21;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.6/32;
            address 127.0.0.1/32;
        }
        family iso {
            address 49.0003.1000.0000.0006.00;
        }
    }
}
}

```

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the **[edit protocols mpls]** hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the **[edit protocols mpls]** hierarchy level on egress router **R6**.

Solution

To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
```

```

user@R6# activate interface so-0/0/3

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete

```

Meaning

The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the **[edit protocols mpls]** hierarchy level. The LSP can now come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

Action

To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Total 0 displayed, Up 0, Down 0

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify That Node-Link Protection Is Up

Purpose

After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in [Figure 7 on page 144](#), two bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

Action

To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

```
show mpls lsp
show mpls lsp extensive
show rsvp interface
show rsvp interface extensive
show rsvp session detail
```

Sample Output

```
user@R1> show mpls lsp
```

Ingress LSP: 1 sessions

To	From	State	Rt	ActivePath	P	LSPname

Total 2 displayed, Up 2, Down 0

```

Meaning

Sample output from **R1** for the **show mpls lsp** command shows a brief description of the state of configured and active LSPs for which **R1** is the ingress, transit, and egress router. All LSPs are up. **R1** is the ingress router for **lsp2-r1-to-r5**, and the egress router for return LSP **r5-to-r1**. Two LSPs transit **R1**, **lsp1-r6-to-r0** and the return LSP **r0-to-t6**. For more detailed information about the LSP, include the **extensive** option when you issue the **show mpls lsp** command.

Sample Output

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample output from **R1** for the **show mpls lsp extensive** command shows detailed information about all LSPs for which **R1** is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass LSP **Bypass->10.0.12.14->10.0.24.2**.

Sample Output

```

user@R1> show rsvp interface
RSVP interface: 4 active

```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample output from **R1** for the **show rsvp interface** command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**. Interface **fe-0/1/0.0** is the connecting interface between **R1** and **R2**, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the **show rsvp interface extensive** command.

Sample Output

```

user@R1> show rsvp interface extensive
RSVP interface: 3 active

```

```

```

Meaning

Sample output from **R1** for the **show rsvp interface extensive** command shows more detailed information about the activity on all RSVP interfaces (3). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14** is a link protection bypass path (**Type: LP**), protecting the link between **R1** and **R2 fe-0/1/0.0**. The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding **R2** in case of node failure.

Sample Output

Meaning

Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5**) originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

Conclusion

Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment. Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

Verify That Link Protection Is Up

Purpose

When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in [Figure 147 on page 1906](#), a bypass path should

be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

Action

To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface
```

Sample Output

```
user@R1> show mpls lsp extensive | no-more

```

Meaning

The sample output from ingress router **R1** shows that **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have link protection up, and both LSPs are using the bypass path, **10.0.12.14**. However, the **show mpls lsp** command does not list the bypass path. For information about the bypass path, use the **show rsvp session** command.

```

Meaning

The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the **show mpls lsp** command. However, because link protection is

an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass > interface-address**, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1 (lsp2-r1-to-r5)** is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0**. Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	35Mbps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

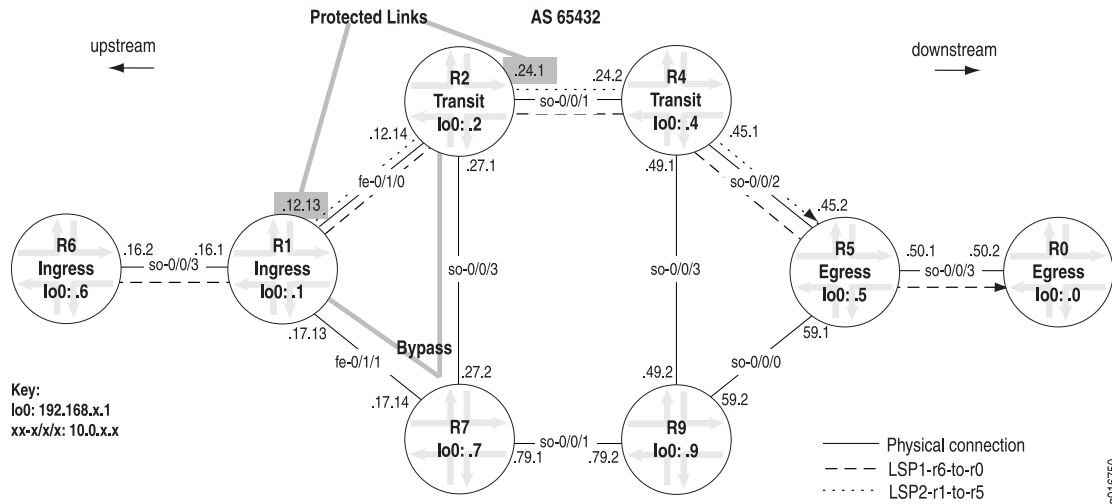

The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

Many-to-One Link Protection (Facility Backup) Overview

Many-to-one (facility backup) is based on interface rather than on LSP. While fast reroute protects interfaces or nodes along the entire path of a LSP, many-to-one protection can be applied on interfaces as needed, as shown in [Figure 147 on page 1906](#). In [Figure 147 on page 1906](#), a bypass path is set up around the link to

be protected (10.0.12.14) using an alternate interface to forward traffic. The bypass path is shared by all protected LSPs traversing the failed link (many LSPs protected by one bypass path).

Figure 147: Many-to-One or Link Protection

In Figure 147 on page 1906, two LSPs (lsp1-r6-to-r0 and lsp2-r1-to-r5) are protected by one preestablished bypass path from R1 to R2 through R7. Both LSPs have strict paths configured that go through interface fe-0/1/0. On R1, the interface 10.0.12.13 has link protection configured that protects the next hop 10.0.12.14.

Link protection (many-to-one or facility backup) allows a router immediately upstream from a link failure to use an alternate interface to forward traffic to its downstream neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link. A single bypass path can safeguard a set of protected LSPs. When an outage occurs, the router immediately upstream from the link outage switches protected traffic to the bypass link, then signals the link failure to the ingress router.

Like fast reroute, link protection provides local repair and restores connectivity faster than the ingress router switching traffic to a standby secondary path. However, unlike fast reroute, link protection does not provide protection against the failure of the downstream neighbor.

Link protection is appropriate in the following situations:

- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

Verify One-to-One Backup

Purpose

You can verify that one-to-one backup is established by examining the ingress router and the other routers in the network.

Action

To verify one-to-one backup, enter the following Junos OS CLI operational mode commands:

```
user@host> show mpls lsp ingress extensive
user@host> show RSVP session
```

Sample Output

The following sample output is from the ingress router **R1** :

```
user@R1> show mpls lsp ingress extensive
Ingress LSP: 1 sessions

```

Meaning

The sample output from **R1** shows that the **FastReroute desired** object was included in the Path messages for the LSP, allowing **R1** to select the active path for the LSP and establish a detour path to avoid **R2**.

In line 8, **Fast-reroute Detour Up** shows that the detour is operational. Lines 6 and 7 indicate that transit routers **R2** and **R4** have established their detour paths.

R2, 10.0.12.14, includes (**flag=9**), indicating that node protection is available for the downstream node and link. **R4, 10.0.24.2**, includes (**flag=1**), indicating that link protection is available for the next downstream link. In this case, **R4** can protect only the downstream link because the node is the egress router **R5**, which cannot be protected. For more information about flags, see the *Junos User Guide*.

The output for the **show mpls lsp extensive** command does not show the actual path of the detour. To see the actual links used by the detour paths, you must use the **show rsvp session ingress detail** command.

Sample Output

The following sample output is from the ingress router **R1** in the network shown in [Figure 163 on page 2163](#).

```
user@R1> show rsvp session ingress detail

```

Meaning

The sample output from **R2** shows the detour is established (**Detour is Up**) and avoids **R4**, and the link connecting **R4** and **R5 (10.0.45.2)**. The detour path is through **R7 (10.0.27.2)** and **R9 (10.0.79.2)** to **R5 (10.0.59.1)**, which is different from the explicit route for the detour from **R1**. **R1** has the detour passing through the **10.0.17.14** link on **R7**, while **R1** is using the **10.0.27.2** link. Both detours merge at **R9** through the **10.0.79.2** link to **R5 (10.0.59.1)**.

Sample Output

The following sample output is from the second transit router **R4** in the network shown in [Figure 163 on page 2163](#):

```

Record route: 10.0.17.13 <self> 10.0.79.2 10.0.59.1

```

Label in: 100752, Label out: 100368

Total 1 displayed, Up 1, Down 0

Meaning

The sample output from **R7** shows the same information as for a regular transit router used in the primary path of the LSP: the ingress address (**192.168.1.1**), the egress address (**192.168.5.1**), and the name of the LSP (**r1-to-r5**). Two detour paths are displayed; the first to avoid **R4** (**192.168.4.1**) and the second to avoid **R2** (**192.168.2.1**). Because **R7** is used as a transit router by **R2** and **R4**, **R7** can merge the detour paths together as indicated by the identical **Label out** value (**100368**) for both detour paths. Whether **R7** receives traffic from **R4** with a label value of **100736** or from **R2** with a label value of **100752**, **R7** forwards the packet to **R5** with a label value of **100368**.

Sample Output

The following sample output is from **R9**, which is a router used in the detour path in the network shown in [Figure 163 on page 2163](#):

```
user@R9> show rsvp session transit detail
```

```
Transit RSVP: 1 sessions, 1 detours
```

```

Label in: 100368, Label out: 3
Total 1 displayed, Up 1, Down 0

```

Meaning

The sample output from **R9** shows that **R9** is the penultimate router for the detour path, the explicit route includes only the egress link address (**10.0.59.1**), and the **Label out** value (**3**) indicates that **R9** has performed penultimate-hop label popping. Also, the detour branch from **10.0.27.1** does not include path information because **R7** has merged the detour paths from **R2** and **R4**. Notice that the **Label out** value in the detour branch from **10.0.17.13** is **100368**, the same value as the **Label out** value on **R7**.

Sample Output

The following sample output is from the egress router **R5** in the network shown in [Figure 163 on page 2163](#):

```

Meaning

The sample output from **R5** shows the main LSP in the **Record route** field and the detours through the network.

Verify That the Primary Path Is Operational

Purpose

Primary paths must always be used in the network if they are available, therefore an LSP always moves back to the primary path after a failure, unless the configuration is adjusted. For more information on

adjusting the configuration to prevent a failed primary path from reestablishing, see [“Preventing Use of a Path That Previously Failed”](#) on page 150.

Action

To verify that the primary path is operational, enter the following Junos OS command-line interface (CLI) operational mode commands:

```
user@host> show mpls lsp extensive ingress
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show mpls lsp extensive ingress
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
    ActivePath: via-r2 (primary)
    LoadBalance: Random
    Encoding type: Packet, Switching type: Packet, GPID: IPv4
*Primary via-r2           State: Up
    Priorities: 6 6
    Bandwidth: 35Mbps
    SmartOptimizeTimer: 180
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 11)
10.0.12.14 S 10.0.24.2 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt):

  SmartOptimizeTimer: 180
    No computed ERO.
  Created: Sat Apr 29 14:40:43 2006
Total 1 displayed, Up 1, Down 0
```

Sample Output 2

```
user@R1> show rsvp interface
RSVP interface: 3 active
```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample output 1 shows that the LSP is operational and is using the primary path (**via-r2**) with **R2 (10.0.12.14)** and **R4 (10.0.24.2)** as transit routers. The priority values are the same for setup and hold, **6 6**. Priority 0 is the highest (best) priority and 7 is the lowest (worst) priority. The Junos OS default for setup and hold priority is 7:0. Unless some LSPs are more important than others, preserving the default is a good practice. Configuring a setup priority that is better than the hold priority is not allowed, resulting in a failed commit in order to avoid preemption loops.

Verify That the Secondary Path Is Established

Purpose

When the secondary path is configured with the **standby** statement, the secondary path should be *up* but *not active*; it will become active if the primary path fails. A secondary path configured without the **standby** statement will not come up unless the primary path fails. To test that the secondary path is correctly configured and would come up if the primary path were to fail, you must deactivate a link or node critical to the primary path, then issue the **show mpls lsp *lsp-path-name* extensive** command.

Action

To verify that the secondary path is established, enter the following Junos OS CLI operational mode command:

Sample Output

```
user@R1> show mpls lsp extensive
```

Sample Output

The following sample output shows a correctly configured secondary path before and after it comes up. In the example, interface **fe-0/1/0** on **R2** is deactivated, which brings down the primary path **via-r2**. The ingress router **R1** switches traffic to the secondary path **via-r7**.

```

Total 1 displayed, Up 1, Down 0

Meaning

The sample output from egress router **R1** shows a correctly configured standby secondary path in a down state because the primary path is still up. Upon deactivation of an interface (**interface fe-0/1/0** on **R2**) critical to the primary path, the primary path **via-r2** goes down and the standby secondary path **via-r7** comes up, allowing **R1** to switch traffic to the standby secondary path.

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```

Meaning

Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-to-R1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only

one LSP is configured in the example network in [Figure 146 on page 1873](#). However, in a large network with many LSPs configured, the results would be quite different between the two commands.

Verify the LSP Route on the Transit Router

Purpose

If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

Action

To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

Sample Output 1

```
user@R3> show route table mpls.0
```

```
mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 21:52:40, metric 1
           Receive
1          *[MPLS/0] 16w2d 21:52:40, metric 1
           Receive
2          *[MPLS/0] 16w2d 21:52:40, metric 1
           Receive
```

Sample Output 2

```
user@R3> show route table mpls.0
```

```
mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

0          *[MPLS/0] 16w2d 22:26:08, metric 1
           Receive
1          *[MPLS/0] 16w2d 22:26:08, metric 1
           Receive
2          *[MPLS/0] 16w2d 22:26:08, metric 1
           Receive
100864     *[RSVP/7] 00:07:23, metric 1
           > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0) *[RSVP/7] 00:07:23, metric 1
           > via so-0/0/2.0, label-switched-path R6-to-R1
100880     *[RSVP/7] 00:07:01, metric 1
           > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0) *[RSVP/7] 00:07:01, metric 1
           > via so-0/0/3.0, label-switched-path R1-to-R6

```

Meaning

Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see [“Checklist for Verifying LSP Use” on page 2090](#).

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries represent two routes. There are two entries per route because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

Verify the LSP Route on the Ingress Router

Purpose

Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

Action

To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

Sample Output 1

```
user@R1> show route 10.0.0.6
```

```
inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.6/32      *[IS-IS/18] 6d 01:41:37, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0
```

```
user@R6> show route 10.0.0.1
```

```
inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32      *[IS-IS/18] 5d 01:01:38, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0
```

Sample Output 2

```
user@R1> show route 10.0.0.6
```

```
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32      *[IS-IS/18] 6d 02:13:42, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

10.0.0.6/32          *[RSVP/7] 00:08:07, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6

user@R6> show route 10.0.0.1

inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32          *[IS-IS/18] 5d 01:34:03, metric 20
                    to 10.1.56.1 via so-0/0/0.0
                    > to 10.1.26.1 via so-0/0/2.0
                    to 10.1.36.1 via so-0/0/3.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32          *[RSVP/7] 00:10:39, metric 20
                    > via so-0/0/3.0, label-switched-path R6-to-R1

```

Meaning

Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in [Figure 146 on page 1873](#).

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

Verify MPLS Labels with the traceroute Command

Purpose

Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is

mapped to IGP routes, not to the LSP. Use the **tracert** command as a debugging tool to determine whether the LSP is being used to forward traffic.

Action

To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

Sample Output 2

```
user@R1> traceroute 100.100.6.1
to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
    MPLS Label=100912 CoS=0 TTL=1 S=1
 2  10.1.36.2 (10.1.36.2)  0.577 ms !N  0.597 ms !N  0.546 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.36.1 (10.1.36.1)  0.802 ms  0.716 ms  0.688 ms
    MPLS Label=100896 CoS=0 TTL=1 S=1
 2  10.1.13.1 (10.1.13.1)  0.570 ms !N  0.568 ms !N  0.546 ms !N
```

Meaning

Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in [Figure 146 on page 1873](#)) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

Verify MPLS Labels with the ping Command

Purpose

When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

Action

To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

Sample Output 1

```
user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.
```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
```

```

1  10.1.15.2 (10.1.15.2)  0.708 ms  0.613 ms  0.576 ms
2  10.0.0.6 (10.0.0.6)  0.763 ms  0.708 ms  0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 69, label 100880
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 69, label 100880
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 69, label 100880
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

user@R6> ping mpls rsvp R6-to-R1 detail
Request for seq 1, to interface 70, label 100864
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 70, label 100864
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 70, label 100864
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 70, label 100864
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 70, label 100864
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

Meaning

Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the `[edit protocols mpls]` hierarchy level on egress router **R6**.

Solution

To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
user@R6# activate interface so-0/0/3
```

```
[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
  to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete
```

Meaning

The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the **[edit protocols mpls]** hierarchy level. The LSP can now come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

Action

To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Checklist for Working with the Layered MPLS Troubleshooting Model

Problem

Description: This checklist provides a link to more detailed information about the layered Multiprotocol Label Switching network.

Solution

[Table 51 on page 1935](#) provides commands for working with the layered MPLS troubleshooting model.

Table 51: Checklist for Working with the Layered MPLS Troubleshooting Model

Tasks	Command or Action
“Understanding the Layered MPLS Troubleshooting Model” on page 1935	show mpls lsp show mpls lsp extensive show mpls lsp name <i>name</i> show mpls lsp name <i>name</i> extensive

Understanding the Layered MPLS Troubleshooting Model

Problem

Description: The layered MPLS troubleshooting model is a disciplined approach to investigating problems with an MPLS network. [Figure 148 on page 1936](#) illustrates the layers in the model, and the commands you can use to structure your investigation. Because of the complexity of the MPLS network, you can obtain much better results from your investigations if you progress through the layers and verify the functioning of each layer on the ingress, egress, and transit routers before moving on to the next layer.

Solution

[Figure 148 on page 1936](#) shows the layered MPLS troubleshooting model that you can use to troubleshoot problems with your MPLS network.

Figure 148: Layered MPLS Network Troubleshooting Model

BGP Layer	traceroute <i>host-name</i> show bgp summary show configuration protocols bgp show route <i>destination-prefix</i> detail show route receive protocol bgp <i>neighbor-address</i>
MPLS Layer	show mpls lsp show mpls lsp extensive show route table mpls.0 show route <i>address</i> traceroute <i>address</i> ping mpls rsvp <i>lsp-name</i> detail
RSVP Layer	show rsvp session show rsvp neighbor show rsvp interface
<div>↩</div> IGP and IP Layers Functioning <div>↪</div>	
OSPF Layer show ospf neighbor show configuration protocols ospf show ospf interface	IS-IS Layer show isis adjacency show configuration protocols isis show isis interface
IP Layer show ospf neighbor extensive show interfaces terse	IP Layer show isis adjacency extensive show interfaces terse
Data Link Layer	show interfaces extensive <i>JUNOS Interfaces Network Operations Guide</i>
Physical Layer	show interfaces show interfaces terse ping <i>host</i>

g015528

As you move from one layer of the model to the next, you verify the correct functioning of a different component of the MPLS network and eliminate that layer as the source of the problem.

Physical Layer

When you investigate the physical layer, you check that the routers are connected, and the interfaces are up and configured correctly. To check the physical layer, enter the **show interfaces**, **show interfaces terse**, and **ping** commands. If there is a problem in the physical layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information on checking the physical layer, see [“Checklist for Verifying the Physical Layer” on page 1943](#).

Data Link Layer

When you investigate the data link layer, you check the encapsulation mode, for example, Point-to-Point Protocol (PPP) or Cisco High-Level Data Link Control (HDLC); PPP options, for example, header encapsulation; frame check sequence (FCS) size; and whether keepalive frames are enabled or disabled. To check the data link layer, enter the **show interfaces extensive** command. If there is a problem in the data link layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information on checking the data link layer, see [“Checking the Data Link Layer” on page 1961](#) and the *Junos Interfaces Operations Guide*.

IP Layer

When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that the interior gateway protocol (IGP) neighbor adjacencies are established. To check the IP layer, enter the **show**

interfaces terse, **show ospf neighbor extensive**, and **show isis adjacency extensive** commands. If there is a problem in the IP layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command.

IGP Layer

When you investigate the IGP layer, you verify that the the Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) protocols are configured and running correctly.

- If you have the OSPF protocol configured, you must check the IP layer first, and then the OSPF configuration. When you investigate the OSPF layer, you check that the protocol, interfaces, and traffic engineering are configured correctly. To check the OSPF layer, enter the **show configuration protocols ospf** and **show ospf interface** commands. If the problem exists in the OSPF layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information about checking the OSPF layer, see [“Verifying the OSPF Protocol” on page 2019](#).
- If you have the IS-IS protocol configured, because IS-IS and IP are independent of each other, it doesn't matter which one you check first. When you check the IS-IS configuration, you verify that IS-IS adjacencies are up, and the interfaces and IS-IS protocol are configured correctly. To check the IS-IS layer, enter the **show isis adjacency**, **show configuration protocols isis**, and **show isis interfaces** commands. If the problem exists in the IS-IS layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command. For more information about checking the IS-IS layer, see *Verifying the IS-IS Protocol*.

NOTE: The IS-IS protocol has traffic engineering enabled by default.

RSVP and MPLS Layers

After you have both the IP and IGP layers functioning and the problem is still not solved, you can begin to check the Resource Reservation Protocol (RSVP) and MPLS layers to determine if the problem is in one of these layers.

- When you investigate the RSVP layer, you are checking that dynamic RSVP signaling is occurring as expected, neighbors are connected, and interfaces are configured correctly for RSVP. To check the RSVP layer, enter the **show rsvp session**, **show rsvp neighbor**, and **show rsvp interface** commands. If there is a problem in the RSVP layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command.
- When you investigate the MPLS layer, you are checking whether the LSP is up and functioning correctly. To check the MPLS layer, enter the **show mpls lsp**, **show mpls lsp extensive**, **show route table mpls.0**, **show route address**, **traceroute address**, and **ping mpls rsvp lsp-name detail** commands. If there is a problem in the MPLS layer, take appropriate action to fix it; then check that the LSP is operating as expected using the **show mpls lsp extensive** command.

BGP Layer

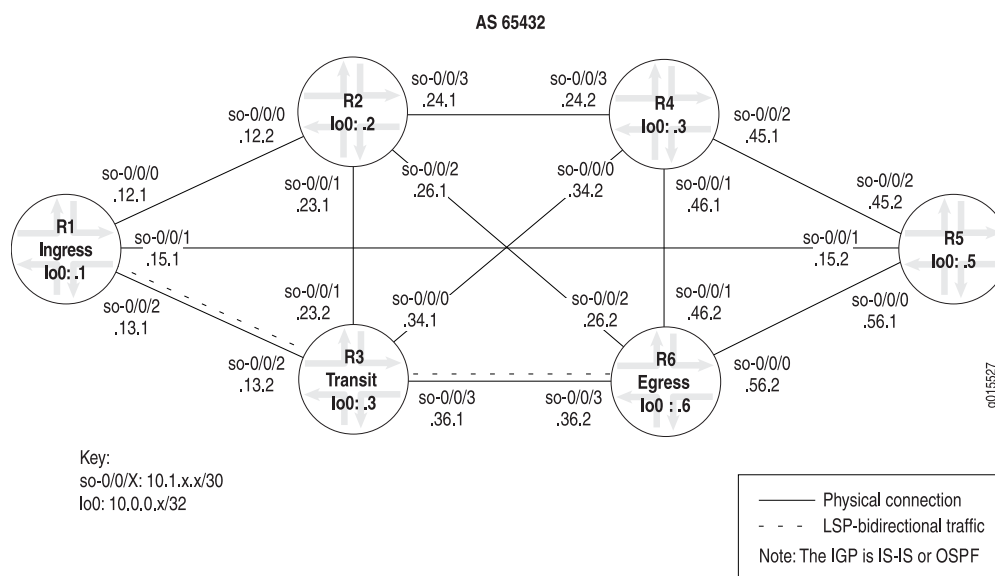

If the problem persists after you have checked the RSVP and MPLS layers, you must verify that the Border Gateway Protocol (BGP) is working correctly. There is no point in checking the BGP layer unless the LSP is established because BGP uses the MPLS LSP to forward traffic. When you check the BGP layer, you verify that the route is present and active, and more importantly, you ensure that the next hop is the LSP. To check the BGP layer, enter the **traceroute host-name**, **show bgp summary**, **show configuration protocols bgp**, **show route destination-prefix detail**, and **show route receive protocol bgp neighbor-address** commands. For more information on checking the BGP layer, see *Checking the BGP Layer*.

In reality, you could start at any level of the MPLS model to investigate a problem with your MPLS network. However, a disciplined approach, as the one described here, produces more consistent and reliable results.

Figure 149 on page 1938 illustrates the basic network topology used in the following topics that demonstrate how to troubleshoot an MPLS network:

- [Checklist for Verifying the Physical Layer on page 1943](#)
- [Checklist for Checking the Data Link Layer on page 1960](#)
- [Checklist for Verifying the IP and IGP Layers on page 1988](#)
- [Checklist for Checking the RSVP Layer on page 2055](#)
- [Checklist for Checking the MPLS Layer on page 1871](#)
- *Checklist for Checking the BGP Layer*

Figure 149: MPLS Basic Network Topology Example

The MPLS network consists of the following components:

- Router-only network with SONET interfaces
- MPLS protocol enabled on all routers, with interfaces selectively deactivated to illustrate a particular problem scenario
- All interfaces configured with MPLS
- A full-mesh IBGP topology, using AS 65432
- IS-IS or OSPF as the underlying IGP, using one level (IS-IS Level 2) or one area (OSPF area 0.0.0.0)
- A **send-statics** policy on routers R1 and R6, allowing a new route to be advertised into the network
- Two LSPs between routers R1 and R6, allowing for bidirectional traffic.

After you have configured an LSP, it is considered best practice to issue the **show mpls lsp** command to verify that the LSP is up, and to investigate further if you find an error message in the output. The error message can indicate a problem at any layer of the MPLS network.

The LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive**) as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To begin the investigation of an error in your MPLS network, from the ingress router, enter some or all of the following Junos OS command-line interface (CLI) operational mode commands:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```
user@R1> show mpls lsp

```

Meaning

The sample output from the ingress router **R1** shows that the label-switched path is traversing the network as intended, from **R1** through **R3** to **R6**, and another LSP in the reverse direction, from **R6** through **R3** to **R1**.

If your network has numerous LSPs, you might consider using the **show mpls lsp** command for quick verification of the LSP state. and the **show mpls lsp name *name* extensive** command to continue your investigation if you find that the LSP is down.

For more information about the status and statistics of the **show mpls lsp** command, see [“Checklist for Determining LSP Status” on page 2087](#). For more information on the availability and valid use of an LSP, see [“Checklist for Verifying LSP Use” on page 2090](#).

In all the following topics, the network topology is broken at different layers of the network so that you can investigate various MPLS network problems. The problems presented are not inclusive. Instead, the problems serve to illustrate one possible process of investigation into the different layers of the troubleshooting model.

Checklist for Verifying the Physical Layer

Problem

Description: This checklist provides the steps and commands for investigating a problem at the physical layer of a Multiprotocol Label Switching (MPLS) network. The checklist provides links to an overview of verifying the physical layer and more detailed information about the commands used to investigate the problem.

Solution

[Table 52 on page 1943](#) provides commands for verifying the physical layer.

Table 52: Checklist for Verifying the Physical Layer

Tasks	Command or Action
“Verifying the Physical Layer” on page 1944	
1. Verify the LSP on page 1946	show mpls lsp extensive
2. Verify Router Connection on page 1948	ping host
3. Verify Interfaces on page 1949	show interfaces terse show configuration interfaces type-fpc/pic/port

Tasks	Command or Action
4. Take Appropriate Action on page 1950	<p>The following sequence of commands addresses the specific problem described in this topic:</p> <pre>[edit interfaces <i>type-fpc/pic/port</i>] set family mpls show commit</pre>
5. Verify the LSP Again on page 1951	<pre>show mpls lsp extensive</pre>

Verifying the Physical Layer

Purpose

After you have configured the LSP, issued the **show mpls lsp extensive** command, and determined that there is an error, you can start investigating the problem at the physical layer of the network.

[Figure 150 on page 1945](#) illustrates the physical layer of the layered MPLS model.

g015543

With this layer, you must ensure that the routers are connected, and that the interfaces are up and configured correctly on the ingress, egress, and transit routers.

If the network is not functioning at this layer, the label-switched path (LSP) does not work as configured.

[Figure 151 on page 1946](#) illustrates the MPLS network and the problem described in this topic.

Figure 151: MPLS Network Broken at the Physical Layer

The network shown in [Figure 151 on page 1946](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, traffic does not use the configured LSP. Instead traffic uses the alternate route from **R1** through **R2** to **R6**, and in the reverse direction, from **R6** through **R5** to **R1**.

When you become aware of a situation where an alternate route is used rather than the configured LSP, verify that the physical layer is functioning correctly. You might find that routers are not connected, or that interfaces are not up and configured correctly on the ingress, egress, or transit routers.

The cross shown in [Figure 151 on page 1946](#) indicates where the LSP is broken because of a configuration error on ingress router **R1**.

To check the physical layer, follow these steps:

1. [Verify the LSP | 1946](#)
2. [Verify Router Connection | 1948](#)
3. [Verify Interfaces | 1949](#)
4. [Take Appropriate Action | 1950](#)
5. [Verify the LSP Again | 1951](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However, for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@ingress-router> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

The sample output from ingress router **R1** shows that the LSP is using an alternate path rather than the configured path. The configured path for the LSP is **R1** through **R3** to **R6**, and for the reverse LSP, **R6** through **R3** to **R1**. The alternate path used by the LSP is **R1** through **R2** to **R6**, and for the reverse LSP, **R6** through **R5** to **R1**.

Verify Router Connection

Purpose

Confirm that the appropriate ingress, transit, and egress routers are functioning by examining whether the packets have been received and transmitted with 0% packet loss.

Action

To determine that the routers are connected, enter the following command from the ingress and transit routers:

```
user@host> ping host
```

Sample Output

```

user@R1> ping 10.0.0.3 count 3
PING 10.0.0.3 (10.0.0.3): 56 data bytes
64 bytes from 10.0.0.3: icmp_seq=0 ttl=254 time=0.859 ms
64 bytes from 10.0.0.3: icmp_seq=1 ttl=254 time=0.746 ms
64 bytes from 10.0.0.3: icmp_seq=2 ttl=254 time=0.776 ms

--- 10.0.0.3 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.746/0.794/0.859/0.048 ms

user@R3> ping 10.0.0.6 count 3
PING 10.0.0.6 (10.0.0.6): 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=0 ttl=255 time=0.968 ms
64 bytes from 10.0.0.6: icmp_seq=1 ttl=255 time=3.221 ms
64 bytes from 10.0.0.6: icmp_seq=2 ttl=255 time=0.749 ms

--- 10.0.0.6 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.749/1.646/3.221/1.117 ms

```

Meaning

The sample output shows that ingress router **R1** is receiving packets from transit router **R3**, and that the transit router is receiving packets from the egress router. Therefore, the routers in the LSP are connected.

Verify Interfaces

Purpose

Confirm that the interfaces are configured correctly with the **family mpls** statement.

Action

To determine that the relevant interfaces are up and configured correctly, enter the following commands from the ingress, transit, and egress routers:

```

user@host> show interfaces terse
user@host> show configuration interfaces type-fpc/pic/port

```

Sample Output

```

user@R1> show interfaces so* terse
Interface          Admin Link Proto Local          Remote
so-0/0/0           up   up
so-0/0/0.0         up   up   inet  10.1.12.1/30
                               iso
                               mpls

}

```

Meaning

The sample output shows that interface **so-0/0/2.0** on the ingress router does not have the **family mpls** statement configured at the **[edit interfaces type-fpc/pic/port]** hierarchy level, indicating that the interface is incorrectly configured to support the LSP. The LSP is configured correctly at the **[edit protocols mpls]** hierarchy level.

The output from the transit and egress routers (not shown) shows that the interfaces on those routers are configured correctly.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the **family mpls** statement, which was missing, is included in the configuration of ingress router **R1**.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces type-fpc/pic/port]  
user@R1# set family mpls  
user@R1# show  
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2 unit 0]  
user@R1# set family mpls  
  
[edit interfaces so-0/0/2 unit 0]  
user@R1# show  
family inet {  
    address 10.1.13.1/30;  
}  
family iso;  
family mpls;  
  
[edit interfaces so-0/0/2 unit 0]  
user@R1# commit  
commit complete
```

Meaning

The sample output from ingress router **R1** shows that the **family mpls** statement is configured correctly for interface **so-0/0/2.0**, and that the LSP is now functioning as originally configured.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the physical layer has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

Sample Output 1 from ingress router **R1** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 2 from ingress router **R1** shows that the LSP is forced to take the intended path because MPLS is deactivated on **R1** interfaces **so-0/0/0.0** and **so-0/0/1.0**. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However, for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@ingress-router> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows that the LSP is using an alternate path rather than the configured path. The configured path for the LSP is **R1** through **R3** to **R6**, and for the reverse LSP, **R6** through **R3** to **R1**. The alternate path used by the LSP is **R1** through **R2** to **R6**, and for the reverse LSP, **R6** through **R5** to **R1**.

Verify Router Connection

Purpose

Confirm that the appropriate ingress, transit, and egress routers are functioning by examining whether the packets have been received and transmitted with 0% packet loss.

Action

To determine that the routers are connected, enter the following command from the ingress and transit routers:

```
user@host> ping host
```

Sample Output

```

user@R1> ping 10.0.0.3 count 3
PING 10.0.0.3 (10.0.0.3): 56 data bytes
64 bytes from 10.0.0.3: icmp_seq=0 ttl=254 time=0.859 ms

```

```

64 bytes from 10.0.0.3: icmp_seq=1 ttl=254 time=0.746 ms
64 bytes from 10.0.0.3: icmp_seq=2 ttl=254 time=0.776 ms

--- 10.0.0.3 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.746/0.794/0.859/0.048 ms

user@R3> ping 10.0.0.6 count 3
PING 10.0.0.6 (10.0.0.6): 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=0 ttl=255 time=0.968 ms
64 bytes from 10.0.0.6: icmp_seq=1 ttl=255 time=3.221 ms
64 bytes from 10.0.0.6: icmp_seq=2 ttl=255 time=0.749 ms

--- 10.0.0.6 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.749/1.646/3.221/1.117 ms

```

Meaning

The sample output shows that ingress router **R1** is receiving packets from transit router **R3**, and that the transit router is receiving packets from the egress router. Therefore, the routers in the LSP are connected.

Verify Interfaces

Purpose

Confirm that the interfaces are configured correctly with the **family mpls** statement.

Action

To determine that the relevant interfaces are up and configured correctly, enter the following commands from the ingress, transit, and egress routers:

```

user@host> show interfaces terse
user@host> show configuration interfaces type-fpc/pic/port

```

Sample Output

```

user@R1> show interfaces so* terse

```

Interface	Admin	Link	Proto	Local	Remote

```

so-0/0/0          up    up
so-0/0/0.0        up    up    inet  10.1.12.1/30
                               iso
                               mpls

so-0/0/1          up    up
so-0/0/1.0        up    up    inet  10.1.15.1/30
                               iso
                               mpls

so-0/0/2          up    up
so-0/0/2.0        up    up    inet  10.1.13.1/30
                               iso    <<< family mpls is missing

so-0/0/3          up    down

user@R1> show configuration interfaces so-0/0/2
unit 0 {
    family inet {
        address 10.1.13.1/30;
    }
    family iso; <<< family mpls is missing
}

```

Meaning

The sample output shows that interface **so-0/0/2.0** on the ingress router does not have the **family mpls** statement configured at the [edit interfaces type-fpc/pic/port] hierarchy level, indicating that the interface is incorrectly configured to support the LSP. The LSP is configured correctly at the [edit protocols mpls] hierarchy level.

The output from the transit and egress routers (not shown) shows that the interfaces on those routers are configured correctly.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the **family mpls** statement, which was missing, is included in the configuration of ingress router **R1**.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces type-fpc/pic/port]
user@R1# set family mpls
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2 unit 0]
user@R1# set family mpls

[edit interfaces so-0/0/2 unit 0]
user@R1# show
family inet {
    address 10.1.13.1/30;
}
family iso;
family mpls;

[edit interfaces so-0/0/2 unit 0]
user@R1# commit
commit complete
```

Meaning

The sample output from ingress router **R1** shows that the **family mpls** statement is configured correctly for interface **so-0/0/2.0**, and that the LSP is now functioning as originally configured.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the physical layer has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive

Meaning

Sample Output 1 from ingress router **R1** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 2 from ingress router **R1** shows that the LSP is forced to take the intended path because MPLS is deactivated on **R1** interfaces **so-0/0/0.0** and **so-0/0/1.0**. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Checklist for Checking the Data Link Layer

Problem

Description: This checklist provides the steps and commands for investigating a problem at the data link layer of the Multiprotocol Label Switching (MPLS) network. The checklist provides links to an overview of the data link layer and more detailed information about the commands used to investigate the problem.

Solution

[Table 53 on page 1961](#) provides commands for checking the data link layer.

Table 53: Checklist for Checking the Data Link Layer

Tasks	Command or Action
“Checking the Data Link Layer” on page 1961	
1. Verify the LSP on page 1963	show mpls lsp extensive
2. Verify Interfaces on page 1964	show interfaces <i>type-fpc/pic/port</i> extensive show interfaces <i>type-fpc/pic/port</i>
3. Take Appropriate Action on page 1969	The following sequence of commands addresses the specific problem described in this topic: [edit interfaces <i>type-fpc/pic/port</i>] show delete encapsulation show commit
4. Verify the LSP Again on page 1970	show mpls lsp extensive

Checking the Data Link Layer

Purpose

After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical layer. Continue investigating the problem at the data link layer of the network.

[Figure 152 on page 1962](#) illustrates the data link layer of the layered MPLS model.

Figure 152: Checking the Data Link Layer

BGP Layer	tracroute <i>host-name</i> show bgp summary show configuration protocols bgp show route <i>destination-prefix</i> detail show route receive protocol bgp <i>neighbor-address</i>
MPLS Layer	show mpls lsp show mpls lsp extensive show route table mpls.0 show route <i>address</i> tracroute <i>address</i> ping mpls rsvp <i>lsp-name</i> detail
RSVP Layer	show rsvp session show rsvp neighbor show rsvp interface
↩ IGP and IP Layers Functioning ↪	
OSPF Layer show ospf neighbor show configuration protocols ospf show ospf interface	IS-IS Layer show isis adjacency show configuration protocols isis show isis interface
IP Layer show ospf neighbor extensive show interfaces terse	IP Layer show isis adjacency extensive show interfaces terse
Data Link Layer	show interfaces extensive "JUNOS Interfaces Operations Guide"
Physical Layer	show interfaces show interfaces terse ping <i>host</i>

With this layer, you must check the encapsulation mode, for example, Point-to-Point Protocol (PPP) or Cisco High-Level Data Link Control (HDLC); PPP options, for example, header encapsulation; frame check sequence (FCS) size; and whether keepalive frames are enabled or disabled. Also, check the ingress, egress, and transit routers.

Figure 153 on page 1962 illustrates the MPLS network used in this topic.

Figure 153: MPLS Network Broken at the Data Link Layer

The network shown in [Figure 153 on page 1962](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

When you verify that the data link layer is not functioning correctly, you might find a mismatch with PPP or Cisco HDLC encapsulation, PPP options, or keepalive frames.

The cross shown in [Figure 153 on page 1962](#) indicates where the LSP is broken because of a configuration error on ingress router **R1** that prevents the LSP from traversing the network as expected.

To check the data link layer, follow these steps:

1. [Verify the LSP | 1963](#)
2. [Verify Interfaces | 1964](#)
3. [Take Appropriate Action | 1969](#)
4. [Verify the LSP Again | 1970](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
```

```

Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows the LSPs within which it participates. The ingress LSP is down, without a path from **R1** to **R6**. Because a reverse LSP is configured in the network shown in [Figure 153 on page 1962](#), we would expect an egress LSP session to be up. However, **R1** does not have any egress LSPs, indicating that the LSP from **R6** to **R1** is not functioning.

Verify Interfaces

Purpose

From your network topology, determine the adjacent interfaces through which the LSP is meant to traverse, and examine the output for the encapsulation type, PPP options, FCS size, and whether keepalive frames are enabled or disabled

NOTE: Before you proceed with this step, check the physical layer to ensure that the problem is not in the physical layer.

Action

To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show interfaces type-fpc/pic/port extensive
user@host> show interfaces type-fpc/pic/port
```

Sample Output 1

```
user@R6> show interfaces so-0/0/3 extensive
Physical interface: so-0/0/3, Enabled, Physical link is Up
  Interface index: 131, SNMP ifIndex: 27, Generation: 14
    Link-level type: Cisco-HDLC , MTU: 4474, Clocking: Internal, SONET mode, Speed: OC3,
    Loopback: None,
    FCS: 16 , Payload scrambler: Enabled
    Device flags      : Present Running

SONET alarms     : None
SONET defects    : None

```

Logical interface so-0/0/3.0 (Index 70) (SNMP ifIndex 51)

Flags: Point-To-Point SNMP-Traps **Encapsulation: PPP**

Protocol inet, MTU: 4470

Flags: None

Addresses, Flags: Is-Preferred Is-Primary

Destination: 10.1.36.0/30, Local: 10.1.36.1, Broadcast: 10.1.36.3

Protocol iso, MTU: 4470

Flags: None

Protocol mpls, MTU: 4458

Flags: None

Meaning

Sample Output 1 from egress router **R6** shows that there are no SONET alarms or defects (**none**), the states are all **OK**, and the path trace shows the distant end (**R3 so-0.0.0**), indicating that the physical link is up. However, the logical link is down, and the link-level type is Cisco HDLC.

Sample Output 2 from transit router **R3** shows that the link-level type is PPP, indicating that the encapsulation types are mismatched, resulting in the LSP going down.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the encapsulation types are mismatched.

Solution

To correct the error in this example, enter the following commands:

```

[edit interfaces so-0/0/3]
user@R1# show
user@R1# delete encapsulation
user@R1# show
user@R1# commit

```

Sample Output

```
[edit interfaces so-0/0/3]
user@R6# show
encapsulation cisco-hdlc;
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# delete encapsulation

[edit interfaces so-0/0/3]
user@R6# show
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# commit
commit complete
```

Meaning

The sample output from egress router **R6** shows that the Cisco HDLC was incorrectly configured on interface **so-0/0/3** which prevented the LSP from using the intended path. The problem was corrected when the **encapsulation** statement was deleted and the configuration committed.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the data link layer has been resolved.

Action

From the ingress, egress, and transit routers, verify that the LSP is up and traversing the network as expected:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample Outputs 1 and 2 from ingress router **R1** and egress router **R6**, respectively, show that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 3 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**.

Sample Output 4 shows the interfaces that were deactivated on the ingress, egress, and transit routers, forcing the LSP to take the intended path. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

The sample output from ingress router **R1** shows the LSPs within which it participates. The ingress LSP is down, without a path from **R1** to **R6**. Because a reverse LSP is configured in the network shown in [Figure](#)

153 on page 1962, we would expect an egress LSP session to be up. However, **R1** does not have any egress LSPs, indicating that the LSP from **R6** to **R1** is not functioning.

Verify Interfaces

Purpose

From your network topology, determine the adjacent interfaces through which the LSP is meant to traverse, and examine the output for the encapsulation type, PPP options, FCS size, and whether keepalive frames are enabled or disabled

NOTE: Before you proceed with this step, check the physical layer to ensure that the problem is not in the physical layer.

Action

To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show interfaces type-fpc/pic/port extensive
user@host> show interfaces type-fpc/pic/port
```

Sample Output 1

```
user@R6> show interfaces so-0/0/3 extensive
Physical interface: so-0/0/3, Enabled, Physical link is Up
  Interface index: 131, SNMP ifIndex: 27, Generation: 14

```

Meaning

Sample Output 1 from egress router **R6** shows that there are no SONET alarms or defects (**none**), the states are all **OK**, and the path trace shows the distant end (**R3 so-0.0.0**), indicating that the physical link is up. However, the logical link is down, and the link-level type is Cisco HDLC.

Sample Output 2 from transit router **R3** shows that the link-level type is PPP, indicating that the encapsulation types are mismatched, resulting in the LSP going down.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the encapsulation types are mismatched.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/3]
user@R1# show
user@R1# delete encapsulation
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/3]
user@R6# show
encapsulation cisco-hdlc;
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# delete encapsulation

[edit interfaces so-0/0/3]
user@R6# show
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# commit
commit complete
```

Meaning

The sample output from egress router **R6** shows that the Cisco HDLC was incorrectly configured on interface **so-0/0/3** which prevented the LSP from using the intended path. The problem was corrected when the **encapsulation** statement was deleted and the configuration committed.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the data link layer has been resolved.

Action

From the ingress, egress, and transit routers, verify that the LSP is up and traversing the network as expected:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
```

```
Ingress LSP: 1 sessions
```

```

Meaning

Sample Outputs 1 and 2 from ingress router **R1** and egress router **R6**, respectively, show that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 3 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**.

Sample Output 4 shows the interfaces that were deactivated on the ingress, egress, and transit routers, forcing the LSP to take the intended path. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Checklist for Verifying the IP and IGP Layers

Problem

Description: This checklist provides the steps and commands for investigating a problem at the Internet Protocol (IP) and interior gateway protocol (IGP) layers of the layered Multiprotocol Label Switching (MPLS) model. The checklist provides links to an overview of the IP and IGP layers and more detailed information about the commands used to investigate the problem.

Solution

Table 54 on page 1988 provides commands for verifying the IP and IGP layers.

Table 54: Checklist for Verifying the IP and IGP Layers

Tasks	Command or Action
“Verifying the IP and IGP Layers” on page 1990	
“Verifying the IP Layer” on page 1992	
1. Verify the LSP on page 1993	<code>show mpls lsp extensive</code>
2. Verify IP Addressing on page 1994	<code>show interfaces terse</code>
3. Verify Neighbors or Adjacencies at the IP Layer on page 1996	<code>show ospf neighbor extensive</code> <code>show isis adjacency extensive</code>
4. Take Appropriate Action on page 2000	The following sequence of commands addresses the specific problem described in this topic: [edit interfaces so-0/0/2] <code>show</code> <code>rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30</code> <code>show</code> <code>commit</code>
5. Verify the LSP Again on page 2002	<code>show mpls lsp extensive</code>
“Verifying the OSPF Protocol” on page 2019

Verifying the IP and IGP Layers

Problem

Description: After you have configured the label-switched path (LSP), issued the `show mpls lsp extensive` command, and determined that there is an error, you might find that the error is not in the physical or data link layers. Continue investigating the problem at the IP and IGP layers of the network.

[Figure 154 on page 1990](#) illustrates the IP and IGP layers of the layered MPLS model.

Solution

At the IP and IGP layers, you must check the following:

- Interfaces have correct IP addressing, and the IGP neighbors or adjacencies are established.

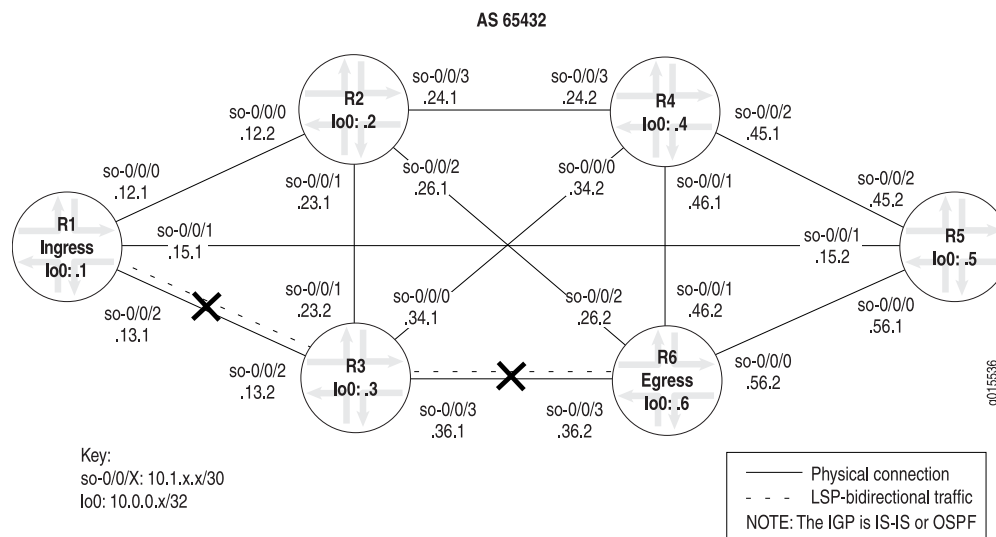

- Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) protocols are configured and running correctly.
- If the OSPF protocol is configured, check the IP layer first, then the OSPF configuration, making sure that the protocol, interfaces, and traffic engineering are configured correctly.
- If the IS-IS protocol is configured, it doesn't matter whether you check IS-IS or IP first because both protocols are independent of each other. Verify that IS-IS adjacencies are up, and that the interfaces and IS-IS protocol are configured correctly.

NOTE: The IS-IS protocol has traffic engineering enabled by default.

If the network is not functioning at the IP or IGP layers, the LSP does not work as configured.

Figure 155 on page 1991 illustrates the MPLS network used in this topic.

Figure 155: MPLS Network Broken at the IP and IGP Layers

The network shown in Figure 155 on page 1991 is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6**, through **R3**, to **R1**, creating bidirectional traffic. The crosses in Figure 155 on page 1991 indicate where the LSP is not working because of the following problems at the IP and IGP layer:

- An IP address is configured incorrectly on the ingress router (**R1**).
- The OSPF protocol is configured with a router ID (RID) but without the loopback (**lo0**) interface, and traffic engineering is missing from the transit router (**R3**).

- Levels in the IS-IS network are mismatched.

RELATED DOCUMENTATION

To check the IP and IGP layers, follow these steps:

[Verifying the IP Layer | 1992](#)

[Verifying the OSPF Protocol | 2019](#)

Verifying the IS-IS Protocol

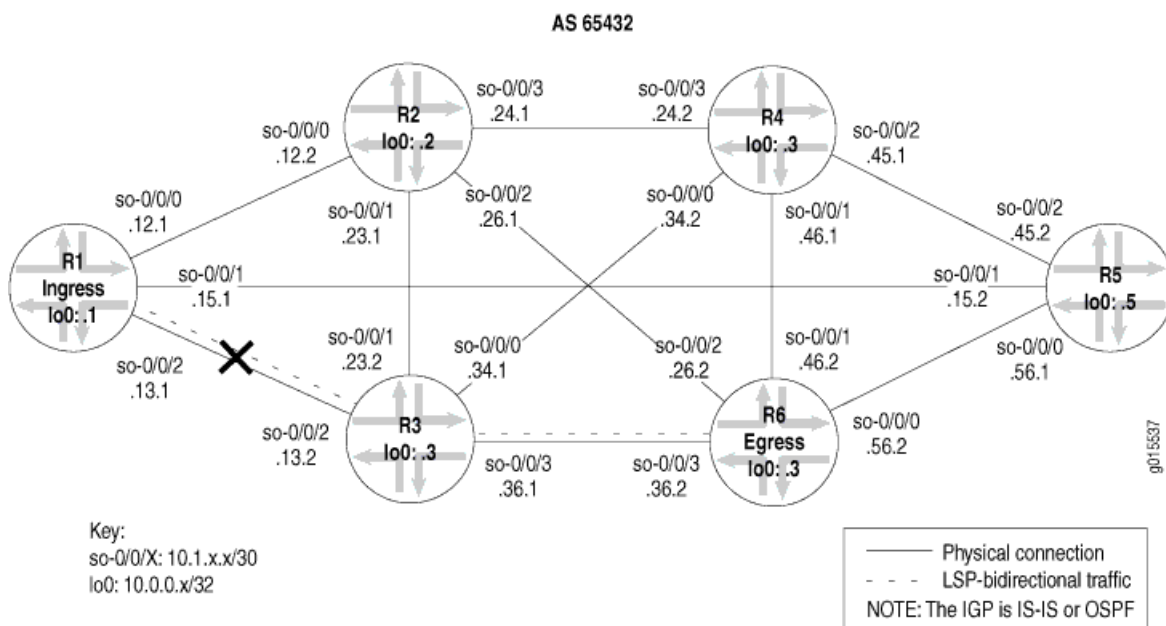

Verifying the IP Layer

Purpose

You can check the IP layer before or after you check the interior gateway protocol (IGP) layer, depending on whether you have OSPF or IS-IS configured as the IGP. If your MPLS network is configured with OSPF as the IGP, you must first verify the IP layer, checking that the interfaces have correct IP addressing and that the OSPF neighbors are established before you check the OSPF layer.

If you have IS-IS configured as the IGP in your MPLS network, you can verify either the IP layer or the IS-IS protocol layer first. The order in which you check the IP or IS-IS layer does not affect the results.

Figure 156: MPLS Network Broken at the IP Layer

The cross in [Figure 156 on page 1992](#) indicates where the LSP is broken because of the incorrect configuration of an IP address on ingress router **R1**.

1. [Verify the LSP | 1993](#)
2. [Verify IP Addressing | 1994](#)
3. [Verify Neighbors or Adjacencies at the IP Layer | 1996](#)
4. [Take Appropriate Action | 2000](#)
5. [Verify the LSP Again | 2002](#)

Verify the LSP

Purpose

After configuring the LSP, you must verify that the LSP is up. LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive**) as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To verify that the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn
    Will be enqueued for recomputation in 25 second(s).
  44 Oct 15 16:56:11 CSPF failed:  no route toward 10.0.0.6 [2685 times]
  43 Oct 14 19:07:09 Clear Call
  42 Oct 14 19:06:56 Deselected as active
  41 Oct 14 19:06:56 10.1.12.1: MPLS label allocation failure
```

```

40 Oct 14 19:06:56 Down
39 Oct 14 18:43:43 Selected as active path
38 Oct 14 18:43:43 Record Route:  10.1.13.2 10.1.36.2
37 Oct 14 18:43:43 Up
[...Output truncated...]
Created: Thu Oct 14 16:04:33 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed , Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed , Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows that an MPLS label allocation failure occurred and the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.6** on **R6**.

Verify IP Addressing

Purpose

When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that OSPF neighbors or IS-IS adjacencies are established. In this example, an IP address is configured incorrectly on the ingress router (**R1**).

Action

To verify IP addressing, enter the following command from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
```

Sample Output

```

user@R1> show interfaces terse
Interface          Admin Link Proto Local                Remote

                                iso
                                mpls
so-0/0/3                up    up
so-0/0/3.0              up    up    inet  10.1.36.2/30
                                iso
                                mpls
lo0.0                   up    up    inet  10.0.0.6
                                iso  49.0004.1000.0000.0006.00

```

Meaning

The sample output shows that the IP addresses for interface **so-0/0/2.0** on **R1** and interface **so-0/0/2.0** on **R3** are identical. Interface IP addresses within a network must be unique for the interface to be identified correctly.

Verify Neighbors or Adjacencies at the IP Layer

Purpose

If the IP addressing is configured incorrectly then the OSPF neighbors or IS-IS adjacencies both need to be checked to determine if one or both of them are established.

Action

To verify neighbors (OSPF) or adjacencies (IS-IS), enter the following commands from the ingress, transit, and egress routers:

```

user@host> show ospf neighbor extensive
user@host> show isis adjacency extensive

```

Sample Output 1

```

user@R1> show ospf neighbor extensive

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that **R1** and **R3** are not established OSPF neighbors. Considering that the two interfaces **so-0/0/2.0** (**R1** and **R3**) are configured with identical IP addresses, you would expect this. The OSPF protocol routes IP packets based solely on the destination IP address contained in the IP packet header. Therefore, identical IP addresses in the autonomous system (AS) result in neighbors not establishing.

Sample Output 2 from the ingress, transit, and egress routers shows that **R1** and **R3** have established an IS-IS adjacency despite the identical IP addresses configured on interfaces **so-0/0/2.0** on **R1** and **R3**. The IS-IS protocol behaves differently from the OSPF protocol because it does not rely on IP to establish an adjacency. However, if the LSP is not up, it is still useful to check the IP subnet addressing in case there is a mistake in that layer. Correcting the addressing error might bring the LSP back up.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the IP address of an interface on transit router **R2** is incorrectly configured.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/2]
user@R1# show
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.2/30; <<< Incorrect IP address
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30

[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.1/30; <<< Correct IP address.
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# commit
commit complete
```

Meaning

The sample output shows that interface **so-0/0/2** on ingress router **R1** is now configured with the correct IP address. This correction results in unique subnet IP addresses for all interfaces in the MPLS network in [Figure 155 on page 1991](#), and the possibility that the LSP might come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the OSPF protocol has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up. The output shows that the egress LSP session **R6-to-R1** received and sent a recovery label.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify the LSP

Purpose

After configuring the LSP, you must verify that the LSP is up. LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive**) as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To verify that the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6

```

Meaning

The sample output from ingress router **R1** shows that an MPLS label allocation failure occurred and the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.6** on **R6**.

Verify IP Addressing

Purpose

When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that OSPF neighbors or IS-IS adjacencies are established. In this example, an IP address is configured incorrectly on the ingress router (**R1**).

Action

To verify IP addressing, enter the following command from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
```

Sample Output

```

user@R1> show interfaces terse
Interface          Admin Link Proto Local          Remote

```

```

                               iso  49.0004.1000.0000.0006.00

```

Meaning

The sample output shows that the IP addresses for interface **so-0/0/2.0** on **R1** and interface **so-0/0/2.0** on **R3** are identical. Interface IP addresses within a network must be unique for the interface to be identified correctly.

Verify Neighbors or Adjacencies at the IP Layer

Purpose

If the IP addressing is configured incorrectly then the OSPF neighbors or IS-IS adjacencies both need to be checked to determine if one or both of them are established.

Action

To verify neighbors (OSPF) or adjacencies (IS-IS), enter the following commands from the ingress, transit, and egress routers:

```

user@host> show ospf neighbor extensive
user@host> show isis adjacency extensive

```

Sample Output 1

```

user@R1> show ospf neighbor extensive

R4

Interface: so-0/0/1.0, **Level: 2, State: Up** , Expires in 25 secs
 Priority: 0, Up/Down transitions: 1, Last transition: 1w1d 00:26:50 ago
 Circuit type: 2, **Speaks: IP** , IPv6

Topologies: Unicast
Restart capable: Yes

IP addresses: 10.1.46.1

Transition log:

When	State	Reason
Thu Oct 28 15:18:45	Up	Seenself

R2

Interface: so-0/0/2.0, **Level: 2, State: Up** , Expires in 24 secs
Priority: 0, Up/Down transitions: 1, Last transition: 2w1d 00:11:40 ago
Circuit type: 2, **Speaks: IP** , IPv6
Topologies: Unicast
Restart capable: Yes

IP addresses: 10.1.26.1

Transition log:

When	State	Reason
Thu Oct 21 15:33:55	Up	Seenself

R3

Interface: so-0/0/3.0, **Level: 2, State: Up** , Expires in 19 secs
Priority: 0, Up/Down transitions: 1, Last transition: 2w1d 00:11:40 ago
Circuit type: 2, **Speaks: IP** , IPv6
Topologies: Unicast
Restart capable: Yes

IP addresses: 10.1.36.1

Transition log:

When	State	Reason
Thu Oct 21 15:33:55	Up	Seenself

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that **R1** and **R3** are not established OSPF neighbors. Considering that the two interfaces **so-0/0/2.0** (**R1** and **R3**) are configured with identical IP addresses, you would expect this. The OSPF protocol routes IP packets based solely on the destination IP address contained in the IP packet header. Therefore, identical IP addresses in the autonomous system (AS) result in neighbors not establishing.

Sample Output 2 from the ingress, transit, and egress routers shows that **R1** and **R3** have established an IS-IS adjacency despite the identical IP addresses configured on interfaces **so-0/0/2.0** on **R1** and **R3**. The IS-IS protocol behaves differently from the OSPF protocol because it does not rely on IP to establish an adjacency. However, if the LSP is not up, it is still useful to check the IP subnet addressing in case there is a mistake in that layer. Correcting the addressing error might bring the LSP back up.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the IP address of an interface on transit router **R2** is incorrectly configured.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/2]
user@R1# show
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.2/30; <<< Incorrect IP address
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30

[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.1/30; <<< Correct IP address.
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
```

```
user@R1# commit
commit complete
```

Meaning

The sample output shows that interface **so-0/0/2** on ingress router **R1** is now configured with the correct IP address. This correction results in unique subnet IP addresses for all interfaces in the MPLS network in [Figure 155 on page 1991](#), and the possibility that the LSP might come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the OSPF protocol has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up. The output shows that the egress LSP session **R6-to-R1** received and sent a recovery label.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

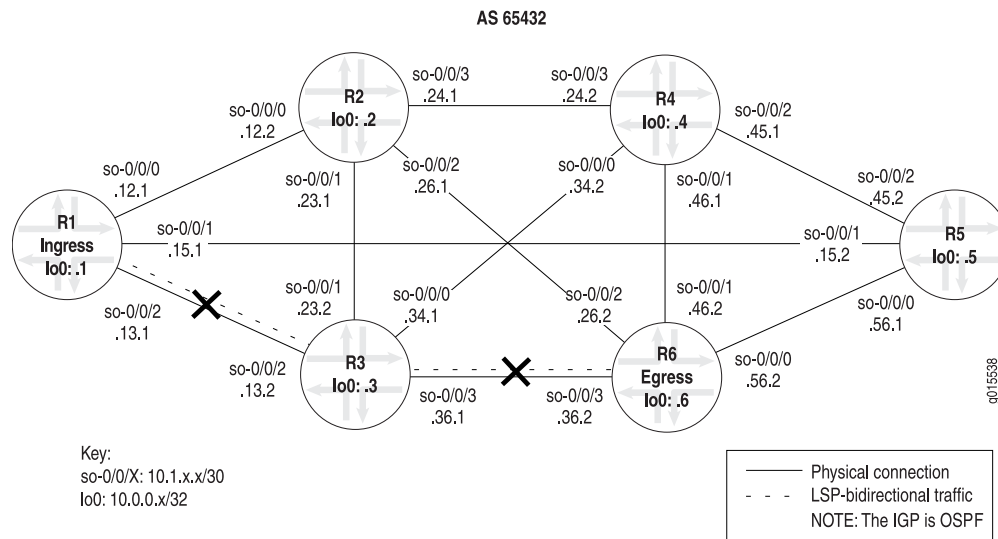

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verifying the OSPF Protocol

Purpose

After you have verified that the LSP is down, and the cause is not in the physical, datalink, or IP layer, verify the OSPF configuration. Check the routers in your network to ensure that the interfaces and the OSPF protocol are configured correctly, and that the neighbors are established.

Figure 157: MPLS Network Broken at the OSPF Protocol Layer

1. [Verify the LSP | 2020](#)
2. [Verify OSPF Interfaces | 2025](#)
3. [Verify OSPF Neighbors | 2027](#)
4. [Verify the OSPF Protocol Configuration | 2028](#)
5. [Take Appropriate Action | 2029](#)
6. [Verify the LSP Again | 2031](#)

Verify the LSP

Purpose

Confirm that interfaces are configured for OSPF, the OSPF protocol is configured correctly and that neighbors are established.

Action

To verify the LSP, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

Meaning

Sample Outputs 1, 2, and 3 show that the LSP and the reverse LSP are down:

- Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** does not have a route towards the destination (**R6**).
- Sample Output 2 from transit router **R3** shows that there are no LSP sessions.
- Sample Output 3 from egress router **R6** also shows that reverse LSP **R6-to-R1** is down.

Sample Outputs 4, 5, and 6 show that the LSP is up and the reverse LSP is down:

- Sample Output 4 from ingress router **R1** shows that LSP **R1-to-R6** is up and there are no egress LSP sessions.

- Sample Output 5 from transit router R3 shows that there is one ingress LSP session (**R1-to-R6**) and no egress LSP sessions.
- Sample Output 6 from egress router **R6** shows that LSP **R6-to-R1** is down due to an MPLS label allocation failure.

Verify OSPF Interfaces

Purpose

After you have verified that the LSP is down, and the cause is not in the physical, data link, or IP layer, check the routers in your network to determine that all relevant OSPF interfaces are configured correctly.

Action

To verify OSPF interfaces, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf interface
```

Sample Output 1

```
user@R1> show ospf interface

so-0/0/1.0	Down	0.0.0.0	0.0.0.0	0.0.0.0	0
so-0/0/2.0	PtToPt	0.0.0.0	0.0.0.0	0.0.0.0	1
so-0/0/3.0	PtToPt	0.0.0.0	0.0.0.0	0.0.0.0	1

Meaning

Sample Output 1 shows that all interfaces on all routers are in the correct area (0.0.0.0), and the loopback (lo0) interface is missing from the list of interfaces on all routers. The missing loopback (lo0) interface is a problem in this configuration.

In an MPLS network configured with OSPF as the IGP, when you manually configure the RID, it is important to explicitly configure the loopback interface at the `[edit protocols ospf]` hierarchy level. If the RID is not manually configured, OSPF automatically advertises the loopback (lo0) interface. In the configuration of all the routers in this network, the RID is configured manually, therefore, the loopback (lo0) interface must be explicitly configured at the `[edit protocols ospf]` hierarchy level. In addition, the loopback (lo0) interface is configured with the **passive** statement to ensure that the protocols are not run over the loopback (lo0) interface and it is correctly advertised throughout the network.

Sample Output 2 shows that all the relevant interfaces on the ingress, transit, and egress routers, including the loopback (lo0) interface, are in the correct area (0.0.0.0). Because the configuration of the interfaces is correct, further investigation is required to determine the reason for the LSP problem.

Verify OSPF Neighbors

Purpose

After you have checked OSPF interfaces, check your network topology to determine that all relevant neighbors are established.

Action

To verify OSPF neighbors, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor
```

Sample Output

```
user@R1> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.12.2	so-0/0/0.0	Full	10.0.0.2	128	39
10.1.15.2	so-0/0/1.0	Full	10.0.0.5	128	39
10.1.13.2	so-0/0/2.0	Full	10.0.0.3	128	33

```
user@R3> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.34.2	so-0/0/0.0	Full	10.0.0.4	128	33
10.1.23.1	so-0/0/1.0	Full	10.0.0.2	128	33
10.1.13.1	so-0/0/2.0	Full	10.0.0.1	128	33
10.1.36.2	so-0/0/3.0	Full	10.0.0.6	128	33

```
user@R6> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.56.1	so-0/0/0.0	Full	10.0.0.5	128	30
10.1.46.1	so-0/0/1.0	Full	10.0.0.4	128	38
10.1.26.1	so-0/0/2.0	Full	10.0.0.2	128	34
10.1.36.1	so-0/0/3.0	Full	10.0.0.3	128	35

Meaning

The sample output shows that all neighbors are fully adjacent, indicating that each router has exchanged a full copy of its link-state database with the other routers, passed through several neighbor states, and become fully adjacent. These adjacencies are created by router link and network link advertisements.

Verify the OSPF Protocol Configuration

Purpose

After you have checked interfaces and neighbors, verify the OSPF protocol configuration.

Action

To verify the OSPF protocol configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols ospf
```

Sample Output 1

```
user@R1> show configuration protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;    <<< The loopback interface (lo0) is missing
}
```

Sample Output 2

```
user@R3>show configuration protocols ospf
area 0.0.0.0 { <<< traffic engineering is missing
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
    interface so-0/0/3.0;    <<< The loopback interface (lo0) is missing
}
```

Sample Output 3

```

user@R6> show configuration protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
    interface so-0/0/3.0;    <<< The loopback interface (lo0) is missing
}

```

Meaning

All three sample outputs show that the loopback interface is not included on any of the routers. Including the loopback (**lo0**) interface is important when you have the RID manually configured.

In addition, Sample Output 2 from transit router **R3** shows that traffic engineering is not configured. Traffic engineering must be manually enabled when you configure OSPF for an MPLS network.

Because the loopback interface and traffic engineering are missing from the OSPF protocol configuration, the LSP does not work as expected.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the loopback (**lo0**) interface is missing from all routers, and traffic engineering is missing from the transit router (**R3**).

Solution

To correct the errors in this example, follow these steps:

1. Include the loopback (**lo0**) interface on all routers that have the RID manually configured. Enter the following configuration mode commands:

```

[edit]
user@R3# edit protocols ospf area 0.0.0.0
[edit protocols ospf area 0.0.0.0]
user@R3# set interface lo0
user@R3# set interface lo0 passive

```

2. Move up one level of the configuration hierarchy:

```
[edit protocols ospf area 0.0.0.0]
user@R3# up
[edit protocols ospf]
user @R3#
```

3. Include traffic engineering on the transit router (**R3**). Enter the following configuration mode command:

```
[edit protocols ospf]
user@R3# set traffic-engineering
```

4. On all routers, verify and commit the configuration:

```
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols ospf area 0.0.0.0

[edit protocols ospf area 0.0.0.0]
user@R3# set interface lo0

[edit protocols ospf area 0.0.0.0]
user@R3# set interface lo0 passive

[edit protocols ospf area 0.0.0.0]
user@R3# up

[edit protocols ospf]
user@R3# set traffic-engineering

[edit protocols ospf]
user@R3# show
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
```

```

interface so-0/0/2.0;
  interface lo0.0; {
    passive
  }
}

[edit protocols ospf]
user@R3# commit
commit complete

```

Meaning

The sample output shows that the loopback (**lo0**) interface and traffic engineering are now correctly configured on transit router **R3**. When traffic engineering is configured, OSPF advertises the traffic engineering capabilities of the links.

In the OSPF configuration, you must manually include the loopback (**lo0**) interface and set it to passive when you manually configure an RID. Setting the loopback (**lo0**) interface to passive ensures that protocols are not run over the loopback (**lo0**) interface and the loopback (**lo0**) interface is advertised correctly throughout the network.. If you do not manually configure an RID, there is no need to explicitly include the loopback interface because the OSPF protocol automatically includes the loopback (**lo0**) interface.

For more information about configuring LSPs and MPLS, see the *Junos MPLS Applications Configuration Guide*.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the IS-IS protocol has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```

user@R1> show mpls lsp extensive

```

Meaning

The sample output from ingress router **R1** and egress router **R6** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to

R1. In addition, the sample output from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6**, and the other from **R6** to **R1**.

Verify the LSP

Purpose

Confirm that interfaces are configured for OSPF, the OSPF protocol is configured correctly and that neighbors are established.

Action

To verify the LSP, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

Meaning

Sample Outputs 1, 2, and 3 show that the LSP and the reverse LSP are down:

- Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** does not have a route towards the destination (**R6**).
- Sample Output 2 from transit router **R3** shows that there are no LSP sessions.
- Sample Output 3 from egress router **R6** also shows that reverse LSP **R6-to-R1** is down.

Sample Outputs 4, 5, and 6 show that the LSP is up and the reverse LSP is down:

- Sample Output 4 from ingress router **R1** shows that LSP **R1-to-R6** is up and there are no egress LSP sessions.
- Sample Output 5 from transit router **R3** shows that there is one ingress LSP session (**R1-to-R6**) and no egress LSP sessions.
- Sample Output 6 from egress router **R6** shows that LSP **R6-to-R1** is down due to an MPLS label allocation failure.

Verify OSPF Interfaces

Purpose

After you have verified that the LSP is down, and the cause is not in the physical, data link, or IP layer, check the routers in your network to determine that all relevant OSPF interfaces are configured correctly.

Action

To verify OSPF interfaces, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf interface
```

Sample Output 1

```
user@R1> show ospf interface
```

Interface	State	Area	DR ID	BDR ID	Nbrs
-----------	-------	------	-------	--------	------

```
so-0/0/0.0    PtToPt  0.0.0.0    0.0.0.0    0.0.0.0    1
so-0/0/1.0    PtToPt  0.0.0.0    0.0.0.0    0.0.0.0    1
so-0/0/2.0    PtToPt  0.0.0.0    0.0.0.0    0.0.0.0    1
```

user@R3> show ospf interface

Interface	State	Area	DR ID	BDR ID	Nbrs
so-0/0/0.0	PtToPt	0.0.0.0	0.0.0.0	0.0.0.0	1

so-0/0/3.0	PtToPt	0.0.0.0	0.0.0.0	0.0.0.0	1

Meaning

Sample Output 1 shows that all interfaces on all routers are in the correct area (**0.0.0.0**), and the loopback (**lo0**) interface is missing from the list of interfaces on all routers. The missing loopback (**lo0**) interface is a problem in this configuration.

In an MPLS network configured with OSPF as the IGP, when you manually configure the RID, it is important to explicitly configure the loopback interface at the **[edit protocols ospf]** hierarchy level. If the RID is not manually configured, OSPF automatically advertises the loopback (**lo0**) interface. In the configuration of all the routers in this network, the RID is configured manually, therefore, the loopback (**lo0**) interface must be explicitly configured at the **[edit protocols ospf]** hierarchy level. In addition, the loopback (**lo0**) interface is configured with the **passive** statement to ensure that the protocols are not run over the loopback (**lo0**) interface and it is correctly advertised throughout the network.

Sample Output 2 shows that all the relevant interfaces on the ingress, transit, and egress routers, including the loopback (**lo0**) interface, are in the correct area (**0.0.0.0**). Because the configuration of the interfaces is correct, further investigation is required to determine the reason for the LSP problem.

Verify OSPF Neighbors

Purpose

After you have checked OSPF interfaces, check your network topology to determine that all relevant neighbors are established.

Action

To verify OSPF neighbors, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show ospf neighbor
```

Sample Output

```
user@R1> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.12.2	so-0/0/0.0	Full	10.0.0.2	128	39

```

10.1.15.2      so-0/0/1.0      Full    10.0.0.5      128    39
10.1.13.2      so-0/0/2.0      Full    10.0.0.3      128    33

```

```
user@R3> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.34.2	so-0/0/0.0	Full	10.0.0.4	128	33
10.1.23.1	so-0/0/1.0	Full	10.0.0.2	128	33
10.1.13.1	so-0/0/2.0	Full	10.0.0.1	128	33
10.1.36.2	so-0/0/3.0	Full	10.0.0.6	128	33

```
user@R6> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.56.1	so-0/0/0.0	Full	10.0.0.5	128	30
10.1.46.1	so-0/0/1.0	Full	10.0.0.4	128	38
10.1.26.1	so-0/0/2.0	Full	10.0.0.2	128	34
10.1.36.1	so-0/0/3.0	Full	10.0.0.3	128	35

Meaning

The sample output shows that all neighbors are fully adjacent, indicating that each router has exchanged a full copy of its link-state database with the other routers, passed through several neighbor states, and become fully adjacent. These adjacencies are created by router link and network link advertisements.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the IS-IS protocol has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```

user@R1> show mpls lsp extensive

```

Meaning

The sample output from ingress router **R1** and egress router **R6** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to

R1. In addition, the sample output from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6**, and the other from **R6** to **R1**.

Verify the LSP

Purpose

Confirm that interfaces are configured for IS-IS, that the IS-IS protocol is configured correctly, and that adjacencies are established.

Action

To verify the label-switched path (LSP), enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

The sample output shows that LSP **R1-to-R6** and the reverse LSP **R6-to-R1** are down, and there are no LSP sessions on transit router R3.

Verify IS-IS Adjacencies and Interfaces

Purpose

When you check the IS-IS layer, you verify that IS-IS adjacencies are up and that the IS-IS interfaces are included at the protocol level.

Action

To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show isis adjacency
user@host> show isis interface
```

Sample Output 1

```
user@R1> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R2	2 Up	20	
so-0/0/1.0	R5	2 Up	23	
so-0/0/2.0	R3	2 Up	26	

```
user@R3> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R4	2 Up	23	
so-0/0/1.0	R2	2 Up	21	
so-0/0/2.0	R1	2 Up	19	
so-0/0/3.0	R6	2 Down		0

```
user@R6> show isis adjacency
IS-IS instance is not running
```

Sample Output 2

```
user@R1> show isis interface
IS-IS interface database:
Interface          L CirID Level 1 DR      Level 2 DR      L1/L2 Metric
lo0.0              0  0x1 Passive            Passive            0/0
so-0/0/0.0         2  0x1 Disabled          Point to Point    10/10
so-0/0/1.0         2  0x1 Disabled          Point to Point    10/10
so-0/0/2.0         2  0x1 Disabled          Point to Point    10/10

user@R3> show isis interface
IS-IS interface database:
Interface          L CirID Level 1 DR      Level 2 DR      L1/L2 Metric

so-0/0/0.0         2  0x1 Disabled          Point to Point    10/10
so-0/0/1.0         2  0x1 Disabled          Point to Point    10/10
so-0/0/2.0         2  0x1 Disabled          Point to Point    10/10
so-0/0/3.0         2  0x1 Disabled          Point to Point    10/10

user@R6> show isis interface
IS-IS interface database:
Interface          L  CirID Level 1 DR      Level 2 DR      L1/L2 Metric
lo0.0              0  0x1 Passive            Passive            0/0
so-0/0/0.0         1   0x1 Point to Point    Disabled          10/10
so-0/0/1.0         1   0x1 Down              Disabled          10/10
so-0/0/2.0         1   0x1 Point to Point    Disabled          10/10
so-0/0/3.0         1   0x1 Point to Point    Disabled          10/10
```

Meaning

Sample Output 1 shows that ingress router R1 has established adjacencies with the relevant routers. Transit router R3 does not have an adjacency with egress router R6, and egress router R6 has no adjacencies established in the network shown in [Figure 155 on page 1991](#), indicating that the problem might be at the IS-IS protocol level.

Sample Output 2 shows that R1 and R2 are Level 2 routers, in contrast to R6 which is a Level 1 router. When a router is configured explicitly as a Level 1 or Level 2 router, it does not communicate with routers

configured at a different level. Level 1 routers communicate with other Level 1 routers within their area, while Level 2 routers communicate with other Level 2 routers, and toward other autonomous systems. Because all the routers in this network are configured for Level 2, they cannot form an adjacency with R6, which is incorrectly configured as a Level 1 router.

RELATED DOCUMENTATION

Understanding IS-IS Areas to Divide an Autonomous System into Smaller Groups

Verify the IS-IS Configuration

Purpose

When you have determined that the problem is probably at the IS-IS protocol level, check the IS-IS configuration of the routers in your network.

Action

To verify the IS-IS configuration, enter the following command from the relevant routers:

```
user@host> show configuration protocols isis
```

Sample Output

```
user@R1> show configuration protocols isis
```

```
level 1 disable;
```

```
interface so-0/0/0.0;
```

```
interface so-0/0/1.0;
```

```
interface so-0/0/2.0;
```

```
interface lo0.0; {  
    passive
```

```
user@R3> show configuration protocols isis
```

```
level 1 disable;
```

```
interface all {  
    level 2 metric 10;  
}
```

```

interface fxp0.0 {
    disable;
}
interface lo0.0; {
    passive

user@R6> show configuration protocols isis
level 2 disable; <<< Incorrect level disabled
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
    disable;
}
interface lo0.0; {
    passive

```

Meaning

The sample output shows that R6 has Level 2 disabled, while R1 and R3 have Level 1 disabled. For IS-IS adjacencies to establish, routers need to be at the same level. Another common configuration error is to omit the loopback interface (lo0) from the configuration at the **[edit protocols isis]** hierarchy level. IS-IS does not function correctly if the loopback interface (lo0) is not configured at this level. In addition, including the **passive** statement ensures that protocols are not run over the loopback interface (lo0) and that the loopback interface (lo0) is advertised correctly throughout the network.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the label-switched path (LSP) needs to be checked again to confirm that the problem in the RSVP layer has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample Outputs 1 and 3 from ingress router R1 and egress router R6 show that the LSP is now traversing the network along the expected path, from R1 through R3 to R6, and the reverse LSP, from R6 through R3 to R1. In addition, Sample Output 2 from transit router R3 shows that there are two transit LSP sessions, one from R1 to R6, and the other from R6 to R1.

Checklist for Checking the RSVP Layer

Problem

Description: This checklist provides the steps and commands for checking the Resource Reservation Protocol (RSVP) layer of the layered Multiprotocol Label Switching (MPLS) model. The checklist provides links to an overview of the RSVP layer and more detailed information about the commands used to investigate the problem.

[Table 55 on page 2055](#) provides commands for checking the RSVP layer.

Solution

Table 55: Checklist for Checking the RSVP Layer

Tasks	Command or Action
“Checking the RSVP Layer” on page 2056	
1. Verify the LSP on page 2059	show mpls lsp extensive
2. Verify RSVP Sessions on page 2060	show rsvp session
3. Verify RSVP Neighbors on page 2063	show rsvp neighbor

Table 55: Checklist for Checking the RSVP Layer (*continued*)

Tasks	Command or Action
4. Verify RSVP Interfaces on page 2064	show rsvp interface
5. Verify the RSVP Protocol Configuration on page 2066	show configuration protocols rsvp
6. Take Appropriate Action on page 2067	<p>The following sequence of commands addresses the specific problem described in this topic:</p> <pre>[edit] edit protocols rsvp [edit protocols rsvp] show set interface <i>type-fpc/pic/port</i> show commit</pre>
7. Verify the LSP Again on page 2069	show mpls lsp extensive

Checking the RSVP Layer

Purpose

After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical, data link, or Internet Protocol (IP) and interior gateway protocol (IGP) layers. Continue investigating the problem at the RSVP layer of the network.

[Figure 158 on page 2057](#) illustrates the RSVP layer of the layered MPLS model.

Physical Layer	show interfaces show interfaces terse ping <i>host</i>

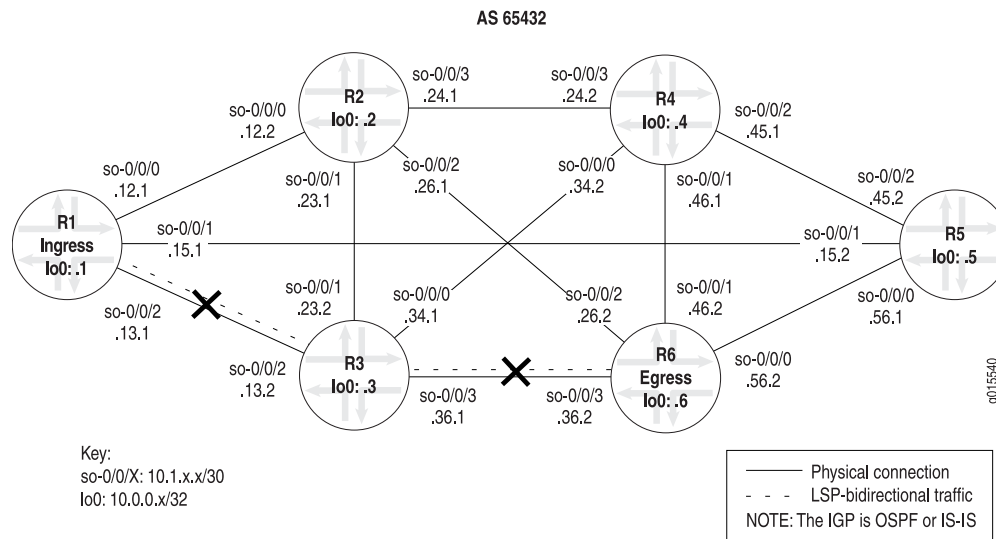

g015546

With this layer, you check that dynamic RSVP signaling is occurring as expected, neighbors are connected, and interfaces are configured correctly for RSVP. Check the ingress, egress, and transit routers.

If the network is not functioning at this layer, the LSP does not work as configured.

Figure 159 on page 2058 illustrates the MPLS network used in this topic.

Figure 159: MPLS Network Broken at the RSVP Layer

The network shown in [Figure 159 on page 2058](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

The crosses shown in [Figure 159 on page 2058](#) indicate where the LSP is broken. Some possible reasons the LSP is broken might include that dynamic RSVP signaling is not occurring as expected, neighbors are not connected, or interfaces are incorrectly configured for RSVP.

In the network in [Figure 159 on page 2058](#), a configuration error on transit router **R3** prevents the LSP from traversing the network as expected.

To check the RSVP layer, follow these steps:

1. [Verify the LSP | 2059](#)
2. [Verify RSVP Sessions | 2060](#)
3. [Verify RSVP Neighbors | 2063](#)
4. [Verify RSVP Interfaces | 2064](#)
5. [Verify the RSVP Protocol Configuration | 2066](#)
6. [Take Appropriate Action | 2067](#)
7. [Verify the LSP Again | 2069](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6

    1 Oct 27 14:59:12  CSPF failed: no route toward 10.0.0.1 [4 times]
  Created: Wed Oct 27 14:57:44 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output shows that the LSP is down in both directions, from **R1** to **R6**, and from **R6** to **R1**. The output from **R1** shows that **R1** is using a no-cspf LSP since it tried to originate the call without being able to reach the destination. The output from **R6** shows that the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.1**.

Verify RSVP Sessions

Purpose

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, the LSP does not work as configured.

Action

To verify currently active RSVP sessions, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp session
```

Sample Output 1

```
user@R1> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions

Total 1 displayed, Up 1 , Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

Sample Output 1 from all routers shows that no RSVP sessions were successfully created, even though the LSP **R6-to-R1** is configured. Continue investigating the problem in [“Verify RSVP Neighbors” on page 2063](#).

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the output from the ingress, transit, and egress routers when the RSVP configuration is correct, and the LSP is traversing the network as configured. **R1** and **R6** both show an ingress and egress RSVP session, with the LSP **R1-to-R6**, and the reverse LSP **R6-to-R1**. Transit router **R3** shows two transit RSVP sessions.

Verify RSVP Neighbors

Purpose

Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors unless the RSVP configuration is removed from the router.

Action

To verify RSVP neighbors, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp neighbor
```

Sample Output 1

```
user@R1> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.2         10  1/0      9:22          9    64/64    32

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1         0  1/0     28:20          9   190/190   41
10.1.36.2        16:50 1/1     15:37          9   105/78   38

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1        17:30 1/1     16:15          9   104/78   39
```

Sample Output 2

```

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1         5  1/0      9:14         9    63/63    33
10.1.36.2         5  1/0      9:05         9    62/62    32

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1         5  1/0      8:54         9    61/61    32

```

Meaning

Sample Output 1 shows that **R1** and **R6** have one RSVP neighbor each, **R3**. However, the values in the **Up/Dn** field are different. **R1** has a value of **1/0** and **R6** has a value of **1/1**, indicating that **R1** is an active neighbor with **R3**, but **R6** is not. When the up count is one more than the down count, the neighbor is active; if the values are equal, the neighbor is down. The values for **R6** are equal, **1/1**, indicating that the neighbor **R3** is down.

Transit router **R3** knows about two neighbors, **R1** and **R6**. The **Up/Dn** field indicates that **R1** is an active neighbor and **R6** is down. At this point it is not possible to determine if the problem resides with **R3** or **R6**, because both neighbors are not active. Continue investigating the problem in [“Verify RSVP Interfaces” on page 2064](#).

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the correct neighbor relationship between transit router **R3** and egress router **R6**. The **Up/Dn** field shows the up count to be one more than the down count, **1/0**, indicating that the neighbors are active.

Verify RSVP Interfaces

Purpose

Display the status of each interface on which RSVP is enabled to determine where the configuration error occurred.

Action

To verify the status of RSVP interfaces, enter the following command from the ingress, transit, and egress routers:

```

user@host> show rsvp interface

```

Sample Output 1

```
user@R1> show rsvp interface
```

```
RSVP interface: 3 active
```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark

```

```
Rsvp interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/2.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample Output 1 shows that even though each router has interfaces that are up and have RSVP active, there are no reservations (**Active resv**) on any of the routers. In this example, we would expect at least one reservation on the ingress and egress routers, and two reservations on the transit router.

In addition, interface **so-0/0/3** on transit router **R3** is not included in the configuration. The inclusion of this interface is critical to the success of the LSP.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the relevant interfaces with active reservations.

Verify the RSVP Protocol Configuration

Purpose

After you have checked RSVP sessions, interfaces, neighbors, and determined that there might be a configuration error, verify the RSVP protocol configuration.

Action

To verify the RSVP configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols rsvp
```

Sample Output

```
user@R1> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}

user@R6> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;
interface fxp0.0 {
    disable;
}
```

Meaning

The sample output shows that **R3** has interface **so-0/0/3.0** missing from the RSVP protocol configuration. This interface is critical for the correct functioning of the LSP.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is missing from the configuration of router R3.

Solution

To correct the error in this example, follow these steps:

1. Include the missing interface in the configuration of transit router R3:

```
user@R3> edit
user@R3# edit protocols rsvp
[edit protocols rsvp]
user@R3# show
user@R3# set interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols rsvp]
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols rsvp

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}
[edit protocols rsvp]
user@R3# set interface so-0/0/3.0

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
```

```

}
interface so-0/0/3.0; <<< Interface now included in the configuration

[edit protocols rsvp]
user@R3# commit
commit complete

```

Meaning

The sample output shows that the missing interface **so-0/0/3.0** on transit router **R3** is now correctly included at the **[edit protocols rsvp]** hierarchy level. This results in the possibility that the LSP might come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the MPLS layer has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0,  LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn
    2 Oct 27 15:06:05 10.1.13.2:  No Route toward dest [4 times]

  From: 10.0.0.6, State: Dn, ActiveRoute: 0,  LSPname: R6-to-R1
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn
    Will be enqueued for recomputation in 22 second(s).
    1 Oct 27 14:59:12  CSPF failed: no route toward 10.0.0.1 [4 times]
  Created: Wed Oct 27 14:57:44 2004
Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output shows that the LSP is down in both directions, from **R1** to **R6**, and from **R6** to **R1**. The output from **R1** shows that **R1** is using a no-cspf LSP since it tried to originate the call without being able to reach the destination. The output from **R6** shows that the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.1**.

Verify RSVP Sessions

Purpose

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, the LSP does not work as configured.

Action

To verify currently active RSVP sessions, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp session
```

Sample Output 1

```
user@R1> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R3> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R6> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

```
Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Sample Output 2

Total 1 displayed,  Up 1 , Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

Sample Output 1 from all routers shows that no RSVP sessions were successfully created, even though the LSP **R6-to-R1** is configured. Continue investigating the problem in [“Verify RSVP Neighbors” on page 2063](#).

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the output from the ingress, transit, and egress routers when the RSVP configuration is correct, and the LSP is traversing the network as configured. **R1** and **R6** both show an ingress and egress RSVP session, with the LSP **R1-to-R6**, and the reverse LSP **R6-to-R1**. Transit router **R3** shows two transit RSVP sessions.

Verify RSVP Neighbors

Purpose

Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors unless the RSVP configuration is removed from the router.

Action

To verify RSVP neighbors, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp neighbor
```

Sample Output 1

```

user@R1> show rsvp neighbor
RSVP neighbor: 1 learned
Address                Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.2              10  1/0      9:22         9     64/64    32

```

```

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1         0  1/0    28:20         9    190/190   41
10.1.36.2        16:50 1/1    15:37         9    105/78   38

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1        17:30 1/1    16:15         9    104/78   39

```

Sample Output 2

```

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1         5  1/0     9:14         9     63/63   33
10.1.36.2         5  1/0     9:05         9     62/62   32

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1         5  1/0     8:54         9     61/61   32

```

Meaning

Sample Output 1 shows that **R1** and **R6** have one RSVP neighbor each, **R3**. However, the values in the **Up/Dn** field are different. **R1** has a value of **1/0** and **R6** has a value of **1/1**, indicating that **R1** is an active neighbor with **R3**, but **R6** is not. When the up count is one more than the down count, the neighbor is active; if the values are equal, the neighbor is down. The values for **R6** are equal, **1/1**, indicating that the neighbor **R3** is down.

Transit router **R3** knows about two neighbors, **R1** and **R6**. The **Up/Dn** field indicates that **R1** is an active neighbor and **R6** is down. At this point it is not possible to determine if the problem resides with **R3** or **R6**, because both neighbors are not active. Continue investigating the problem in [“Verify RSVP Interfaces” on page 2064](#).

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the correct neighbor relationship between transit router **R3** and egress router **R6**. The **Up/Dn** field shows the up count to be one more than the down count, **1/0**, indicating that the neighbors are active.

Verify RSVP Interfaces

Purpose

Display the status of each interface on which RSVP is enabled to determine where the configuration error occurred.

Action

To verify the status of RSVP interfaces, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show rsvp interface
RSVP interface: 3 active
```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps

```
user@R6> show rsvp interface
```

```
Rsvp interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/2.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample Output 1 shows that even though each router has interfaces that are up and have RSVP active, there are no reservations (**Active resv**) on any of the routers. In this example, we would expect at least one reservation on the ingress and egress routers, and two reservations on the transit router.

In addition, interface **so-0/0/3** on transit router **R3** is not included in the configuration. The inclusion of this interface is critical to the success of the LSP.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the relevant interfaces with active reservations.

Verify the RSVP Protocol Configuration

Purpose

After you have checked RSVP sessions, interfaces, neighbors, and determined that there might be a configuration error, verify the RSVP protocol configuration.

Action

To verify the RSVP configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols rsvp
```

Sample Output

```
user@R1> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}

user@R6> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
```

```
interface so-0/0/3.0;
interface fxp0.0 {
    disable;
}
```

Meaning

The sample output shows that **R3** has interface **so-0/0/3.0** missing from the RSVP protocol configuration. This interface is critical for the correct functioning of the LSP.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is missing from the configuration of router R3.

Solution

To correct the error in this example, follow these steps:

1. Include the missing interface in the configuration of transit router R3:

```
user@R3> edit
user@R3# edit protocols rsvp
[edit protocols rsvp]
user@R3# show
user@R3# set interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols rsvp]
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols rsvp
```

```

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}
[edit protocols rsvp]
user@R3# set interface so-0/0/3.0

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
interface so-0/0/3.0; <<< Interface now included in the configuration

[edit protocols rsvp]
user@R3# commit
commit complete

```

Meaning

The sample output shows that the missing interface **so-0/0/3.0** on transit router **R3** is now correctly included at the **[edit protocols rsvp]** hierarchy level. This results in the possibility that the LSP might come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the MPLS layer has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Checklist for Determining LSP Status

Purpose

This checklist provides the steps and commands to verify the state of a label-switched path (LSP) in an MPLS network. The checklist includes links to more detailed information about the commands to verify the LSP and supporting protocols. [Table 56 on page 2087](#) provides commands for determining the LSP state.

Action

Table 56: Checklist for Determining the LSP State

Record route: 10.1.56.2 10.1.15.2 <self>
Total 1 displayed, Up 1, Down 0
```

```
Transit RSVP: 0 sessions
```

```
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output shows that there is one ingress and one egress RSVP session. The ingress session has a source address of **10.0.0.1 (R1)**, and the session is up, with one active route. The LSP name is **R1-to-R6** and it is the primary path for the LSP.

The recovery label (**100064**) is sent by a graceful restart router to its neighbor to recover a forwarding state. It is probably the old label that the router advertised before it went down.

This session is using the fixed filter (**FF**) reservation style (**Resv style**). Since this is an ingress router, there is no inbound label. The outbound label (provided by the next downstream router) is **100064**.

The **Time Left** field provides the number of seconds remaining in the RSVP session, and the **Tspec** object provides information about the controlled load rate (**rate**) and maximum burst size (**peak**), an infinite value (**Infbps**) for the guaranteed delivery option, and the indication that packets smaller than 20 bytes are treated as 20 bytes, while packets larger than 1500 bytes are treated as 1500 bytes.

The port number is the IPv4 tunnel ID, while the sender/receiver port number is the LSP ID. The IPv4 tunnel ID is unique for the life of the LSP, while the sender/receiver LSP ID can change, for example, with an SE style reservation.

The **PATH rcvfrom** field includes the source of the path message. Since this is the ingress router, the local client originated the path message.

The **PATH sentto** field includes the path message destination (**10.1.13.2**) and outgoing interface (**so-0/0/2.0**). The **RESV rcvfrom** field includes both the source of the Resv message received (**10.1.13.2**) and the incoming interface (**so-0/0/2.0**).

The RSVP explicit route and the route record values are identical: **10.1.13.2** and **10.1.36.2**. In most cases, the explicit route and the record route values are identical. Differences indicate that some path rerouting has occurred, typically during Fast-Reroute.

The **Total** fields indicate the total number of ingress, egress, and transit RSVP sessions, with the total being equal to the sum of the up and down sessions. In this example, there is one ingress session, one egress session, and no transit RSVP sessions.

Checklist for Verifying LSP Use

Purpose

This checklist provides the steps and commands to verify the use of the LSP in an MPLS network. The checklist includes links to more detailed information about verifying the LSP on the ingress and transit routers in the network.

This checklist describes how to verify the availability and valid use of a label-switched path (LSP) in your network.

Action

Table 57: Checklist for Verifying LSP Use

Tasks	Command or Action
"Verifying LSP Use in Your Network" on page 2090	
"Verifying an LSP on the Ingress Router" on page 2091	<code>show route table inet.3</code>
"Verifying an LSP on a Transit Router" on page 2093	<code>show route table mpls.0</code>

[Table 57 on page 2090](#) provides commands for verifying LSP use.

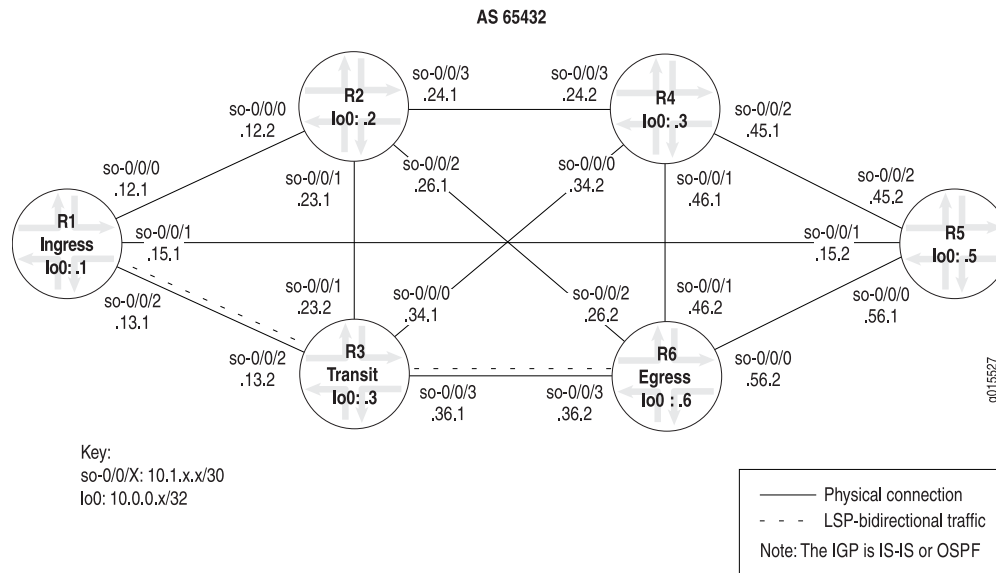

Verifying LSP Use in Your Network

Purpose

When you verify the valid use of an LSP on the ingress and transit routers in your network, you can determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network.

[Figure 160 on page 2091](#) describes the example network used in this topic.

Figure 160: MPLS Topology for Verifying LSP Use

The MPLS network in [Figure 160 on page 2091](#) illustrates a router-only network with SONET interfaces that consist of the following components:

- A full-mesh interior Border Gateway Protocol (IBGP) topology, using AS 65432
- MPLS and Resource Reservation Protocol (RSVP) enabled on all routers
- A **send-statics** policy on routers R1 and R6 that allows a new route to be advertised into the network
- An LSP between routers R1 and R6

The network shown in [Figure 160 on page 2091](#) is a Border Gateway Protocol (BGP) full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

To verify LSP use in your network, follow these steps:

1. [Verifying an LSP on the Ingress Router | 2091](#)
2. [Verifying an LSP on a Transit Router | 2093](#)

Verifying an LSP on the Ingress Router

Purpose

You can verify the availability of an LSP when it is up by examining the **inet.3** routing table on the ingress router. The **inet.3** routing table contains the host address of each LSP's egress router. This routing table

is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses.

Action

To verify an LSP on an ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show route table inet.3
```

Sample Output

```
user@R1> show route table inet.3
```

```
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32          *[RSVP/7] 4w0d 22:40:57, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6
```

Meaning

The sample output shows the **inet.3** routing table. By default, only BGP and MPLS virtual private networks (VPNs) can use the **inet.3** route table to resolve next-hop information. One destination is listed in the route table, **10.0.0.6**. This destination (**10.0.0.6**) is signaled by RSVP, and is the current active path, as indicated by the asterisk (*). The protocol preference for this route is **7**, and the metric associated with it is **20**. The label-switched path is **R1-to-R6**, through interface **so-0/0/2.0**, which is the physical next-hop transit interface.

Typically, the penultimate router in the LSP either pops the packet's label or changes the label to a value of 0. If the penultimate router pops the top label and an IPv4 packet is underneath, the egress router routes the IPv4 packet, consulting the IP routing table **inet.0** to determine how to forward the packet. If another type of label (such as one created by Label Distribution Protocol (LDP) tunneling or VPNs, but not IPv4) is underneath the top label, the egress router does not examine the **inet.0** routing table. Instead, it examines the **mpls.0** routing table for forwarding decisions.

If the penultimate router changes the packet's label to a value of 0, the egress router strips off the 0 label, indicating that an IPv4 packet follows. The packet is examined by the **inet.0** routing table for forwarding decisions.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or whether this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the **inet.0** and **inet.3** routing tables, seeking the next hop with the lowest preference; for example, RSVP preference 7 is preferred over OSPF preference 10. The RSVP signaled LSP is used to reach the BGP next hop. This is the default when the BGP next hop equals the LSP egress address. Once the BGP next hop is resolved through an LSP, the BGP traffic uses the LSP to forward BGP transit traffic.

Verifying an LSP on a Transit Router

Purpose

You can verify the availability of an LSP when it is up by examining the **mpls.0** routing table on a transit router. MPLS maintains the **mpls.0** routing table, which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Action

To verify an LSP on a transit router, enter the following Junos OS CLI operational mode command:

```
user@host> show route table mpls.0
```

Sample Output

```
user@R3> show route table mpls.0
```

```
mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          * [MPLS/0] 7w3d 22:20:56, metric 1
            Receive
1          * [MPLS/0] 7w3d 22:20:56, metric 1
            Receive
2          * [MPLS/0] 7w3d 22:20:56, metric 1
            Receive
100064     * [RSVP/7] 2w1d 04:17:36, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6
100064 (S=0) * [RSVP/7] 2w1d 04:17:36, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning

The sample output from transit router **R3** shows route entries in the form of MPLS label entries, indicating that there is only one active route, even though there are five active entries.

The first three MPLS labels are reserved MPLS labels defined in RFC 3032. Packets received with these label values are sent to the Routing Engine for processing. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label and Label 2 is the IPv6 explicit null label.

The two entries with the **100064** label are for the same LSP, **R1-to-R6**. There are two entries because the stack values in the MPLS header may be different. The second entry, **100064 (S=0)**, indicates that the stack depth is not 1 and additional label values are included in the packet. In contrast, the first entry of **100064** has an inferred S=1 which indicates a stack depth of 1 and makes it the last label in the packet. The dual entry indicates that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

The incoming label is the MPLS header of the MPLS packet, and is assigned by RSVP to the upstream neighbor. Juniper Networks routers dynamically assign labels for RSVP traffic-engineered LSPs in the range from 100,000 through 1,048,575.

The router assigns labels starting at label 100,000, in increments of 16. The sequence of label assignments is 100,000, 100,016, 100,032, 100,048, and so on. At the end of the assigned labels, the label numbers start over at 100001, incrementing in units of 16. Juniper Networks reserves labels for various purposes. [Table 58 on page 2094](#) lists the various label range allocations for incoming labels.

Table 58: MPLS Label Range Allocations

Incoming Label	Status
0 through 15	Reserved by IETF
16 through 1023	Reserved for static LSP assignment
1024 through 9999	Reserved for internal use (for example, CCC labels)
10,000 through 99,999	Reserved for static LSP assignment
100,000 through 1,048,575	Reserved for dynamic label assignment

Verifying an LSP on the Ingress Router

Purpose

You can verify the availability of an LSP when it is up by examining the **inet.3** routing table on the ingress router. The **inet.3** routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses.

Action

To verify an LSP on an ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show route table inet.3
```

Sample Output

```
user@R1> show route table inet.3
```

```
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32          *[RSVP/7] 4w0d 22:40:57, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6
```

Meaning

The sample output shows the **inet.3** routing table. By default, only BGP and MPLS virtual private networks (VPNs) can use the **inet.3** route table to resolve next-hop information. One destination is listed in the route table, **10.0.0.6**. This destination (**10.0.0.6**) is signaled by RSVP, and is the current active path, as indicated by the asterisk (*). The protocol preference for this route is **7**, and the metric associated with it is **20**. The label-switched path is **R1-to-R6**, through interface **so-0/0/2.0**, which is the physical next-hop transit interface.

Typically, the penultimate router in the LSP either pops the packet's label or changes the label to a value of 0. If the penultimate router pops the top label and an IPv4 packet is underneath, the egress router routes the IPv4 packet, consulting the IP routing table **inet.0** to determine how to forward the packet. If another type of label (such as one created by Label Distribution Protocol (LDP) tunneling or VPNs, but not IPv4) is underneath the top label, the egress router does not examine the **inet.0** routing table. Instead, it examines the **mpls.0** routing table for forwarding decisions.

If the penultimate router changes the packet's label to a value of 0, the egress router strips off the 0 label, indicating that an IPv4 packet follows. The packet is examined by the **inet.0** routing table for forwarding decisions.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or whether this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the **inet.0** and **inet.3** routing tables, seeking the next hop with the lowest preference; for example, RSVP preference 7 is preferred over OSPF preference 10. The RSVP signaled LSP is used to reach the BGP next hop. This is the default when the BGP next hop

equals the LSP egress address. Once the BGP next hop is resolved through an LSP, the BGP traffic uses the LSP to forward BGP transit traffic.

Verifying an LSP on a Transit Router

Purpose

You can verify the availability of an LSP when it is up by examining the **mpls.0** routing table on a transit router. MPLS maintains the **mpls.0** routing table, which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Action

To verify an LSP on a transit router, enter the following Junos OS CLI operational mode command:

```
user@host> show route table mpls.0
```

Sample Output

```
user@R3> show route table mpls.0
```

```
mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                * [MPLS/0] 7w3d 22:20:56, metric 1
                  Receive
1                * [MPLS/0] 7w3d 22:20:56, metric 1
                  Receive
2                * [MPLS/0] 7w3d 22:20:56, metric 1
                  Receive
100064            * [RSVP/7] 2w1d 04:17:36, metric 1
                  > via so-0/0/3.0, label-switched-path R1-to-R6
100064 (S=0)      * [RSVP/7] 2w1d 04:17:36, metric 1
                  > via so-0/0/3.0, label-switched-path R1-to-R6
```

Meaning

The sample output from transit router **R3** shows route entries in the form of MPLS label entries, indicating that there is only one active route, even though there are five active entries.

The first three MPLS labels are reserved MPLS labels defined in RFC 3032. Packets received with these label values are sent to the Routing Engine for processing. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label and Label 2 is the IPv6 explicit null label.

The two entries with the **100064** label are for the same LSP, **R1-to-R6**. There are two entries because the stack values in the MPLS header may be different. The second entry, **100064 (S=0)**, indicates that the stack depth is not 1 and additional label values are included in the packet. In contrast, the first entry of **100064** has an inferred S=1 which indicates a stack depth of 1 and makes it the last label in the packet. The dual entry indicates that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

The incoming label is the MPLS header of the MPLS packet, and is assigned by RSVP to the upstream neighbor. Juniper Networks routers dynamically assign labels for RSVP traffic-engineered LSPs in the range from 100,000 through 1,048,575.

The router assigns labels starting at label 100,000, in increments of 16. The sequence of label assignments is 100,000, 100,016, 100,032, 100,048, and so on. At the end of the assigned labels, the label numbers start over at 100001, incrementing in units of 16. Juniper Networks reserves labels for various purposes. [Table 58 on page 2094](#) lists the various label range allocations for incoming labels.

Table 59: MPLS Label Range Allocations

Incoming Label	Status
0 through 15	Reserved by IETF
16 through 1023	Reserved for static LSP assignment
1024 through 9999	Reserved for internal use (for example, CCC labels)
10,000 through 99,999	Reserved for static LSP assignment
100,000 through 1,048,575	Reserved for dynamic label assignment

Verify That Load Balancing Is Working

Purpose

After configuring load balancing, check that traffic is load-balanced equally across paths. In this section, the command output reflects the load-balancing configuration of the example network shown in [“Load-Balancing Network Topology” on page 2101](#). The **clear** commands are used to reset LSP and interface counters to zero so that the values reflect the operation of the load-balancing configuration.

Action

To verify load balancing across interfaces and LSPs, use the following command on the ingress router:

```
user@host# show configuration
```

To verify load balancing across interfaces and LSPs, use the following commands on a transit router:

```
user@host# show route
user@host# show route forwarding-table
user@host# show mpls lsp statistics
user@host# monitor interface traffic
user@host# clear mpls lsp statistics
user@host# clear interface statistics
```

Sample Output

The following sample output is for the configuration on ingress router **R1**:

```
user@R1> show configuration | no-more
[...Output truncated...]
routing-options {
  [...Output truncated...]
  forwarding-table {
    export lbpp;
  }
}
[...Output truncated...]
policy-options {
  policy-statement lbpp {
    then {
      load-balance per-packet;
    }
  }
}
```

Meaning

The sample output for the **show configuration** command on ingress router **R1** shows that load balancing is correctly configured with the **lbpp** policy statement. Also, the **lbpp** policy is exported into the forwarding table at the **[edit routing-options]** hierarchy level.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route 192.168.0.1 terse

inet.0: 25 destinations, 27 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
A Destination      P Prf  Metric 1   Metric 2  Next hop      AS path
* 192.168.0.1/32   O  10           3           so-0/0/1.0
                                >so-0/0/2.0

[...Output truncated...]
```

Meaning

The sample output for the **show route** command issued on transit router **R2** shows the two equal-cost paths (**so-0/0/1** and **so-0/0/2**) through the network to the loopback address to **R0 (192.168.0.1)**. Even though the right angle bracket (>) usually indicates the active route, in this instance it does not, as shown in the following four sample outputs.

Sample Output

The following sample output is from transit router R2:

```
user@R2> monitor interface traffic

R2                               Seconds: 65                               Time: 11:41:14

Interface  Link  Input packets  (pps)  Output packets  (pps)
so-0/0/0   Up    0              (0)    0              (0)
so-0/0/1   Up    126            (0)    164659         (2128)
so-0/0/2   Up    85219          (1004) 164598         (2128)
so-0/0/3   Up    0              (0)    0              (0)
fe-0/1/0   Up    328954         (4265) 85475          (1094)
fe-0/1/1   Up    0              (0)    0              (0)
fe-0/1/2   Up    0              (0)    0              (0)
fe-0/1/3   Up    0              (0)    0              (0)

[...Output truncated...]
```

Meaning

The sample output for the **monitor interface traffic** command issued on transit router **R2** shows that output traffic is evenly distributed across the two interfaces **so-0/0/1** and **so-0/0/2**.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show mpls lsp statistics
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 5 sessions
To          From          State   Packets   Bytes LSPname
192.168.0.1 192.168.1.1 Up      87997    17951388 lsp1
192.168.0.1 192.168.1.1 Up      87997    17951388 lsp2
192.168.0.1 192.168.1.1 Up      87997    17951388 lsp3
192.168.0.1 192.168.1.1 Up      87997    17951388 lsp4
192.168.6.1 192.168.0.1 Up        0          0 r0-r1
Total 5 displayed, Up 5, Down 0
```

Meaning

The sample output for the **show mpls lsp statistics** command issued on transit router **R2** shows that output traffic is evenly distributed across the four LSPs configured on ingress router **R6**.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route forwarding-table destination 10.0.90.14
Routing table: inet
Internet:
Destination      Type RtRef Next hop          Type Index NhRef Netif
10.0.90.12/30    user    0                ulst 262144 6
                  ucst 345  5 so-0/0/1.0
                  ucst 339  2 so-0/0/2.0
```

Meaning

The sample output for the **show route forwarding-table destination** command issued on transit router **R2** shows **ulst** in the **Type** field, which indicates that load balancing is working. The two unicast (**ucst**) entries in the **Type** field are the two next hops for the LSPs.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route forwarding-table | find mpls
```

Routing table: mpls

MPLS:

Destination	Type	RtRef	Next hop	Type	Index	NhRef	Netif
default	perm	0		dscd	38	1	
0	user	0		recv	37	3	
1	user	0		recv	37	3	
2	user	0		recv	37	3	
100112	user	0		Swap	100032		so-0/0/1.0
100128	user	0		Swap	100048		so-0/0/1.0
100144	user	0	10.0.12.13	Swap	100096		fe-0/1/0.0
100160	user	0		Swap	100112		so-0/0/2.0
100176	user	0		Swap	100128		so-0/0/2.0

Meaning

The sample output for the **show route forwarding-table | find mpls** command issued on transit router R2 shows the MPLS routing table that contains the labels received and used by this router to forward packets to the next-hop router. This routing table is used mostly on transit routers to route packets to the next router along an LSP. The first three labels in the **Destination** column (Label 0, Label 1, and Label 2) are automatically entered by MPLS when the protocol is enabled. These labels are reserved MPLS labels defined in RFC 3032. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label, and Label 2 is the IPv6 explicit null label.

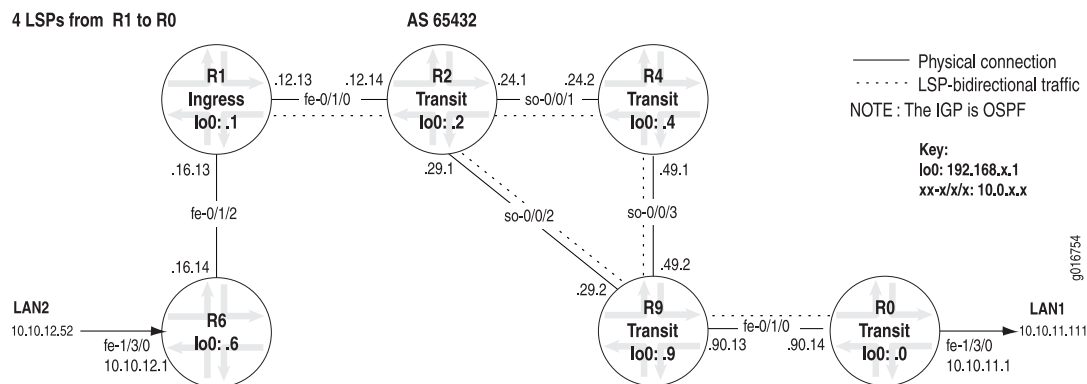

The remaining five labels in the **Destination** column are nonreserved labels that the router uses to forward traffic, and the last column **Netif**, shows the interfaces used to send the labeled traffic. For nonreserved labels, the second **Type** column shows the operation performed on matching packets. In this example, all non-reserved packets are swapped for outgoing packet labels. For example, packets with the label **100112** have their label swapped for **100032** before they are pushed out of interface **so-0/0/1.0**.

Example: Load-Balanced MPLS Network

When you configure several RSVP LSPs to the same egress router, the LSP with the lowest metric is selected and carries all traffic. If all of the LSPs have the same metric, one of the LSPs is selected at random and all traffic is forwarded over it. To distribute traffic equally across all LSPs, you can configure load balancing on the ingress or transit routers, depending on the type of load balancing configured.

Figure 161 on page 2102 illustrates an MPLS network with four LSPs configured to the same egress router (R0). Load balancing is configured on ingress router R1. The example network uses Open Shortest Path First (OSPF) as the interior gateway protocol (IGP) with OSPF area 0.0.0.0. An IGP is required for the Constrained Shortest Path First (CSPF) LSP, which is the default for the Junos OS. In addition, the example network uses a policy to create BGP traffic.

Figure 161: Load-Balancing Network Topology

The network shown in Figure 161 on page 2102 consists of the following components:

- A full-mesh interior BGP (IBGP) topology, using AS 65432
- MPLS and RSVP enabled on all routers
- A send-statics policy on routers R1 and R0 that allows a new route to be advertised into the network
- Four unidirectional LSPs between R1 and R0, and one reverse direction LSP between R0 and R1, which allows for bidirectional traffic
- Load balancing configured on ingress router R1

The network shown in Figure 161 on page 2102 is a BGP full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

Router Configurations for the Load-Balanced MPLS Network

Purpose

The configurations in this topic are for the six routers in the example network illustrated in “Load-Balancing Network Topology” on page 2101.

Action

To display the configuration of a router, use the following Junos OS CLI operational mode command:

```
user@host> show configuration | no-more
```

Sample Output 1

The following configuration output is for edge router **R6**.

```
user@R6> show configuration | no-more
[...Output truncated...]
interfaces {
    fe-0/1/2 {
        unit 0 {
            family inet {
                address 10.0.16.14/30;
            }
            family mpls; #MPLS enabled on relevant interfaces
        }
    }
    fe-1/3/0 {
        unit 0 {
            family inet {
                address 10.10.12.1/24;
            }
        }
    }

      }
      then accept;
    }
  }
}
}

```

Meaning

Sample Outputs 1 through 6 show the base interfaces, routing options, protocols, and policy options configurations for all six routers in the example network illustrated in [“Example: Load-Balanced MPLS Network” on page 2101](#).

All routers in the network have MPLS, RSVP, and BGP enabled. OSPF is configured as the IGP, and relevant interfaces have basic IP information and MPLS support.

In addition, all routers have the router ID (RID) configured manually at the **[edit routing-options]** hierarchy level to avoid duplicate RID problems. The **passive** statement is included in the OSPF configuration to ensure that protocols are not run over the loopback (**lo0**) interface and that the loopback (**lo0**) interface is advertised correctly throughout the network.

Sample Outputs 1, 3, 4, and 5 for **R6**, **R2**, **R4**, and **R9** show the base configuration for transit label-switched routers. The base configuration includes all interfaces enabled for MPLS, the RID manually configured, and the relevant protocols (RSVP, MPLS, BGP, and OSPF).

Sample Output 2 from ingress router **R1** shows the base configuration plus four LSPs (**lsp1** through **lsp4**) configured to **R0**. The four LSPs are configured with different primary paths that specify a loose hop through **R4** for **lsp1** and **lsp4**, and through **R2** for **lsp2** and **lsp3**.

To create traffic, **R1** has a static route (**100.100.1.0/24**) configured at the **[edit routing-options static route]** hierarchy level. The prefix is included in the send-statics policy at the **[edit policy-options send statics]** hierarchy level so the routes can become BGP routes.

In addition, on the ingress router **R1**, load balancing is configured using the **per-packet** option, and the policy is exported at the **[edit routing-options forwarding-table]** hierarchy level.

Sample Output 6 from egress router **R0** shows one LSP (**r0-r6**) to **R6** used to create bidirectional traffic. OSPF requires bidirectional LSP reachability before it will advertise the LSP into the IGP. Although the

LSP is advertised into the IGP, no hello messages or routing updates occur over the LSP—only user traffic is sent over the LSP. The router uses its local copy of the IGP database to verify bidirectional reachability.

In addition, **R0** has a static route (**100.100.10.0/24**) configured at the **[edit routing-options static route]** hierarchy level. The prefix is included in the send-statics policy at the **[edit policy-options send statics]** hierarchy level so the routes can become BGP routes.

Traffic Flows Before Load Balancing

Purpose

The following sample output illustrates the details to look for when you issue different **show** commands to check if traffic is balanced. The following output is before load balancing is configured and is taken from transit router R2 in the network shown in [“Load-Balancing Network Topology” on page 2101](#).

Action

To check the distribution of traffic across interfaces and LSPs, use the following CLI operational mode commands:

```
user@host> show route | find mpls
user@host> monitor interface traffic
user@host> show mpls lsp statistics
```

Sample Output 1

```
user@R2> show route | find mpls

mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 1d 00:12:08, metric 1
            Receive
1          *[MPLS/0] 1d 00:12:08, metric 1
            Receive
2          *[MPLS/0] 1d 00:12:08, metric 1
            Receive
100112     *[RSVP/7] 13:10:36, metric 1
            > via so-0/0/1.0, label-switched-path lsp1
100128     *[RSVP/7] 13:01:08, metric 1
            > via so-0/0/1.0, label-switched-path lsp4
100144     *[RSVP/7] 00:26:49, metric 1
            > to 10.0.12.13 via fe-0/1/0.0, label-switched-path r0-r6
```

```

100160      *[RSVP/7] 00:23:25, metric 1
             > via so-0/0/2.0, label-switched-path lsp2
100176      *[RSVP/7] 00:23:25, metric 1
             > via so-0/0/2.0, label-switched-path lsp3

```

Sample Output 2

```
user@R2> monitor interface traffic
```

```

R2                               Seconds: 89                               Time: 14:33:09

Interface    Link  Input packets      (pps)      Output packets      (pps)

192.168.0.1	192.168.6.1	Up	0	0	lsp4
192.168.6.1	192.168.0.1	Up	0	0	r0-r6
Total 5 displayed, Up 5, Down 0					

Meaning

Sample Outputs 1 through 3 from transit router **R2** show that traffic is not balanced across LSPs or interfaces.

Sample Output 1 for the **show route** command shows that all LSPs have the same metric (1) to the destination, even though they are traversing different interfaces. **lsp1** and **lsp4** are using **so-0/0/1**, while **lsp2** and **lsp3** are using **so-0/0/2**.

Sample Output 2 for the **monitor interface traffic** command shows that traffic is not evenly balanced across interfaces **so-0/0/1** and **so-0/0/2**. Almost all traffic is going out **so-0/0/2**.

Sample Output 3 for the **show mpls lsp statistics** command shows that traffic across LSPs is not balanced. All traffic is going over **lsp1**.

Verify the Operation of Uneven Bandwidth Load Balancing

Purpose

When a router is performing unequal-cost load balancing between LSPs paths, the **show route detail** command displays a balance field associated with each next hop being used.

Action

To verify that an RSVP LSP is unevenly load-balanced, use the following Junos OS CLI operational mode commands:

```
user@host> show route protocol rsvp detail
user@host> show mpls lsp statistics
```

Sample Output

```
user@R1> show route protocol rsvp detail

inet.0: 25 destinations, 25 routes (25 active, 0 holddown, 0 hidden)

Meaning

The sample output from ingress router **R1** shows that traffic is distributed according to the LSP bandwidth configuration, as indicated by the **Balance: xx%** field. For example, **lsp1** has 10 Mbps of bandwidth configured, as reflected in the **Balance: 10%** field.

Checklist for Collecting Crash Data

Problem

Description: [Table 60 on page 2122](#) provides links commands for collection crash data.

Solution

Table 60: Checklist for Collecting Crash Data

Tasks	Command or Action
“Understand Crash Data Collection” on page 2123	
“Collect Crash Data for a Routing Engine Kernel” on page 2124	
1. Check the Routing Engine Core Files on page 2124	<code>file list detail /var/crash</code>
2. Clear the NVRAM Contents on page 2147	
a. List the Core Files on page 2125	<pre>start shell su root password cd /var/crash ls -l</pre>

Understand Crash Data Collection

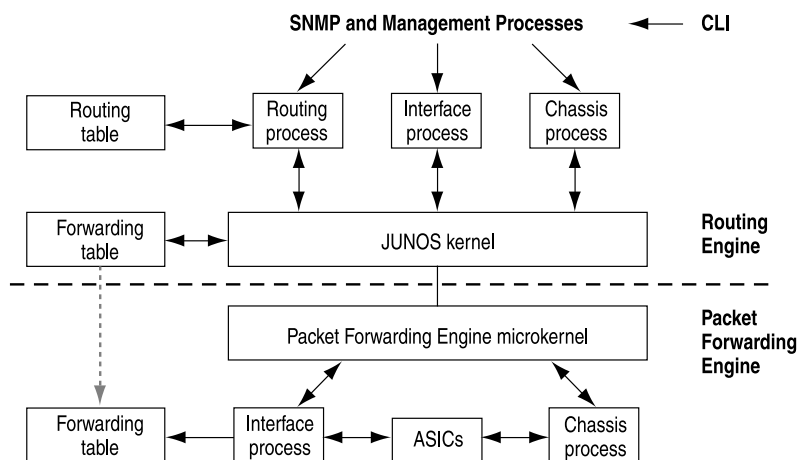

A crash can occur in one of three areas in the Junos OS architecture (see [Figure 162 on page 2124](#)):

- Routing Engine kernel

- Routing Engine daemons (processes)
- Packet Forwarding Engine microkernel

Figure 162: Three Areas Where a Software Crash Can Occur

Software Architecture

Collect Crash Data for a Routing Engine Kernel

Purpose

When a Routing Engine kernel crashes, the Routing Engine automatically reboots. By default, the Juniper Networks router does not attempt to dump a core if the Routing Engine kernel crashes. As a result, there is no crash data on the router to help investigate the crash. In addition, the system log messages are similar to those generated when the router is powered down and restarted, so you cannot tell if the Routing Engine restart was caused by a kernel crash or a normal power restart.

To collect crash data for a Routing Engine kernel crash, follow these steps:

1. [Check the Routing Engine Core Files | 2124](#)
2. [List the Core Files | 2125](#)
3. [Compress the vmcore File | 2126](#)
4. [Log Software Version Information | 2127](#)
5. [Open a Case with JTAC | 2128](#)

Check the Routing Engine Core Files

Purpose

If you observe disruption to the Routing Engine kernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action

To check the **/var/crash** directory, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
```

```
total 1577912
drwxr-x---  2 root  wheel      512 Sep  9 11:59 ./
drwxr-xr-x 22 root  wheel      512 Oct 29 2001 ../
-rw-r--r--  1 root  wheel        2 Jul 20 01:11 bounds
-rw-r--r--  1 root  wheel 2166913 Jul 20 01:11 kernel.0
-rw-r--r--  1 root  wheel        5 Feb 15 2002 minfree
-rw-----  1 root  wheel 805306368 Jul 20 01:11 vmcore.0
```

Meaning

The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any kernel core files created around the time of the crash. In the example above, two core files are listed: **kernel.0** and **vmcore.0**.

List the Core Files

Purpose

To list the core files, follow these steps:

Action

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

```
root@host% cd /var/crash
root@host% ls -l
```

4. Look for any core files created around the time of the crash.

Sample Output

user@host> **start shell**

```
% su
Password: ****
root@host% cd /var/crash
root@host% ls -l
total 1577908
-rw-r--r-- 1 root wheel          2 Jul 20 01:11 bounds
-rw-r--r-- 1 root wheel 2166913 Jul 20 01:11 kernel.0
-rw-r--r-- 1 root wheel          5 Feb 15 2002 minfree
-rw----- 1 root wheel 805306368 Jul 20 01:11 vmcore.0
```

Meaning

The sample output lists the contents of the **/var/crash** directory and shows the current core files **kernel.0** and **vmcore.0**.

Compress the vmcore File

Purpose

The **gzip** compression utility is used to compress files. Compress the **vmcore** file if it is larger than 50 MB. Files created using the **gzip** command end with the file extension **.gz**.

NOTE: Use lowercase for the **gzip** command when you are in the shell.

Action

To compress the **vmcore** file with gzip, use the following command from the shell:

```
root@host% gzip vmcore .number
```

To unzip the **vmcore** file with gzip, use the following command from the shell:

```
root@host% gzip -d vmcore .number.gz
```

Meaning

The contents of the **vmcore** file are compressed into a single compressed file named **vmcore.number.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose

To log the Junos OS version information.

Action

To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output

```
user@host> show version
```

```

Problem

Description: To open a case with JTAC, call one of the Support phone numbers or create a case via [Case Manager](#).

Collect Crash Data for Routing Engine Daemons

To collect crash data for Routing Engine daemons, follow these steps:

1. [Check for Daemon Core Files | 2132](#)
2. [List the Daemon Core Files | 2134](#)
3. [Compress the Daemon Core Files | 2135](#)
4. [Log Software Version Information | 2136](#)
5. [Open a Case with JTAC | 2137](#)

Check for Daemon Core Files

Purpose

If you observe disruption to routing protocol operation, system log operation, Simple Network Management Protocol (SNMP) operation, or other operations handled by Routing Engine daemons, check the **/var/tmp** directory for any daemon core files created around the time of the crash.

Action

To check the **/var/tmp** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/tmp
```

Sample Output

```
user@host> file list detail /var/tmp
```

```
total 1292622
drwxrwxrwt  3 root  field      512 Dec 31 06:48 ./
drwxr-xr-x 21 root  field      512 Mar  5 1999 ../
-rw-rw----  1 root  field 119713792 Nov 17 21:58 rpd.core.0
-rw-rw----  1 root  field 120782848 Nov 17 22:12 rpd.core.1
```

Meaning

The sample output lists the contents of the **/var/tmp/** directory. Look for any daemon core files created around the time of the crash. In the example above, two core files are listed: **rpd.core.0** and **rpd.core.1**.

[Table 61 on page 2133](#) lists the major Routing Engine daemons supported by the Junos OS.

Table 61: Major Routing Engine Daemons

Executable Name	Definition	Description
rpd	Routing protocol daemon	Provides routing protocol intelligence (Border Gateway Protocol [BGP], Intermediate System-to-Intermediate System [ISIS], Open Shortest Path First [OSPF], and so on).
dcd	Device control daemon	Manages all interface devices.
mgd	Management daemon	Provides user configuration access to the system. The CLI is a client of mgd .
snmpd	Simple Network Management Protocol daemon	Provides remote network management information to the network management system.

Table 61: Major Routing Engine Daemons (continued)

Executable Name	Definition	Description
chassisd	Chassis daemon	Monitors and manages Flexible PIC Concentrator (FPC) slots and other environmental components.
alarmd	Alarm daemon	Manages system alarm notifications.
apspd	Automatic protection switching daemon	Provides SONET Automatic Protection Switching (APS) functionality.
sampld	Traffic sampling daemon	Gathers traffic sampling information.
vrrpd	Virtual Router Redundancy Protocol daemon	Provides Virtual Router Redundancy Protocol (VRRP) functionality.
syslogd	System log daemon	Manages the router system logging operation.
mib2d	MIB2 daemon	Management Information Base (MIB) subagent for MIB2.

List the Daemon Core Files

Purpose

To list the daemon core files.

Action

To list the daemon core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is **%** instead of **>**, for example:

```
% su
Password: ****
```

3. Change the directory to **/var/tmp** and type **ls -l**, for example:

```
root@host% cd /var/tmp
root@host% ls -l
```

4. Look for any daemon core files created around the time of the crash.

Sample Output

user@host> **start shell**

```
% su
Password: ****
root@host% cd /var/tmp
root@host% ls -l
total 1292618
-rw-rw----  1 root  field  119713792 Nov 17 21:58  rpd.core.0
-rw-rw----  1 root  field  120782848 Nov 17 22:12  rpd.core.1
```

Meaning

The sample output lists the contents of the **/var/tmp** directory and shows the current core file (**rpd.core.1**) and one previous core file (**rpd.core.0**) for the routing protocol daemon (**rpd**). For each daemon, you can have a total of five core files in the **/var/tmp** directory: the current core file and the four previous core files numbered 0 through 4 (from oldest to newest).

Compress the Daemon Core Files

Purpose

The **gzip** compression utility is used to compress the files if they are large. Files created using the **gzip** command end with the file extension **.gz**. Compress the core file if it is over 50 MB.

NOTE: Use lowercase for the **gzip** command when you are in the shell.

You only need to compress the daemon core files when the tarball file is not created.

Action

To compress the daemon core file with **gzip**, use the following command from the shell:

```
root@host% gzip daemon-executable-name.core.number
```

Sample Output

```
root@host% gzip rpd.core.0
gzip rpd.core.0
```

Meaning

The contents of the daemon core file are compressed into a single compressed file named **daemon.number.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose

To log the Junos OS version information.

Action

```

Meaning

The sample output lists the contents of the **/var/tmp/** directory. Look for any daemon core files created around the time of the crash. In the example above, two core files are listed: **rpd.core.0** and **rpd.core.1**.

[Table 61 on page 2133](#) lists the major Routing Engine daemons supported by the Junos OS.

Table 62: Major Routing Engine Daemons

Executable Name	Definition	Description
rpdd	Routing protocol daemon	Provides routing protocol intelligence (Border Gateway Protocol [BGP], Intermediate System-to-Intermediate System [ISIS], Open Shortest Path First [OSPF], and so on).
dcd	Device control daemon	Manages all interface devices.
mgd	Management daemon	Provides user configuration access to the system. The CLI is a client of mgd .
snmpd	Simple Network Management Protocol daemon	Provides remote network management information to the network management system.
chassisd	Chassis daemon	Monitors and manages Flexible PIC Concentrator (FPC) slots and other environmental components.
alarmd	Alarm daemon	Manages system alarm notifications.
apsd	Automatic protection switching daemon	Provides SONET Automatic Protection Switching (APS) functionality.
sampled	Traffic sampling daemon	Gathers traffic sampling information.
vrripd	Virtual Router Redundancy Protocol daemon	Provides Virtual Router Redundancy Protocol (VRRP) functionality.
syslogd	System log daemon	Manages the router system logging operation.
mib2d	MIB2 daemon	Management Information Base (MIB) subagent for MIB2.

List the Daemon Core Files

Purpose

To list the daemon core files.

Action

To list the daemon core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Change the directory to **/var/tmp** and type **ls -l**, for example:

```
root@host% cd /var/tmp
root@host% ls -l
```

4. Look for any daemon core files created around the time of the crash.

Sample Output

```
user@host> start shell
```

```
% su
Password: ****
root@host% cd /var/tmp
root@host% ls -l
total 1292618
-rw-rw----  1 root  field  119713792 Nov 17 21:58  rpd.core.0
-rw-rw----  1 root  field  120782848 Nov 17 22:12  rpd.core.1
```

Meaning

The sample output lists the contents of the **/var/tmp** directory and shows the current core file (**rpd.core.1**) and one previous core file (**rpd.core.0**) for the routing protocol daemon (**rpd**). For each daemon, you can have a total of five core files in the **/var/tmp** directory: the current core file and the four previous core files numbered 0 through 4 (from oldest to newest).

Compress the Daemon Core Files

Purpose

The gzip compression utility is used to compress the files if they are large. Files created using the **gzip** command end with the file extension **.gz**. Compress the core file if it is over 50 MB.

NOTE: Use lowercase for the **gzip** command when you are in the shell.

You only need to compress the daemon core files when the tarball file is not created.

Action

To compress the daemon core file with gzip, use the following command from the shell:

```
root@host% gzip daemon-executable-name.core.number
```

Sample Output

```
root@host% gzip rpd.core.0
gzip rpd.core.0
```

Meaning

The contents of the daemon core file are compressed into a single compressed file named **daemon.number.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Collect Crash Data for the Packet Forwarding Engine Microkernel

Purpose

Each of the following Packet Forwarding Engine components of a Juniper Networks router runs a microkernel:

- Flexible PIC Concentrator (FPC) on M-series platforms except for the M5 and M10 Internet routers
- Gibson Flexible PIC Concentrator (GFPC) on T640 and T320 Internet routing nodes
- Switched Printed Mezzanine Board (SPMB) on T640 and T320 Internet routing nodes
- Forwarding Engine Board (FEB) on M5 and M10 Internet routers

- System Switching Board (SSB) on an M20 Internet router
- System Control Board (SCB) on an M40 Internet router
- Switching and Forwarding Module (SFM) on M160 and M40e Internet routers

When a crash occurs, crash stack traceback and registration information is placed into nonvolatile random access memory (NVRAM) on the different components. [Table 63 on page 2142](#) shows where the NVRAM is located for the components for each router.

Table 63: NVRAM Location on the Microkernel of the Packet Forwarding Engine Components

Router Type	NVRAM Location
M5 and M10	FEB
M20	SSB and crash stack traceback and register information for the FPC
M40	SCB and crash stack traceback and register information for the FPC
M40e	FPC SFM
M160	FPC SFM
T320	GFPC SPMB
T640	GFPC SPMB

To collect crash data for the Packet Forwarding Engine microkernel, follow these steps:

1. [Display the Crash Stack Traceback and Registration Information | 2143](#)
2. [Clear the NVRAM Contents | 2147](#)
3. [Check Packet Forwarding Engine Microkernel Core Files | 2148](#)
4. [List the Core Files Generated by the Crash | 2148](#)
5. [Compress the Core Files | 2149](#)
6. [Log Software Version Information | 2150](#)
7. [Open a Case with JTAC | 2151](#)

Display the Crash Stack Traceback and Registration Information

Purpose

To display the crash stack traceback and registration information.

Action

To display the crash stack traceback and registration information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Establish a vty session to the appropriate component. Use the **vtty** command followed by the executable name for the component; for example, **scb**, **ssb0**, **ssb1**, **fpc0**, or **fpc1**:

```
root@host% vty sfm0
```

NOTE: For the M40e and M160 routers, you can also create a **cty** session to the components if the components are not online.

4. Type the **show nvram** command to view the NVRAM information.
5. Type the **show syslog messages** command to view the system log messages.

Sample Output 1

```
user@host> start shell
```

```
% su
Password: ****
root@host% vty sfm0
```

SFM platform (266Mhz PPC 603e processor, 64Mb memory, 512Kb flash)

FPC1(host vty)# show syslog messages
[0+00:00:00.780 LOG: Info] Version 4.0R5 by tlim on 2000-08-10 04:45:54 UTC
[0+00:00:00.780 LOG: Info] On-board NVRAM contains diagnostic information.
[0+00:00:03.175 LOG: Info] PFEMAN: Established connection to Master
[Jan 30 21:53:05.804 LOG: Info] SNTPD: Initial time of day set.

```

Meaning

Sample output 1 and 2 show the stack trace from the microkernel crash. Save the output from the **show nvram** and **show syslog** commands so that you can send them to JTAC when you open a case.

Clear the NVRAM Contents

Purpose

Currently the storage area for the logs on the NVRAM is limited to 4 KB. You need to delete old NVRAM logs to make room for new ones.

Action

To clear the content of the NVRAM after you have captured the necessary information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Establish a vty session to the appropriate component. Use the **vtty** command followed by the abbreviation for the component, for example:

```
root@host% vtty sfm0
SFM3(host vty)#
```

```
FPC1(host vty)#
```

4. Type the **clear nvram** command, for example:

```
SFM3(host vty)# clear nvram
FPC1(host vty)# clear nvram
```

Check Packet Forwarding Engine Microkernel Core Files

Purpose

If you observe disruption to the Packet Forwarding Engine microkernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action

To check the **/var/crash** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
```

```
var/crash:
total 456630
-rw-r--r--  1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--  1 root  wheel    65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--  1 root  wheel    65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--  1 root  wheel    65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning

The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any core files created around the time of the crash. In the example above, four core files are listed.

List the Core Files Generated by the Crash

Purpose

To list the core files generated by the crash.

Action

To list the core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

```
root@host% cd /var/crash
root@host% ls -l
```

4. Look for any core files created around the time of the crash.

Sample Output

```
user@host> start shell
```

```
% su
Password: ****
root@host% cd /var/crash
root@host% ls -l
total 456630
-rw-r--r--  1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--  1 root  wheel    65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--  1 root  wheel    65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--  1 root  wheel    65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning

The sample output shows the current core files for the different components on the router; for example, **core-FPC4.100111808032** and **core-SCB.100111004570**.

Compress the Core Files

Purpose

gzip is a compression utility used to compress the core files. Files created using the **gzip** command end with the file extension **.gz**. Compress the core files if they are larger than 50 MB.

Action

To compress the core files with gzip, use the following command from the shell:

```
root@host% gzip filename
```

Sample Output

```
root@host% gzip core-SCB.101010920452
```

Meaning

The contents of the core file are compressed into a single compressed file named **core-SCB.10101092045.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Log Software Version Information

Purpose

To log the Junos OS version information.

Action

To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output

```
user@host> show version
```

```
Hostname: host

```

Meaning

The sample output shows the hostname, router model, and the different Junos OS packages, processes, and documents.

Open a Case with JTAC

Problem

Description: To open a case with JTAC, call one of the Support phone numbers or create a case via [Case Manager](#).

Display the Crash Stack Traceback and Registration Information

Purpose

To display the crash stack traceback and registration information.

Action

To display the crash stack traceback and registration information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Establish a vty session to the appropriate component. Use the **vtty** command followed by the executable name for the component; for example, **scb**, **ssb0**, **ssb1**, **fpc0**, or **fpc1**:

```
root@host% vty sfm0
```

NOTE: For the M40e and M160 routers, you can also create a **cty** session to the components if the components are not online.

4. Type the **show nvram** command to view the NVRAM information.
5. Type the **show syslog messages** command to view the system log messages.

Sample Output 1

```
user@host> start shell
```

```
% su
Password: ****
root@host% vty sfm0

FPC1(host vty)# show syslog messages
[0+00:00:00.780 LOG: Info] Version 4.0R5 by tlim on 2000-08-10 04:45:54 UTC
[0+00:00:00.780 LOG: Info] On-board NVRAM contains diagnostic information.
```

```
[0+00:00:03.175 LOG: Info] PFEMAN: Established connection to Master
[Jan 30 21:53:05.804 LOG: Info] SNTPD: Initial time of day set.
```

Meaning

Sample output 1 and 2 show the stack trace from the microkernel crash. Save the output from the **show nvram** and **show syslog** commands so that you can send them to JTAC when you open a case.

Clear the NVRAM Contents

Purpose

Currently the storage area for the logs on the NVRAM is limited to 4 KB. You need to delete old NVRAM logs to make room for new ones.

Action

To clear the content of the NVRAM after you have captured the necessary information, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Establish a vty session to the appropriate component. Use the **vty** command followed by the abbreviation for the component, for example:

```
root@host% vty sfm0
SFM3(host vty)#
FPC1(host vty)#
```

4. Type the **clear nvram** command, for example:

```
SFM3(host vty)# clear nvram
FPC1(host vty)# clear nvram
```

Check Packet Forwarding Engine Microkernel Core Files

Purpose

If you observe disruption to the Packet Forwarding Engine microkernel, check the **/var/crash** directory for any core files created around the time of the crash.

Action

To check the **/var/crash** directory, use the following Junos OS CLI operational mode command:

```
user@host> file list detail /var/crash
```

Sample Output

```
user@host> file list detail /var/crash
```

```
var/crash:
total 456630
-rw-r--r--  1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--  1 root  wheel    65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--  1 root  wheel    65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--  1 root  wheel    65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning

The sample output lists the contents of the **/var/crash/** directory. Check the date and timestamp for any core files created around the time of the crash. In the example above, four core files are listed.

List the Core Files Generated by the Crash

Purpose

To list the core files generated by the crash.

Action

To list the core files, follow these steps:

1. Exit from the CLI environment and create a UNIX-level shell by entering the **start shell** command:

```
user@host> start shell
```

2. Type **su** and the root password when prompted. You are now in the shell and the prompt is % instead of >, for example:

```
% su
Password: ****
```

3. Change the directory to **/var/crash** and type **ls -l**, for example:

```
root@host% cd /var/crash
root@host% ls -l
```

4. Look for any core files created around the time of the crash.

Sample Output

user@host> **start shell**

```
% su
Password: ****
root@host% cd /var/crash
root@host% ls -l
total 456630
-rw-r--r--  1 root  wheel    6814720 Dec 18 08:03 core-FPC4.100111808032
-rw-r--r--  1 root  wheel    65613824 Dec 10 04:58 core-SCB.100111004570
-rw-r--r--  1 root  wheel    65613824 Dec 19 00:23 core-SCB.100111900221
-rw-r--r--  1 root  wheel    65545216 Feb  9 20:46 core-SCB.101010920452
```

Meaning

The sample output shows the current core files for the different components on the router; for example, **core-FPC4.100111808032** and **core-SCB.100111004570**.

Compress the Core Files

Purpose

gzip is a compression utility used to compress the core files. Files created using the **gzip** command end with the file extension **.gz**. Compress the core files if they are larger than 50 MB.

Action

To compress the core files with **gzip**, use the following command from the shell:

```
root@host% gzip filename
```

Sample Output

```
root@host% gzip core-SCB.101010920452
```

Meaning

The contents of the core file are compressed into a single compressed file named **core-SCB.10101092045.gz**. The **gzip** command preserves the mode, ownership, and timestamps of files when compressing or decompressing them.

Configure a Primary Path

Action

To configure a primary path with an ERO list, bandwidth, and priority, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols mpls
```

2. Configure the primary ERO list:

```
[edit protocols mpls]
user@host# set path path-name address strict
```

For example:

```
[edit protocols mpls]
user@R1# set path via-r2 10.0.12.14 strict
user@R1# set path via-r2 10.0.24.2 strict
```

3. Configure the LSP:

```
[edit protocols mpls]
user@host# set label-switched-path lsp-path-name to destination;
```

For example:

```
[edit protocols mpls]
user@R1# set label-switched-path r1-to-r5 to 192.168.5.1;
```

4. Configure the primary path:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r5]
user@R1# set primary via-r2
```

5. Configure the bandwidth:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name bandwidth bandwidth
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r5]
user@R1# set primary via-r2 bandwidth 35m
```

6. Configure the priority value:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name priority reservation-priority setup-priority
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r5]
user@R1# set primary via-r2 priority 6 6
```

7. Verify and commit the configuration:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# show
user@host# commit
```

Sample Output

The sample output below illustrates the configuration of the primary path on ingress router **R1**.

```

[edit protocols mpls]
user@R1# show
label-switched-path r1-to-r5 {
  to 192.168.5.1;
  primary via-r2 { # Bandwidth and priority configured at the primary path
    bandwidth 35m; # level of the hierarchy
    priority 6 6; # Priority setup and hold values
  }
}
path via-r2 { # Primary ERO list
  10.0.12.14 strict;
  10.0.24.2 strict;
[...Output truncated...]

[edit protocols mpls]
user@R1# commit
commit complete

```

Meaning

The sample output shows a label-switched path (LSP) with bandwidth and priority applied to only one primary path. The same parameters specified one level up in the hierarchy, at the **[edit protocols mpls label-switched-path *lsp-path-name*]** hierarchy level, affect all paths.

The path, **via-r2**, specifies the complete strict path from the ingress to the egress routers through **10.0.12.14**, **10.0.24.2**, in that order. There cannot be any intermediate routers except the ones specified. However, there can be intermediate routers between **10.0.24.2** and the egress router because the egress router is not specifically listed in the path statement. To prevent intermediate routers before egress, configure the egress router as the last router, with a strict type.

Ensuring That Secondary Paths Establish When Resources Are Diminished

The Junos OS does not require that a primary and secondary path share the same parameters. You may decide to configure your primary paths with strict resource requirements, and configure your secondary paths with less strict requirements, allowing your secondary paths to establish more readily during periods of diminished resources.

Action

To ensure that secondary paths establish when resources are diminished, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit protocols mpls]
user@host# edit label-switched-path lsp-path-name
```

For example:

```
[edit protocols mpls]
user@R1# edit label-switched-path r1-to-r4
```

2. Configure the bandwidth for the primary path, and do not configure any bandwidth for the secondary path:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# set primary primary-name bandwidth bandwidth
```

For example:

```
[edit protocols mpls label-switched-path r1-to-r4]
user@R1# set primary via-r2 bandwidth 35m
```

3. Verify and commit the configuration:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@host# show
user@host# commit
```

Sample Output

The sample output below illustrates a bandwidth configuration on ingress router R1.

```
[edit protocols mpls]
user@R1# show
label-switched-path r1-to-r4 {
  to 192.168.4.1;
  primary via-r2 {
    bandwidth 35m;
  }
  secondary via-r7 { # In this example, bandwidth is not configured for the
secondary path.
    standby;        # However you could configure a bandwidth value different
from
  }                  # that on the primary path.
```

```
}
[...Output truncated...]
```

Meaning

The sample output shows the primary path **via-r2** requires 35 Mbps of bandwidth, while secondary path **via-r7** has no constraints. The primary path is configured with strict resource requirements, while the secondary path is configured with no bandwidth requirements, allowing the secondary path to establish more readily during periods of diminished resources. One thing to keep in mind when configuring a secondary path without bandwidth requirements is that it can be subject to traffic loss due to congestion.

One-to-One Backup Overview

Fast reroute or one-to-one backup is a short-term solution to reduce packet loss associated with a particular LSP. One-to-one backup is appropriate under the following circumstances:

- Protection of a small number of LSPs relative to the total number of LSPs.
- Path selection criteria, such as bandwidth, priority, and link coloring for detour paths is critical.
- Control of individual LSPs is important.

In one-to-one backup, the ingress router adds the fast reroute object to the RSVP Path message requesting that downstream routers establish detours. Downstream routers generate Path messages and establish detours to avoid the downstream link or node. Detours are always calculated to avoid the immediate downstream link and node, providing against both link and node failure, as shown in [Figure 163 on page 2163](#).

Figure 163: One-to-One Backup Detours

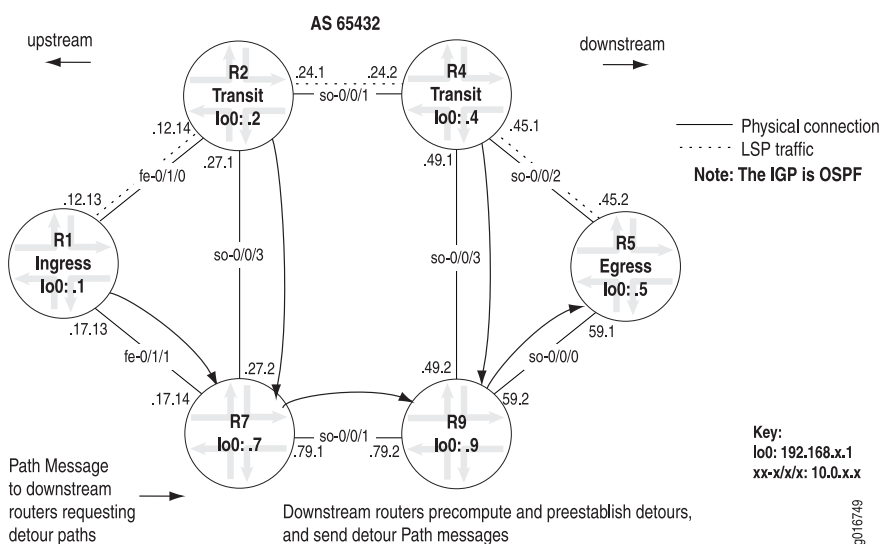

Figure 163 on page 2163 shows a network with one LSP configured from the ingress router **R1** to the egress router **R5**, transiting **R2** and **R4**. The following detours are established:

- **R1** creates a detour to **R5** via **R7** and **R9**
- **R2** creates a detour to **R5** via **R7** and **R9**
- **R4** creates a detour to **R5** via **R9**

Each detour is dedicated to a particular LSP traversing the router (one detour to one LSP). If the network topology has insufficient links and nodes, it may be impossible to establish a detour. Also, detour paths are not meant for long-term use because they may provide inadequate bandwidth and can result in congestion on the links. As soon as the ingress router calculates a new path avoiding the failure, traffic is redirected along the new path, detours are torn down, and new detours established.

Configure Link Protection

Purpose

Configuring link protection is a two-part process. The first part involves configuring link protection on the RSVP interface, and the second part sets link protection for any LSPs traversing the protected link that require use of the bypass path.

Action

To configure link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit protocols rsvp interface type-fpc/pic/port
```

For example:

```
[edit]
user@R1# edit protocols rsvp interface fe-0/1/0
```

2. Configure link protection for the interface:

```
[edit protocols rsvp interface type-fpc/pic/port]
user@R1# set link-protection
```

3. Verify the link protection configuration for the interface:

```
[edit protocols rsvp interface type-fpc/pic/port]
```

```
user@R1# show
```

4. Configure link protection for LSPs requiring use of the bypass path:

```
[edit protocols rsvp interface fe-0/1/0.0]
user@R1# top
[edit]
user@R1# edit protocols mpls label-switched-path lsp-path-name
```

For example:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
```

5. Configure link protection for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# set link-protection
```

6. Verify and the link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
user@R1# commit
```

Sample Output

The following sample output illustrates the configuration of the link protection on ingress router R1 in the network shown in [Figure 147 on page 1906](#):

```
[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
    link-protection; #Protection for the RSVP interface
}

[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
```

```

label-switched-path lsp2-r1-to-r5 { #Path level of the hierarchy
    #to 192.168.5.1;
    link-protection;

[edit protocols mpls]
user@R1# commit
commit complete

```

Meaning

The sample output shows link protection for a specific interface. After link protection is configured, a bypass path is signaled to avoid that link in case of a failure. Having a bypass path available does not in itself provide protection for LSPs that traverse the protected link. You must configure link protection on the ingress router for each LSP that will benefit from the bypass path.

Configuring and Verifying Link Protection

The following sections describe the steps you must take to configure and verify link protection (many-to-one backup):

1. [Configure Link Protection | 2166](#)
2. [Verify That Link Protection Is Up | 2168](#)

Configure Link Protection

Purpose

Configuring link protection is a two-part process. The first part involves configuring link protection on the RSVP interface, and the second part sets link protection for any LSPs traversing the protected link that require use of the bypass path.

Action

To configure link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```

[edit]
user@R1# edit protocols rsvp interface type-fpc/pic/port

```

For example:

```
[edit]
user@R1# edit protocols rsvp interface fe-0/1/0
```

2. Configure link protection for the interface:

```
[edit protocols rsvp interface type-fpc/pic/port]
user@R1# set link-protection
```

3. Verify the link protection configuration for the interface:

```
[edit protocols rsvp interface type-fpc/pic/port]
user@R1# show
```

4. Configure link protection for LSPs requiring use of the bypass path:

```
[edit protocols rsvp interface fe-0/1/0.0]
user@R1# top
[edit]
user@R1# edit protocols mpls label-switched-path lsp-path-name
```

For example:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
```

5. Configure link protection for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# set link-protection
```

6. Verify and the link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
user@R1# commit
```

Sample Output

The following sample output illustrates the configuration of the link protection on ingress router R1 in the network shown in [Figure 147 on page 1906](#):

```

[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
    link-protection; #Protection for the RSVP interface
}

[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
label-switched-path lsp2-r1-to-r5 { #Path level of the hierarchy
    #to 192.168.5.1;
    link-protection;

[edit protocols mpls]
user@R1# commit
commit complete

```

Meaning

The sample output shows link protection for a specific interface. After link protection is configured, a bypass path is signaled to avoid that link in case of a failure. Having a bypass path available does not in itself provide protection for LSPs that traverse the protected link. You must configure link protection on the ingress router for each LSP that will benefit from the bypass path.

Verify That Link Protection Is Up

Purpose

When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in [Figure 147 on page 1906](#), a bypass path should be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

Action

To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```

user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface

```

Sample Output

```

user@R1> show mpls lsp extensive | no-more
Ingress LSP: 1 sessions

```

Meaning

The sample output from ingress router **R1** shows that **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have link protection up, and both LSPs are using the bypass path, **10.0.12.14**. However, the **show mpls lsp** command does not list the bypass path. For information about the bypass path, use the **show rsvp session** command.

Sample Output

```

Meaning

The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the **show mpls lsp** command. However, because link protection is an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass > interface-address**, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1** (**lsp2-r1-to-r5**) is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0**. Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	35Mbps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

Configure Node-Link Protection

Configuring node-link protection is a two-part process. The first part involves configuring node-link protection for any LSPs traversing the protected node that require use of the bypass path, and the second part sets link protection on the outgoing RSVP interface on routers in the LSP.

Action

To configure node-link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp-path-name
```

For example:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
```

2. Configure node-link protection for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
```

```
user@R1# set node-link-protection
```

3. Verify the node-link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
```

4. Configure link protection for the interface:

```
[edit protocols]
user@R1# edit protocols rsvp interface interface-name
```

For example:

```
[edit protocols]
user@R1# edit protocols rsvp interface fe-0/1/0
```

5. Configure link protection:

```
[edit protocols rsvp interface interface-name]
user@R1# set link-protection
```

6. Verify the link protection configuration for the interface, and commit both configurations:

```
[edit protocols rsvp interface interface-name]
user@R1# show
user@R1# commit
```

7. Repeat Step 1 through Step 3 on any other ingress routers that have LSPs requiring use of the bypass path.
8. Repeat Step 4 and Step 5 on routers with outgoing interfaces in the LSP.

Sample Output

The following sample output shows the configuration of node-link protection on ingress router R1 in the network shown in [Figure 147 on page 1906](#):

```
[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
```

```

user@R1# show
label-switched-path lsp2-r1-to-r5 { #Label-switched-path level of the hierarchy

    to 192.168.5.1;
    node-link-protection; #LSP node-link protection

[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
    link-protection; #Link protection for the RSVP interface
}

[edit protocols rsvp]
user@R1# commit
commit complete

```

Meaning

The sample output shows the configuration of node-link protection for an LSP. After node-link protection is configured, bypass paths are signaled to avoid the protected link or node in case of failure. Having bypass paths available does not in itself provide protection for LSPs that traverse the protected node. You must include the **node-link-protection** statement on the ingress router for each LSP that will benefit from the bypass path.

Configuring and Verifying Node-Link Protection

The following section describes the steps you must take to configure and verify many-to-one backup.

1. [Configure Node-Link Protection | 2175](#)
2. [Verify That Node-Link Protection Is Up | 2177](#)

Configure Node-Link Protection

Configuring node-link protection is a two-part process. The first part involves configuring node-link protection for any LSPs traversing the protected node that require use of the bypass path, and the second part sets link protection on the outgoing RSVP interface on routers in the LSP.

Action

To configure node-link protection, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp-path-name
```

For example:

```
[edit]
user@R1# edit protocols mpls label-switched-path lsp2-r1-to-r5
```

2. Configure node-link protection for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# set node-link-protection
```

3. Verify the node-link protection configuration for the LSP:

```
[edit protocols mpls label-switched-path lsp-path-name]
user@R1# show
```

4. Configure link protection for the interface:

```
[edit protocols]
user@R1# edit protocols rsvp interface interface-name
```

For example:

```
[edit protocols]
user@R1# edit protocols rsvp interface fe-0/1/0
```

5. Configure link protection:

```
[edit protocols rsvp interface interface-name]
user@R1# set link-protection
```

6. Verify the link protection configuration for the interface, and commit both configurations:

```
[edit protocols rsvp interface interface-name]
user@R1# show
user@R1# commit
```

7. Repeat Step 1 through Step 3 on any other ingress routers that have LSPs requiring use of the bypass path.
8. Repeat Step 4 and Step 5 on routers with outgoing interfaces in the LSP.

Sample Output

The following sample output shows the configuration of node-link protection on ingress router R1 in the network shown in [Figure 147 on page 1906](#):

```
[edit protocols mpls label-switched-path lsp2-r1-to-r5]
user@R1# up

[edit protocols mpls]
user@R1# show
label-switched-path lsp2-r1-to-r5 { #Label-switched-path level of the hierarchy

    to 192.168.5.1;
    node-link-protection; #LSP node-link protection

[edit protocols rsvp]
user@R1# show
interface fe-0/1/0.0 {
    link-protection; #Link protection for the RSVP interface
}

[edit protocols rsvp]
user@R1# commit
commit complete
```

Meaning

The sample output shows the configuration of node-link protection for an LSP. After node-link protection is configured, bypass paths are signaled to avoid the protected link or node in case of failure. Having bypass paths available does not in itself provide protection for LSPs that traverse the protected node. You must include the **node-link-protection** statement on the ingress router for each LSP that will benefit from the bypass path.

Verify That Node-Link Protection Is Up

Purpose

After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in [Figure 7 on page 144](#), two

bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

Action

To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

```
show mpls lsp
show mpls lsp extensive
show rsvp interface
show rsvp interface extensive
show rsvp session detail
```

Sample Output

```
user@R1> show mpls lsp

Total 2 displayed, Up 2, Down 0
```

Meaning

Sample output from **R1** for the **show mpls lsp** command shows a brief description of the state of configured and active LSPs for which **R1** is the ingress, transit, and egress router. All LSPs are up. **R1** is the ingress router for **lsp2-r1-to-r5**, and the egress router for return LSP **r5-to-r1**. Two LSPs transit **R1**, **lsp1-r6-to-r0** and the return LSP **r0-to-t6**. For more detailed information about the LSP, include the **extensive** option when you issue the **show mpls lsp** command.

Sample Output

```

user@R1> show mpls lsp extensive

Ingress LSP: 1 sessions

Meaning

Sample output from **R1** for the **show mpls lsp extensive** command shows detailed information about all LSPs for which **R1** is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has

link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass LSP **Bypass->10.0.12.14->10.0.24.2**.

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample output from **R1** for the **show rsvp interface** command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**. Interface **fe-0/1/0.0** is the connecting interface between R1 and R2, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the **show rsvp interface extensive** command.

Sample Output

```
user@R1> show rsvp interface extensive
RSVP interface: 3 active
fe-0/1/0.0 Index 67, State Ena/Up
  NoAuthentication, NoAggregate, NoReliable, LinkProtection
  HelloInterval 9(second)

```

Meaning

Sample output from **R1** for the **show rsvp interface extensive** command shows more detailed information about the activity on all RSVP interfaces (3). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14** is a link protection bypass path (**Type: LP**), protecting the link between **R1** and **R2 fe-0/1/0.0**. The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding **R2** in case of node failure.

Sample Output

```

```

Meaning

Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5**) originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

Conclusion

Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment. Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

Configure IS-IS as the IGP

Before you can run MPLS on your network, you should have an IGP running on all specified routers and interfaces. The IGP can be either IS-IS or OSPF. For the steps to configure OSPF, see [“Configure OSPF as the IGP” on page 2196](#).

Figure 164: IS-IS Network Topology

The IS-IS IGP in the MPLS network in [Figure 164 on page 2186](#) consists of the following:

- All routers are configured for Level 2, therefore default CSPF LSPs can occur.
- All routers are in IS-IS area 49.0004. However, the routers in this network could be in any area because Level 2 adjacencies occur between all directly connected Level 2 routers regardless of which area they are in.
- Level 2 adjacencies between all directly connected Level 2 routers as follows:
 - R1 is adjacent to R2, R3, and R5
 - R2 is adjacent to R1, R3, R4, and R6
 - R3 is adjacent to R1, R2, R4, and R6
 - R4 is adjacent to R2, R3, R5, and R6
 - R5 is adjacent to R1, R4, and R6
 - R6 is adjacent to R2, R3, R4, and R5

When you configure IS-IS as the IGP, you must enable IS-IS on the router, configure International Organization for Standardization (ISO) addressing, and enable IS-IS on all router interfaces.

You can enable IS-IS throughout the rest of the network by repeating Step 1, “[Enable IS-IS on Routers in Your Network](#)” on page 2187 through Step 3, “[Enable IS-IS on Router Interfaces](#)” on page 2191 as appropriate on other routers until all routers and interfaces establish IS-IS adjacencies.

To configure IS-IS and establish IS-IS adjacencies, follow these steps:

1. [Enable IS-IS on Routers in Your Network](#) | 2187
2. [Configure ISO Addressing](#) | 2190

3. [Enable IS-IS on Router Interfaces | 2191](#)
4. [Verify That IS-IS Adjacencies Are Established | 2193](#)

Enable IS-IS on Routers in Your Network

Action

To enable IS-IS on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols isis
```

2. Disable Level 1 if appropriate for your network:

```
[edit protocols isis]
user@host# set level 1 disable
```

3. Configure the interface:

```
[edit protocols isis]
user@host# edit interface type-fpc/pic/port level level-number metric metric
```

4. Disable the management interface if you have included the **interface all** statement, as shown in [Sample Output 2 on page 2189](#):

```
[edit protocols isis]
user@host# set interface fxp0.0 disable
```

5. Include the loopback interface (**lo0**) if you have listed all interfaces separately, as shown in [Sample Output 1 on page 2188](#):

```
[edit protocols isis]
user@host# set interface lo0.0
```

6. Set the loopback interface (**lo0**) to passive:

```
[edit protocols isis]
user@R1# set interface lo0 passive
```

7. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output 1

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols isis

[edit protocols isis]
user@R1# set level 1 disable

[edit protocols isis]
user@host# edit interface all level 2 metric 10

[edit protocols isis]
user@host# set interface lo0.0

[edit protocols isis]
user@host# set interface lo0 passive

[edit protocols isis]
user@R1# show
level 1 disable;
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface lo0.0;
    passive;
}

[edit protocols isis]
user@R1# commit
commit complete
```

Sample Output 2

```
[edit protocols isis]
user@R6# show
level 1 disable;
interface all {
    level 2 metric 15;
}
interface fxp0.0 {
    disable;
}
interface lo0.0 {
    passive;
}
```

Meaning

Sample Output 1 shows that IS-IS Level 1 is disabled, making this a Level 2 router. When all routers in the network are running at one IS-IS level (Level 2), default CSPF LSPs can occur.

Because **R1** in Sample Output 1 has all IS-IS enabled interfaces listed, including the loopback interface (**lo0**), you do not need to include the **disable** statement for the management interface (**fxp0**). All interfaces have unit number **0**, the default if a unit number is not specified. When you configure an interface at the **[edit protocols isis]** hierarchy level, and you do not include the logical unit, the default **0** is appended to the interface name, for example, **so-0/0/1.0**.

Sample Output 2 does not list the interfaces configured with IS-IS; instead, all interfaces are configured, including the loopback interface (**lo0**) and the management interface (**fxp0**). Therefore, you do not need to include a separate statement for the loopback (**lo0**) interface. However, in this instance, it is best practice to disable the management interface (**fxp0**) so that IS-IS packets are not sent over it. If you do not disable the management interface (**fxp0**) when you include the **interface-all** statement, the IS-IS protocol can form adjacencies over the management backbone, but traffic does not flow because transit traffic does not go out of the management interface.

Sample Output 2 also shows that all interfaces on **R6** are configured with a metric of **15**. A metric is not required to configure IS-IS on your interfaces. The default metric value is **10** (with the exception of the loopback [**lo0**] interface, which has a default metric of **0**). A metric is included to demonstrate that you can configure a metric for IS-IS if the default (**10**) is not appropriate for your network.

Both sample outputs show the **passive** statement included in the configuration of the loopback (**lo0**) interface. Including the **passive** statement is considered best practice and ensures the following:

- Protocols are not run over the loopback (**lo0**) interface
- When the router ID (RID) is configured manually, ensures that the loopback (**lo0**) interface is advertised to other networks.

NOTE: It is considered best practice to configure the RID manually to avoid duplicate RID problems.

Configure ISO Addressing

Purpose

For a router to support IS-IS, you must configure an ISO network entity title (NET) address on one of the router's interfaces, preferably the loopback interface (**lo0**).

Action

To configure ISO addressing, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Include a NET address for the loopback interface:

```
[edit interfaces]
user@host# set lo0 unit number family iso address address
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set lo0 unit 0 family iso address 49.0004.1000.0000.0001.00
```

```

[edit interfaces]
userR1# show
[...Output truncated...]
lo0 {
    unit 0 {
        family inet {
            address 10.0.0.1/32;
        }
        family iso {
            address 49.0004.1000.0000.0001.00;
        }
    }
}

[edit interfaces]
user@R1# commit
commit complete

```

Meaning

The sample output shows that the loopback (**lo0**) interface is configured with the NET address **49.0004.1000.0000.0001.00**. The loopback interface (**lo0**) becomes a point of connection from the router to the IS-IS network. Every router in an IS-IS network must have at least one ISO NET address that identifies a point of connection to the IS-IS network. The NET address is generally configured on the loopback (**lo0**) interface. Routers that participate in multiple areas can have multiple NET addresses.

All the routers in the network share a Level 2 database containing identical information. A common Level 2 database occurs in this case because all adjacencies are Level 2, and all routers are within the same IS-IS area (**49.0004**). Level 2 LSP flooding reaches all routers in the network due to the presence of a single level. For more information on determining the NET address, see the *Junos Routing Protocols Configuration Guide*.

Enable IS-IS on Router Interfaces

Purpose

Enable reception and transmission of ISO protocol data units (PDUs) on each router interface in the network with the **family** statement, which identifies which protocol packets are accepted into the interfaces. For example, valid IS-IS packets are dropped if the interface is not configured with the **family iso** statement.

Action

To configure support for IS-IS on router interfaces in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure IS-IS:

```
[edit interfaces]
user@host# set type-fpc/pic/port unit number family iso
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set so-0/0/2 unit 0 family iso

[edit interfaces]
user@R1# show
[...Output truncated...]
so-0/0/2 {
    unit 0 {
        family inet {
            address 10.1.13.1/30;
        }
        family iso;
    }
}

[edit interfaces]
user@R1# commit
commit complete
```

Meaning

The sample output shows that the interface **so-0/0/2** is configured with IS-IS.

Verify That IS-IS Adjacencies Are Established**Purpose**

After configuring IS-IS, you must verify that neighboring routers have formed adjacencies with each other.

Action

To verify IS-IS adjacencies, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show isis adjacency
```

Sample Output

```
user@R1> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R2	2 Up	25	
so-0/0/1.0	R5	2 Up	23	
so-0/0/2.0	R3	2 Up	20	

```
user@R3> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA

```

Meaning

The sample output from the ingress, transit, and egress routers shows that all routers in the network have formed IS-IS adjacencies.

Verify That IS-IS Adjacencies Are Established

Purpose

After configuring IS-IS, you must verify that neighboring routers have formed adjacencies with each other.

Action

To verify IS-IS adjacencies, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show isis adjacency
```

Sample Output

```
user@R1> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R2	2 Up	25	
so-0/0/1.0	R5	2 Up	23	
so-0/0/2.0	R3	2 Up	20	

```
user@R3> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R4	2 Up	25	
so-0/0/1.0	R2	2 Up	25	
so-0/0/2.0	R1	2 Up	26	
so-0/0/3.0	R6	2 Up	25	

```
user@R6> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R5	2 Up	19	
so-0/0/1.0	R4	2 Up	22	
so-0/0/2.0	R2	2 Up	22	
so-0/0/3.0	R3	2 Up	19	

Sample Output

```
user@R1> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R2	2 Up	25	
so-0/0/1.0	R5	2 Up	23	
so-0/0/2.0	R3	2 Up	20	

```
user@R3> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R4	2 Up	25	
so-0/0/1.0	R2	2 Up	25	
so-0/0/2.0	R1	2 Up	26	
so-0/0/3.0	R6	2 Up	25	

```
user@R6> show isis adjacency
```

Interface	System	L State	Hold (secs)	SNPA
-----------	--------	---------	-------------	------

so-0/0/0.0	R5	2 Up	19
so-0/0/1.0	R4	2 Up	22
so-0/0/2.0	R2	2 Up	22
so-0/0/3.0	R3	2 Up	19

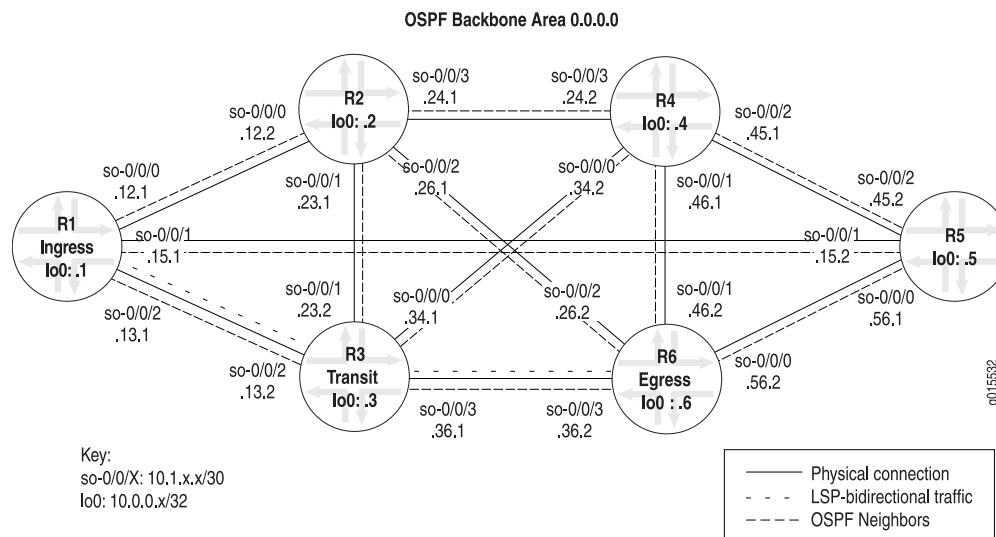

Meaning

The sample output from the ingress, transit, and egress routers shows that all routers in the network have formed IS-IS adjacencies.

Configure OSPF as the IGP

Before you can run MPLS on your network, you must have an IGP running on all specified routers and interfaces. The IGP can be either OSPF or IS-IS. For the steps to configure IS-IS, see [“Configure IS-IS as the IGP” on page 2185](#).

Figure 165: OSPF Network Topology

The OSPF IGP in the MPLS network in [Figure 164 on page 2186](#) consists of the following:

- All routers are configured for the backbone OSPF area 0.0.0.0.
- All routers have the RID manually configured to avoid possible problems when the OSPF RID changes; for example, when multiple loopback addresses are configured.
- All routers have traffic engineering enabled. When traffic engineering is enabled for OSPF, the SPF algorithm takes into account the various LSPs configured under MPLS and configures OSPF to generate

link-state advertisements (LSAs) that carry traffic engineering parameters. These routes are installed into the primary routing table **inet.0**, but the LSPs are installed by default into the **inet.3** routing table.

- Adjacencies between all OSPF neighbors are as follows:

- R1 is adjacent to R2, R3, and R5
- R2 is adjacent to R1, R3, R4, and R6
- R3 is adjacent to R1, R2, R4, and R6
- R4 is adjacent to R2, R3, R5, and R6
- R5 is adjacent to R1, R4, and R6
- R6 is adjacent to R2, R3, R4, and R5

When you configure OSPF as the IGP, you must enable OSPF and traffic engineering on the router. We also recommend that you manually configure the RID and include the loopback interface (**lo0**) at the **[edit protocols ospf]** hierarchy level.

You can enable OSPF throughout the rest of the network by repeating this step as appropriate on other routers until all routers and interfaces establish OSPF neighbors.

To configure OSPF and establish OSPF neighbors, follow these steps:

1. [Enable OSPF on Routers in Your Network | 2197](#)
2. [Verify That OSPF Neighbors Are Established | 2200](#)

Enable OSPF on Routers in Your Network

Action

To enable OSPF on routers in your MPLS network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols ospf
```

2. Configure the area and the interface:

```
[edit protocols ospf]
user@host# set area area-id interface type-fpc/pic/port
```

3. Disable the management interface if you have included the **interface all** statement in the previous step:

```
[edit protocols ospf]
```

```
user@host# set interface fxp0.0 disable
```

4. Include the loopback (**lo0**) interface if you intend to manually configure the RID:

```
[edit protocols ospf]
user@host# set area 0.0.0.0 interface lo0
```

5. Set the loopback interface (**lo0**) to passive:

```
[edit protocols ospf]
user@host# set area 0.0.0.0 interface lo0 passive
```

6. Configure traffic engineering:

```
[edit protocols ospf]
user@host# set traffic-engineering
```

7. Manually configure the RID at the [**routing-options**] hierarchy level:

```
[edit]
user@host# edit routing-options
[edit routing-options]
user@host# set router-id router-id
```

8. Verify and commit the entire configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols ospf

[edit protocols ospf]
user@R6# set area 0.0.0.0 interface so-0/0/0.0
```

```

[edit protocols ospf]
user@R6# set area 0.0.0.0 interface lo0

[edit protocols ospf]
user@R6# set area 0.0.0.0 interface lo0 passive

[edit protocols ospf]
user@R6# set traffic-engineering

[edit protocols ospf]
user@R6# show
traffic-engineering;
area 0.0.0.0 {
    interface so-0/0/0.0;
    interface so-0/0/1.0;
    interface so-0/0/2.0;
    interface so-0/0/3.0;
    interface lo0.0 {
        passive;
    }
}

[edit protocols ospf]
user@R6# commit
commit complete

[edit]
user@R6# edit routing-options

[edit routing-options]
user@R6# set router-id 10.0.0.6

[edit routing-options]
user@R6# show
[...Output truncated...]
router-id 10.0.0.6;
autonomous-system 65432;

[edit routing-options]
user@R6# commit
commit complete

```

Meaning

The sample output shows that OSPF, with traffic engineering, is enabled on the interfaces on egress router **R6**. In addition, the RID is configured manually to avoid possible problems when the OSPF RID changes; for example, when multiple loopback addresses are configured. The RID uniquely identifies the router within the OSPF network. It is transmitted within the LSAs used to populate the link-state database and calculate the shortest-path tree. In a link-state network, it is important that two routers do not share the same RID value, otherwise IP routing problems may occur.

The sample outputs also shows the **passive** statement included in the configuration of the loopback (**lo0**) interface. Including the **passive** statement is considered best practice and ensures the following:

- Protocols are not run over the loopback (**lo0**) interface
- When the router ID (RID) is configured manually, ensures that the loopback (**lo0**) interface is advertised to other networks.

Verify That OSPF Neighbors Are Established

Purpose

After configuring OSPF, you must verify that neighboring routers have formed adjacencies with each other.

Action

To verify OSPF neighbors, enter the following Junos OS CLI operational mode command:

```
user@host> show ospf neighbor
```

Sample Output

```
user@R1> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.12.2	so-0/0/0.0	Full	10.0.0.2	128	37
10.1.15.2	so-0/0/1.0	Full	10.0.0.5	128	35
10.1.13.2	so-0/0/2.0	Full	10.0.0.3	128	38

```
user@R3> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.34.2	so-0/0/0.0	Full	10.0.0.4	128	38
10.1.23.1	so-0/0/1.0	Full	10.0.0.2	128	35
10.1.13.1	so-0/0/2.0	Full	10.0.0.1	128	37
10.1.36.2	so-0/0/3.0	Full	10.0.0.6	128	36

```
user@R6> show ospf neighbor
```

Address	Interface	State	ID	Pri	Dead
10.1.56.1	so-0/0/0.0	Full	10.0.0.5	128	39
10.1.46.1	so-0/0/1.0	Full	10.0.0.4	128	37
10.1.26.1	so-0/0/2.0	Full	10.0.0.2	128	36
10.1.36.1	so-0/0/3.0	Full	10.0.0.3	128	37

Meaning

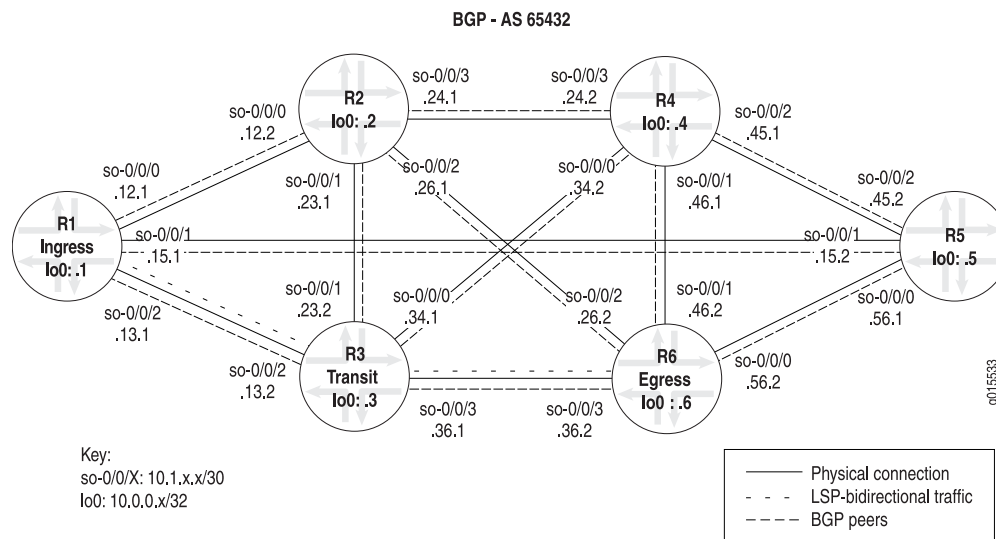

The sample output from the ingress, transit, and egress routers shows that all routers in the network have formed OSPF neighbor adjacencies.

Set Up BGP on Routers in Your Network

Before BGP can function in your MPLS network, you must define the autonomous system (AS) number on the routers in your network, and configure at least one group that includes at least one peer.

Optionally, you can configure a routing policy. The routing policy allows you to control the information shared with BGP neighbors and provides the opportunity to filter and modify the information you receive.

Figure 166: BGP Network Topology

The BGP configuration in the MPLS network in [Figure 166 on page 2201](#) consists of the following:

- A full-mesh IBGP topology, using AS 65432.
- All IBGP sessions peer between loopback addresses because significant stability advantages are gained.

- All routers are configured with one group, **group internal**.
- A **send-statics** policy on routers R1 and R6 allows a new route to be advertised into the network.

The example network uses IS-IS Level 2 and a policy to create routes that are reachable through the LSP. However, IS-IS Level 1 or an OSPF area can be used and the policy omitted if the network has existing BGP traffic.

You can set up BGP throughout the rest of the network by repeating Step 1, [“Define the Local Autonomous System” on page 2202](#) through Step 3, [“Configure a Simple Routing Policy” on page 2205](#) as appropriate on other routers until all routers are set up with BGP.

To set up BGP on routers in your network, follow these steps:

1. [Define the Local Autonomous System | 2202](#)
2. [Configure BGP Neighbor Connections | 2203](#)
3. [Configure a Simple Routing Policy | 2205](#)
4. [Verify That BGP Sessions Are Up | 2208](#)

Define the Local Autonomous System

Purpose

Before BGP can function, you need to define a local AS number on the routers in your network. In the example network in [Figure 166 on page 2201](#), all routers are in AS 65432.

Action

To define an AS number on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit routing-options
```

2. Configure all interfaces to a specific AS:

```
[edit routing-options]
user@host# set autonomous-system as-number
```

3. Verify the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```

user@R1> edit
Entering configuration mode

[edit]
user@R1# edit routing-options

[edit routing-options]
user@R1# set autonomous-system 65432

[edit routing-options]
user@R1# show
[...Output truncated...]
autonomous-system 65432;

[edit routing-options]
user@R6# commit
commit complete

```

Meaning

The output shows that router **R1** resides in **AS 65432**. All other routers in the example network shown in [Figure 166 on page 2201](#) also reside in **AS 65432**.

Configure BGP Neighbor Connections

Purpose

You must configure at least one group that includes at least one peer for BGP to run in your network. First determine which neighbors are internal or external to your local AS boundary. Internal neighbors are inside your local AS boundary. In the example network shown in [Figure 166 on page 2201](#), all the routers are in one AS and are therefore internal. In this example, all IBGP sessions peer between loopback addresses because significant stability advantages are gained. For more information about configuring BGP neighbor connections, see the *Junos Routing Protocols Configuration Guide*.

Action

To configure BGP neighbor connections, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```

[edit]
user@host# edit protocols bgp

```

2. Configure the group and peer's IP address:

```
[edit protocols bgp]
user@host# set group group-name type type neighbor neighbor-address
```

NOTE: For external neighbors, use the following form of the command that includes the peer's AS number:

```
user@host# set group group-name neighbor neighbor-address peer-as peer-as-number
```

3. Configure the local address:

```
[edit protocols bgp]
user@host# set group group-name local-address local-address
```

4. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols bgp

[edit protocols bgp]
user@R1# set group internal type internal neighbor 10.0.0.2

[edit protocols bgp]
users@R1# set group internal local-address 10.0.0.1

[edit protocols bgp]
user@R1# show
group internal {
    type internal;
    local-address 10.0.0.1;
```

```

    neighbor 10.0.0.2;
    neighbor 10.0.0.3;
    neighbor 10.0.0.5;
    neighbor 10.0.0.4;
    neighbor 10.0.0.6;
}

[edit protocols bgp]
user@R1# commit
commit complete

```

Meaning

The sample output shows that router **R1** is in an internal group with five BGP neighbors. The **local-address** statement is included in this example configuration because IBGP is used. It is considered best practice to configure a local address when you use an IBGP. BGP messages are sourced from the loopback address because the **local-address** statement is included in the configuration. Generally, you would not configure a local address when external BGP is configured.

Configure a Simple Routing Policy

Purpose

Routing policy allows you to control the information shared with BGP neighbors and provides the opportunity to filter and modify the information you receive. Typically, a network is injected into BGP using a policy. This may also be done through a static route. In the network in [Figure 166 on page 2201](#), a static route export policy is used to inject routes into BGP.

Action

To configure a simple routing policy, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```

[edit]
user@host# edit routing-options

```

2. Configure a static route for redistribution to other autonomous systems:

```

[edit routing-options]
user@host# set static route destination/24 reject

```

3. Configure a routing policy that matches and accepts the configured static routes into BGP updates:

```
[edit]
user@host# edit policy-options
[edit policy-options]
user@host# set policy-statement policy-name term term-name from route-filter address exact
user@host# set policy-statement policy-name term term-name then accept
```

4. Apply the policy created in Step 3 to all BGP neighbors:

```
[edit]
user@host# edit protocols bgp
[edit protocols bgp]
user@host# set export policy-name
```

5. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit routing-options

[edit routing-options]
user@R1# set static route 100.100.1.0/24 reject

[edit routing-options]
user@R1# show
[...Output truncated...]
    route 100.100.1.0/24 reject;
}
router-id 10.0.0.1;
autonomous-system 65432;

[edit routing-options]
user@R1# top
```

```

[edit]
user@R1# edit policy-options

[edit policy-options]
user@R1# set policy-statement send-statics term statics from route-filter 100.100.1.0/24 exact

[edit policy-options]
user@R1# set policy-statement send-statics term statics then accept

[edit policy-options]
user@R1# top

[edit]
user@R1# edit protocols bgp

[edit protocols bgp]
user@R1# set export send-statics

[edit protocols bgp]
user@R1# show
export send-statics;
group internal {
    type internal;
    local-address 10.0.0.1;
    neighbor 10.0.0.2;
    neighbor 10.0.0.3;
    neighbor 10.0.0.5;
    neighbor 10.0.0.4;
    neighbor 10.0.0.6;
}

[edit protocols bgp]
user@R1# commit
commit complete

```

Meaning

The sample output shows that routing policy **send-statics** is configured on the router. The routing policy matches and accepts the configured static routes into the routing table and injects the routes into BGP updates. Typically, a routing policy is applied at the group level, although it can be applied at the global level, as shown in this example.

Verify That BGP Sessions Are Up

Purpose

After configuring BGP, you must verify that BGP peers are established and the sessions are up.

Action

To verify BGP peers and sessions, enter the following Junos OS CLI operational mode command:

```
user@host> show bgp summary
```

Sample Output

```
user@R1> show bgp summary
```

```
Groups: 1 Peers: 5 Down peers: 0
```

Table	Tot Paths	Act Paths	Suppressed	History	Damp	State	Pending

10.0.0.4        65432          1347          1350        0        0    11:13:54 0/0/0
                  0/0/0
10.0.0.5        65432          1347          1350        0        0    11:13:50 0/0/0
                  0/0/0

```

Meaning

The sample output from the ingress, transit, and egress routers shows that all routers in the network shown in [Figure 166 on page 2201](#) have BGP peers established and sessions up.

Define the Local Autonomous System

Purpose

Before BGP can function, you need to define a local AS number on the routers in your network. In the example network in [Figure 166 on page 2201](#), all routers are in AS 65432.

Action

To define an AS number on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```

[edit]
user@host# edit routing-options

```

2. Configure all interfaces to a specific AS:

```
[edit routing-options]  
user@host# set autonomous-system as-number
```

3. Verify the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit  
Entering configuration mode  
  
[edit]  
user@R1# edit routing-options  
  
[edit routing-options]  
user@R1# set autonomous-system 65432  
  
[edit routing-options]  
user@R1# show  
[...Output truncated...]  
autonomous-system 65432;  
  
[edit routing-options]  
user@R6# commit  
commit complete
```

Meaning

The output shows that router **R1** resides in **AS 65432**. All other routers in the example network shown in [Figure 166 on page 2201](#) also reside in **AS 65432**.

Enable MPLS and RSVP

You can enable MPLS and RSVP throughout the rest of the network by repeating Step 1, “[Enable MPLS and RSVP on Routers](#)” on page 2211 and Step 2, “[Enable MPLS on Transit Router Interfaces](#)” on page 2213 as appropriate on other routers until all routers are enabled with MPLS and RSVP.

1. [Enable MPLS and RSVP on Routers](#) | 2211
2. [Enable MPLS on Transit Router Interfaces](#) | 2213

Enable MPLS and RSVP on Routers

Action

To enable MPLS and RSVP on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols
```

2. Configure MPLS and RSVP:

```
[edit protocols]
user@host# set mpls interface all
user@host# set rsvp interface all
```

3. Disable the management interface for MPLS and RSVP:

```
[edit protocols mpls]
user@host# set interface fxp0.0 disable
[edit protocols rsvp]
user@host# set interface fxp0.0 disable
```

4. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```

user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols

[edit protocols]
user@R1# set mpls interface all

[edit protocols]
user@R1# set rsvp interface all

[edit protocols]
user@R1# show
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    interface all;
    interface fxp0.0 {
        disable;
    }
}

[edit protocols]
user@R1# commit
commit complete

```

Meaning

The sample output shows that router **R1** has MPLS and RSVP enabled on all interfaces, except for the management interface (**fxp0.0**), which is disabled. It is considered best practice to disable the management interlace (**fxp0.0**) for MPLS and RSVP to preempt any problems.

Typically every interface that you want to use is listed. For an example of a router configured with specific interfaces, see [“Enable IS-IS on Routers in Your Network” on page 2187](#).

Enable MPLS on Transit Router Interfaces

Purpose

Even though transit interfaces are enabled with MPLS when you include the **family mpls** statement in the configuration, MPLS as a whole is not configured on your router or in your network. You must complete all five steps in this topic to have the MPLS protocol running on your network.

NOTE: The management interface (**fxp0**) and the loopback interface (**lo0**) are not transit interfaces.

Action

To configure transit interfaces to support MPLS, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure MPLS:

```
[edit interfaces]
user@host# set type-fpc/pic/port unit number family mpls
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set so-0/0/2 unit 0 family mpls
```

```
[edit interfaces]
user@R1# show
so-0/0/2 {
  unit 0 {
    family inet {
      address 10.1.13.1/30;
    }
    family iso;
    family mpls;
  }
}

[edit interfaces]
user@R1# commit
commit complete
```

Meaning

The sample output shows that the interface **so-0/0/2** is configured to support MPLS. The **family** statement identifies which protocol packets are accepted into the interfaces. For example, valid MPLS packets are dropped if the interface is not configured with the MPLS protocol.

Enable MPLS and RSVP on Routers

Action

To enable MPLS and RSVP on routers in your network, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols
```

2. Configure MPLS and RSVP:

```
[edit protocols]
user@host# set mpls interface all
user@host# set rsvp interface all
```

3. Disable the management interface for MPLS and RSVP:

```
[edit protocols mpls]
user@host# set interface fxp0.0 disable
[edit protocols rsvp]
user@host# set interface fxp0.0 disable
```

4. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit protocols

[edit protocols]
user@R1# set mpls interface all

[edit protocols]
user@R1# set rsvp interface all

[edit protocols]
user@R1# show
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    interface all;
    interface fxp0.0 {
        disable;
    }
}

[edit protocols]
```

```
user@R1# commit
commit complete
```

Meaning

The sample output shows that router **R1** has MPLS and RSVP enabled on all interfaces, except for the management interface (**fxp0.0**), which is disabled. It is considered best practice to disable the management interface (**fxp0.0**) for MPLS and RSVP to preempt any problems.

Typically every interface that you want to use is listed. For an example of a router configured with specific interfaces, see [“Enable IS-IS on Routers in Your Network” on page 2187](#).

Enable MPLS on Transit Router Interfaces

Purpose

Even though transit interfaces are enabled with MPLS when you include the **family mpls** statement in the configuration, MPLS as a whole is not configured on your router or in your network. You must complete all five steps in this topic to have the MPLS protocol running on your network.

NOTE: The management interface (**fxp0**) and the loopback interface (**lo0**) are not transit interfaces.

Action

To configure transit interfaces to support MPLS, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure MPLS:

```
[edit interfaces]
user@host# set type-fpc/pic/port unit number family mpls
```

3. Verify and commit the configuration:

```
user@host# show
```

```
user@host# commit
```

Sample Output

```
user@R1> edit
Entering configuration mode

[edit]
user@R1# edit interfaces

[edit interfaces]
user@R1# set so-0/0/2 unit 0 family mpls

[edit interfaces]
user@R1# show
so-0/0/2 {
  unit 0 {
    family inet {
      address 10.1.13.1/30;
    }
    family iso;
    family mpls;
  }
}

[edit interfaces]
user@R1# commit
commit complete
```

Meaning

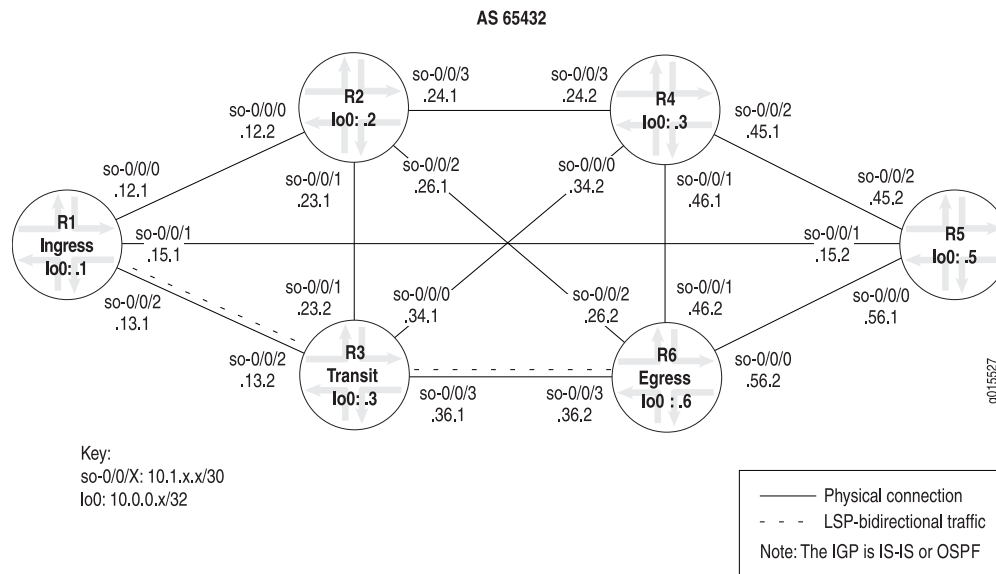

The sample output shows that the interface **so-0/0/2** is configured to support MPLS. The **family** statement identifies which protocol packets are accepted into the interfaces. For example, valid MPLS packets are dropped if the interface is not configured with the MPLS protocol.

Verifying the MPLS Configuration

After configuring MPLS on your network, you must verify the correct configuration of both the MPLS and RSVP protocols. Incorrect configuration of either protocol prevents successful LSP creation.

Figure 167 on page 2218 illustrates the network with the example configurations used in this topic.

Figure 167: MPLS Network Topology

To verify the MPLS configuration, follow these steps:

1. [Verify the RSVP Protocol | 2218](#)
2. [Verify RSVP Interfaces | 2220](#)
3. [Verify Protocol Families | 2222](#)

Verify the RSVP Protocol

Purpose

If the RSVP protocol is not enabled on the routers in your network, the interface cannot signal LSPs.

Action

To verify that the RSVP protocol is enabled, enter the following Junos OS CLI command:

```
user@host> show rsvp version
```

Sample Output

```
user@R1> show rsvp version
Resource ReSerVation Protocol, version 1. rfc2205
```

```

RSVP protocol           = Enabled
R(refresh timer)        = 30 seconds
K(keep multiplier)      = 3
Preemption              = Normal
Soft-preemption cleanup = 30 seconds
Graceful restart        = Disabled
Restart helper mode     = Enabled
Restart time            = 0 msec

```

Meaning

The sample output shows that the RSVP protocol is enabled on **R1**. The supported RSVP protocol is version 1, as defined in RFC 2205.

The RSVP refresh timer is set to 30 seconds, indicating that every 30 seconds, plus or minus 50 percent, the router will refresh the RSVP state with its directly connected neighbors by sending either a **Path** or a **Resv** message. The variable refresh time helps prevent harmonic oscillations in network traffic caused by periodic protocol updates.

The keepalive multiplier, **K(keep multiplier)**, is input to a formula that helps determine the lifetime of an RSVP session. The session lifetime is reset each time the state is updated. The lifetime represents the duration of an RSVP session that does not receive any state updates (**Path** or **Resv** messages). The formula is:

$$\text{RSVP session lifetime} = (\text{keep-multiplier} + 0.5) * 1.5 * \text{refresh-time}$$

The RSVP **preemption** state is currently configured for normal preemption, indicating that only an LSP with a stronger priority can preempt an existing session; that is, the setup value of the new LSP is lower than the hold value of the existing LSP. Other options include **aggressive** preemption, which always preempts when there is insufficient bandwidth, and **disabled**, which prevents any preemption, regardless of LSP priority values.

Graceful restart is currently disabled and **Restart helper mode** is enabled. There are four combinations for **Graceful restart** and **restart helper mode**:

1. Both **Graceful restart** and **Restart helper mode** are enabled.
2. **Graceful restart** is enabled but **Restart helper mode** is disabled. An LSR with this configuration can restart gracefully but cannot help a neighbor with its restart and recovery procedures.
3. **Graceful restart** is disabled but **Restart helper mode** is enabled. An LSR with this configuration can only help a restarting neighbor. It cannot restart gracefully itself.
4. **Graceful restart** and **Restart helper mode** are both disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). It is the same as an LSR that is not supported by RSVP graceful restart.

Restart time is the estimated time (in milliseconds) for an LSR to restart the RSVP traffic engineering component. In the example output, the restart time is 0 milliseconds, indicating that it is disabled.

The output is identical for all routers in the network shown in [“MPLS Network Topology” on page 2217](#).

Verify RSVP Interfaces

Purpose

If the RSVP protocol is not configured correctly on the routers in your network, the interfaces cannot signal LSPs.

Action

To verify RSVP interfaces, enter the following Junos OS CLI operational mode command:

```
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show rsvp interface
```

```
RSVP interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	2	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/2.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps

```
user@R2> show rsvp interface
```

```
RSVP interface: 5 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/2.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

```
user@R3> show rsvp interface
```

```
RSVP interface: 5 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps

```
so-0/0/2.0 Up          0 100% 155.52Mbps 155.52Mbps 0bps      0bps

so-0/0/3.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps

Sample Output 2

user@R6> **show rsvp interface**

RSPV interface: 3 active

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/2.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps

#so-0/0/3.0 is missing

Sample Output 3

```
user@host# show rsvp interface
RSVP not configured
```

Meaning

Sample Output 1 shows that all interfaces on all routers in the network are enabled with RSVP, including the management interface (**fxp0**). The output for all routers in the network includes similar information, so we will examine R6 in detail.

R6 has five interfaces enabled with RSVP (**Up**). Interface **so-0/1/1.0** has a single active RSVP reservation (**Active resv**) that did not change the default subscription percentage of 100 percent (**Subscription**).

Interface **so-0/1/1.0** did not assign a static bandwidth (**Static BW**) to the logical unit and therefore inherited 100 percent of the physical interface rate as the bandwidth available (**Available BW**) for RSVP sessions. Interface **so-0/1/1.0** has no bandwidth assigned (**Reserved BW**), and no RSVP bandwidth allocation at any single instant in time (**Highwater mark**).

Sample Output 2 shows that interface **so-0/0/3.0** is missing. If you do not configure the correct interface at the **[edit protocols rsvp]** hierarchy level, the interface cannot signal LSPs, and does not appear in the output for the **show rsvp interface** command.

Sample Output 3 shows that the RSVP protocol is not configured at the **[edit protocols rsvp]** hierarchy level.

Verify Protocol Families

Purpose

If a logical interface does not have MPLS enabled, it cannot perform MPLS switching. This step allows you to quickly determine which interfaces are configured with MPLS and other protocol families.

Action

To verify the protocol families configured on the routers in your network, enter the following Junos OS CLI operational mode command:

```
user@host> show interfaces terse
```

Sample Output 1

user@R1> show interfaces terse

Interface	Admin	Link	Proto	Local	Remote
so-0/0/0	up	up			
so-0/0/0.0	up	up	inet	10.1.12.1/30	
			iso		
			mpls		
so-0/0/1	up	up			
so-0/0/1.0	up	up	inet	10.1.15.1/30	
			iso		
			mpls

so-0/0/3.0         up    up   inet  10.1.36.2/30

```

```
iso
mpls
```

Meaning

Sample Output 1 shows the interface, the administrative status of the link (**Admin**), the data link layer status of the link (**Link**), the protocol families configured on the interface (**Proto**), and the local and remote addresses on the interface.

All interfaces on all routes in the network shown in [Figure 167 on page 2218](#) are administratively enabled and functioning at the data link layer with MPLS and IS-IS, and have an **inet** address. All are configured with an IPv4 protocol family (**inet**), and have the IS-IS (**iso**) and MPLS (**mpls**) protocol families configured at the `[edit interfaces type-fpc/pic/port unit number]` hierarchy level.

Sample Output 2 shows that interface **so-0/0/2.0** on **R6** does not have the **mpls** statement included at the `[edit interfaces type-fpc/pic/port unit number]` hierarchy level.

Verify the RSVP Protocol

Purpose

If the RSVP protocol is not enabled on the routers in your network, the interface cannot signal LSPs.

Action

To verify that the RSVP protocol is enabled, enter the following Junos OS CLI command:

```
user@host> show rsvp version
```

Sample Output

```
user@R1> show rsvp version
Resource ReSerVation Protocol, version 1. rfc2205

  RSVP protocol           = Enabled
  R(refresh timer)        = 30 seconds
  K(keep multiplier)      = 3
  Preemption              = Normal
  Soft-preemption cleanup = 30 seconds
  Graceful restart        = Disabled
```

```
Restart helper mode    = Enabled
Restart time           = 0 msec
```

Meaning

The sample output shows that the RSVP protocol is enabled on **R1**. The supported RSVP protocol is version 1, as defined in RFC 2205.

The RSVP refresh timer is set to 30 seconds, indicating that every 30 seconds, plus or minus 50 percent, the router will refresh the RSVP state with its directly connected neighbors by sending either a **Path** or a **Resv** message. The variable refresh time helps prevent harmonic oscillations in network traffic caused by periodic protocol updates.

The keepalive multiplier, **K(keep multiplier)**, is input to a formula that helps determine the lifetime of an RSVP session. The session lifetime is reset each time the state is updated. The lifetime represents the duration of an RSVP session that does not receive any state updates (**Path** or **Resv** messages). The formula is:

$$\text{RSVP session lifetime} = (\text{keep-multiplier} + 0.5) * 1.5 * \text{refresh-time}$$

The RSVP **preemption** state is currently configured for normal preemption, indicating that only an LSP with a stronger priority can preempt an existing session; that is, the setup value of the new LSP is lower than the hold value of the existing LSP. Other options include **aggressive** preemption, which always preempts when there is insufficient bandwidth, and **disabled**, which prevents any preemption, regardless of LSP priority values.

Graceful restart is currently disabled and **Restart helper mode** is enabled. There are four combinations for **Graceful restart** and **restart helper mode**:

1. Both **Graceful restart** and **Restart helper mode** are enabled.
2. **Graceful restart** is enabled but **Restart helper mode** is disabled. An LSR with this configuration can restart gracefully but cannot help a neighbor with its restart and recovery procedures.
3. **Graceful restart** is disabled but **Restart helper mode** is enabled. An LSR with this configuration can only help a restarting neighbor. It cannot restart gracefully itself.
4. **Graceful restart** and **Restart helper mode** are both disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). It is the same as an LSR that is not supported by RSVP graceful restart.

Restart time is the estimated time (in milliseconds) for an LSR to restart the RSVP traffic engineering component. In the example output, the restart time is 0 milliseconds, indicating that it is disabled.

The output is identical for all routers in the network shown in [“MPLS Network Topology” on page 2217](#).

Define a Load-Balancing Policy

Purpose

On the ingress or transit router, you can include a policy statement that performs load balancing on all routes. For information on including a policy statement that performs load balancing on specific routes, see “Configuring Per-Packet Load Balancing” in the *Junos Routing Protocols Configuration Guide*.

Action

On the ingress or transit router, to define a load-balancing policy for all routes, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit policy-options
```

2. Define the load-balance policy and action:

```
[edit policy-options]
user@host# set policy-statement policy-name then load-balance per-packet
```

3. Verify and commit the configuration:

```
user@host# show
user@host# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit policy-options

[edit policy-options]
user@R6# set policy-statement load-balance-traffic then load-balance per-packet

[edit policy-options]
user@R6# show
policy-statement load-balance-traffic {
    then {
        load-balance per-packet;
    }
}
```

```

}

[edit policy-options]
user@R6# commit
commit complete

```

Meaning

The sample output from ingress router **R6** shows the process for configuring load balancing. On an Internet Processor I ASIC, packets with the same parameters are spread across multiple equal-cost next hops; while an Internet Processor II ASIC sends packets with the same parameters to the same next hop, since they are in the same flow. The Junos OS command to turn on load balancing uses the action **load-balance per-packet**, which is misnamed in relation to the Internet Processor II ASIC. On the Internet Processor II ASIC, this command actually enables per-flow load balancing.

Use the traceroute Command to Verify MPLS Labels

Purpose

You can use the **traceroute** command to verify that packets are being sent over the LSP.

Action

To verify MPLS labels, enter the following Junos OS CLI operational mode command, where **host-name** is the IP address or the name of the remote host:

```
user@host> traceroute host-name
```

Sample Output 1

```

user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.861 ms  0.718 ms  0.679 ms
    MPLS Label=100048 CoS=0 TTL=1 S=1
 2  10.1.24.2 (10.1.24.2)  0.822 ms  0.731 ms  0.708 ms
    MPLS Label=100016 CoS=0 TTL=1 S=1
 3  10.1.46.2 (10.1.46.2)  0.571 ms !N  0.547 ms !N  0.532 ms !N

```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.605 ms  0.548 ms  0.503 ms
 2  10.0.0.6 (10.0.0.6)  0.761 ms  0.676 ms  0.675 ms
```

Meaning

Sample Output 1 shows that MPLS labels are used to forward packets through the network. Included in the output is a label value (**MPLS Label=100048**), the time-to-live value (**TTL=1**), and the stack bit value (**S=1**).

The **MPLS Label** field is used to identify the packet to a particular LSP. It is a 20-bit field, with a maximum value of $(2^{20}-1)$, or approximately 1,000,000.

The TTL value contains a limit on the number of hops that this MPLS packet can travel through the network (1). It is decremented at each hop, and if the TTL value drops below one, the packet is discarded.

The bottom of the stack bit value (**S=1**) indicates that is the last label in the stack and that this MPLS packet has one label associated with it. The MPLS implementation in the Junos OS supports a stacking depth of 3 on the M-series routers and up to 5 on the T-series platforms. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

MPLS labels appear in Sample Output 1 because the **traceroute** command is issued to a BGP destination where the BGP next hop for that route is the LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 shows that MPLS labels do not appear in the output for the **traceroute** command. If the BGP next hop does not equal the LSP egress address or the destination is an IGP route, the BGP traffic does not use the LSP. Instead of using the LSP, the BGP traffic is using the IGP (IS-IS, in this case) to reach the egress address (**R6**).

Apply the Load-Balancing Policy to the Forwarding Table

Purpose

Apply the policy configured in Step 1 to routes exported from the routing table to the forwarding table.

Action

To apply a load-balancing policy to the forwarding table, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit routing-options
```

2. Define a load-balance per packet action:

```
[edit routing-options]
user@host# set forwarding-table export policy-name
```

3. Verify and commit the configuration:

```
user@host# show
user@host# commit
```

Sample Output

```
[edit]
user@R6# edit routing-options

[edit routing-options]
user@R6# set forwarding-table export load-balance-traffic

[edit routing-options]
user@R6# show
static {
[...Output truncated...]
}
router-id 192.168.6.1;
autonomous-system 65432;
forwarding-table {
    export load-balance-traffic;
}

[edit routing-options]
user@R6# commit
commit complete
```

Meaning

The sample output shows the process for applying a load-balancing policy to export routes from the routing table to the forwarding table.

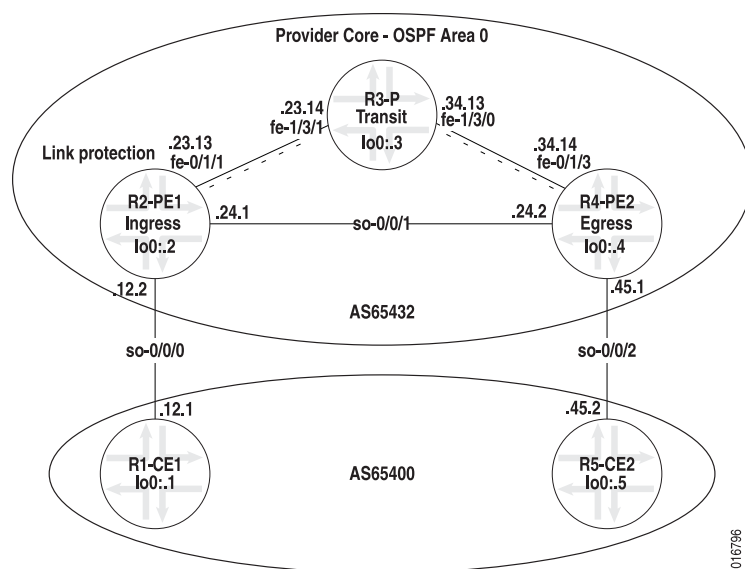

Fast Reroute Problem Overview

Problem

Description: Incorrect configuration is a common mistake when trying to establish protection for an MPLS LSP. Protection with either fast reroute or link protection requires a **per-packet load-balance policy** exported at the [edit routing-options forwarding-table] hierarchy level. Correctly configured protection for an MPLS LSP results in two next-hop forwarding table entries per destination, either an incoming MPLS label or an IP destination.

Figure 168 on page 2232 illustrates a network topology with link protection and load balancing enabled to ensure that routes are correctly placed in to the forwarding table.

Figure 168: Fast Reroute Problem Network

The network shown in Figure 168 on page 2232 illustrates an MPLS-based VPN with traffic protection and load balancing, consisting of the following:

- All physical interfaces addresses are from the 10.0.x.x/30 address space.
- All loopback addresses are from the 192.168.x.1/32 block.
- The IGP is a single-area (Area 0) OSPF.
- RSVP is deployed as the MPLS signaling protocol between PE routers.
- LSPs (r2-r4 and r4-r2) established between PE routers.
- MP-IBGP mesh between PE routers, loopback peering, and VPN-IPv4 NLRI.
- CE-PE link running EBGp.
- Full-mesh Layer 3 VPN between CE1 and CE2.

- Traffic protection for the link between the PE1 and P routers.
- Load balancing on PE1.

The overall goal of this network is to provide point-to-point connectivity between the two CE routers and traffic protection in the core of the network.

Symptom

In the network shown in [Figure 168 on page 2232](#), the external symptom is that local repair is taking about one second to complete, which is slow. Use the **show route forwarding-table vpn vpn-a destination** command to check that the correct routes are included in the forwarding table. In the example output below, there is only one route installed in the forwarding table, when for fast local repair, there should be multiple next hops installed.

Sample Output

```
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive
Routing table: vpn-a.inet [Index 2]
Internet:

Destination: 192.168.5.0/24
Route type: user
Route reference: 0                               Route interface-index: 0
Flags: sent to PFE, prefix load balance
Next-hop type: indirect                          Index: 262142   Reference: 2
Next-hop type: Push 100160
Next-hop interface: so-0/0/1.0 #Only one next hop in the forwarding table.
```

Cause

Slow local repair is caused by the forwarding table not including the necessary next-hops to support local repair. The forwarding table shows only a single next-hop, when local repair requires additional next-hops for fast recovery.

Troubleshooting Commands

The Junos OS includes commands that are useful when troubleshooting a problem. This topic provides a brief description of each command followed by sample output, and a discussion of the output in relation to the problem.

The following commands can be used when troubleshooting a fast reroute error in an MPLS-VPN network:

```
user@R2-PE1> show configuration routing-instances vpn-a
user@R2-PE1> show configuration routing-options
user@R2-PE1> show bgp summary instance vpn-a
```

```

user@R2-PE1> show configuration protocols mpls
user@R2-PE1> show mpls lsp ingress
user@R2-PE1> show rsvp session ingress
user@R2-PE1> show rsvp session ingress detail
user@R2-PE1> show route table vpn-a 192.168.5.1 detail
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive

```

Sample Output

The **show configuration *statement-path*** command is used to display a specific configuration hierarchy; in this case, to verify the correct configuration of a specific routing instance named **vpn-a**.

```

user@R2-PE1> show configuration routing-instances vpn-a
instance-type vrf ;
interface so-0/0/0.0 ;
vrf-target {
    import target:65432:100;
    export target:65432:100;
}
protocols {
    bgp {
        group CE1 {
            type external;
            peer-as 65400;
            neighbor 10.0.12.1 ;
        }
    }
}

```

Meaning

The sample output for the **show configuration** command shows the current running configuration of the specific routing instance named **vpn-a** configured on the ingress PE1 router. The **vpn-a** instance configuration has a VRF table that supports EBGp routing on the PE-CE link (**so-0/0/0.0**). This interface is the correct interface for the CE1-PE1 link in the network topology shown in [Figure 168 on page 2232](#).

The VRF instance is linked to a VFR target community configured at the [edit policy-options] hierarchy level, allowing advertising of L3 VPN routes between PE routers. (See the PE1 configuration in [“Router Configurations” on page 2241](#) for the policy options configuration.) The import statement places, into the vpn-a.inet.0 table, all received L3 VPN MP-BGP routes tagged with the correct target community. The export statement advertises and tags all routes in the vpn-a.inet.o table with the listed target community to all MP-BGP peers.

The BGP protocols configuration within the routing instance applies the BGP import and export policies to the exchange of BGP routes on the PE-CE routing instance.

Sample Output

The **show bgp summary** command is used to display summary information about BGP and its neighbors to determine if routes are received from peers in the autonomous system (AS). In this case, information for the specified instance **vpn-a** is displayed.

```
user@R2-PE1> show bgp summary instance vpn-a
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State    Pending
vpn-a.inet.0      11         7         0         0         0         0
Peer            AS          InPkt    OutPkt    OutQ   Flaps Last Up/Dwn
State|#Active/Received/Damped...
10.0.12.1  65400   2471   2473    0    0  20:35:20 Establ
vpn-a.inet.0: 5/5/0
```

Meaning

The sample output for the **show bgp summary instance vpn-a** command shows that the peering session between the CE1 and PE1 routers is established, indicating that the peers are exchanging update messages.

Sample Output

The **show configuration statement-path** command is used to display a specific configuration hierarchy; in this case, the MPLS hierarchy.

```
user@R2-PE1> show configuration protocols mpls
label-switched-path r2-r4 {
    to 192.168.4.1;
    link-protection ;
    primary direct ;
}
path direct {
    10.0.24.2 strict;
}
interface all;
interface fxp0.0 {
    disable;
}
```

Meaning

The sample output for the **show configuration protocols mpls** command shows the current running MPLS configuration on the ingress PE1 router. The configuration include the LSP **r2-r4**, link protection, and the strict primary path **direct**.

Sample Output

The **show mpls lsp** command is used to display summarized information about the configured and active LSPs on a router; in this case, the command shows only the ingress LSPs on the ingress PE1 router.

```
user@R2-PE1> show mpls lsp ingress
Ingress LSP: 1 sessions
To          From          State Rt ActivePath      P      LSPname
192.168.4.1 192.168.2.1 Up      0 direct        *      r2-r4
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output for the **show mpls lsp ingress** command shows that the ingress LSP **r2-r4** is up and following the configured path **direct**.

Sample Output

The **show rsvp session** command is used to display summarized information about active RSVP sessions on a router; in this case, the command shows summarized information about ingress RSVP sessions on the PE1 router

```
user@R2-PE1> show rsvp session ingress
Ingress RSVP: 2 sessions
To          From          State Rt Style Labelin Labelout LSPname
192.168.4.1 192.168.2.1 Up      0 1 SE      -          3 r2-r4
192.168.4.1 192.168.2.1 Up      0 1 SE      - 100064 Bypass->10.0.24.2
Total 2 displayed, Up 2, Down 0
```

Meaning

The sample output for the **show rsvp session ingress** command shows two RSVP sessions are up; the main LSP **r2-r4** and a bypass path protecting the main LSP. Both RSVP sessions are in the Shared Explicit (**SE**) style, creating a shared reservation among for the two paths.

Sample Output

The **show rsvp session ingress detail** command is used to display more detailed information about the two ingress RSVP sessions on the PE1 router.

```
user@R2-PE1> show rsvp session ingress detail
```

```
Ingress RSVP: 2 sessions
```

```
192.168.4.1
```

```

```
Record route: <self> 10.0.23.14 10.0.34.14
```

```
Total 2 displayed, Up 2, Down 0
```

Meaning

The sample output for the **show rsvp session ingress detail** command shows the RSVP session for the ingress LSP and the bypass path, which appears as a separate RSVP ingress session for the protected interface **10.0.24.2**. The bypass path is automatically generated. By default, the name appears as **Bypass > interface-address**, where the interface address is the next downstream router's interface (**10.0.24.2**). The explicit route **10.0.23.14 10.0.34.14** for the session shows **R3** as the transit node and **R4** as the egress node.

Sample Output

The **show route table routing-table-name** command is used to display information about a particular routing table. In this case, the **vpn-a.inet.0** routing table.

```
user@R2-PE1> show route table vpn-a 192.168.5.1 detail
vpn-a.inet.0: 9 destinations, 13 routes (9 active, 0 holddown, 0 hidden)
192.168.5.0/24 (1 entry, 1 announced)
    *BGP      Preference: 170/-101
              Route Distinguisher: 192.168.4.1:4
              Next-hop reference count: 11
              Source: 192.168.4.1
              Next hop: via so-0/0/1.0 weight 0x1, selected
              Label-switched-path r2-r4
              Label operation: Push 100160
              Next hop: 10.0.23.14 via fe-0/1/1.0 weight 0x8001
              Label-switched-path r2-r4
              Label operation: Push 100160, Push 100064(top)
              Protocol next hop: 192.168.4.1
              Push 100160
              Indirect next hop: 8791000 262142
              State: <Secondary Active Int Ext>
              Local AS: 65432 Peer AS: 65432
              Age: 1d 5:22:31      Metric2: 1
              Task: BGP_65432.192.168.4.1+2056
              Announcement bits (1): 0-KRT
              AS path: 65400 I
              Communities: target:65432:100
              VPN Label: 100160
              Localpref: 100
              Router ID: 192.168.4.1
              Primary Routing Table bgp.l3vpn.0
```

Meaning

The sample output for the **show route table vpn-a 192.168.5.1 detail** command shows routes associated with the remote PE-CE location as indicated by the loopback address of the PE2 router **192.168.5.1**. In this case, there are different next hops with unequal weights (**0x1** and **0x8001**) associated with the remote location. For correct traffic protection, those two routes must appear in the forwarding table.

Sample Output

The **show route forwarding-table** command displays the route entries in the kernel's forwarding table. This is the version of the forwarding table in the Routing Engine. The Routing Engine copies this table to the Packet Forwarding Engine. In this case, the set of routes installed in the forwarding table to verify that the routing protocol process (rpd) has relayed the correct information to the forwarding table for the specified destination.

```
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1      extensive
Routing table: vpn-a.inet [Index 2]
Internet:

Destination:  192.168.5.0/24
Route type:   user
Route reference: 0                      Route interface-index: 0
Flags: sent to PFE, prefix load balance
Next-hop type: indirect                  Index: 262142   Reference: 2
Next-hop type: Push 100160
Next-hop interface: so-0/0/1.0
```

Meaning

The sample output for the **show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive** command shows only one next hop **so-0/0/1.0** is installed in the forwarding table, indicating that the information in the forwarding table is not correct. We would expect to see the same paths installed in the forwarding table as appear in the routing table in the output for the **show route table vpn-a 192.168.5.1 detail**.

Solution

The solution is to enable load-balancing and ensure that multiple next-hop forwarding table entries appear in the forwarding table for each destination. The forwarding-table entries can be an incoming MPLS label or an IP destination.

A load-balancing policy applied to the forwarding-table is the same mechanism required for ECMP (equal-cost multipath) load-balancing to install multiple next-hops into the forwarding-table. The extra paths installed for local repair are not used for load-balancing, because the paths are differently weighted, as demonstrated in the sample output for the **show routing table** and the **show route forwarding-table** commands.

NOTE: The load-balancing policy must be applied to all provider (P) and provider-edge (PE) routers that are required to support local repair.

The following sample output shows an example load-balancing configuration and the commands used to verify that the required two next-hop entries appear in the forwarding table.

Sample Output

Use the following two **show configuration statement-path** commands to display a specific configuration hierarchy; in this case, policy-options and routing-options.

```
user@R2-PE1> show configuration policy-options
policy-statement lbpf {
    then {
        load-balance per-packet ;
    }
}
[...Output truncated...]

user@R2-PE1> show configuration routing-options
static {
    [...Output truncated...]
    route 100.100.1.0/24 reject;
}
router-id 192.168.2.1;
route-distinguisher-id 192.168.2.1;
autonomous-system 65432;
forwarding-table {
    export lbpf ;
}
```

Meaning

The sample output for the **show configuration policy-options** and **show configuration routing-options** commands shows the two parts required to configure a load balancing policy. The **lbpf** policy includes the **load-balance per-packet** statement. The policy is then applied at the **[edit routing options forwarding-table]** hierarchy level with the **export lbpf** statement. Enabling load balancing results in the export of routes from the routing table to the forwarding table, and a solution to the problem.

NOTE: The **load-balance per-packet** statement is named *per-packet* for historical reasons. When the Packet Forwarding Engine was an IP Processor-1 (before Junos 4.0), Junos supported only per-packet load balancing. When the IP Processor-II was introduced the behavior was changed to per-flow load balancing without changing the statement.

Sample Output

Use the **show route forwarding-table** command to display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. In this case, the option **vpn vpn** is used to display routing table entries for the specified VPN **vpn-a**.

```
user@R2-PE1> show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive
Routing table: vpn-a.inet [Index 2]
Internet:

Destination: 192.168.5.0/24
Route type: user
Route reference: 0                               Route interface-index: 0
Flags: sent to PFE
Next-hop type: indirect                          Index: 262142   Reference: 2
Next-hop type: unilist                           Index: 262146   Reference: 1
Next-hop type: Push 100160
Next-hop interface: so-0/0/1.0   Weight: 0x1
Nexthop: 10.0.23.14
Next-hop type: Push 100160, Push 100064(top)
Next-hop interface: fe-0/1/1.0   Weight: 0x8001
```

Meaning

The sample output for the **show route forwarding-table vpn vpn-a destination 192.168.5.1 extensive** command shows the correct two routes were relayed from the routing table to the forwarding table.

Conclusion

In conclusion, a load balancing policy is required for link protection to work effectively. The principles are the same for the configuration of the **fast reroute** and the **node-link protection** statements.

Router Configurations

The following output shows the configurations of all routers in the network. The **no-more** option entered after the pipe (|) prevents the output from being paginated if the output is longer than the length of the terminal screen.

Sample Output

The following sample output is for the customer edge (CE) 1 router:

```
user@R1-CE1> show configuration | no-more

Problem Establishing a GRE Tunnel Checklist

Problem

Description: This checklist provides the links and commands for troubleshooting a case study about a problem establishing a Generalized Multiprotocol Label Switching (GMPLS) label-switched path (LSP). Specifically, the configuration of the data channel is incorrect because the configuration includes different interface types at both ends of the tunnel. The principles and solution used in this case study also apply to control channel configuration.

The checklist includes the links to a brief summary of GRE tunnels within the context of GMPLS, an example network scenario, and more detailed information about the commands used to troubleshoot and resolve the problem.

The troubleshooting process described in this case study should not be followed rigidly; it is a basis from which you can develop your own process to suit your particular situation. (See [Table 64 on page 2257](#))

Solution

Table 64: Problem Establishing a GRE Tunnel Checklist

Tasks	Command or Action
“Troubleshooting GMPLS and GRE Tunnel” on page 2258	

Table 64: Problem Establishing a GRE Tunnel Checklist (continued)

Tasks	Command or Action
"Symptom" on page 2261	<pre>show mpls lsp show rsvp session</pre>
"Cause" on page 2262	The cause of the problem with the GMPLS LSP is the configuration of different interface types at both ends of the GMPLS data channel.

"Conclusion" on page 2271	Both ends of a GMPLS data must be the same encapsulation or interface type.
"Router Configurations" on page 2271	<code>show configuration no-more</code>

Troubleshooting GMPLS and GRE Tunnel

Problem

Description: The logical control channel for GMPLS must be a point-to-point link and must have some form of IP reachability. On broadcast interfaces or when there are multiple hops between control channel peers, use a GRE tunnel for the control channel. For more detailed information on GMPLS and GRE tunnels see the *Junos MPLS Applications Configuration Guide* and the *Junos User Guide*.

A tunnel PIC is *not* required to configure a GRE tunnel for the GMPLS control channel. Instead, use the software-based **gre** interface, rather than the hardware-based **gr-fpc/pic/port** interface.

CAUTION: Due to restrictions to the software-based **gre** interface, the GMPLS control channel is the only supported use of the software-based **gre** interface. Any other use is expressly unsupported and might cause an application failure.

The following example shows a basic **gre** interface configuration. In this case, the tunnel source is the loopback address of the local router and the destination address is the loopback destination of the remote router. Traffic that has a next hop of the tunnel destination will use the tunnel. The tunnel is not automatically used by all the traffic passing through the interface. Only traffic with the tunnel destination as the next hop uses the tunnel.

Sample Output

```
user@R1> show configuration interfaces
[...Output truncated...]
gre {
    unit 0 {
        tunnel {
            source 10.0.12.13;
            destination 10.0.12.14;
        }
        family inet {
            address 10.35.1.6/30;
        }
        family mpls;
    }
}
```

Sample Output

The following sample output for the **show interfaces** command shows the encapsulation type and header, the maximum speed, packets through the logical interface, the destination, and logical address.

```
user@R1> show interfaces gre
Physical interface: gre, Enabled, Physical link is Up
Interface index: 10, SNMP ifIndex: 8
  Type: GRE, Link-level type: GRE, MTU: Unlimited, Speed: Unlimited
Device flags      : Present Running
Interface flags: Point-To-Point SNMP-Traps
Input packets    : 0
Output packets   : 0
```

```

Logical interface gre.0 (Index 70) (SNMP ifIndex 47)
  Flags: Point-To-Point SNMP-Traps 0x4000
    IP-Header 10.0.12.14:10.0.12.13:47:df:64:0000000000000000
    Encapsulation: GRE-NULL
    Input packets : 171734
    Output packets: 194560
    Protocol inet, MTU: 1476
      Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.35.1.4/30, Local: 10.35.1.6, Broadcast: 10.35.1.7
    Protocol mpls, MTU: 1464
      Flags: None

```

The following are various requirements when you configure a GMPLS LSP using a GRE tunnel:

- The data channel must start and end on the same type of interface.
- The control channel can be a GRE tunnel that starts and ends on the same or different interface type.
- The GRE tunnel must be configured indirectly with the **peer-interface *peer-name*** statement at the **[edit protocols ospf]** hierarchy level.
- The GRE interface must be disabled at the **[edit protocols ospf]** and **[edit protocols rsvp]** hierarchy levels.
- Data and control channels must be defined correctly in the LMP configuration .
- It is optional to disable Constrained Shortest Path First (CSPF) with the **no-cspf** statement.

This case focuses on the incorrect configuration of the endpoints of the GRE tunnel. However, you can use a similar process and commands to diagnose other GRE tunnel problems. [Figure 169 on page 2260](#) illustrates a network topology with MPLS tunneled through a GRE interface.

Figure 169: GMPLS Network Topology

The MPLS network topology in [Figure 169 on page 2260](#) shows Juniper Networks routers configured with a GRE tunnel that consists of the following components:

- A strict GMPLS LSP path from the ingress router to the egress router.
- On the ingress router, CSPF disabled with the **no-cspf** statement at the [edit protocol mpls label-switched-path *lsp-name*] hierarchy level.
- Traffic-engineering links and control channels within the **peer** statement at the [edit protocols link-management] hierarchy level on all routers.
- OSPF and OSPF traffic engineering configured on all routers.
- A reference to the **peer-interface** in both OSPF and RSVP on all routers.
- A switching-type problem between **R2** and **R3**.

Symptom

The LSP in the network shown in [Figure 169 on page 2260](#) is down, as indicated by the output from the **show mpls lsp** and **show rsvp session** commands, which display very similar information. The **show mpls lsp** command shows all LSPs configured on the router, as well as all transit and egress LSPs. The **show rsvp session** command displays summary information about RSVP sessions. You can use either command to verify the state of the LSP. In this case, LSP **gmpls-r1-to-r3** is down (**Dn**).

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From          State Rt ActivePath      P      LSPname
192.168.4.1 192.168.1.1 Dn  0 -      gmpls-r1-to-r3
Bidir
Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R1> show rsvp session
Ingress RSVP: 1 sessions
To          From          State  Rt Style Labelin Labelout LSPname
192.168.4.1 192.168.1.1 Dn    0 0 -    -    - gmpls-r1-to-r3
Bidir
Total 1 displayed, Up 0, Down 1

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

```
Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Cause

The cause of the problem with the GMPLS LSP is the configuration of different interface types at both ends of the GMPLS data channel.

Troubleshooting Commands

The Junos OS includes commands that are useful when troubleshooting a problem. This topic provides a brief description of each command, followed by sample output, and a discussion of the output in relation to the problem.

You can use the following commands when troubleshooting a GMPLS problem:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show link-management peer
user@host> show link-management te-link
user@host> show configuration protocols mpls
user@host> monitor start filename
user@host> show log filename
```

Sample Output

Use the show mpls lsp extensive command on transit router R1 to display detailed information about all LSPs transiting, terminating, and configured on the router.

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

192.168.4.1
  From: 192.168.1.1, State: Dn, ActiveRoute: 0, LSPname: gmpls-r1-to-r3
  Bidirectional
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: SDH/SONET, Switching type: PSC-1, GPID: IPv4
  Primary   pl                               State: Dn
    SmartOptimizeTimer: 180
8 Dec 20 18:08:02 192.168.4.1: MPLS label allocation failure [3 times]
  7 Dec 20 18:07:53 Originate Call
  6 Dec 20 18:07:53 Clear Call
  5 Dec 20 18:07:53 Deselected as active
```

```

    4 Dec 20 18:06:13 Selected as active path
    3 Dec 20 18:06:13 Record Route:  100.100.100.100 93.93.93.93
    2 Dec 20 18:06:13 Up
    1 Dec 20 18:06:13 Originate Call
Created: Wed Dec 20 18:06:12 2006
Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output for the **show mpls lsp extensive** command shows an error message (**MPLS label allocation failure**) in the log section of the output. This LSP event indicates that the MPLS protocol or the **family mpls** statement were not configured properly. When the LSP event is preceded by an IP address, the address is typically the router that has the MPLS configuration error. In this case, it appears that the router with the **lo0** address of **192.168.4.1 (R3)** has an MPLS configuration error.

Sample Output

Use the **show rsvp session detail** command to display detailed information about RSVP sessions.

```

user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

192.168.4.1
  From: 192.168.1.1,  LSPstate: Dn, ActiveRoute: 0
    LSPname: gmpls-r1-to-r3, LSPpath: Primary
  Bidirectional, Upstream label in: 21253, Upstream label out: -
  Suggested label received: -,  Suggested label sent: 21253
  Recovery label received: -, Recovery label sent: -
    Resv style: 0 - , Label in: -, Label out: -
  Time left:    -, Since: Wed Dec 20 18:07:53 2006
  Tspec: rate 0bps size 0bps peak 155.52Mbps m 20 M 1500

  Adspec: sent MTU 1500
  Path MTU: received 0
  PATH sentto: 10.35.1.5 (tester2) 3 pkts
    Explt route: 100.100.100.100 93.93.93.93

```

Record route: <self> ...incomplete

Total 1 displayed, Up 0, Down 1

Egress RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning

The sample output for the **show rsvp session detail** command shows that LSP **gmpls-r1-to-r3** is down (**LSPstate: Dn**). The route record is incomplete, indicating a problem with the explicit route **100.100.100.100 93.93.93.93**. The address **100.100.100.100** is the data channel on **R2 so-0/0/0**, and the address **93.93.93.93** is the data channel on **R3**.

Sample Output

Use the **show link-management peer** command to display MPLS peer link information.

```
user@R1> show link-management peer
```

Peer name: tester2, System identifier: 48428

State: Up, Control address: 10.35.1.5

Control-channel	State
gre.0	Active

TE links:

tester2

```
user@R2> show link-management peer
```

Peer name: tester2, System identifier: 48428

State: Up, Control address: 10.35.1.6

Control-channel	State
gre.0	Active

TE links:

te-tester2

Peer name: tester3 , System identifier: 48429

State: Up , Control address: 10.35.1.2

Control-channel	State
gre.1	Active

TE links:

te-tester3

```

user@R3> show link-management peer
Peer name: tester3, System identifier: 48429
State: Up, Control address: 10.35.1.1
Control-channel          State
gre.0                    Active
TE links:
te-tester3

```

Meaning

The sample output from all routers in the example network in [Figure 169 on page 2260](#) for the **show link-management peer** command shows that all control channels are up and active. A detailed analysis of the output shows the following information:

- Name of the peer, **tester2** or **tester3**, which is the same on neighboring routers for ease of troubleshooting.
- Internal identifier for the peer, **48428** for **tester2** and **48429** for **tester3**. The internal identifier is a range of values from 0 through 64,000.
- The state of the peer, which can be up or down. In this case, all peers are up.
- The address to which a control channel is established, for example, **10.35.1.5**.
- The state of the control channel, which can be up, down, or active.
- The traffic-engineered links that are managed by their peer, indicating that control channel **gre.0** is managed by **tester3**.

Sample Output

Use the **show link-management te-link** command to display the resources used to set up Multiprotocol Label Switching (MPLS) traffic-engineered forwarding paths.

```

user@R1> show link-management te-link
TE link name:  tester2, State: Up
Local identifier: 2005, Remote identifier: 21253, Local address: 90.90.90.90,
Remote address: 100.100.100.100,
Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
Available bandwidth: 0bps

```

Name	State	Local ID	Remote ID	Bandwidth	Used	LSP-name
so-0/0/0	Up	21253	21253	155.52Mbps	Yes	gmpls-r1-to-r3

```

user@R2> show link-management te-link

```

```

TE link name:  te-tester2, State: Up

  Available bandwidth: 0bps
    Name          State Local ID  Remote ID      Bandwidth Used   LSP-name
    so-0/0/1      Dn          21252         21252        155.52Mbps  No

```

Meaning

The sample output for the **show link-management te-link** command issued on the three routers in the network in [Figure 169 on page 2260](#) shows the resources allocated to the traffic-engineered links **te-tester2** and **te-tester3**. The resources are the SONET interfaces **so-0/0/0** and **so-0/0/1**. On **R1** and **R2**, the SONET interfaces are used for the LSP **gmpls-r1-to-r3**, as indicated by **Yes** in the **Used** field. However, the SONET interface **so-0/0/1** on **R3** is down (**Dn**) and is not used for the LSP (**Used No**). Further investigation is required to discover why the SONET interface on **R3** is down.

Sample Outut

Use the `show log filename` command to display the contents of the specified log file. In this case, the log file `rsvp.log` is configured at the `[edit protocols rsvp traceoptions]` hierarchy level. When the log file is configured, you must issue the `monitor start filename` command to begin logging messages to the file.

```
user@R1> show configuration protocols rsvp
traceoptions {
    file rsvp.log size 3m world-readable;
    flag state detail;
    flag error detail;
    flag packets detail;
}

user@R1> monitor start rsvp.log
```

NOTE: The **find Error** option entered after the pipe (|) searches the output for an instance of the term *Error*.

Sample Output

```
user@R3>
show log rsvp.log | find Error

```

Meaning

The sample output from the egress router **R3** for the **show log rsvp.log** command is a snippet taken from the log file. The snippet shows a Link Management Protocol (LMP) resource request for the LSP **gmpls-r1-to-r3**. The request has problems with the encoding type (SDH/SONET), indicating a possible error with the SONET interface connecting **R2** and **R3**. Further investigation of the configuration of the LMP on **R2** and **R3** is required.

Sample Output

Use the show configuration *statement-path* command to display a specific configuration hierarchy; in this instance, link-management.

```

user@R2> show configuration protocols link-management
te-link te-tester2 {
    local-address 100.100.100.100;
    remote-address 90.90.90.90;
    remote-id 22292;

    }
}
te-link te-tester3 {
    local-address 103.103.103.103;
    remote-address 93.93.93.93;
    remote-id 21254;
    interface so-0/0/1 {
        local-address 103.103.103.103;
        remote-address 93.93.93.93;
        remote-id 21252;
    }
}
peer tester2 {
    address 10.35.1.6;
}

```

```

        control-channel gre.0;
        te-link te-tester2;
    }
    peer tester3 {
        address 10.35.1.2;
        control-channel gre.1;
        te-link te-tester3;
    }

user@R3> show configuration protocols link-management
te-link te-tester3 {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
}
    interface at-0/3/1 {
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}

```

Meaning

The sample output from transit router **R2** and ingress router **R3** for the **show configuration protocols link-management** command shows that the interface type on the two routers is different. The resource allocated to **te-tester3** on transit router **R2** is a SONET interface, while the resource allocated to **te-tester3** on egress router **R3** is an ATM interface. The interface type on each end of the data or control channels must be of the same type. In this case, both ends should be SONET or ATM.

Solution

Solution

The solution to the problem of different interface or encapsulation types at either end of the GMPLS LSP is to make sure that the interface type is the same at both ends. In this case, the ATM interface was deleted from the link-management configuration on **R3**, and a SONET interface was configured instead.

The following commands illustrate the correct configuration and commands to verify that the GMPLS LSP is up and using the data channel:

```

user@R3> show configuration protocols link-management
user@R3> show mpls lsp
user@R3> show link-management te-link

```

Sample Output

```

user@R3> show configuration protocols link-management
te-link te-tester3 {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
    interface so-0/0/1 { # SONET interface replaces the incorrect ATM interface
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}

user@R3> show mpls lsp
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
Egress LSP: 1 sessions

```

To	From	State	Rt	Style	Labelin	Labelout	LSPname
192.168.4.1	192.168.1.1	Up	0	1 FF	21252	-	gmpls-r1-to-r3

```

Bidir
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R3> show link-management te-link
TE link name: te-tester3, State: Up
Local identifier: 7003, Remote identifier: 21254, Local address: 93.93.93.93,
Remote address: 103.103.103.103,
Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
Available bandwidth: 0bps

```

Name	State	Local ID	ID	Remote ID	Bandwidth Used	LSP-name
so-0/0/1	Up	21252	21252	155.52Mbps	Yes	gmpls-r1-to-r3

Meaning

The sample output for the **show protocols link-management**, **show mpls lsp**, and **show link-management te-link** commands from ingress router **R3** show that the problem is solved. LMP is correctly configured, and the LSP **gmpls-r1-to-r3** is up and using the data channel **so-0/0/1**.

Conclusion

In conclusion, both ends of a GMPLS data channel must be the same encapsulation or interface type. This case illustrates the correct configuration of the data channel. The principles are the same for the control channel.

Router Configurations

Output that shows the configurations of the ingress router in the network. The **no-more** option entered after the pipe (|) prevents the output from being paginated if the output is longer than the length of the terminal screen.

Sample Output

The following sample output is for ingress router R1:

```
user@R1> show configuration | no-more
[...Output truncated...]

```

Verify Protocol Families

Purpose

If a logical interface does not have MPLS enabled, it cannot perform MPLS switching. This step allows you to quickly determine which interfaces are configured with MPLS and other protocol families.

Action

To verify the protocol families configured on the routers in your network, enter the following Junos OS CLI operational mode command:

```
user@host> show interfaces terse
```

Sample Output 1

user@R1> show interfaces terse

Interface	Admin	Link	Proto	Local	Remote
so-0/0/0	up	up			
so-0/0/0.0	up	up	inet	10.1.12.1/30	
			iso		
			mpls

Meaning

Sample Output 1 shows the interface, the administrative status of the link (**Admin**), the data link layer status of the link (**Link**), the protocol families configured on the interface (**Proto**), and the local and remote addresses on the interface.

All interfaces on all routes in the network shown in [Figure 167 on page 2218](#) are administratively enabled and functioning at the data link layer with MPLS and IS-IS, and have an **inet** address. All are configured with an IPv4 protocol family (**inet**), and have the IS-IS (**iso**) and MPLS (**mpls**) protocol families configured at the `[edit interfaces type-fpc/pic/port unit number]` hierarchy level.

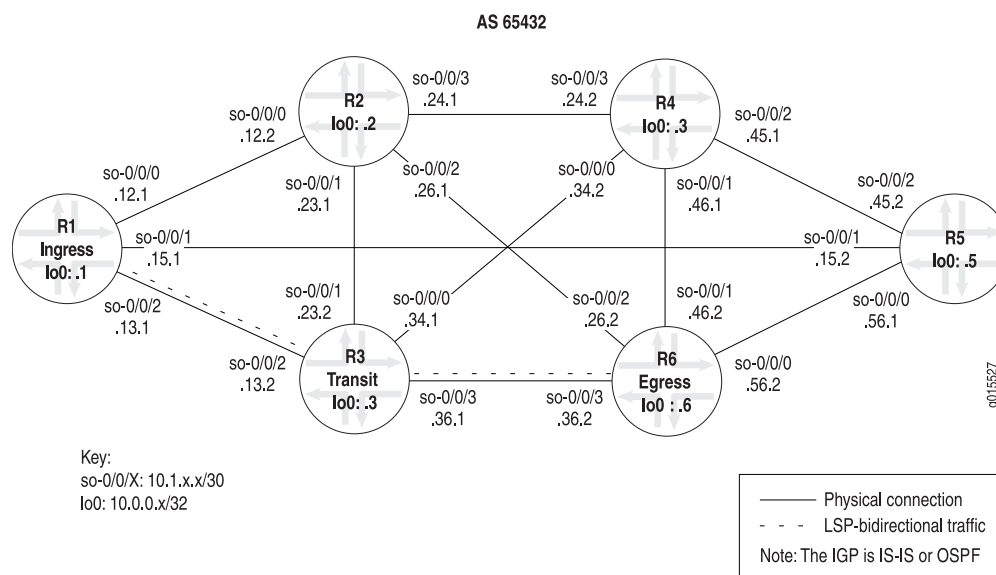

Sample Output 2 shows that interface `so-0/0/2.0` on **R6** does not have the **mpls** statement included at the `[edit interfaces type-fpc/pic/port unit number]` hierarchy level.

Determining LSP Status

Display detailed information about Resource Reservation Protocol (RSVP) objects and the label-switched path (LSP) history to pinpoint a problem with the LSP.

[Figure 170 on page 2285](#) illustrates the network topology used in this topic.

Figure 170: MPLS Network Topology

To determine the LSP state, follow these steps:

1. [Check the Status of the LSP | 2286](#)
2. [Display Extensive Status About the LSP | 2287](#)

Check the Status of the LSP

Purpose

Display the status of the label-switched pathe (LSP).

Action

To determine the LSP status, on the ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp
```

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From          State Rt ActivePath      P      LSPname
10.0.0.6    10.0.0.1    Up    1      *   R1-to-R6
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To          From          State Rt  Style  Labelin Labelout LSPname
10.0.0.1    10.0.0.6    Up    0 1 FF   3    - R6-to-R1
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information. Ingress information is for the sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1 (10.0.0.1)** to **R6 (10.0.0.6)**. This route is currently up, and is an active route installed in the routing table (**Rt**). The LSP **R1-to-R6** is the primary path (**P**) as opposed to the secondary path, and is indicated by an asterisk (*). The route to **R6** does not contain a named path (**ActivePath**).

There is one egress LSP from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see [“Checklist for Working with the Layered MPLS Troubleshooting Model” on page 1935](#).

Display Extensive Status About the LSP

Purpose

Display extensive information about LSPs, including all past state history and the reasons why an LSP might have failed.

Action

To display extensive information about LSPs, on the ingress router, enter the following Junos OS CLI operational mode command:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Total 0 displayed, Up 0, Down 0

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information in detail, including all past state history and the reasons why an LSP failed. Ingress information is for sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1 (10.0.0.1)** to **R6 (10.0.0.6)**. This route is currently up (**State**), with one route actively using the LSP, **R1-to-R6**. The LSP active path is the primary path. Even if the LSP does not

contain a **primary** or **secondary** keyword, the router still treats the LSP as a primary LSP, indicating that if the LSP fails, the router will attempt to signal inactive LSPs at 30-second intervals, by default.

Load balancing is **Random**, which is the default, indicating that when selecting the physical path for an LSP, the router randomly selects among equal-cost paths that have an equal hop count. Other options that you can configure are **Least-fill** and **Most-fill**. **Least-fill** places the LSP over the least utilized link of the equal-cost paths with equal hop count. **Most-fill** places the LSP over the most utilized link of the equal-cost paths sharing an equal hop count. Utilization is based on the percentage of available bandwidth.

The **Encoding type** field shows Generalized MPLS (GMPLS) signaling parameters (**Packet**), indicating IPv4. The **Switching type** is **Packet**, and the Generalized Payload Identifier (**GPID**) is IPv4.

The primary path is the active path, as indicated by an asterisk (*). The state of the LSP is **Up**.

The Explicit Route Object (**ERO**) includes the Constrained Shortest Path First (CSPF) cost (**20**) for the physical path that the LSP follows. The presence of the CSPF metric indicates that this is a CSPF LSP. The absence of the CSPF metric indicates a no-CSPF LSP.

The field **10.1.13.2 S** indicates the actual ERO. The RSVP signaling messages went to **10.1.13.2** strictly (as a next hop) and finished at **10.1.36.2** strictly. All ERO addresses are strict hops when the LSP is a CSPF LSP. Loose hops can only display in a no-CSPF LSP.

The received Record Route Object (**RRO**) has the following protection flags:

- **0x01**—Local protection available. The link downstream of this node is protected by a local repair mechanism. This flag can only be set if the Local protection flag was set in the **SESSION_ATTRIBUTE** object of the corresponding path message.
- **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).
- **0x04**—Bandwidth protection. The downstream router has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.
- **0x08**—Node protection. The downstream router has a backup path providing protection against link and node failure on the corresponding path section. If the downstream router can set up only a link-protection backup path, the “Local protection available” bit is set but the “Node protection” bit is cleared.
- **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engineered LSP. This indicates to the ingress label edge router (LER) of this LSP that it should be rerouted.

For more information on protection flags, see the *Junos Routing Protocols and Policies Command Reference*.

The field **10.1.13.2.10.1.36.2** is the actual received record route (**RRO**). Note that the addresses in the **RRO** field match those in the **ERO** field. This is the normal case for CSPF LSPs. If the RRO and ERO addresses do not match for a CSPF LSP, the LSP has to reroute or detour.

The lines numbered 91 through 42 contain the 49 most recent entries to the history log. Each line is time stamped. The most recent entries have the largest log history number and are at the top of the log, indicating that line 91 is the most recent history log entry. When you read the log, start with the oldest entry (42) to the most recent (91).

The history log was started on July 10, and displays the following sequence of activities: an LSP was selected as active, was found to be down, MPLS label allocation failed several times, was deleted several times, was preempted because of an ResvTear, was deselected as active, and was cleared. In the end, the router computed a CSPF ERO, signaled the call, the LSP came up with the listed RRO (line 90), and was listed as active.

For more information on error messages, see the *Junos MPLS Network Operations Guide Log Reference*.

The total number of ingress LSPs displayed is **1**, with **1** up and **0** down. The number in the **Up** field plus the number in the **Down** field should equal the total.

There is one egress LSP session from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see [“Checklist for Working with the Layered MPLS Troubleshooting Model” on page 1935](#).

Check the Status of the LSP

Purpose

Display the status of the label-switched path (LSP).

Action

To determine the LSP status, on the ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp
```

Sample Output

```

user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From          State Rt ActivePath      P      LSPname

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information. Ingress information is for the sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1 (10.0.0.1)** to **R6 (10.0.0.6)**. This route is currently up, and is an active route installed in the routing table (**Rt**). The LSP **R1-to-R6** is the primary path (**P**) as opposed to the secondary path, and is indicated by an asterisk (*). The route to **R6** does not contain a named path (**ActivePath**).

There is one egress LSP from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see [“Checklist for Working with the Layered MPLS Troubleshooting Model” on page 1935](#).

Display Extensive Status About the LSP

Purpose

Display extensive information about LSPs, including all past state history and the reasons why an LSP might have failed.

Action

To display extensive information about LSPs, on the ingress router, enter the following Junos OS CLI operational mode command:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive

```

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information in detail, including all past state history and the reasons why an LSP failed. Ingress information is for sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1 (10.0.0.1)** to **R6 (10.0.0.6)**. This route is currently up (**State**), with one route actively using the LSP, **R1-to-R6**. The LSP active path is the primary path. Even if the LSP does not contain a **primary** or **secondary** keyword, the router still treats the LSP as a primary LSP, indicating that if the LSP fails, the router will attempt to signal inactive LSPs at 30-second intervals, by default.

Load balancing is **Random**, which is the default, indicating that when selecting the physical path for an LSP, the router randomly selects among equal-cost paths that have an equal hop count. Other options that you can configure are **Least-fill** and **Most-fill**. **Least-fill** places the LSP over the least utilized link of the equal-cost paths with equal hop count. **Most-fill** places the LSP over the most utilized link of the equal-cost paths sharing an equal hop count. Utilization is based on the percentage of available bandwidth.

The **Encoding type** field shows Generalized MPLS (GMPLS) signaling parameters (**Packet**), indicating IPv4. The **Switching type** is **Packet**, and the Generalized Payload Identifier (**GPID**) is IPv4.

The primary path is the active path, as indicated by an asterisk (*). The state of the LSP is **Up**.

The Explicit Route Object (**ERO**) includes the Constrained Shortest Path First (CSPF) cost (**20**) for the physical path that the LSP follows. The presence of the CSPF metric indicates that this is a CSPF LSP. The absence of the CSPF metric indicates a no-CSPF LSP.

The field **10.1.13.2 S** indicates the actual ERO. The RSVP signaling messages went to **10.1.13.2** strictly (as a next hop) and finished at **10.1.36.2** strictly. All ERO addresses are strict hops when the LSP is a CSPF LSP. Loose hops can only display in a no-CSPF LSP.

The received Record Route Object (**RRO**) has the following protection flags:

- **0x01**—Local protection available. The link downstream of this node is protected by a local repair mechanism. This flag can only be set if the Local protection flag was set in the `SESSION_ATTRIBUTE` object of the corresponding path message.
- **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).
- **0x04**—Bandwidth protection. The downstream router has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.
- **0x08**—Node protection. The downstream router has a backup path providing protection against link and node failure on the corresponding path section. If the downstream router can set up only a link-protection backup path, the “Local protection available” bit is set but the “Node protection” bit is cleared.
- **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engineered LSP. This indicates to the ingress label edge router (LER) of this LSP that it should be rerouted.

For more information on protection flags, see the *Junos Routing Protocols and Policies Command Reference*.

The field **10.1.13.2.10.1.36.2** is the actual received record route (**RRO**). Note that the addresses in the **RRO** field match those in the **ERO** field. This is the normal case for CSPF LSPs. If the RRO and ERO addresses do not match for a CSPF LSP, the LSP has to reroute or detour.

The lines numbered 91 through 42 contain the 49 most recent entries to the history log. Each line is time stamped. The most recent entries have the largest log history number and are at the top of the log, indicating that line 91 is the most recent history log entry. When you read the log, start with the oldest entry (**42**) to the most recent (**91**).

The history log was started on July 10, and displays the following sequence of activities: an LSP was selected as active, was found to be down, MPLS label allocation failed several times, was deleted several times, was preempted because of an ResvTear, was deselected as active, and was cleared. In the end, the router computed a CSPF ERO, signaled the call, the LSP came up with the listed RRO (line 90), and was listed as active.

For more information on error messages, see the *Junos MPLS Network Operations Guide Log Reference*.

The total number of ingress LSPs displayed is **1**, with **1** up and **0** down. The number in the **Up** field plus the number in the **Down** field should equal the total.

There is one egress LSP session from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see [“Checklist for Working with the Layered MPLS Troubleshooting Model” on page 1935](#).

Checking That RSVP Path Messages Are Sent and Received

Purpose

The presence or absence of various RSVP messages can help determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network. For example, if path messages occur in the output without Resv messages, it might indicate that label-switched paths (LSPs) are not being created.

Action

To check that RSVP Path messages are sent and received, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show rsvp statistics
```

Sample Output

```
user@R1> show rsvp statistics
```

PacketType		Total		Last 5 seconds	
		Sent	Received	Sent	Received
Path	114523	80185	1	0	
PathErr	5	10	0	0	
PathTear	12	6	0	0	
Resv FF	80515	111476	0	0	
Resv WF		0	0	0	0
Resv SE		0	0	0	0
ResvErr		0	0	0	0
ResvTear	0	5	0	0	
ResvConf		0	0	0	0
Ack		0	0	0	0
SRefresh		0	0	0	0
Hello	915851	915881	0	0	
EndtoEnd RSVP		0	0	0	0
Errors		Total		Last 5 seconds	
Rcv pkt bad length		0		0	
Rcv pkt unknown type		0		0	

Rcv pkt bad version	0	0
Rcv pkt auth fail	0	0
Rcv pkt bad checksum	0	0
Rcv pkt bad format	0	0
Memory allocation fail	0	0
No path information	0	0
Resv style conflict	0	0
Port conflict	0	0
Resv no interface	0	0
PathErr to client	15	0
ResvErr to client	0	0
Path timeout	0	0
Resv timeout	0	0
Message out-of-order	0	0
Unknown ack msg	0	0
Recv nack	0	0
Recv duplicated msg-id	0	0
No TE-link to recv Hop	0	0

Meaning

The sample output shows RSVP messages sent and received. The total number of RSVP Path messages is 11,4532 sent and 80,185 received. Within the last 5 seconds, no messages have been sent or received.

A total of 5 **PathErr** messages were sent and 10 received. When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. In this case, **R1** sent at least 10 path messages with an error, as indicated by the 10 PathErr messages that **R1** has received. The downstream router sent **R1** five path messages with an error, as indicated by the five PathErr messages that **R1** has sent. PathErr messages transmit in the opposite direction to path messages.

A total of 12 **PathTear** messages were sent and 6 received, none in the last 5 seconds. In contrast to PathErr messages, PathTear messages travel in the same direction as path messages. Since path messages are both sent and received, PathTear messages are also sent and received. However, if only path messages are sent, then only the PathTear messages that are sent appear in the output.

A total of 80,515 reservation (**Resv**) messages with the fixed filter (**FF**) reservation style were sent and 111,476 received, none in the last 5 seconds. An **FF** reservation style indicates that within each session, each receiver establishes its own reservation with each upstream sender, and that all selected senders are listed. No messages for the wildcard filter (**WF**) or shared explicit (**SE**) reservation styles are sent or received. For more information on RSVP reservation styles, see the *Junos MPLS Applications Configuration Guide*.

Other RSVP message types are not sent or received. For information on the ResvErr, ResvTear, and Resvconf message types, see the *Junos MPLS Applications Configuration Guide*.

Ack and summary refresh (SRefresh) messages do not appear in the output. Ack and summary refresh messages are defined in RFC 2961 and are part of the RSVP extensions. Ack messages are used to reduce the amount of RSVP control traffic in the network.

A total of 915,851 hello messages were sent and 915,881 received, with none transmitted or received in the last 5 seconds. The RSVP hello interval is 9 seconds. If more than one hello message is sent or received in the last 5 seconds, it implies that more than one interface supports RSVP.

EndtoEnd RSVP messages are legacy RSVP messages that are not used for RSVP traffic engineering. These counters increment only when RSVP forwards legacy RSVP messages issued by a virtual private network (VPN) customer for transit across the backbone to the other site(s) in the VPN. They are called end-to-end messages because they are intended for the opposite side of the network and only have meaning at the two ends of the provider network.

The **Errors** section of the output shows statistics about RSVP packets with errors. A total of 15 **PathErr to client** packets were sent to the Routing Engine. The total combines the sent and received **PathErr** packets. For more information about error statistics and packets, see the *Junos System Basics and Services Command Reference*.

Determining the Current RSVP Neighbor State

Purpose

Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors.

Action

To determine the current RSVP neighbor state, enter the following Junos OS CLI operational mode command:

```
user@host> show rsvp neighbor
```

Sample Output

```
user@R6> show rsvp neighbor
RSVP neighbor:  2  learned
Address      Idle Up/Dn LastChange  HelloInt  HelloTx/Rx  MsgRcvd
10.1.36.1     5  1/0  1w5d 6:30:50    9      116734/116734  23558
10.1.56.1    10  1/0  2w2d 23:44:15    9      161600/161600  23570
```

Meaning

The sample output shows that **R6** has learned about two different RSVP neighbors. Each neighbor has one line of output that includes the neighbor RSVP address, the length of time the interface was idle, the current interface up/down counter, the time of the last interface state change, the current RSVP hello interval, the total number of RSVP hello messages transmitted and received, and the total number of RSVP messages received on the interface.

The **show rsvp neighbor** command only indicates a neighbor after a session is established. Once an interface is displayed in this command output, it always appears, even if the RSVP neighbor state is down.

The RSVP neighbor **10.1.36.1** was idle for 5 seconds, came up once and has not gone down, indicating that the interface is currently in an **Up** state. As long as the up counter is one greater than the down counter, the RSVP interface is up. If the up/down counters are equal, the interface is down.

The last state change occurred 6 hours and 30 minutes ago. The current hello interval is 9 seconds. A total of 116,734 hello messages were transmitted and received on this interface, and a total of 23,558 RSVP Path/Resv messages were processed.

The RSVP neighbor **10.1.56.1** was idle for 10 seconds, came up once and has not gone down, indicating that the interface is currently in an **Up** state. The last state change occurred 23 hours and 44 minutes ago. The current Hello interval is 9 seconds. A total of 161,600 hello messages were transmitted and received on this interface, and a total of 23,570 RSVP Path/Resv messages were processed.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the routers are configured to function at different levels of the IS-IS protocol.

Solution

To correct the error in this example, enter the following commands:

Sample Output

```
[edit protocols isis]
user@R6# show
level 2 disable;
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
```

```

        disable;
    }
    interface lo0.0; {
    passive

[edit protocols isis]
user@R6# delete level 2

[edit protocols isis]
user@R6# set level 1 disable

[edit protocols isis]
user@R6# show
level 1 disable;
interface all {
    level 2 metric 10;
}
interface fxp0.0 {
    disable;
}
interface lo0.0; {
    passive

[edit protocols isis]
user@R6# commit
commit complete

[edit protocols isis]
user@R6# run show isis adjacency

```

Interface	System	L State	Hold (secs)	SNPA
so-0/0/0.0	R5	2 Up	22	
so-0/0/1.0	R4	2 Up	22	
so-0/0/2.0	R2	2 Up	22	
so-0/0/3.0	R3	2 Up	22	

Meaning

The sample output shows that the configuration error on egress router R6 has been corrected, and IS-IS adjacencies are now established.

RELATED DOCUMENTATION

Examine BGP Routes

Purpose

You can examine the BGP path selection process to determine the single, active path when BGP receives multiple routes to the same destination. In this step, we examine the reverse LSP **R6-to-R1**, making **R6** the ingress router for that LSP.

Action

To examine BGP routes and route selection, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix detail
```

Sample Output 1

```
user@R6> show route 100.100.1.1 detail
```

```
inet.0: 30 destinations, 46 routes (29 active, 0 holddown, 1 hidden)
100.100.1.0/24 (1 entry, 1 announced)
    *BGP      Preference: 170/-101
              Source: 10.1.13.1
              Next hop: via so-0/0/3.0, selected
              Protocol next hop: 10.1.13.1  Indirect next hop: 8671594 304
              State: <Active Int Ext>
              Local AS: 65432 Peer AS: 65432
              Age: 4d 5:15:39      Metric2: 2
              Task: BGP_65432.10.1.13.1+3048
              Announcement bits (2): 0-KRT 4-Resolve inet.0
              AS path: I
              Localpref: 100
              Router ID: 10.0.0.1
```

Sample Output 2

```
user@R6> show route 100.100.1.1 detail
```

```

inet.0: 30 destinations, 46 routes (29 active, 0 holddown, 1 hidden)
100.100.1.0/24 (1 entry, 1 announced)
  *BGP      Preference: 170/-101
            Source: 10.0.0.1
            Next hop: via so-0/0/3.0 weight 1, selected
            Label-switched-path R6-to-R1
            Label operation: Push 100000
            Protocol next hop: 10.0.0.1   Indirect next hop: 8671330 301
            State: <Active Int Ext>
            Local AS: 65432 Peer AS: 65432
            Age: 24:35      Metric2: 2
            Task: BGP_65432.10.0.0.1+179
            Announcement bits (2): 0-KRT 4-Resolve inet.0
            AS path: I
            Localpref: 100
            Router ID: 10.0.0.1

```

Meaning

Sample Output 1 shows that the BGP next hop (**10.1.13.1**) does not equal the LSP destination address (**10.0.0.1**) in the **to** statement at the `[edit protocols mpls label-switched-path label-switched-path-name]` hierarchy level when the BGP configuration of **R6** and **R1** is incorrect.

Sample Output 2, taken after the configurations on R1 and R6 are corrected, shows that the BGP next hop (**10.0.0.1**) and the LSP destination address (**10.0.0.1**) are the same, indicating that BGP can use the LSP to forward BGP traffic.

CLI Operational Mode Top-Level Commands

In operational mode, you enter commands to monitor and diagnose the software, network connectivity, and the router. When you log in to the router and the CLI starts, you are at the top level of the CLI operational mode. At this level, there are several broad groups of CLI commands. [Table 65 on page 2304](#) lists the top-level CLI operational mode commands and describes the options available for each command. The commands are listed in alphabetical order.

Table 65: CLI Operational Mode Top-Level Commands

Command	Description
clear	<p>Clear statistics and protocol database information.</p> <p>Syntax: clear (arp bgp firewall helper igmp ike ilmi interfaces ipsec ipv6 isis ldp log mpls msdp multicast ospf pim rip ripng route rsvp snmp system vrrp)</p>
configure	<p>Enter CLI configuration mode.</p> <p>Alternative commands: configure <exclusive> <private></p>
file	<p>Perform file manipulation operations, such as copy, delete, list, rename, and show.</p> <p>Syntax: file (compare copy delete list rename show)</p>
help	<p>Provide help information.</p> <p>Syntax: help (reference syslog topic)</p>
monitor	<p>Monitor a log file or interface traffic in real time.</p> <p>Syntax: monitor (interface list start stop traffic)</p>
mtrace	<p>Display trace information about a multicast path from a source to a receiver.</p> <p>Syntax: mtrace (from-source monitor to-gateway)</p>
ping	<p>Verify IP connectivity to another IP host or Asynchronous Transfer Mode (ATM) connectivity (ping ATM) using Operation Administration and Maintenance (OAM) cells to an ATM endstation.</p> <p>Syntax: ping host <interface source-interface > <bypass-routing> <count requests > <do-not-fragment> <interval seconds > <pattern string > <record-route> <routing-instance routing-instance-name > <size bytes > <strict> <tos type-of-service > <tll value > <via route > <rapid detail></p> <p>Syntax: ping atm interface interface <count count > <end-to-end segment> <interval interval> <sequence-number sequence-number > <vci vci > <brief></p> <p>Syntax: ping vpn-interface vpn-interface host <local echo-address></p>
pipe	<p>Filter the output of an operational mode or configuration mode command.</p> <p>Syntax: (compare count display <detail inheritance xml> except <i>pattern</i> find <i>pattern</i> last <i>lines</i> match <i>pattern</i> no-more resolve <file-names> save <i>filename</i> trim <i>columns</i>)</p>
quit	<p>Log out from the CLI process.</p> <p>Syntax: quit</p>

Table 65: CLI Operational Mode Top-Level Commands (*continued*)

Command	Description
request	<p>Make system-level requests, such as halt or reboot the router, load software packages, and back up the router's file systems.</p> <p>Syntax: request system (halt reboot snapshot software)</p>
restart	<p>Restart the router hardware or software processes.</p> <p>Syntax: restart (fpc class-of-service gracefully immediately interface-control mib-process network-access-service remote-operations routing sampling sfm snmp soft)</p>
set	<p>Set CLI properties, the router's date and time, and the craft interface display text.</p> <p>Syntax: set (chassis cli date)</p>
show	<p>Show information about all aspects of the software, including interfaces and routing protocols.</p> <p>Syntax: show (accounting aps arp as-path bgp chassis cli configuration connections dvmrp firewall helper host igmp ike ilmi interfaces ipsec ipv6 isis l2circuit l2vpn ldp link-management log mpls msdp multicast ntp ospf pfe pim policer policy rip ripng route rsvp sap snmp system task ted version vrrp)</p>
ssh	<p>Open a secure shell to another host.</p> <p>Syntax: ssh host <bypass-routing> <routing-instance routing-instance-name> <source address> <vpn-interface vpn-interface> <v1 v2></p>
start	<p>Start a software process.</p> <p>Syntax: start shell</p>
telnet	<p>Start a telnet session to another host.</p> <p>Syntax: telnet host <8bit> <bypass-routing> <inet inet6> <noresolve> <port port> <interface interface-name> <routing-instance routing-instance-name> <source address> <vpn-interface vpn-interface></p>
test	<p>Run various diagnostic debugging commands.</p> <p>Syntax: test (configuration interface msdp policy)</p>
traceroute	<p>Trace the route to a remote host.</p> <p>Syntax: traceroute host <as-number-lookup> <bypass-routing> <gateway address> <inet inet6> <noresolve> <routing-instance routing-instance-name> <source address> <tos value> <ttd value> <vpn-interface vpn-interface> <wait seconds></p>

CLI Keyboard Shortcuts

In the CLI, you can use keyboard sequences to move around and edit a command line. You can also use keyboard sequences to scroll through a list of recently executed commands.

Table 15 on page 23 lists some of the CLI keyboard sequences.

Table 66: CLI Keyboard Shortcuts

Keyboard sequence	Action
Ctrl+b	Move the cursor back one character.
Esc+b or Alt+b	Move the cursor back one word.
Ctrl+f	Move the cursor forward one character.
Esc+f or Alt+f	Move the cursor forward one word.
Ctrl+a	Move the cursor to the beginning of the command line.
Ctrl+e	Move the cursor to the end of the command line.
Ctrl+h, Delete, or Backspace	Delete the character before the cursor.
Ctrl+d	Delete the character at the cursor.
Ctrl+k	Delete the all characters from the cursor to the end of the command line.
Ctrl+u or Ctrl+x	Delete the all characters from the command line.
Ctrl+w, Esc+Backspace, or Alt+Backspace	Delete the word before the cursor.
Esc+d or Alt+d	Delete the word after the cursor.
Ctrl+y	Insert the most recently deleted text at the cursor.
Ctrl+l	Redraw the current line.
Ctrl+p	Scroll backward through the list of recently executed commands.
Ctrl+n	Scroll forward through the list of recently executed commands.

Table 66: CLI Keyboard Shortcuts (*continued*)

Keyboard sequence	Action
Ctrl+r	Search the CLI history incrementally in reverse order for lines matching the search string.
Esc+/ or Alt+/ 	Search the CLI history for words for which the current word is a prefix.
Esc+. or Alt+ 	Scroll backward through the list of recently entered words in a command line.
Esc+ <i>number sequence</i> or Alt+ <i>number sequence</i>	Specify the number of times to execute a keyboard sequence.

Manage Output at the ---(more)--- Prompt

If the output is longer than the screen length, it appears one screen at a time with the UNIX ---(more)--- prompt at the end of the screen. The ---(more)--- prompt indicates that more output is available. The following table lists the keyboard sequences you can use at the --(more)--- prompt.

Table 67: Keyboard Shortcuts at the ---(more)--- Prompt

Keyboard Shortcut	Action
Enter, Return, k, Ctrl+m, Ctrl+n, or down arrow	Scroll down one line.
Tab, d, Ctrl+d, or Ctrl+x	Scroll down one-half screen.
Space or Ctrl+f	Scroll down one whole screen.
Ctrl+e or g	Scroll down to the bottom of the output.
n (or no-more)	Display the output all at once instead of one screen at a time.
j, Ctrl-h, Ctrl-p, or up arrow	Scroll up one line.
u or Ctrl-u	Scroll up one-half screen.
b or Ctrl-b	Scroll up one whole screen.
Ctrl-a or g	Scroll up to the bottom of the output.
/string	Search forward for a string.

Table 67: Keyboard Shortcuts at the ---(more)--- Prompt (*continued*)

Keyboard Shortcut	Action
? <i>string</i>	Search backward for a string.
n	Repeat previous search for a string.
m or M (or <i>match string</i>)	Find a text string. You are prompted for the string to match
e or E (or <i>except string</i>)	Find, ignoring a text string. You are prompted for the string to ignore.
Ctrl-C, q, Q, or Ctrl-k	Interrupt the display of output.
H (Same as specifying <i>hold</i>)	Hold the CLI at the —more- prompt after displaying all output.
c or C	Clear any match conditions and display the complete output.
Ctrl-l	Redraw the output on the screen.
s or S (or <i>save filename</i>)	Save the command output to a file. You are prompted for a filename.

Working with Problems on Your Network

Problem

Description: This checklist provides links to troubleshooting basics, an example network, and includes a summary of the commands you might use to diagnose problems with the router and network.

Solution

Table 68: Checklist for Working with Problems on Your Network

Tasks	Command or Action
“Isolating a Broken Network Connection” on page 2309	
1. <i>Identifying the Symptoms of a Broken Network Connection</i>	<p>ping (<i>ip-address</i> <i>hostname</i>)</p> <p>show route (<i>ip-address</i> <i>hostname</i>)</p> <p>traceroute (<i>ip-address</i> <i>hostname</i>)</p>
2. <i>Isolating the Causes of a Network Problem</i>	<p>show < configuration interfaces protocols route</p> <p>></p>

Table 68: Checklist for Working with Problems on Your Network (continued)

Tasks	Command or Action
3. Taking Appropriate Action for Resolving the Network Problem	<code>[edit]</code> <code>delete routing options static route destination-prefix</code> <code>commit and-quit</code> <code>show route destination-prefix</code>
4. Evaluating the Solution to Check Whether the Network Problem Is Resolved	<code>show route (ip-address hostname)</code> <code>ping (ip-address hostname) count 3</code> <code>traceroute (ip-address hostname)</code>

Isolating a Broken Network Connection

By applying the standard four-step process illustrated in [Figure 171 on page 2309](#), you can isolate a failed node in the network. Note that the functionality described in this section is not supported in versions 15.1X49, 15.1X49-D30, or 15.1X49-D40.

Figure 171: Process for Diagnosing Problems in Your Network

Before you embark on the four-step process, however, it is important that you are prepared for the inevitable problems that occur on all networks. While you might find a solution to a problem by simply trying a variety of actions, you can reach an appropriate solution more quickly if you are systematic in your approach to the maintenance and monitoring of your network. To prepare for problems on your network, understand how the network functions under normal conditions, have records of baseline network activity, and carefully observe the behavior of your network during a problem situation.

[Figure 172 on page 2310](#) shows the network topology used in this topic to illustrate the process of diagnosing problems in a network.

Figure 172: Network with a Problem

The network in [Figure 172 on page 2310](#) consists of two autonomous systems (ASs). AS 65001 includes two routers, and AS 65002 includes three routers. The border router (**R1**) in AS 65001 announces aggregated prefixes **100.100/24** to the AS 65002 network. The problem in this network is that **R6** does not have access to **R5** because of a loop between **R2** and **R6**.

To isolate a failed connection in your network, follow the steps in these topics:

- *Isolating the Causes of a Network Problem*
- *Taking Appropriate Action for Resolving the Network Problem*
- *Taking Appropriate Action for Resolving the Network Problem*
- *Evaluating the Solution to Check Whether the Network Problem Is Resolved*

Display Junos OS Information

Purpose

Display Junos OS information and status to determine if the version of Junos OS that you are running supports particular features or hardware. You can also determine whether particular software bugs will affect your version of Junos OS.

Action

To display Junos OS information, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show version
```

Sample Output

```
user@host> show version
```

```
Hostname: my-router.net
Model: m160
JUNOS Base OS boot [5.5R2.3]
JUNOS Base OS Software Suite [5.5R2.3]
JUNOS Kernel Software Suite [5.5R2.3]
JUNOS Packet Forwarding Engine Support [5.5R2.3]
JUNOS Routing Software Suite [5.5R2.3]
JUNOS Online Documentation [5.5R2.3]
JUNOS Crypto Software Suite [5.5R2.3]

```

Meaning

The sample output shows the hostname, the version information for the Junos OS packages installed on the machine, and the version information for each software process.

Display Version Information for Junos OS Packages

Purpose

Display version information for Junos OS packages to determine if they support particular features or hardware. You can also determine whether particular software bugs will affect your version of Junos OS.

Action

To display brief information and status for the kernel and Packet Forwarding Engine, use the following CLI operational mode command:

```
user@host> show version brief
```

The following sample output is for worldwide nonencrypted Junos OS:

Sample Output

```
user@host> show version brief
Hostname: my-router.net
Model: m10
JUNOS Base OS boot [5.5R2.3]
JUNOS Base OS Software Suite [5.5R2.3]
JUNOS Kernel Software Suite [5.5R2.3]
JUNOS Packet Forwarding Engine Support [5.5R2.3]
JUNOS Routing Software Suite [5.5R2.3]
JUNOS Online Documentation [5.5R2.3]
```

The following sample output is for Canada and USA encrypted Junos OS:

```
user@host> show version brief
Hostname: my-router.net
```

```

Model: m10
JUNOS Base OS boot [5.5R2.3]
JUNOS Base OS Software Suite [5.5R2.3]
JUNOS Kernel Software Suite [5.5R2.3]
JUNOS Packet Forwarding Engine Support [5.5R2.3]
JUNOS Routing Software Suite [5.5R2.3]
JUNOS Online Documentation [5.5R2.3]
JUNOS Crypto Software Suite [5.5R2.3]

```

Meaning

The sample output shows version information for the Junos OS packages installed on the router. If the **Junos Crypto Software Suite** is listed, the router has Canada and USA encrypted Junos OS. If the **Junos Crypto Software Suite** is not listed, the router is running worldwide nonencrypted Junos OS.

Display the Current Active Router Configuration

Purpose

Examine the current active router configuration.

Action

To display the current, active router configuration, use the following command-line interface (CLI) operational mode command:

```
user@host> show configuration
```

Sample Output

```

user@host> show configuration
version "10.4R2";
groups {
  global {
    system {
      host-name potter;
      domain-name harry.potter.net;
      domain-search [ harry.potter.net potter.net hrypтр.net ];
      backup-router 10.110.12.254;
      time-zone America/Los_Angeles;
    }
  }
}

```

```

    }
}
[...Output truncated...]

```

Meaning

The sample output shows the current, active configuration for the router. When displaying the configuration, the CLI indents each subordinate hierarchy level, inserts braces to indicate the beginning and end of each hierarchy level, and places semicolons at the end of statements that are at the lowest level of the hierarchy.

The configuration statements appear in a fixed order. Interfaces appear alphabetically by type, and then in numerical order by slot number, Physical Interface Card (PIC) number, and port number.

Copy Junos OS to the Router

Action

Copy the software packages from the server to the router. We recommend that you copy them to the **/var/tmp** directory, which is on the rotating medium (hard disk) and is a large file system. Use the following CLI command:

```
user@host> file copy ftp://username: prompt@ftp.hostname.
net/jinstall-package-name/var/tmp/jinstall-package-name
```

Add New Software

Action

To add new software packages, use the following Junos OS CLI operational mode command:

```
user@host> request system software add /var/tmp/jinstall-package--name
```

package-name is the full URL to the file and **release-number** is the major software release number; for example, 4.2R1. Before the new software is added, the existing software is automatically deleted.

NOTE: Even though you are adding the new software, the changes do not take effect until the router has completed rebooting.

Sample Output

```
user@host> request system software add /var/tmp/jinstall-5.2R2.3-domestic.tgz
Installing package '/var/tmp/jinstall-5.2R2.3-domestic.tgz'
Auto-deleting old jroute...
Auto-deleting old jdocs...
Auto-deleting old jpfe...
Auto-deleting old jkernel...
Adding JUNOS base software 5.2R2.3
Adding jkernel...
Adding jpfe...
Adding jdocs...
Adding jroute...
NOTICE: uncommitted changes have been saved in
/var/db/config/juniper.conf.pre-install
Saving package file in /var/sw/pkg/jinstall-5.2R2.3-domestic.tgz
```

Compare Information Logged Before and After the Upgrade

Purpose

Compare the operation of the system before and after the upgrade to ensure that everything is working as expected.

Action

To obtain system information, use the following Junos OS CLI operational mode commands:

```
user@host> show version
user@host> show chassis hardware
user@host> show configuration
user@host> show interface terse
user@host> show bgp summary
user@host> show isis adjacency brief
user@host> show ospf neighbor brief
user@host> show system storage
```

Compare the information from these commands with the information you logged before the upgrade.

Displaying LSP Status Events

Purpose

Display extensive information about LSPs, including the 50 most recent history events and the reasons why an LSP might have failed.

Action

To examine status messages, enter the following Junos OS command-line interface (CLI) operational mode command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
```

```

```

Meaning

Sample Output 1 from ingress router R1 shows extensive ingress LSP information, including LSP events that led to an LSP failure and the 50 most recent state events.

LSP events in bold are described in this topic. Descriptions include sample output of the LSP event, an explanation of what the event means, the possible cause of the event, and any possible actions that you can take.

For completeness, events not included in this example output are also described in this topic to show LSP events that did not occur in the example network configuration, but might occur in your network. The LSP events are organized alphabetically.

Sample Output 2 shows the state of the route received in the Received Record Route (**Received RRO**) created by fast reroute configurations in the network. The **Received RRO** indicates a series of hops. Each hop has an address followed by a flag. For more information on flags, see the *Junos MPLS Network Operations Guide*. In most cases, the **Received RRO** is the same as the computed Explicit Route Object (ERO).

Sample Output 3 shows a **Computed ERO** and a **Received RRO**. In this instance they are the same. However, if **Received RRO** is different from the **Computed ERO**, there is a topology change in the network, and the route is taking a detour.

Call Was Cleared by RSVP Event

LSP Event

Call was cleared by RSVP

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
ActivePath: (none)
LoadBalance: Random
Encoding type: Packet, Switching type: Packet, GPID: IPv4
Primary State: Dn
Will be enqueued for recomputation in 10 second(s).
11 Jan 26 14:58:32 CSPF failed: no route toward 10.0.0.6
10 Jan 26 14:58:25 Deselected as active
9 Jan 26 14:58:25 CSPF failed: no route toward 10.0.0.6
8 Jan 26 14:58:25 Call was cleared by RSVP
7 Jan 26 14:58:25 Session preempted
6 Jan 26 14:58:25 Down
[...Output truncated...]
```

Meaning

This LSP event indicates that the Resource Reservation Protocol (RSVP) session corresponding to the LSP path was preempted and the corresponding RSVP state deleted.

Cause

This LSP event occurs when you issue the **clear rsvp session** command or trigger preemption of an RSVP session at the ingress router. Depending on the timer value, Constrained Shortest Path First (CSPF) recomputes the path and the LSP comes up again.

Action

Not applicable.

Change in Active Path Event

LSP Event

Change in active path

Sample Output

```

user@R1> show mpls lsp extensive
[...Output truncated...]
13 Sep 19 00:02:20 Deselected as active
12 Sep 19 00:02:20 ResvTear received
11 Sep 19 00:02:20 Down
10 Sep 19 00:02:20   Change in active path
9 Sep 19 00:02:20
8 Sep 19 00:02:20 10.222.28.2: Explicit Route: bad strict routeChange in active
path
7 Sep 19 00:02:20 CSPF failed: no route toward 192.168.32.1
6 Sep 19 00:02:20 10.222.28.2: No Route toward dest
5 Sep 19 00:00:54 Selected as active path
4 Sep 19 00:00:54 Record Route: 10.222.28.2 10.222.4.2 10.222.44.2
3 Sep 19 00:00:54 Up
2 Sep 19 00:00:54 Originate Call
1 Sep 19 00:00:54 CSPF: computation result accepted
[...Output truncated...]

```

Meaning

This LSP event indicates that even though the active physical path has changed, the LSP stays up. Because this network configuration has an alternate (fast-reroute) path available, the event is a **Change in active path** rather than a **Session preempted** event.

Cause

The active path might have failed.

Action

Not applicable.

Clear Call Event

LSP Event

Clear call

Sample Output

```

user@R1> show mpls lsp extensive
[...Output truncated...]

```

```

65 Jan  5 09:58:33  Clear Call
64 Jan  5 09:58:33 Session preempted
63 Jan  5 09:58:33 Down
[...Output truncated...]

```

Meaning

This LSP event indicates that the LSP was disconnected and restarted.

Cause

The **clear mpls lsp** command was issued on the ingress router to disconnect existing RSVP sessions, release the routes and states associated with the LSP, and then start a new LSP. Issuing this command might impact traffic travelling along the LSP, because a time lag might occur between tearing down the old path and setting up a new path.

Action

Not applicable.

Deselected as Active Event

LSP Event

Deselected as active

Sample Output

```

user@R1> show mpls lsp extensive
[...Output truncated...]
Will be enqueued for recomputation in 18 second(s).
53 Jan  4 18:11:28 CSPF failed: no route toward 10.0.0.6[2 times]
52 Jan  4 18:10:44  Deselected as active
51 Jan  4 18:10:44 CSPF failed: no route toward 10.0.0.6
50 Jan  4 18:10:44 CSPF: link down/deleted
[...Output truncated...]

```

Meaning

This LSP event indicates that the LSP is no longer the active path.

Cause

Typically, other events, similar to those in lines 50 and 51, indicate the reason that the LSP is no longer the active path.

Action

Refer to events on either side of this event to determine the appropriate action.

Link Protection Down Event

LSP Event

Link protection down

Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
    link-protection;
}
interface fxp0.0 {
    disable;
}
interface all;
```

Sample Output 2

```
user@R1> show mpls lsp extensive
[...Output truncated...]

48 Feb 10 10:48:32 Link-protection Up
47 Feb 10 10:48:32 Selected as active path
[...Output truncated...]

```

Meaning

Sample Output 1 shows the MPLS link-protection configuration on R1 for the LSP **R1-to-R6**.

Sample Output 2 shows that link protection came up and down several times. Link protection comes up when the LSP signals. Line 60 shows the result when RSVP is disabled on all alternate paths out of R6. Lines 68 to 70 are the result when the **clear mpls lsp** command is issued.

Cause

This LSP event is caused by a failure or configuration change that deletes or resignals the bypass LSP. For example, you clear the LSP using the **clear mpls lsp** command, or you disable RSVP on all alternate paths for the LSP. The bypass LSP does not use the primary path, instead it looks for an alternate path.

Action

Include the **family mpls** statement for all alternate paths for the LSP at the [edit interfaces type-fpc/pic/port.unit] hierarchy level.

Originate Call Event

LSP Event

Originate call

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
 43 Jan  4 18:06:09 Record Route:  10.1.13.2 10.1.36.2
 42 Jan  4 18:06:09 Up
 41 Jan  4 18:06:09  Originate Call
 40 Jan  4 18:06:09 CSPF: computation result accepted
 39 Jan  4 18:05:40 CSPF failed: no route toward 10.0.0.6[2 times]
[...Output truncated...]
```

Meaning

This LSP event indicates that the router is issuing an RSVP Path message.

Cause

A Path message is transmitted by the ingress router toward the egress router to establish an LSP.

Action

To analyze the contents of the Path message, enable RSVP tracing. To configure RSVP tracing, include the **traceoptions** statement at the **[edit protocols rsvp]** hierarchy level. Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**. To examine the contents of the **rsvp-log** file, issue the **file show /var/log/rsvp-log** command.

ResvTear Received Event

LSP Event

ResvTear received

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
 23 Dec 28 13:46:39 CSPF failed: no route toward 10.0.0.6
```

```

22 Dec 28 13:46:39 Clear Call
21 Dec 28 13:46:39   ResvTear received
20 Dec 28 13:46:39 Down
19 Dec 28 13:46:39 10.1.13.2: Session preempted
18 Dec 28 13:42:07 Selected as active path
[...Output truncated...]

```

Meaning

This LSP event indicates that an RSVP ResvTear message was received. ResvTear messages remove RSVP reservation states along a path. These messages travel upstream toward senders of the session. This message usually appears in the middle of a run of messages that tear the LSP down.

Cause

In some cases, an ResvTear event is received because a router's reservation state times out. In other cases, when the downstream link fails, the upstream node must eliminate all RSVP states and initiates a ResvTear event. If you are running Fast ReRoute, the upstream node initiates a PathErr message, not a ResvTear message. It is beyond the scope of this document to include all possible reasons for an ResvTear event.

Action

Analyze the status to determine if this is the required behavior. If this is not the required behavior, verify the surrounding LSP events to identify the cause of the problem.

Session Preempted Event

LSP Event

Session preempted

Sample Output 1

```

user@R1> show mpls lsp extensive
[...Output truncated...]
 21 Dec 28 13:46:39 ResvTear received
 20 Dec 28 13:46:39 Down
 19 Dec 28 13:46:39   10.1.13.2: Session preempted
 18 Dec 28 13:42:07 Selected as active path
 17 Dec 28 13:42:07 Record Route:  10.1.13.2 10.1.36.2
[...Output truncated...]

```

Sample Output 2

```

user@R1> show mpls lsp extensive
[...Output truncated...]
 66 Jan  5 09:58:33 CSPF failed: no route toward 10.0.0.6
 65 Jan  5 09:58:33 Clear Call

    : no route toward 10.0.0.6[2 times]
61 Jan  5 09:57:55 10.1.36.2: Explicit Route: wrong delivery
 60 Jan  5 09:57:34 CSPF failed: no route toward 10.0.0.6[2 times]
 59 Jan  5 09:57:28 CSPF: link down/deleted
10.1.36.1(R3.00/10.0.0.3)->10.1.36.2(R6.00/10.0.0.6)
[...Output truncated...]

```

Meaning

This LSP event indicates that the LSP session was taken over. Sample Output 1 shows the IP address (10.1.13.2) included with the event, indicating the IP address of the router that sent the message. Sample Output 2 does not include an IP address, indicating that the message originated on the ingress router.

Cause

The state of the network might have changed, as shown in Sample Output 1, or an LSP with a higher priority might be using the bandwidth of the LSP.

Action

Refer to the events preceding this event in the history log for more information on what might have caused the preemption. For example, in line 62, the **CSPF failed** message may indicate that you specified a disable constrained-path (**no-cspf**) LSP and an explicit route address that is strict and not directly connected. Additionally, the egress router might have changed its configuration, making the destination address unreachable.

Displaying General LSP Error Events

Purpose

Display extensive information about LSPs, including the 50 most recent history events and the possible reasons why an LSP failed.

Action

To examine error messages, enter the following Junos OS command-line interface (CLI) operational mode command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn, No-decrement-ttl
    Bandwidth: 100Mbps
  14 Jan 21 15:43:39 Requested bandwidth unavailable[3 times]
  13 Jan 21 15:43:21 Deselected as active
  12 Jan 21 15:43:21   Requested bandwidth unavailable
  11 Jan 21 15:43:21 Clear Call
  10 Jan 21 15:42:32 Selected as active path
   9 Jan 21 15:42:32 Record Route:  10.1.12.2 10.1.26.2
   8 Jan 21 15:42:32 Up
[...Output truncated...]
```

Meaning

The sample output from ingress router R1 is a section from the complete output. Typically, the output includes LSP events that led to an LSP failure and the 50 most recent state events. Only one example of a general LSP error event is displayed because it is impossible to provide all of the events described in this topic in one sequence of log history.

For completeness, events not generated by the example network used throughout this book are described to show LSP events that might occur in your network. The output for these events includes the prompt **user@host** rather than the usual **user@R1** prompt.

Admission Control Failure Event

LSP Event

Admission control failure

Sample Output

Not available.

Meaning

This LSP error event indicates that a Resource Reservation Protocol (RSVP) Admission control failure occurred along the LSP path. This event is logged because of an error notification (PathErr message) received from RSVP for the label-switched path.

Cause

This LSP event is caused by inadequate bandwidth on a link along the LSP path. The available bandwidth could not satisfy the requested traffic parameters and no other sessions were pre-empted to accommodate this request.

Action

This error event is not generated by Juniper Networks routers. However, when this event is received by a Juniper Networks router, it appears in the log output of the **show mpls lsp extensive** command.

interface all;

```

Meaning

This LSP error event indicates that there is an error in the loose hop specified in the Explicit Route Object (ERO) of a Path message received by a label-switched router (LSR) along the LSP path, indicating an LSP setup failure.

Cause

This LSP error event is caused by control plane unreachability or data plane incompatibility.

Action

Check the LSP configuration at the **[edit protocols mpls]** hierarchy level.

16 Jun 27 00:39:49 204.70.192.26: Routing loop detected [3370 times]
[...Output truncated...]
```

Meaning

This LSP event indicates that a poorly formed ERO was generated. Sample Outputs 1 and 2 show that this LSP event was caused by different situations described below.

Cause

This LSP event can be caused by several factors:

- A strict hop address specified for an LSP on a link that does not have RSVP enabled.
- The **no-cspf** statement included in the LSP configuration.
- An error with the configuration of constraints on a Constrained Shortest Path First (CSPF) LSP generates the **CSPF: No route towards dest** message, followed by the **Explicit Route: bad strict route** event.
- An ERO that causes a routing loop. See Sample Output 2.

Action

Examine the strict hop address, remove the **no-cspf** statement, or examine the path and verify that RSVP is enabled on each interface.

Explicit Route: Format Error Event

LSP Event

Explicit route: format error

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary    to-R6                State: Dn, No-decrement-ttl
    5 Jan 21 14:37:06 10.1.34.2: Explicit Route: format error [2 times]
    4 Jan 21 14:37:03 Originate Call
```

```
3 Jan 21 14:37:03 Clear Call
[...Output truncated...]
```

Meaning

This LSP event indicates an LSP setup failure in which a Path message error in the the ERO was received by a router along the LSP path.

Cause

This LSP event can be caused by several factors:

- An incorrectly formed ERO in the RSVP Path message.
- A strict hop address specified in the middle of an ERO that is not contiguous.
- An unsupported subobject in the ERO of a router along the LSP path.
- The hop indicated by the RSVP hop object does not match the hop indicated by the ERO.

Action

Examine the strict hop address configuration and make any necessary changes.

Explicit Route: Wrong Delivery Event

LSP Event

Explicit route: wrong delivery

Sample Output 1

```
user@host> show mpls lsp extensive
[...Output truncated...]
Primary use-TOKYO State: Dn, No-decrement-ttl
  3 Sep 19 00:25:45 10.222.45.2: Explicit Route: wrong delivery
  2 Sep 19 00:25:34 No Route[8 times]
  1 Sep 19 00:23:01 Originate Call
[...Output truncated...]

  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary    to-R6                State: Dn
    40 Jan 26 16:35:26  10.1.36.2: Explicit Route: wrong delivery [2 times]
    39 Jan 26 16:35:23 Originate Call
    38 Jan 26 16:35:23 Clear Call
[...Output truncated...]

```

Sample Output 3

```

user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
  to 10.0.0.6;
  no-cspf;
  primary to-R6;
}
path to-R6 {
  10.1.13.2 strict;
  10.1.56.1 strict;      <<< IP address not directly connected to 10.1.13.2
  10.1.26.1 strict;
}

```

Meaning

This LSP event indicates that a RSVP message with an ERO arrived at the wrong router, even though a strict route was specified. The receiving router determines that the address is inconsistent with the ERO, and generates the error message. Note that the IP address of the sending router precedes the error event; for example, **10.222.45.2** in Sample Output 1, and **10.1.36.2** in Sample Output 2.

Cause

This LSP event can be caused by several factors:

- The loopback (**lo0**) interface on the ingress router is not configured at the **[edit protocols isis]** hierarchy level. After the loopback (**lo0**) interface is included in the Intermediate System-to-Intermediate System (IS-IS) configuration, and while IS-IS is forming adjacencies, an RSVP packet is forwarded to an incorrect destination, **10.222.45.2**, as shown in Sample Output 1.
- A strict path is configured to a directly connected router, then another strict path is configured to an IP address that is not directly connected. For example, Sample Output 3 shows that the path **to-R6** includes three IP addresses, one of which (**10.1.56.1**) is not directly connected to the other IP addresses in the path.

Action

Take appropriate action. On the ingress router, include the loopback (lo0) interface at the [edit protocols isis] hierarchy level, change the definition of the strict path at the [edit protocols mpls path *path-name*] hierarchy level, or verify the validity of all IP addresses listed in the named path referenced by the LSP hop by hop.

Invalid Destination Address Event

LSP Event

Invalid Dest addr

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.1
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Metric: 100
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn
    4 Apr 22 10:22:15   Invalid Dest Addr
    3 Apr 22 10:22:15   Originate Call
    2 Apr 22 10:22:15   Invalid Dest Addr
    1 Apr 22 10:22:15   Originate Call
  Created: Fri Apr 22 10:22:16 2005
Total 1 displayed, Up 0, Down 1
```

Meaning

This LSP event indicates that the **to** address configured at the [edit protocols mpls labeled-switched-path *name*] hierarchy level is invalid.

Cause

This LSP event is caused when the **to** address of the LSP is the loopback address of the ingress router. A contributing factor may be that the **no-cspf** statement is included in the LSP configuration.

Action

Verify that the LSP destination address is not the local router's loopback address, and check that the addresses on the local router are correctly configured.

Invalid Filter for Policing Event

LSP Event

Invalid filter for policing

Sample Output

Not available. This LSP event indicates an abnormal condition and is difficult to recreate.

Meaning

Although a policer was configured on the LSP, the corresponding firewall filter index was not found, indicating a failure in the routing protocol process (rpd) or the firewall process (dfwd).

Cause

A possible cause is that the routing protocol process (rpd) or the firewall process (dfwd) were restarted in a situation in which the LSP was established.

Action

Not applicable.

MPLS Graceful Restart: Recovery Failed Event

LSP Event

MPLS graceful restart: recovery failed

Sample Output

Not available.

Meaning

This LSP event indicates unsuccessful recovery of an LSP path after graceful restart, resulting in potential traffic loss.

Cause

This LSP event is caused by several factors:

- MPLS graceful restart procedures may have been aborted by this LSR.
- MPLS graceful restart is disabled, by configuration, during the recovery period.
- An MPLS LSP path is disabled either due to a configuration change or due to an error during the recovery period.
- CSPF computation failed for the restarted LSP path with parameters and constraints preserved across the restart.

- A signaling failure occurred and an RSVP PathErr was received on the LSP path signaled after a restart.
- A network failure occurred on some hop that the LSP was traversing during the recovery period.

Action

Check the MPLS logs for more details about the failure.

MPLS Label Allocation Failure Event

LSP Event

MPLS label allocation failure

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
 24 Jan 20 09:25:35 CSPF failed: no route toward 10.0.0.6
 23 Jan 20 09:25:35 Clear Call
 22 Jan 20 09:25:35 Deselected as active
 21 Jan 20 09:25:35 10.1.13.1: MPLS label allocation failure
 20 Jan 20 09:25:34 MPLS label allocation failure
 19 Jan 20 09:25:34 Down
[...Output truncated...]
```

Meaning

This LSP event indicates that the MPLS protocol or the **family mpls** statement were not configured properly. When the LSP event is preceded by an IP address, the address is typically the router that has the MPLS configuration error.

Cause

This LSP event is caused by the omission of interfaces at the **[edit protocols mpls]** hierarchy level or failure to configure the **family mpls** statement at the **[edit interfaces type-fpc/pic/port]** hierarchy level. The **family mpls** statement specifies to the interface ASICs to permit protocol code 0x8847 (unicast MPLS) into the router.

Action

Include interfaces at the **[edit protocols mpls]** hierarchy level, or include the **family mpls** statement at the **[edit interfaces type-fpc/pic/port]** hierarchy level. You must configure the **family mpls** statement, in the same way that you must configure the **family iso** statement for IS-IS.

NOTE: Do not configure the **family mpls** statement on the loopback (lo0) interface.

Non-RSVP Capable Router Detected Event

LSP Event

Non-RSVP capable router detected

Sample Output

```
user@host> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn, No-decrement-ttl
    19 Jan 21 15:05:37 10.1.24.2:  Non-RSVP capable router detected
    18 Jan 21 15:04:52 10.1.26.2:  Non-RSVP capable router detected [4 times]
    17 Jan 21 15:04:34 Originate Call
    16 Jan 21 15:04:34 Clear Call
[...Output truncated...]
```

Meaning

This LSP event indicates that a router, forwarding packets to the egress router, was not configured for RSVP.

Cause

This LSP event might be caused when a router not configured for RSVP forwards an RSVP packet toward the egress router without decrementing the **Send_TTL** value in the RSVP common header. The next downstream router detects that the **Send_TTL** value and the **IP_TTL** value are different, and generates this LSP event. Note that two different routers generated the same error message at different times.

Action

Configure the router in question with RSVP.

No Route Toward Destination Event

LSP Event

No route toward destination

Sample Output 1

```
user@R1> show mpls lsp extensive
[...Output truncated...]
 35 Oct 26 22:48:36 Down
 34 Oct 26 22:48:29 CSPF failed: no route toward 10.0.0.1[4 times]

Primary                               State: Dn
  Will be enqueued for recomputation in 7 second(s).
 13 Oct 25 16:29:28 Deselected as active
 12 Oct 25 16:29:27 CSPF failed: no route toward 10.0.0.6
 11 Oct 25 16:29:27 CSPF: link down/deleted
10.1.13.1(R1.00/10.0.0.1)->10.1.13.2(R3.00/10.0.0.3)
 10 Oct 25 16:29:27 CSPF failed: no route toward 10.0.0.6
  9 Oct 25 16:29:27 Clear Call
  8 Oct 25 16:29:27 Explicit Route: bad strict route
  7 Oct 25 16:29:27 No Route toward dest
  6 Oct 25 16:29:27 Down
[...Output truncated...]
```

Meaning

This LSP event indicates that the router at address **10.1.36.1** in Sample Output 1 does not have a route to the specified destination. Sample Output 2 shows that the local router, ingress router **10.0.0.1**, does not have a route to the specified destination.

Cause

This LSP event is caused by different factors. The egress interface of a transit router might not have RSVP enabled, or IP reachability to the destination (either the egress router or the next address in the ERO) does not exist.

Action

Enable RSVP on the transit router's egress interface, or examine the IP configuration of the relevant router.

Unsupported Traffic Class Event

LSP Event

Unsupported traffic class

Sample Output

Not available. This LSP event indicates an abnormal condition and is difficult to recreate.

Meaning

This LSP error event is a Juniper Networks proprietary error, indicating that a DiffServ-traffic engineering (TE) LSP was signaled with one or more traffic classes with values greater than the four traffic classes currently supported.

Cause

Not available.

Action

Not available.

CSPF: Computation Result Accepted Event

LSP Event

CSPF: computation result accepted

Sample Output

```
user@R1> show mpls lsp extensive
[...Output truncated...]
 57 Jan  5 09:54:37 Record Route:  10.1.13.2 10.1.36.2
 56 Jan  5 09:54:37 Up
 55 Jan  5 09:54:37 Originate Call
 54 Jan  5 09:54:37  CSPF: computation result accepted
[...Output truncated...]
```

Meaning

This LSP event indicates that CSPF pruned the traffic engineering database of noncompliant links and found a shortest path. CSPF generated an ERO, which was then passed to the RSVP.

Cause

Not applicable.

Action

Not applicable

CSPF: Reroute Due to Re-Optimization Event

LSP Event

CSPF: Reroute due to re-optimization

Sample Output

```
user@host> show mpls lsp extensive
[...Output truncated...]
 9 Dec 11 17:32:35  Up
   8 Dec 11 17:32:35  Clear Call
   7 Dec 11 17:32:35  CSPF: computation result accepted
   6 Dec 11 17:32:35  CSPF: Reroute due to re-optimization
   5 Dec 11 17:28:29  CSPF: computation result ignored
   4 Dec 11 17:24:23  Record Route:  10.35.38.2 S 192.168.135.29 S
10.35.39.1 S 10.35.40.2 S 10.35.41.1 S
   3 Dec 11 17:24:23  Up
[...Output truncated...]
```

Meaning

This LSP event indicates that CSPF found an optimal path for LSP traffic, and switched over to the new path.

Cause

This is a periodic or one-time reoptimization event.

Action

Not applicable.

Retry Limit Exceeded Event

LSP Event

Retry limit exceeded

Sample Output 1

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  Primary                               State: Dn
    RetryCount: 13
    RetryLimit: 1
    12 Jan 14 15:39:30 Clear Call
    11 Jan 14 15:39:30 Retry limit exceeded
    10 Jan 14 15:39:10 10.1.12.1: MPLS label allocation failure[11 times]
[...Output truncated...]
```

Sample Output 2

```
user@R1> show mpls lsp extensive
[...Output truncated...]
10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6
  ActivePath: (none)
  LoadBalance: Random
```

```

Encoding type: Packet, Switching type: Packet, GPID: IPv4
Primary                               State: Dn
14 Jan 14 15:44:07 10.1.12.1: MPLS label allocation failure[3 times]
13 Jan 14 15:43:58 Originate Call
12 Jan 14 15:39:30 Clear Call
11 Jan 14 15:39:30   Retry limit exceeded
10 Jan 14 15:39:10 10.1.12.1: MPLS label allocation failure[11 times]
[...Output truncated...]

```

Meaning

This LSP event indicates that the number of CSPF path computations for a particular path exceeded a configured retry limit. After this point, the path is not recomputed or signaled, unless the user intervenes.

Cause

The number of CSPF path computations for an LSP path exceeded the configured non-zero retry limit. Sample Output 1 shows that a configured retry limit of 1 was exceeded by the retry count of 13.

Action

Enter the **clear mpls lsp** command to disconnect and restart the LSP. Sample Output 2 shows that events 13 and 14 were generated after the **clear mpls lsp** command was issued. This operation disconnects existing RSVP sessions on the ingress router, releases the routes and states associated with the LSPs, and starts a new LSP. Issuing this command might impact traffic travelling along the LSP, because of a time lag that can occur between the old path being torn down and the new path being set up.

Log the Software Version Information

Purpose

The purpose of this action is to log the Junos OS version information.

Action

Use the following Junos OS CLI operational mode command:

```
user@host> show version | save filename
```

Sample Output

```

user@host> show version | save test
Wrote 39 lines of output to 'test'

```

```

user@host> show version

```

Meaning

The sample output shows the hostname, router model, and the different Junos OS packages, processes, and documents.

Log the Hardware Version Information

Purpose

You should log hardware version information in the rare event that a router cannot successfully reboot and you cannot obtain the Routing Engine serial number. The Routing Engine serial number is necessary for Juniper Networks Technical Assistance Center (JTAC) to issue a return to manufacturing authorization

(RMA). Without the Routing Engine serial number, an onsite technician must be dispatched to issue the RMA.

Action

To log the router chassis hardware version information, use the following Junos OS CLI operational mode command:

```
user@host> show chassis hardware | save filename
```

Sample Output

The output for the M-series routers varies depending on the chassis components of each router. All routers have a chassis, midplanes or backplanes, power supplies, and Flexible PIC Concentrators (FPCs). Refer to the hardware guides for information about the different chassis components.

```
user@host> show chassis hardware | save test
Wrote 43 lines of output to 'test'
```

```
user@host> show chassis hardware
```

Item	Version	Part number	Serial number	Description

PIC 0	REV 01			1x OC-192 SM SR-2

Meaning

The sample output shows the hardware inventory for an M160 router with a chassis serial number of 101. For each component, the output shows the version number, part number, serial number, and description.

Log the System Boot-Message Information

Action

To log the system boot-message information, use the following Junos OS CLI operational mode command:

```
user@host> show system boot-messages | save filename
```

Sample Output

```
user@host> show system boot-messages | save test

Meaning

The sample output shows the initial messages generated by the system kernel upon boot. This is the content of the `/var/run/dmesg.boot` file.

Log the BGP, IS-IS, and OSPF Adjacency Information

Purpose

The following commands log useful information about Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), and Open Shortest Path First (OSPF) protocols. If you have other protocols installed, such as Multiprotocol Label Switching (MPLS), Resource Reservation Protocol (RSVP), or Protocol Independent Multicast (PIM), you also might log summary information for them.

Action

To log the protocol peer information, use the following Junos OS CLI operational mode commands:

```

user@host> show bgp summary | save filename
user@host> show isis adjacency brief | save filename
user@host> show ospf neighbor brief | save filename

```

Sample Output 1

```

user@host> show bgp summary | save test
Wrote 45 lines of output to 'test'

user@host> show bgp summary

```

```

Groups: 1 Peers: 1 Down peers: 0

```

Meaning

Sample output 1 displays summary information about BGP and its neighbors. Sample output 2 displays information about IS-IS neighbors. Sample output 3 displays information about all OSPF neighbors.

Back Up the Currently Running and Active File System

To back up the currently running and active file system so that you can recover to a known, stable environment in case there is a problem during the reinstall, use the following operational mode command:

```
user@host> request system snapshot
```

Sample Output

```
user@host> request system snapshot
```

```
umount: /altroot: not currently mounted
Copying / to /altroot.. (this may take a few minutes)
umount: /altconfig: not currently mounted
Copying /config to /altconfig.. (this may take a few minutes)
The following filesystems were archived: / /config
```

Meaning

On devices running Junos OS, this command backs up the root file system to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

On devices running Junos OS Evolved, this command only copies the contents of the **/soft** directory, which includes the running version of Junos OS Evolved.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Reinstall Junos OS

Action

To reinstall Junos OS, follow these steps:

1. Insert the removable medium (boot floppy) into the router.
2. Reboot the router, either by power-cycling it or by issuing the **request system reboot** command from the CLI.
3. At the following prompt, type **y**:

```
WARNING: The installation will erase the contents of your disk. Do you wish to  
continue (y/n)?
```

The router copies the software from the removable medium onto your system, occasionally displaying status messages. This can take up to 10 minutes.

4. Remove the removable medium when prompted.

The router reboots from the primary boot device on which the software is installed. When the reboot is complete, the router displays the login prompt.

Reconfigure Junos OS

After you have reinstalled the software, you must copy the router's configuration files back to the router. (You also can configure the router from scratch, as described in *Junos System Basics Configuration Guide*) However, before you can copy the configuration files, you must establish network connectivity.

To reconfigure the software, follow these steps:

1. [Configure Host Names, Domain Names, and IP Addresses | 2356](#)
2. [Protecting Network Security by Configuring the Root Password | 2357](#)
3. [Check Network Connectivity | 2359](#)

Configure Host Names, Domain Names, and IP Addresses

To configure the machine name, domain name, and various addresses, follow these steps:

1. Log in as **root**. There is no password.
2. Start the CLI:

```
root# cli  
root@>
```

3. Enter configuration mode:

```
cli> configure  
[edit]  
root@#
```

4. Configure the name of the machine. If the name includes spaces, enclose the entire name in quotation marks (" "):

```
[edit]  
root@# set system host-name host-name
```

5. Configure the machine's domain name:

```
[edit]  
root@# set system domain-name domain-name
```

6. Configure the IP address and prefix length for the router's management Ethernet interface:

```
[edit]  
root@# set interfaces fxp0 unit 0 family inet address address / prefix-length
```

7. Configure the IP address of a default router. This system is called the backup router because it is used only while the routing protocol process is not running.

```
[edit]  
root@# set system backup-router address
```

8. Configure the IP address of a Domain Name Server (DNS) server:

```
[edit]  
root@# set system name-server address
```

Protecting Network Security by Configuring the Root Password

Configuring the root password on your Junos OS-enabled router helps prevent unauthorized users from making changes to your network. The root user (also referred to as superuser) has unrestricted access and full permissions within the system, so it is crucial to protect this account by setting a strong password when setting up a new router.

After a new router is initially powered on, you log in as the user **root** with no password. Junos OS requires configuration of the root password before it accepts a commit operation.

To set the root password, you have a few options as shown in the following procedure.

- Enter a plain-text password that Junos OS encrypts.
- Enter a password that is already encrypted.
- Enter a secure shell (ssh) public key string.

The most secure options of these three are using an already encrypted password or an ssh public key string. Pre-encrypting your password or using a ssh public key string means the plain-text version of your password will never be transferred over the internet, protecting it from being intercepted by a man-in-the-middle attack.

BEST PRACTICE: Optionally, instead of configuring the root password at the **[edit system]** hierarchy level, you can use a configuration group to strengthen security.

To set the root password:

1. Use one of these methods to configure the root password:

- To enter a plain-text password that the system encrypts for you:

```
[edit groups global system]
root@# set root-authentication plain-text-password
New Password: type password here
Retype new password: retype password here
```

As you enter a plain-text password into the CLI, Junos OS hides it from view and encrypts it immediately. You do not have to configure Junos OS to encrypt the password as in some other systems. In the resulting configuration, the encrypted password is marked as **## SECRET-DATA** so that it cannot be seen.

- To enter a password that is already encrypted:

CAUTION: Do not use the **encrypted-password** option unless the password is *already* encrypted, and you are entering the encrypted version of the password.

If you accidentally configure the **encrypted-password** option with a plain-text password or with blank quotation marks (" "), you will not be able to log in to the device as root, and you will need to complete the root password recovery process.

```
[edit groups global system]
root@# set root-authentication encrypted-password password
```

- To enter an ssh public key string:

```
[edit groups global system]
root@# set root-authentication (ssh-dsa | ssh-eccdsa | ssh-rsa key)
```

2. If you used a configuration group, apply it with the command **set apply-groups**, replacing *<group name>* with the configuration group name.

For example:

```
[edit]
user@host# set apply-groups <group name>
```

3. Commit the changes.

```
root@# commit
```

SEE ALSO

| *Accessing a Junos OS Device the First Time*

Check Network Connectivity

Purpose

Establish that the router has network connectivity.

Action

To check that the router has network connectivity, issue a **ping** command to a system on the network:

```
root@> ping address
```

If there is no response, verify that there is a route to the **address** using the **show route** command. If the address is outside your **fxp0** subnet, add a static route. Once the backup configuration is loaded and committed, the static route is no longer needed and should be deleted.

Configure Host Names, Domain Names, and IP Addresses

To configure the machine name, domain name, and various addresses, follow these steps:

1. Log in as **root**. There is no password.
2. Start the CLI:

```
root# cli
root@>
```

3. Enter configuration mode:

```
cli> configure
[edit]
root@#
```

4. Configure the name of the machine. If the name includes spaces, enclose the entire name in quotation marks (" "):

```
[edit]
root@# set system host-name host-name
```

5. Configure the machine's domain name:

```
[edit]
root@# set system domain-name domain-name
```

6. Configure the IP address and prefix length for the router's management Ethernet interface:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address / prefix-length
```

7. Configure the IP address of a default router. This system is called the backup router because it is used only while the routing protocol process is not running.

```
[edit]
root@# set system backup-router address
```

8. Configure the IP address of a Domain Name Server (DNS) server:

```
[edit]
root@# set system name-server address
```

Check Network Connectivity

Purpose

Establish that the router has network connectivity.

Action

To check that the router has network connectivity, issue a **ping** command to a system on the network:

```
root@> ping address
```

If there is no response, verify that there is a route to the ***address*** using the **show route** command. If the address is outside your **fxp0** subnet, add a static route. Once the backup configuration is loaded and committed, the static route is no longer needed and should be deleted.

Automatic Autobandwidth Adjustment Failed Event

LSP Event

Autobw adjustment failed

Sample Output 1

```

  Created: Thu Feb 17 15:36:23 2005
[...Output truncated...]

```

Meaning

This LSP event indicates that a periodic (timer-based) autobandwidth adjustment for the LSP is triggered at the end of the adjust interval. The adjustment fails, and the LSP stays up on the existing path with its current bandwidth.

Cause

Adjustment failure may be due to a path CSPF computation failure with the adjust bandwidth or a signaling failure on the new path.

At the end of the time interval specified at the `[edit protocols mpls label-switched-path auto-bandwidth]` hierarchy level, the current maximum average bandwidth usage is compared to the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

Action

Take action appropriate to the situation:

- Verify the MPLS and RSVP configuration on all available paths to the LSP endpoint.
- Check available bandwidth on alternate paths using the **show rsvp interface** command. If not enough bandwidth is available on any available paths, adjust the minimum-bandwidth parameter for the LSP in order to establish or adjust the priority to allow the LSP to preempt another LSP of lesser priority. For an LSP to be preempted, its hold priority must be lower than the LSP you are trying to establish.

Configuring Automatic Bandwidth Allocation for LSPs

IN THIS SECTION

- [Configuring Automatic Bandwidth Allocation on LSPs | 2364](#)
- [Requesting Automatic Bandwidth Allocation Adjustment | 2370](#)

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth, and this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

At the end of the automatic bandwidth allocation time interval, the current maximum average bandwidth usage is compared with the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

NOTE: In calculating the value for **Max AvgBW** (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

If you have configured link and node protection for the LSP and traffic has been switched to the bypass LSP, the automatic bandwidth allocation feature continues to operate and take bandwidth samples from the bypass LSP. For the first bandwidth adjustment cycle, the maximum average bandwidth usage taken from the original link and node-protected LSP is used to resignal the bypass LSP if more bandwidth is needed. (Link and node protection are not supported on QFX Series switches.)

If you have configured fast-reroute for the LSP, you might not be able to use this feature to adjust the bandwidth. Because the LSPs use a fixed filter (FF) reservation style, when a new path is signaled, the bandwidth might be double-counted. Double-counting can prevent a fast-reroute LSP from ever adjusting its bandwidth when automatic bandwidth allocation is enabled. (Fast reroute is not supported on QFX Series switches.)

To configure automatic bandwidth allocation, complete the steps in the following sections:

NOTE: On the QFX10000 switches, you can only configure automatic bandwidth allocation at the **edit protocols mpls** hierarchy level. Logical systems are not supported.

Configuring Automatic Bandwidth Allocation on LSPs

IN THIS SECTION

- [Configuring the Automatic Bandwidth Allocation Interval | 2365](#)
- [Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth | 2366](#)
- [Configuring the Automatic Bandwidth Adjustment Threshold | 2367](#)
- [Configuring a Limit on Bandwidth Overflow and Underflow Samples | 2368](#)
- [Configuring Passive Bandwidth Utilization Monitoring | 2370](#)

To enable automatic bandwidth allocation on an LSP, include the **auto-bandwidth** statement:

If an LSP has an automatic bandwidth configuration, you can disable automatic bandwidth adjustments on a particular path (either primary or secondary) by configuring a static bandwidth value and by disabling the CSPF computation (using the **no-cspf** statement).

For example:

```
user@host> show protocols mpls
label-switched-path primary-path {
  to 192.168.0.1;
  ldp-tunneling;
  optimize-timer 3571;
  least-fill;
  link-protection;
  adaptive;
  auto-bandwidth {
    adjust-interval 7177;
    adjust-threshold 5;
    minimum-bandwidth 1m;
    maximum-bandwidth 2500000000;
    adjust-threshold-overflow-limit 2;
    resignal-minimum-bandwidth;
  }
  primary primary-path;
  secondary secondary-path {
    bandwidth 0;
    no-cspf;
    priority 0 0;
  }
}
```

The statements configured at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level are optional and explained in the following sections:

Configuring the Automatic Bandwidth Allocation Interval

At the end of the automatic bandwidth allocation interval, the automatic bandwidth computation and new path setup process is triggered.

NOTE: To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (**interval** statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (**adjust-interval** statement at the **[edit protocols mpls label-switched-path label-switched-path-name auto-bandwidth]** hierarchy level). See also [“Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs” on page 556](#).

To specify the bandwidth reallocation interval in seconds for a specific LSP, include the **adjust-interval** statement:

```
adjust-interval seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path lsp-name auto-bandwidth]**
- **[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth]**

Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth

You can maintain the LSP's bandwidth between minimum and maximum bounds by specifying values for the **minimum-bandwidth** and **maximum-bandwidth** statements.

NOTE: For a label-switched path (LSP) that has both **bandwidth** and **minimum-bandwidth** for autobandwidth configured under the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the maximum bandwidth.

To specify the minimum amount of bandwidth allocated for a specific LSP, include the **minimum-bandwidth** statement:

```
minimum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]

To specify the maximum amount of bandwidth allocated for a specific LSP, include the **maximum-bandwidth** statement:

```
maximum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]

Configuring the Automatic Bandwidth Adjustment Threshold

Use the **adjust-threshold** statement to specify the sensitivity of the automatic bandwidth adjustment of an LSP to changes in bandwidth utilization. You can set the threshold for when to trigger automatic bandwidth adjustments. When configured, bandwidth demand for the current interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the specified **adjust-threshold** percentage, the LSP's bandwidth is adjusted to the current bandwidth demand.

For example, assume that the current bandwidth allocation is 100 megabits per second (Mbps) and that the percentage configured for the **adjust-threshold** statement is 15 percent. If the bandwidth demand increases to 110 Mbps, the bandwidth allocation is not adjusted. However, if the bandwidth demand increases to 120 Mbps (20 percent over the current allocation) or decreases to 80 Mbps (20 percent under the current allocation), the bandwidth allocation is increased to 120 Mbps or decreased to 80 Mbps, respectively.

To configure the threshold for automatic bandwidth adjustment, include the **adjust-threshold** statement:

```
adjust-threshold percent;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]

Configuring a Limit on Bandwidth Overflow and Underflow Samples

The automatic bandwidth adjustment timer is a periodic timer which is triggered every adjust interval to determine whether any bandwidth adjustments are required on the LSP's active path. This interval is typically configured as a long period of time, usually hours. If, at the end of adjust interval, the change in bandwidth is above a certain adjust threshold, the LSP is resignaled with the new bandwidth.

During the automatic bandwidth adjustment interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Every statistics interval, the router samples the average bandwidth utilization of an LSP and if this has exceeded the current maximum average bandwidth utilization, the maximum average bandwidth utilization is updated.

During each sample period, the following conditions are also checked:

- Is the current average bandwidth utilization above the active bandwidth of the path?
- Has the difference between the average bandwidth utilization and the active bandwidth exceeded the adjust threshold (bandwidth utilization has changed significantly)?

If these conditions are true, it is considered to be one bandwidth overflow sample. Using the **adjust-threshold-overflow-limit** statement, you can define a limit on the number of bandwidth overflow samples such that when the limit is reached, the current automatic bandwidth adjustment timer is expired and a bandwidth adjustment is triggered. Once this adjustment is complete, the normal automatic bandwidth adjustment timer is reset to expire after the periodic adjustment interval.

To specify a limit on the number of bandwidth overflow samples before triggering an automatic bandwidth allocation adjustment, configure the **adjust-threshold-overflow-limit** statement:

```
adjust-threshold-overflow-limit number;
```

Similarly, if the current average bandwidth utilization is below the active bandwidth of the path by the configured adjusted threshold (meaning that bandwidth utilization has gone down significantly), the sample is considered to be an underflow sample. The adjusted (new signaling) bandwidth after an adjustment due to underflow is the maximum average bandwidth among the underflow samples. Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

You can specify a limit on the number of bandwidth underflow samples before triggering an automatic bandwidth allocation adjustment by configuring the **adjust threshold-underflow-limit** statement:

```
adjust-threshold-underflow-limit number;
```

These statements can be configured at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]

You must configure the **adjust-threshold** and **minimum-bandwidth** statements whenever you configure the **adjust-threshold-underflow-limit** statement. You must configure the **adjust-threshold** and **maximum-bandwidth** statements whenever you configure the **adjust-threshold-overflow-limit** statement.

- You must configure a nonzero value for the **adjust-threshold** statement if you configure the **adjust-threshold-overflow-limit** or **adjust-threshold-underflow-limit** statement.
- Any bandwidth increase or decrease below the value configured for the **adjust-threshold** statement does not constitute an overflow or underflow condition.
- To prevent unlimited increases in LSP bandwidth (to limit overflow beyond a certain bandwidth), you must also configure the **maximum-bandwidth** statement when you configure the **adjust-threshold-overflow-limit** statement.

The following describes the other aspects of the **adjust-threshold-overflow-limit** statement:

- It only applies to bandwidth overflows. If the bandwidth is decreasing, the normal automatic bandwidth adjustment interval is used.
- It does not affect manually triggered automatic bandwidth adjustment.
- It applies to single-class DiffServ-TE LSPs.
- Because the **adjust-threshold-overflow-limit** statement can trigger a bandwidth adjustment, it cannot be enabled at the same time as the **monitor-bandwidth** statement (for information about that statement, see [“Configuring Passive Bandwidth Utilization Monitoring” on page 554](#)).
- You cannot configure automatic bandwidth adjustments to occur more often than every 300 seconds. The **adjust-threshold-overflow-limit** statement is subject to the same minimum value with regard to the minimum frequency of adjustment allowed. Overflow condition based adjustments can occur no sooner than 300 seconds from the start of the overflow condition. Therefore it is required that:

sample interval x adjust-threshold-overflow-limit >= 300s

These values are checked during the commit operation. An error is returned if the value is less than 300 seconds.

- If you change the value of the **adjust-threshold-overflow-limit** statement on a working router, you can expect the following behavior:
 - If you increase the current value of the **adjust-threshold-overflow-limit** statement, the old value is replaced with the new one.
 - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is less than the new value, the old value is replaced with the new one.

- If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is greater than the new value, the adjustment timer is immediately expired and a bandwidth adjustment is initiated.

Configuring Passive Bandwidth Utilization Monitoring

Use the **monitor-bandwidth** statement to switch to a passive bandwidth utilization monitoring mode. In this mode, no automatic bandwidth adjustments are made, but the maximum average bandwidth utilization is continuously monitored and recorded.

To configure passive bandwidth utilization monitoring, include the **monitor-bandwidth** statement:

```
monitor-bandwidth;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth**]

If you have configured an LSP with primary and secondary paths, the automatic bandwidth allocation statistics are carried over to the secondary path if the primary path fails. For example, consider a primary path whose adjustment interval is half complete and whose maximum average bandwidth usage is currently calculated as 50 Mbps. If the primary path suddenly fails, the time remaining for the next adjustment and the maximum average bandwidth usage are carried over to the secondary path.

Requesting Automatic Bandwidth Allocation Adjustment

For MPLS LSP automatic bandwidth allocation adjustment, the minimum value for the adjustment interval is 5 minutes (300 seconds). You might find it necessary to trigger a bandwidth allocation adjustment manually, for example in the following circumstances:

- When you are testing automatic bandwidth allocation in a network lab.
- When the LSP is configured for automatic bandwidth allocation in monitor mode (the **monitor-bandwidth** statement is included in the configuration as described in [“Configuring Passive Bandwidth Utilization Monitoring” on page 554](#)), and want to initiate an immediate bandwidth adjustment.

To use the **request mpls lsp adjust-autobandwidth** command, the following must be true:

- Automatic bandwidth allocation must be enabled on the LSP.
- The criteria required to trigger a bandwidth adjustment have been met (the difference between the adjust bandwidth and the current LSP path bandwidth is greater than the threshold limit).

A manually triggered bandwidth adjustment operates only on the active LSP path. Also, if you have enabled periodic automatic bandwidth adjustment, the periodic automatic bandwidth adjustment parameters (the adjustment interval and the maximum average bandwidth) are not reset after a manual adjustment.

For example, suppose the periodic adjust interval is 10 hours and there are currently 5 hours remaining before an automatic bandwidth adjustment is triggered. If you initiate a manual adjustment with the **request mpls lsp adjust-autobandwidth** command, the adjust timer is not reset and still has 5 hours remaining.

To manually trigger a bandwidth allocation adjustment, you need to use the **request mpls lsp adjust-autobandwidth** command. You can trigger the command for all affected LSPs on the router, or you can specify a particular LSP:

```
user@host> request mpls lsp adjust-autobandwidth
```

Once you execute this command, the automatic bandwidth adjustment validation process is triggered. If all the criteria for adjustment are met, the LSP's active path bandwidth is adjusted to the adjusted bandwidth value determined during the validation process.

Release History Table

Release	Description
14.1R9	Starting in Junos OS Release 14.1R9, 15.1R7, 16.1R5, 16.1X2, 16.2R3, and 17.2R2, all zero value bandwidth samples are considered as underflow samples, except for the zero value samples that arrive after an LSP comes up for the first time, and the zero value samples that arrive first after a Routing Engine switchover.

Displaying DiffServ-Aware Traffic-Engineered LSP Events

Purpose

A DiffServ-aware traffic-engineered LSP is configured with a bandwidth reservation for a specific class type, and carries traffic for a single class type. On the packets, the class type is specified by the experimental (EXP) bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, instead of being signaled in Resource Reservation Protocol (RSVP).

The class type must be configured consistently across the DiffServ domain, and must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link. For more information about forwarding classes and class of service, see the Junos Class of Service Configuration Guide. For more information about differentiated services, see RFC 3270, *MPLS Applications User Guide Support of Differentiated Services*.

When the configuration of a DiffServ-aware traffic-engineered LSP is incorrect, an even or error message might occur in the output of the **show mpls lsp extensive** command.

Action

To display LSP events that can occur with a DiffServ-aware LSP, enter the following Junos OS command-line interface (CLI) operational mode command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output

Not available.

Unsupported Traffic Class Event

LSP Event

Unsupported traffic class

Sample Output

Not available.

Meaning

This LSP error event is a Juniper Networks proprietary error indicating that a Diffserv traffic engineering LSP was signaled with one or more traffic classes with values greater than the four traffic classes currently supported by the Junos OS.

Cause

Not available.

Action

Not available.

Traffic Class Value Out of Allowed Range Event

LSP Event

Traffic class value out of allowed range

Sample Output

Not available.

Meaning

This LSP error event is a Juniper Networks proprietary error indicating that a single class, IETF-style DiffServ traffic engineering LSP was signaled with a traffic class value of zero, which is invalid.

Cause

Not available.

Action

Not available.

The Combination of Setup Priority and Traffic Class Is Not One of the Configured TE Classes Event

LSP Event

The combination of setup-priority and traffic class is not one of the configured TE-classes

Sample Output

Not available.

Meaning

This LSP error event is a Juniper Networks proprietary error that indicates the setup priority signaled in the Path message for the LSP does not match the supported DiffServ traffic engineering classes configured on a label-switching router (LSR) along the LSP path.

Cause

This LSP error event is caused by incorrect configuration of the LSP setup priority on the ingress LSR, or the incorrect configuration of a DiffServ traffic engineering class on an LSR along the LSP path.

Action

Correct the configuration depending on the supported traffic engineering classes.

RSVP Error, Subcode 7, Signal Type Does Not Match Link Encoding Event

LSP Event

RSVP error, subcode 7, signal-type does not match link encoding

Sample Output

Not available

Meaning

This LSP error event is a Juniper Networks proprietary error reported for GMPLS LSPs when the configured signal bandwidth does not match the encoding type of the traffic engineering link selected on the first hop.

Cause

An incorrect Sender Tspec is used with a particular LSP switching or encoding type.

Action

Not available.

Unacceptable Label Value Event

LSP Event

Unacceptable label value event

Sample Output

Not available.

Meaning

This LSP error event indicates that the label value signaled in either the Path or Resv message was unacceptable to a label-switched router (LSR) along the LSP path.

Cause

For GMPLS LSPs, this LSP error event is generated by incorrect label mapping configured on one of the LSRs, or by deletion of a resource that was being used by an LSP.

Action

Not available.

Unsupported Switching Type Event

LSP Event

Unsupported switching type

Sample Output

Not available.

Meaning

This LSP error event indicates that the switching type requested in the generalized label request for a GMPLS LSP is unsupported on the corresponding selected traffic engineering link.

Cause

Not available.

Action

Not available.

Gather Component Alarm Information

Purpose

When you obtain information about component alarms and error messages, you determine when a problem with a component first appeared and the details of the situation.

To gather component alarm information, follow these steps:

1. [Display the Current Router Alarms | 2375](#)
2. [Display Error Messages in the Messages Log File | 2376](#)
3. [Display Error Messages in the Chassis Process Log File | 2376](#)

Display the Current Router Alarms

Purpose

To determine the details of the alarms and when they first appeared in the component.

Action

To display the current router component alarms, use the following CLI command:

```
user@host> show chassis alarms
```

The command output displays the number of alarms currently active, the time when the alarm began, the severity level, and an alarm description. Note the date and time of an alarm so that you can correlate it with error messages in the **messages** system log file.

For examples of sample output, see the *Junos System Basics and Services Command Reference*.

Display Error Messages in the Messages Log File

Purpose

To determine the details of the error messages in the Messages Log File.

Action

To display router component error messages in the **messages** system log file, use the following CLI command:

```
user@host> show log messages
```

The **messages** system log file records the time the failure or event occurred, the severity level, a code, and a message description. Error messages in the **messages** system log file are logged at least 5 minutes before and after the alarm event.

To search for specific information in the log file, use the **| match component-name** command; for example, use **show log messages | match fpc**. If there is a space in the component name, enclose the component name in quotation marks; for example, **| match "power supply"**.

To search for multiple items in the log file, use the **| match** command followed by the multiple items, separated by the **|** (pipe), and enclosed in quotation marks; for example, **| match "fpc | sfm | kernel | tnp"**.

To monitor the **messages** file in real time, use the **monitor start messages** CLI command. This command displays the new entries in the file until you stop monitoring by using the **monitor stop messages** CLI command.

For more information about system log messages, see the *Junos System Log Messages Reference*.

Display Error Messages in the Chassis Process Log File

Purpose

To determine the details of the error messages in the Chassis Process Log File.

Action

To display router component errors in the chassis process (**chassisd**) system log file, use the following CLI command:

```
user@host> show log chassisd
```

The chassis process (**chassisd**) log file tracks the state of each chassis component. For examples of sample output, see the *Junos System Basics and Services Command Reference*.

To search for specific information in the log file, use the **| match component-name** command; for example, **show log messages | match fpc**. If there is a space in the component name, enclose the component name in quotation marks; for example, **| match "power supply"**.

To search for multiple items in the log file, use the **| match** command followed by the multiple items, separated by the **|** (pipe), and enclosed in quotation marks; for example, **| match "fpc | sfm | kernel | tnp"**.

To monitor the **chassisd** file in real time, use the **monitor start chassisd** CLI command. This command displays the new entries in the file until you stop monitoring by using the **monitor stop chassisd** CLI command.

Case Study for a CSPF Failure

Purpose

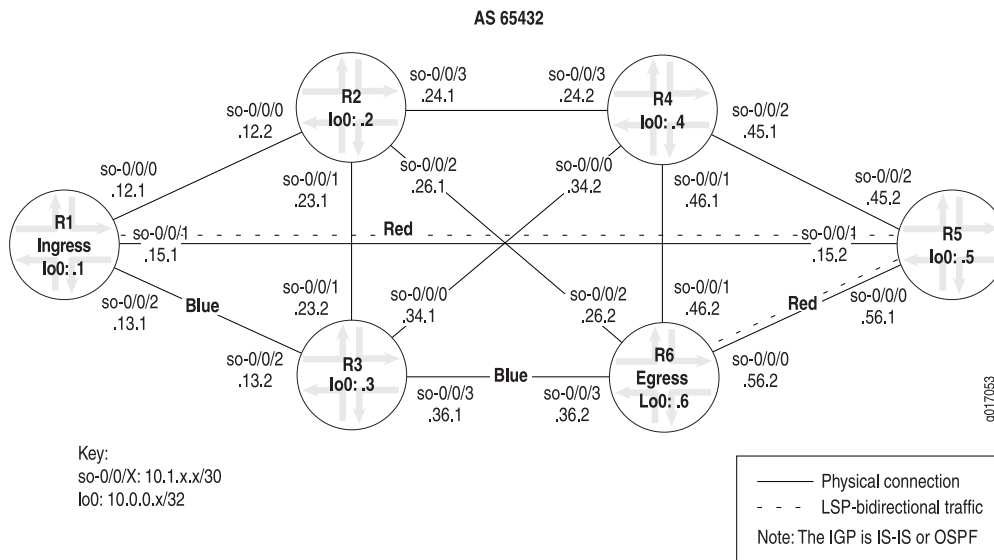

This case study presents a Multiprotocol Label Switching (MPLS) network topology and CSPF failure scenario designed to demonstrate techniques and commands that are particularly useful when addressing CSPF problems in your network. The focus of the study is the incorrect association of user-provided constraints, specifically administrative groups (also known as link coloring).

When calculating a path, the CSPF algorithm factors in user-provided constraints. The ingress router determines the physical path for each LSP by applying a CSPF algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first (SPF) algorithm that has been modified to take into account constraints when calculating the shortest path across the network. Links that do not comply with the restrictions are removed from the tree and cannot be factored into the resulting SPF calculations.

CSPF integrates topology link-state information that is learned from interior gateway protocol (IGP) traffic engineering extensions and is maintained in the traffic engineering database. The information stored in the traffic engineering database includes attributes associated with the state of network resources.

The network topology shown in [Figure 173 on page 2378](#) illustrates a network in which the LSP is constrained by administrative group coloring (also known as link coloring), and CSPF tracing is configured on the ingress router **RI**. In this example, the LSP is forced to transit **R5** in accordance with the restrictions imposed.

Figure 173: CSPF Topology with Administrative Group Coloring

The network shown in [Figure 173 on page 2378](#) is an MPLS router-only network with SONET interfaces.

The MPLS network shown in [Figure 173 on page 2378](#) is configured with administrative group coloring as follows:

- The LSP **R1-to-R6** is established with **R1** as the ingress router and **R6** as the egress router.
- The required path to **R6** transits **R5** on the redlinks. The inclusion of red coloring is not strictly necessary. To force the LSP to transit **R5**, you could color the links on **R3** and **R2** blue and then exclude the blue links.
- Both red and blue colors are used with the **include** and **exclude** statements to ensure that the LSP always transits **R5**. For information on configuring administrative group coloring, see the *MPLS Applications User Guide*.

To check that the network is configured correctly and the LSP is established, follow these steps:

1. [Verify That the LSP Is Established | 2378](#)
2. [Check the Administrative Group Configuration | 2380](#)

Verify That the LSP Is Established

Purpose

Check that the LSP shown in [Figure 173 on page 2378](#) is established and traversing the path from **R1** to **R6** through the red links.

Action

To verify that the LSP is established, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp extensive
user@host> show mpls lsp
```

Sample Output

```
user@R1> show mpls lsp extensive | no-more
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Up, ActiveRoute: 1, LSPname: R1-to-R6
  ActivePath: (primary)

Transit LSP: 2 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.0.0.1	10.0.0.6	Up	1	1 FF	100352	3	R6-to-R1
10.0.0.6	10.0.0.1	Up	1	1 FF	100384	3	R1-to-R6

```
Total 2 displayed, Up 2, Down 0
```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** is successfully established as indicated by the Explicit Route Object (ERO) **10.1.15.2 S 10.1.56.2 S**, the log message **CSPF: computation result accepted**, and **State: Up**. Also, the LSP is routing packets correctly over the red links, avoiding the blue links or the links without any coloring.

Sample Output 2 from transit router **R5** shows that LSP **R1-to-R6** is transiting **R5** as expected.

Check the Administrative Group Configuration

Purpose

Check that the administrative group coloring is correct and the relevant interfaces are associated with each administrative group correctly

Action

To check the administrative group configuration, enter the following Junos OS CLI operational mode commands, or issue the **show** command at the **[edit protocols mpls]** hierarchy level, as shown in the example below:

```
user@host> show configuration protocols mpls
user@host> show mpls interface
user@host> show ted database extensive nodeID
```

Sample Output 1

```
[edit protocols mpls]

Meaning

Sample Output 1 shows that administrative group coloring is correctly configured on all relevant routers. Administrative groups red and blue are configured at the `[edit protocols mpls]` hierarchy level, and relevant interfaces are associated with each administrative group correctly.

R3 is configured with blue coloring and the **include** and **exclude** statements are included in the configuration of **R1** to ensure that LSP **R1-to-R6** always transits **R5**. The inclusion of red coloring is not strictly necessary. To force the LSP to transit **R5**, you could color the links on **R2** and **R3** blue and then exclude the blue links. Red coloring is included in this example to demonstrate the fact that the CSPF algorithm excludes links that do not have a color configured, when the **include** statement is configured at the `[edit protocols mpls]` hierarchy level.

In addition, ingress router **R1** has CSPF tracing configured in preparation for gathering information when the CSPF algorithm fails later in this example.

Sample Output 2 shows that the correct interfaces are associated with the red and blue administration groups on **R1**, **R3**, **R5**, and **R6**.

Sample Output 3 confirms that link coloring is correctly reported in the traffic engineering database for **R1**. Not shown is the traffic engineering database output for the remaining routers, which is similar to the **R1** output, and correct.

Examining a CSPF Failure

When a local CSPF failure indicates that no path meets the constraints configured for the LSP, you must perform CSPF-based tracing and be familiar with the contents of the traffic engineering database to resolve the problem. See [“Examine the Traffic Engineering Database” on page 2390](#) for an analysis of the traffic engineering database.

NOTE: If an LSP does not establish immediately, wait at least a minute or so before taking diagnostic or corrective action. This is because the RSVP retry timer is set to a 30-second default, resulting in a slight delay before the correct state of the LSP is available.

To examine a CSPF failure, follow these steps:

1. [Verify the CSPF Failure | 2386](#)
2. [Examine the CSPF Log File | 2388](#)
3. [Examine the Traffic Engineering Database | 2390](#)
4. [Check the Administrative Group Configuration on R5 | 2393](#)

Verify the CSPF Failure

Purpose

To simulate a configuration error on the network, router **R5** has the administrative group coloring removed from interface **so-0/0/0**. The result is a CSPF failure at **R5** because there is no longer a path between **R1** and **R6** that includes the red color.

Action

To confirm that the LSP is down and verify the configuration on routers **R1** and **R5**, enter the following Junos OS CLI operational mode commands:

```
user@host> clear mpls lsp
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> clear mpls lsp
[edit protocols mpls]
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample Output 1 from ingress router **R1** shows that the **clear mpls lsp** command was issued to confirm that **R1** cannot reestablish LSP **R1-to-R6**. The sample output from the **show mpls lsp extensive** command shows that LSP **R1-to-R6** is down, **State: Dn** and **ActivePath: (None)**; and that the CSPF has failed, **CSPF failed: no route toward 10.0.0.6**.

Sample Output 2 from transit router **R5** shows that LSP **R1-to-R6** is not included in the output, indicating that the LSP is not transiting **R5**.

Most network problems appear as a local CSPF failure, as shown in the sample output. The CSPF failure indicates that no path meeting the constraints for the LSP can be found in the router's traffic engineering

database. To resolve these problems effectively, use CSPF tracing on the ingress router, and analyze the traffic engineering database to locate the node that should meet the constraints.

Examine the CSPF Log File

Purpose

After you have confirmed that the LSP is down, obtain more information about the possible cause of the failure.

NOTE: To obtain useful information from the CSPF log file, make sure that CSPF tracing is configured on the ingress router.

Action

To examine the CSPF log file, enter the following Junos OS CLI operational mode commands:

```
user@host> monitor start filename
user@host> show log filename
```

NOTE: To stop monitoring CSPF, issue the **monitor stop** command.

Sample Output

```
user@R1> monitor start cspf

[edit protocols mpls]
user@R1# run show log cspf-failed3
May 27 10:22:23 trace_on:   Tracing to "/var/log/cspf"

monitor stop

```

Meaning

The sample output shows that the **monitor start cspf** command was issued to start displaying entries in the **cspf** log file in real time. The **cspf** log file is generated by the routing protocol process after the file is configured with the **traceoptions** statement at the **[edit protocols mpls]** hierarchy level. In this example, the **cspf** log file is configured with the **cspf**, **cspf-node**, and **cspf-link** flags to provide the most granular information about the steps taken by the CSPF algorithm.

The only link that passes the color constraint is between **R1** and **R5**, **10.1.15.0/32**. The CSPF algorithm is a locally run algorithm, which makes its calculations on a given router. When the CSPF algorithm runs on **R5**, it prunes **10.1.15.2** and selects **10.1.56.1** to send the message to **R6**. The link between **R5** and **R6** **10.1.56.0/32** does not pass the color constraints, indicating a problem with **R5**. At this stage, it is useful to examine the traffic engineering database to determine which link on **R5** should be associated with the red color.

Examine the Traffic Engineering Database

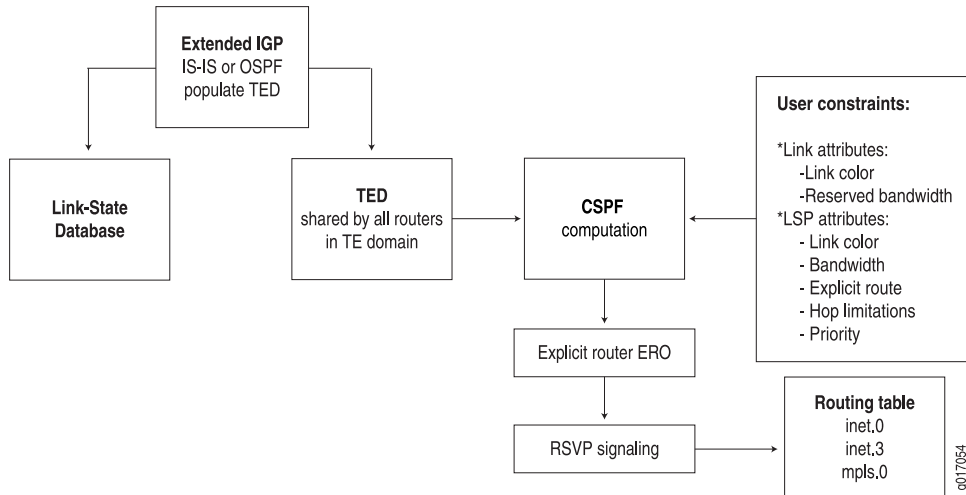

Purpose

Examining the traffic engineering database is another way to locate the node that should meet the constraints but does not. Once identified, you can concentrate your troubleshooting efforts on why that node is not being represented accurately in the database.

The contents of the traffic engineering database are consistent among all routers within a given traffic engineering domain. Therefore, you can issue the **show ted database** command from any router in the same traffic engineering domain to obtain more granular information about the CSPF failure.

CSPF integrates topology link-state information that is learned from the IGP traffic engineering extensions and maintained in the traffic engineering database. The information stored in the traffic engineering database includes attributes associated with the state of the network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color). When calculating a path, the CSPF algorithm factors in user-provided information such as bandwidth requirements, maximum allowed hop count, and administrative groups, all of which are obtained from user configuration. (See [Figure 174 on page 2391](#)).

Figure 174: User-Provided Constraints

Action

To examine the traffic engineering database, enter the following Junos OS CLI operational mode commands:

```

user@host> show ted database extensive
user@host> show ted database extensive NodeID | match "(NodeID|To:|Color)"

```

```

Meaning

Sample Output 1 from ingress router **R1** shows a wealth of information on each node in the network, although only a portion is included in this example. The output shows the total number of IS-IS and INET nodes in the traffic engineering domain. The portion of the traffic engineering database shown represents a node (**R5**), and the **Type** field indicates **Rtr** (router). The **Type** field could also indicate Net (network) if the node were a pseudo node. The node (**R5**) has three input and output links that are running IS-IS Level 2, **Protocol: IS-IS(2)**. The links lead to nodes **R1**, **R4**, and **R6**. The local address and remote address for each link is specified. The information on each node includes administrative groups (**Color:**), metrics, static bandwidth, reservable bandwidth, and available bandwidth priority level. The information contained in the traffic engineering database should be the same across all routers in the same traffic engineering domain. For a detailed description of the fields in the output of the **show ted database extensive** command, see the *Junos Routing Protocols and Policies Command Reference*.

Sample Output 2 shows filtered output that allows you to focus on exactly what is missing or incorrect.

Both outputs confirm that the link between **R1** and **R5**, **10.1.15.0/32**, is associated with the red color, while the link between **R5** and **R6**, **10.1.56.0/32**, is not associated with a color. In the network shown in [Figure 173 on page 2378](#), for the LSP to establish correctly, link **10.1.56.1** must be associated with the red color.

Check the Administrative Group Configuration on R5

Purpose

Focus on R5 to determine which interfaces are associated with the red color, and make any necessary corrections.

Action

To check the administrative group configuration on R5 and make any necessary corrections, enter the following Junos OS CLI commands:

```

user@R5> edit
[edit protocols mpls]
user@R5# show
user@R5# delete interface so-0/0/1 admin-group
user@R5# set interface so-0/0/0 admin-group red
user@R5# show
user@R5# commit

```

Sample Output 1

```

user@R5> edit
Entering configuration mode

[edit protocols mpls]
user@R5# show
admin-groups {
    red 8;
}
interface fxp0.0 {
    disable;
}
interface so-0/0/0.0;
interface so-0/0/1.0 { <<<incorrect interface configured with admin-group
    admin-group red;
}
interface so-0/0/2.0;

```

Sample Output 2

```

[edit protocols mpls]
user@R5# delete interface so-0/0/1 admin-group

[edit protocols mpls]
user@R5# set interface so-0/0/0 admin-group red

[edit protocols mpls]

```

```

user@R5# show

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

Sample Output 1 from transit router **R5** shows that at the `[edit protocols mpls]` hierarchy level, interface **so-0/0/1** is incorrectly configured with the **admin-group red** statement. The **so-0/0/0** interface should be configured with the **admin-group red** statement.

Sample Output 2 shows the steps taken to correct the configuration. The administration group has been deleted from **so-0/0/1** and **so-0/0/0** is now associated with the red color.

Sample Output 3 shows that LSP **R1-to-R6** is established.

Verify the CSPF Failure

Purpose

To simulate a configuration error on the network, router **R5** has the administrative group coloring removed from interface **so-0/0/0**. The result is a CSPF failure at **R5** because there is no longer a path between **R1** and **R6** that includes the red color.

Action

To confirm that the LSP is down and verify the configuration on routers **R1** and **R5**, enter the following Junos OS CLI operational mode commands:

```
user@host> clear mpls lsp
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> clear mpls lsp
[edit protocols mpls]
user@R1# run show mpls lsp extensive
Ingress LSP: 1 sessions

```

Total 1 displayed, Up 1
, Down 0

```

Meaning

Sample Output 1 from ingress router **R1** shows that the **clear mpls lsp** command was issued to confirm that **R1** cannot reestablish LSP **R1-to-R6**. The sample output from the **show mpls lsp extensive** command shows that LSP **R1-to-R6** is down, **State: Dn** and **ActivePath: (None)**; and that the CSPF has failed, **CSPF failed: no route toward 10.0.0.6**.

Sample Output 2 from transit router **R5** shows that LSP **R1-to-R6** is not included in the output, indicating that the LSP is not transiting **R5**.

Most network problems appear as a local CSPF failure, as shown in the sample output. The CSPF failure indicates that no path meeting the constraints for the LSP can be found in the router's traffic engineering database. To resolve these problems effectively, use CSPF tracing on the ingress router, and analyze the traffic engineering database to locate the node that should meet the constraints.

Examining the Hello Message

Purpose

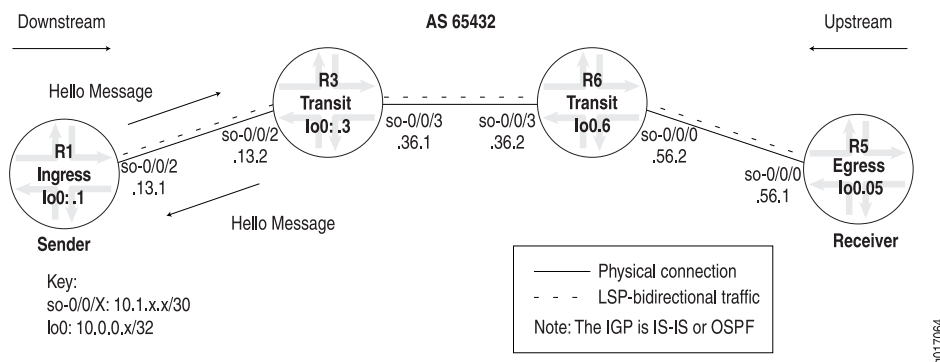

RSVP monitors the status of the interior gateway protocol (IGP) (Intermediate System-to-Intermediate System [ISIS] or Open Shortest Path First [OSPF]) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because Hello messages are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

RSVP Hello messages are exchanged between neighbors. The destination address is the neighbor node. RSVP Hello messages are used to determine loss of interface more quickly than determined by the RSVP state timeout.

NOTE: RSVP Hello messages are required to establish the protocol or to maintain adjacency information. RSVP Hello messages do not establish state.

Figure 175 on page 2398 shows two RSVP Hello messages exchanged between routers R1 and R3.

Figure 175: RSVP Hello Message

To ensure that Hello messages are displayed in the output, include the **packets** flag at the **[edit protocols rsvp traceoptions]** hierarchy level.

Action

To examine the Hello message, enter the following Junos OS CLI command:

```
user@R1> monitor start filename
```

Sample Output 1

```
[edit protocols rsvp]
user@R1# show
traceoptions {
    file rsvp-log;
    flag packets detail;
}
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}
```

Sample Output 2

```
user@R1> clear log rsvp-log

user@R1> monitor start rsvp-log

user@R1>
*** rsvp-log ***
[...Output truncated...]
Jun 29 15:48:59  RSVP send Hello New 10.1.13.1->10.1.13.2 Len=32 so-0/0/2.0
Jun 29 15:48:59  HelloReq Len 12
Jun 29 15:48:59  RestartCap Len 12 restart time 0, recovery time 0
Jun 29 15:48:59  RSVP rcv Hello New 10.1.13.2->10.1.13.1 Len=32 so-0/0/2.0
Jun 29 15:48:59  HelloRply Len 12
Jun 29 15:48:59  RestartCap Len 12 restart time 0, recovery time 0
monitor stop
```

Meaning

Sample Output 1 shows the configuration of RSVP tracing on ingress router **R1**. The **packets** flag is included at the **[edit protocols rsvp traceoptions]** hierarchy level to provide information about RSVP traffic. The **detail** option is included to show granular details about the configured flag.

Sample Output 2 shows **clear** commands, the output for the **rsvp-log** file, and that monitoring was started and then stopped. The **rsvp-log** output shows two RSVP Hello messages exchanged between **R1** and **R3**.

The first Hello message in the **rsvp-log** output is a request sent from **R1 (10.1.13.1)** to **R3 (10.1.13.2)**. The outgoing interface is **so-0/0/2.0** on **R1**. The second Hello message was a reply sent from **R3** to **R1**, also through the outgoing interface **so-0/0/2.0** on **R3**.

The next two lines of output indicate object values for the two Hello messages, and are indented in the output. To facilitate this discussion, each line of output for each object is displayed before the corresponding explanation.

- **HelloReq Len 12**

The Hello request (**HelloReq**) object indicates that this is a Hello request. RFC 3209 defines the RSVP Hello message. An RSVP Hello message can either be a request or a reply. Every request should generate a reply.

- **RestartCap Len 12 restart time 0, recovery time 0**

The restart object (**RestartCap**) indicates the graceful restart capability of the sender node. The restart time of 0 milliseconds is the length of time that this node takes to restart its RSVP traffic engineering functionality. At the end of this time, the node can send and receive RSVP messages again. The recovery time of 0 milliseconds indicates the length of time the LSR retains MPLS forwarding information. A recovery time of 0 in this case indicates that no forwarding state was preserved across a restart. Because both values are set to 0, graceful restart was not enabled for this RSVP session.

- **HelloRply Len 12**

The Hello reply (**HelloRply**) object indicates that this is an RSVP Hello message sent from **R3** to **R1** out of interface **so-0/0/2.0**.

In standard RSVP, node failure detection occurs as a consequence of the RSVP soft-state timeout model. However, detection typically requires several minutes to time out the soft state. Hello packets allow the detection of the neighboring node state changes more quickly.

In Junos OS, RSVP Hello messages are optional and are backward-compatible with RSVP implementations that do not support Hello messages. For neighboring routers that do not support Hello messages or on which RSVP Hello is disabled, RSVP uses the soft-state timeout for loss detection and cannot benefit from fast IGP Hello detection.

Configuring a short time for the IS-IS or OSPF Hello timers allows these protocols to detect node failures more quickly. RSVP also benefits from early detection by the IGP protocols. It is not necessary to explicitly configure a short RSVP Hello timer. If you do configure the RSVP Hello timer, you can configure a longer value and can still expect the failure of a neighboring router to be quickly detected by IGP.

Between Hello-capable neighbors, Hello messages are sent unicast toward each other. A loss of (2 x keep-multiplier + 1) consecutive Hello messages causes the neighbor's state to go down, and all RSVP sessions to and from that neighbor are declared to be down.

By default, RSVP sends Hello messages every 9 seconds.

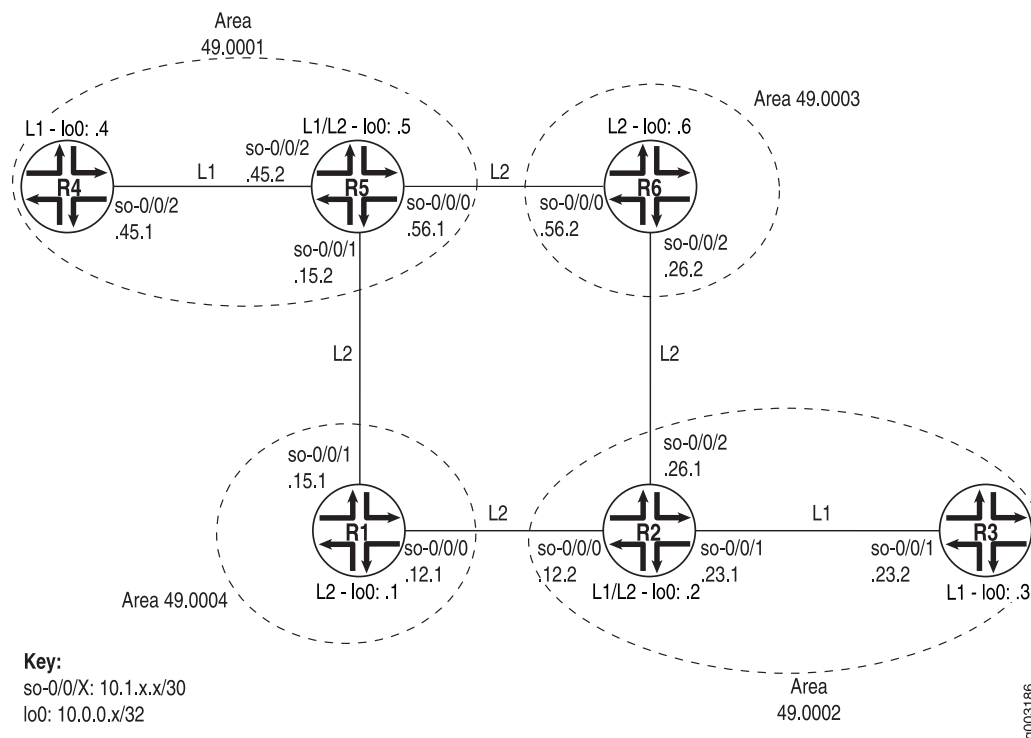

Displaying the Status of IS-IS Adjacencies

Purpose

Assuming that all the routers are correctly configured for IS-IS, you can verify which neighbors are adjacent and able to exchange IS-IS data. In addition, you can examine the set of routes installed in the forwarding table to verify that the routing protocol process (rpd) has relayed the correct information into the forwarding table.

Figure 176 on page 2401 illustrates the example IS-IS topology used for the procedures in this topic.

Figure 176: IS-IS Network Topology

The network consists of Level 1 and Level 2 adjacencies. Level 1 adjacencies are within areas 49.0001 and 49.0002. Level 2 adjacencies occur between all directly connected Level 2 routers regardless of which area they are in. For example, R5 is in area 49.0001, R6 is in area 49.0003, R1 is in area 49.0004, and R2 is in area 49.0002. The network in Figure 176 on page 2401 should have the following adjacencies:

- Level 2 adjacencies between all directly connected Level 2 routers (R1, R2, R5, and R6).
- Level 1 adjacencies between routers in area 49.0001 (R4 and R5) and between routers in area 49.0002 (R2 and R3).

To verify that routers are adjacent and able to exchange IS-IS data, follow these steps:

1. [Verifying Adjacent Routers | 2402](#)
2. [Examine the Forwarding Table | 2403](#)

Verifying Adjacent Routers

Purpose

Verify that routers are adjacent and able to exchange IS-IS data.

Action

To verify that routers are adjacent and able to exchange IS-IS data, enter the following CLI operational mode command:

```
user@host> show isis adjacency
```

The following sample output shows the adjacencies that formed for all routers shown in [“Displaying the Status of IS-IS Adjacencies” on page 2401](#).

Sample Output

```
user@R1> show isis adjacency
Interface          System      L State      Hold (secs) SNPA
so-0/0/0.0         R2          2 Up         19
so-0/0/1.0         R5          2 Up         18

user@R2> show isis adjacency
Interface          System      L State      Hold (secs) SNPA
so-0/0/0.0         R1          2 Up         19
so-0/0/1.0         R3          1 Up         26
so-0/0/2.0         R6          2 Up         21

user@R3> show isis adjacency
Interface          System      L State      Hold (secs) SNPA
so-0/0/1.0         R2          1 Up         24

user@R4> show isis adjacency
Interface          System      L State      Hold (secs) SNPA
so-0/0/2.0         R5          1 Up         23
```

```

user@R5> show isis adjacency
Interface          System      L State      Hold (secs) SNPA
so-0/0/0.0         R6          2 Up         22
so-0/0/1.0         R1          2 Up         20
so-0/0/2.0         R4          1 Up         20

user@R6> show isis adjacency
Interface          System      L State      Hold (secs) SNPA
so-0/0/0.0         R5          2 Up         21
so-0/0/2.0         R2          2 Up         20

```

Meaning

The sample output shows the adjacencies that formed in the network illustrated in [“Displaying the Status of IS-IS Adjacencies” on page 2401](#). The Level 1/Level 2 routers (R2 and R5) formed Level 1 adjacencies with Level 1 routers (R3 and R4), and Level 2 adjacencies with the Level 2 routers (R1 and R6). To view the status of the adjacency, examine the State column. In this example, all adjacencies in the network are up.

If the state is not **Up** for a particular neighbor, you must first examine the IS-IS configuration for the particular interface. Make sure that the NET address is correct and that the loopback interface (lo0) is configured. Use the **show isis interface** or **show isis interface detail** command to display the IS-IS parameters for all interfaces configured with IS-IS. With these two commands, you can see which interfaces are configured for IS-IS, whether they are configured for Level 1 or Level 2, the IS-IS metric, and other IS-IS information.

Example: Configuring a Multi-Level IS-IS Topology to Control Interarea Flooding

Examine the Forwarding Table

Purpose

You can display the set of routes installed in the forwarding table to verify that the routing protocol process (rpd) has relayed the correct information into the forwarding table. This is especially important when there are network problems, such as connectivity. In this procedure, you verify that the routes displayed in Step 2 appear in the forwarding table for Router R5.

Action

To examine the forwarding table for a router, enter the following CLI command:

```
user@host> show route forwarding-table destination destination-prefix
```

Sample Output

```
user@R5> show route forwarding-table destination 10.0.0.3
```

```
Routing table: inet
Internet:
Destination          Type RtRef Next hop          Type Index NhRef Netif
10.0.0.3/32          user    0 10.1.15.0          ucst  285    7  so-0/0/1.0

user@R5> show route forwarding-table destination 10.0.0.3
Routing table: inet
Internet:
Destination          Type RtRef Next hop          Type Index NhRef Netif
10.0.0.3/32          user    0 10.1.56.0          ucst  281    9  so-0/0/0.0
```

Meaning

The sample output shows the selected next hop between Routers R5 and R3 sent from the inet routing table and installed into the forwarding table. The first instance shows the route through Router R1, and the second instance shows the route through Router R6. In both instances, the preferred route displayed in Step 2 is installed in the forwarding table.

In general, the sample output includes the destination address and destination type, the next-hop address and next-hop type, the number of references to the next hop, an index number into an internal next-hop database, and the interface used to reach the next hop.

Check OSPF on a Stub Router

Purpose

To verify the OSPF configuration on a stub router.

Action

To verify the OSPF configuration on a stub router in your network, enter the following commands:

```
user@host> show configuration
user@host> show ospf interface
```

The following sample output is for an OSPF configuration on **R5**, a stub router:

Sample Output

```
user@R5> show configuration
[...Output truncated...]
interfaces {
    so-0/0/2 {
        unit 0 {
            family inet {
                address 10.1.45.2/30;
            }
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 10.0.0.5/32;
            }
        }
    }
}
routing-options {
    router-id 10.0.0.5;
}
protocols {

        area 0.0.0.2 {
            stub;
        }
    }
}
```

```

        interface so-0/0/2.0;
        interface lo0.0 {
            passive;
        }
    }
}

```

```

user@R5> show ospf interface

```

Interface	State	Area	DR ID	BDR ID	Nbrs
lo0.0	DRother	0.0.0.2	0.0.0.0	0.0.0.0	0
so-0/0/2.0	PtToPt	0.0.0.2	0.0.0.0	0.0.0.0	1

Meaning

The sample output shows a basic OSPF configuration at the [edit protocols ospf] and [edit interfaces] hierarchy levels on **R5**, a stub router.

R5 has two interfaces included at the [edit protocols ospf] hierarchy level, and those interfaces have the **family inet** statement included at the [edit interfaces] hierarchy level. Both interfaces, **so-0/0/2.0** and the loopback interface (**lo0**), are in the stub area (**0.0.0.2**).

R5 has the router ID configured manually to avoid possible problems when the OSPF router ID (RID) changes; for example, when multiple loopback addresses are configured. The RID uniquely identifies the router within the OSPF network. It is transmitted within the LSAs used to populate the link-state database and calculate the shortest-path tree. In a link-state network, it is important that two routers do not share the same RID value, otherwise IP routing problems may occur.

A stub area does not allow AS external advertisements to flood within that area. **R5** relies on a default route (**0.0.0.0/0**) to reach destinations outside the AS. The default route can be statically configured on **R5** or advertised by an ABR (**R4**). In this network, the default LSA is advertised by **R4**.

A stub area is useful if you want to reduce the size of the topological database and therefore the amount of memory required from the routers in the stub area. However, some restrictions apply to a stub area. You cannot create a virtual link through a stub area, and a stub area cannot contain an ASBR.

Checklist for Verifying the BGP Protocol and Peers

Purpose

[Table 69 on page 2407](#) provides links and commands for verifying whether the Border Gateway Protocol (BGP) is configured correctly on a Juniper Networks router in your network, the internal Border Gateway Protocol (IBGP) and exterior Border Gateway Protocol (EBGP) sessions are properly established, the

external routes are advertised and received correctly, and the BGP path selection process is working properly.

Action

Table 69: Checklist for Verifying the BGP Protocol and Peers

Tasks	Command or Action
“Verify BGP Peers” on page 2407	
1. <i>Verify BGP on an Internal Router</i>	<code>show configuration</code>
2. <i>Verify BGP on a Border Router</i>	<code>show configuration</code>
2. <i>Verify Advertised BGP Routes</i>	<code>show route advertising-protocol bgp neighbor-address</code>
3. <i>Verify That a Particular BGP Route Is Received on Your Router</i>	<code>show route receive-protocol bgp neighbor-address</code>
“Examine BGP Routes and Route Selection” on page 2418	
1. Examine the Local Preference Selection on page 2420	<code>show route destination-prefix < detail ></code>
2. Examine the Multiple Exit Discriminator Route Selection on page 2422	<code>show route destination-prefix < detail ></code>
3. Examine the EBGp over IBGP Selection on page 2423	<code>show route destination-prefix < detail ></code>
4. Examine the IGP Cost Selection on page 2425	<code>show route destination-prefix < detail ></code>
“Examine Routes in the Forwarding Table” on page 2432	<code>show route forwarding-table</code>

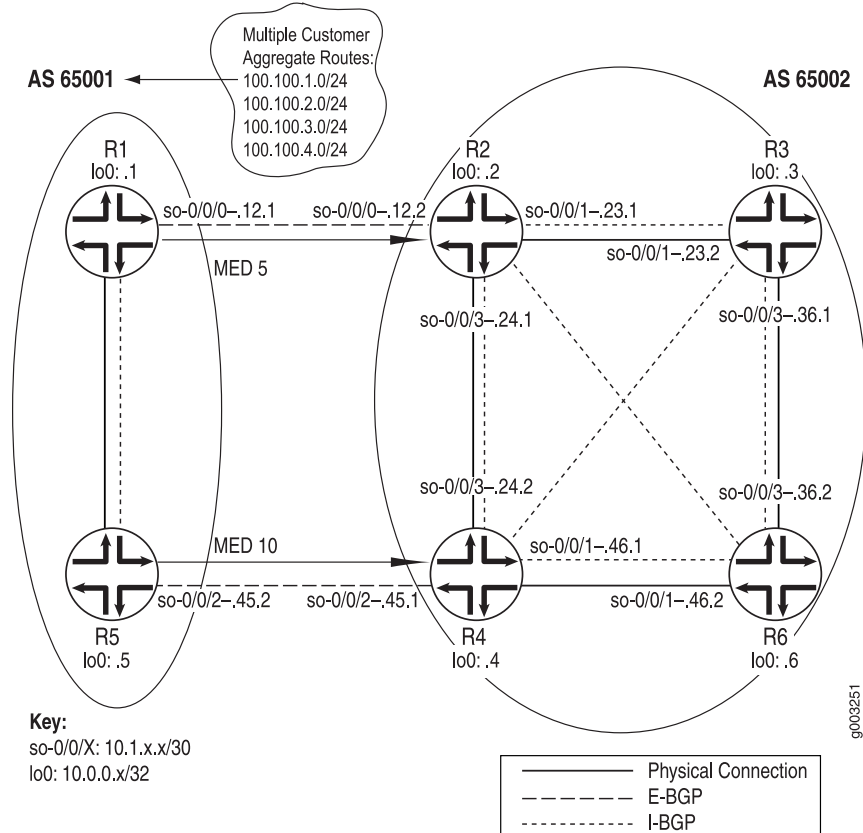

Verify BGP Peers

Purpose

Assuming that all the routers are correctly configured for BGP, you can verify if IBGP and EBGp sessions are properly established, external routes are advertised and received correctly, and the BGP path selection process is working properly.

[Figure 177 on page 2408](#) illustrates an example BGP network topology used in this topic.

Figure 177: BGP Network Topology

The network consists of two directly connected ASs consisting of external and internal peers. The external peers are directly connected through a shared interface and are running EBGp. The internal peers are connected through their loopback (lo0) interfaces through IBGP. AS 65001 is running OSPF and AS 65002 is running IS-IS as its underlying IGP. IBGP routers do not have to be directly connected, the underlying IGP allows neighbors to reach one another.

The two routers in AS 65001 each contain one EBGp link to AS 65002 (R2 and R4) over which they announce aggregated prefixes: **100.100.1.0**, **100.100.2.0**, **100.100.3.0**, and **100.100.4.0**. Also, R1 and R5 are injecting multiple exit discriminator (MED) values of 5 and 10, respectively, for some routes.

The internal routers in both ASs are using a full mesh IBGP topology. A full mesh is required because the networks are not using confederations or route reflectors, so any routes learned through IBGP are not distributed to other internal neighbors. For example, when R3 learns a route from R2, R3 does not distribute that route to R6 because the route is learned through IBGP, so R6 must have a direct BGP connection to R2 to learn the route.

In a full mesh topology, only the border router receiving external BGP information distributes that information to other routers within its AS. The receiving router does not redistribute that information to other IBGP routers in its own AS.

From the point of view of AS 65002, the following sessions should be up:

- The four routers in AS 65002 should have IBGP sessions established with each other.
- R2 should have an EBGP session established with R1.
- R4 should have an EBGP session established with R5.

To verify BGP peers, follow these steps:

1. [Verify BGP on an Internal Router | 2409](#)
2. [Verify BGP on a Border Router | 2412](#)
3. [Verify Advertised BGP Routes | 2417](#)
4. [Verify That a Particular BGP Route Is Received on Your Router | 2417](#)

Verify BGP on an Internal Router

Purpose

To verify the BGP configuration of an internal router.

Action

To verify the BGP configuration of an internal router, enter the following Junos OS command-line interface (CLI) command:

```
user@host> show configuration
```

The following sample output is for a BGP configuration on R3:

Sample Output

```
user@R3> show configuration

            type internal;
            local-address 10.0.0.6;
            neighbor 10.0.0.2;
            neighbor 10.0.0.3;
            neighbor 10.0.0.4;

```

```

    }
  }
  isis {
    level 1 disable;
    interface all {
      level 2 metric 10;
    }
    interface lo0.0;
  }
}

```

Meaning

The sample output shows a basic BGP configuration on routers **R3** and **R6**. The local AS (65002) and one group (**internal**) are configured on both routers. **R3** has three internal peers—**10.0.0.2**, **10.0.0.4**, and **10.0.0.6**—included at the `[protocols bgp group group]` hierarchy level. **R6** also has three internal peers: **10.0.0.2**, **10.0.0.3**, and **10.0.0.4**. The underlying IGP protocol is Intermediate System-to-Intermediate System (IS-IS), and relevant interfaces are configured to run IS-IS.

Note that in this configuration the router ID is manually configured to avoid any duplicate router ID problems.

Verify BGP on a Border Router

Purpose

To verify the BGP configuration of a border router.

Action

To verify the BGP configuration of a border router, enter the following Junos OS CLI operational mode command:

```
user@host> show configuration
```

Sample Output

The following sample output is for a BGP configuration on two border routers, R2 and R4 from AS 65002:

```

user@R2> show configuration
[...Output truncated...]
interfaces {

```

```

so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.12.2/30;
        }
        family iso;
    }
}
so-0/0/1 {
    unit 0 {
        family inet {
            address 10.1.23.1/30;
        }
        family iso;
    }
}
so-0/0/3 {
    unit 0 {
        family inet {

                next-hop self;
            }
        }
    }
}

```

Meaning

The sample output shows a basic BGP configuration on border routers **R2** and **R4**. Both routers have the AS (65002) included at the **[routing-options]** hierarchy level. Each router has two groups included at the **[protocols bgp group group]** hierarchy level. External peers are included in the external group, either **toR1** or **toR5**, depending on the router. Internal peers are included in the **internal** group. The underlying IGP protocol is IS-IS on both routers, and relevant interfaces are configured to run IS-IS.

Note that in the configuration on both routers, the router ID is manually configured to avoid duplicate router ID problems, and the **next-hop-self** statement is included to avoid any BGP next-hop reachability problems.

Verify Advertised BGP Routes

Purpose

You can determine if a particular route that you have configured is being advertised to a neighbor.

Action

To verify the routing information as it has been prepared for advertisement to the specified BGP neighbor, enter the following Junos OS CLI operational mode command:

```
user@host> show route advertising-protocol bgp neighbor-address
```

Sample Output

```
user@R2> show route advertising-protocol bgp 10.0.0.4\
```

```
inet.0: 20 destinations, 22 routes (20 active, 0 holddown, 0 hidden)
  Prefix                Nexthop          MED      Lclpref    AS path
* 100.100.1.0/24        Self             5         200        65001 I
* 100.100.2.0/24        Self             5         100        65001 I
* 100.100.3.0/24        Self             100       100        65001 I
* 100.100.4.0/24        Self             100       100        65001 I
```

Meaning

The sample output shows the BGP routes advertised from **R2** to its neighbor, **10.0.0.4 (R4)**. Out of 22 total routes in the **inet.0** routing table, 20 are active destinations. No routes are **hidden** or in the **hold-down** state. Routes reside in the **hold-down** state prior to being declared active, and routes rejected by a routing policy can be placed into the **hidden** state. The information displayed reflects the routes that the routing table exported to the BGP routing protocol.

Verify That a Particular BGP Route Is Received on Your Router

Purpose

Display the routing information as it is received through a particular BGP neighbor and advertised by the local router to the neighbor.

Action

To verify that a particular BGP route is received on your router, enter the following Junos OS CLI operational mode command:

```
user@host> show route receive-protocol bgp neighbor-address
```

Sample Output

```
user@R6> show route receive-protocol bgp 10.0.0.2
```

```
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
  Prefix                Nexthop                MED      Lclpref    AS path
* 100.100.1.0/24        10.0.0.2              5    200    65001 I
* 100.100.2.0/24        10.0.0.2              5    100    65001 I
  100.100.3.0/24        10.0.0.2              100           65001 I
  100.100.4.0/24        10.0.0.2              100           65001 I
iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)

user@R6> show route receive-protocol bgp 10.0.0.4
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
  Prefix                Nexthop                MED      Lclpref    AS path
* 100.100.3.0/24        10.0.0.4              100           65001 I
* 100.100.4.0/24        10.0.0.4              100           65001 I
iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
```

Meaning

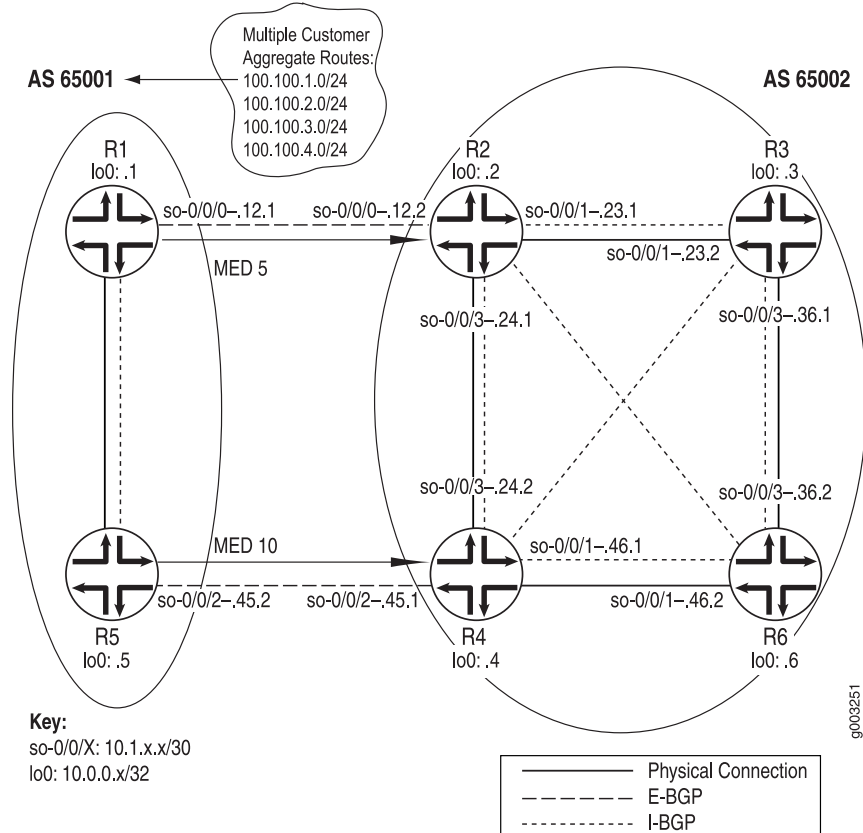

The sample output shows four BGP routes from **R2** and two from **R4**. Of the four routes from **R2**, only two are active in the routing table, as indicated by the asterisk (*), while both routes received from **R4** are active in the routing table. All BGP routes came through AS 65001.

Examine BGP Routes and Route Selection

Purpose

You can examine the BGP path selection process to determine the single, active path when BGP receives multiple routes to the same destination prefix.

Figure 178: BGP Network Topology

The network in [Figure 178 on page 2419](#) shows that **R1** and **R5** announce the same aggregate routes to **R2** and **R4**, which results in **R2** and **R4** receiving two routes to the same destination prefix. The route selection process on **R2** and **R4** determines which of the two BGP routes received is active and advertised to the other internal routers (**R3** and **R6**).

Before the router installs a BGP route, it must make sure that the BGP **next-hop** attribute is reachable. If the BGP next hop cannot be resolved, the route is not installed. When a BGP route is installed in the routing table, it must go through a path selection process if multiple routes exist to the same destination prefix. The BGP path selection process proceeds in the following order:

1. Route preference in the routing table is compared. For example, if an OSPF and a BGP route exist for a particular destination, the OSPF route is selected as the active route because the OSPF route has a default preference of 110, while the BGP route has a default preference of 170.
2. Routes are compared for local preference. The route with the highest local preference is preferred. For example, see [“Examine the Local Preference Selection” on page 2420](#).
3. The AS path attribute is evaluated. The shorter AS path is preferred.
4. The origin code is evaluated. The lowest origin code is preferred (**I (IGP)** < **E (EGP)** < **? (Incomplete)**).

5. The MED value is evaluated. By default, if any of the routes are advertised from the same neighboring AS, the lowest MED value is preferred. The absence of a MED value is interpreted as a MED of 0. For an example, see [“Examine the Multiple Exit Discriminator Route Selection” on page 2422](#).
6. The route is evaluated as to whether it is learned through EBGP or IBGP. EBGP learned routes are preferred to IBGP learned routes. For an example, see [“Examine the EBGP over IBGP Selection” on page 2423](#)
7. If the route is learned from IBGP, the route with the lowest IGP cost is preferred. For an example, see [“Examine the IGP Cost Selection” on page 2425](#). The physical next hop to the IBGP peer is installed according to the following three rules:
 - a. After BGP examines the **inet.0** and **inet.3** routing tables, the physical next hop of the route with the lowest preference is used.
 - b. If the preference values in the **inet.0** and the **inet.3** routing tables are a tie, the physical next hop of the route in the **inet.3** routing table is used.
 - c. When a preference tie exists in the same routing table, the physical next hop of the route with more paths is installed.
8. The route reflection cluster list attribute is evaluated. The shortest length cluster list is preferred. Routes without a cluster list are considered to have a cluster list length of 0.
9. The router ID is evaluated. The route from the peer with the lowest router ID is preferred (usually the loopback address).
10. The peer address value is examined. The peer with the lowest peer IP address is preferred.

To determine the single, active path when BGP receives multiple routes to the same destination prefix, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

The following steps illustrate the inactive reason displayed when BGP receives multiple routes to the same destination prefix and one route is selected as the single, active path:

1. [Examine the Local Preference Selection | 2420](#)
2. [Examine the Multiple Exit Discriminator Route Selection | 2422](#)
3. [Examine the EBGP over IBGP Selection | 2423](#)
4. [Examine the IGP Cost Selection | 2425](#)

Examine the Local Preference Selection

Purpose

To examine a route to determine if local preference is the selection criteria for the single, active path.

Action

To examine a route to determine if local preference is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.1.0 detail
```

```
inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.1.0/24 (2 entries, 1 announced)
    *BGP      Preference: 170/-201
        Source: 10.0.0.2
        Next hop: 10.1.24.1 via so-0/0/3.0, selected
        Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
        State: <Active Int Ext>
        Local AS: 65002 Peer AS: 65002
        Age: 2:22:34      Metric: 5      Metric2: 10
        Task: BGP_65002.10.0.0.2+179
        Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0
        AS path: 65001 I
        Localpref: 200
        Router ID: 10.0.0.2
    BGP      Preference: 170/-101
        Source: 10.1.45.2
        Next hop: 10.1.45.2 via so-0/0/2.0, selected
        State: <Ext>
        Inactive reason: Local Preference
        Local AS: 65002 Peer AS: 65001
        Age: 2w0d 1:28:31      Metric: 10
        Task: BGP_65001.10.1.45.2+179
        AS path: 65001 I
        Localpref: 100
        Router ID: 10.0.0.5
```

Meaning

The sample output shows that **R4** received two instances of the **100.100.1.0** route: one from **10.0.0.2 (R2)** and one from **10.1.45.2 (R5)**. **R4** selected the path from **R2** as its active path, as indicated by the asterisk

(*). The selection is based on the local preference value contained in the **Localpref** field. The path with the *highest* local preference is preferred. In the example, the path with the higher local preference value is the path from **R2**, 200.

The reason that the route from **R5** is not selected is in the **Inactive reason** field, in this case, **Local Preference**.

Note that the two paths are from the same neighboring network: AS 65001.

Examine the Multiple Exit Discriminator Route Selection

Purpose

To examine a route to determine if the MED is the selection criteria for the single, active path.

Action

To examine a route to determine if the MED is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.2.0 detail
```

```
inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.2.0/24 (2 entries, 1 announced)
    *BGP      Preference: 170/-101
        Source: 10.0.0.2
        Next hop: 10.1.24.1 via so-0/0/3.0, selected
        Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
        State: <Active Int Ext>
        Local AS: 65002 Peer AS: 65002
        Age: 2:32:01      Metric: 5      Metric2: 10
        Task: BGP_65002.10.0.0.2+179
        Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0
        AS path: 65001 I
        Localpref: 100
        Router ID: 10.0.0.2
    BGP      Preference: 170/-101
        Source: 10.1.45.2
        Next hop: 10.1.45.2 via so-0/0/2.0, selected
```

```

State: <NotBest Ext>
  Inactive reason: Not Best in its group
Local AS: 65002 Peer AS: 65001
Age: 2w0d 1:37:58      Metric: 10
Task: BGP_65001.10.1.45.2+179
  AS path: 65001 I
Localpref: 100
Router ID: 10.0.0.5

```

Meaning

The sample output shows that **R4** received two instances of the **100.100.2.0** route: one from **10.0.0.2 (R2)**, and one from **10.1.45.2 (R5)**. **R4** selected the path from **R2** as its active route, as indicated by the asterisk (*). The selection is based on the MED value contained in the **Metric:** field. The path with the lowest MED value is preferred. In the example, the path with the lowest MED value (5) is the path from **R2**. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path is not selected is displayed in the **Inactive reason:** field, in this case, **Not Best in its group**. The wording is used because the Junos OS uses the process of deterministic MED selection, by default.

Examine the EBGW over IBGP Selection

Purpose

To examine a route to determine if EBGW is selected over IBGP as the selection criteria for the single, active path.

Action

To examine a route to determine if EBGW is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.3.0 detail
```

```

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.3.0/24 (2 entries, 1 announced)

```

```

*BGP      Preference: 170/-101
          Source: 10.1.45.2

          State: <Active Ext>
          Local AS: 65002 Peer AS: 65001
          Age: 5d 0:31:25
          Task: BGP_65001.10.1.45.2+179
          Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0
          AS path: 65001 I
          Localpref: 100
          Router ID: 10.0.0.5
BGP      Preference: 170/-101
          Source: 10.0.0.2
          Next hop: 10.1.24.1 via so-0/0/3.0, selected
          Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
          State: <NotBest Int Ext>
          Inactive reason: Interior > Exterior > Exterior via Interior
          Local AS: 65002 Peer AS: 65002
          Age: 2:48:18      Metric2: 10
          Task: BGP_65002.10.0.0.2+179
          AS path: 65001 I
          Localpref: 100
          Router ID: 10.0.0.2

```

Meaning

The sample output shows that **R4** received two instances of the **100.100.3.0** route: one from **10.1.45.2 (R5)** and one from **10.0.0.2 (R2)**. **R4** selected the path from **R5** as its active path, as indicated by the asterisk (*). The selection is based on a preference for routes learned from an EBGp peer over routes learned from an IBGP. **R5** is an EBGp peer.

You can determine if a path is received from an EBGp or IBGP peer by examining the **Local As** and **Peer As** fields. For example, the route from **R5** shows the local AS is 65002 and the peer AS is 65001, indicating that the route is received from an EBGp peer. The route from **R2** shows that both the local and peer AS is 65002, indicating that it is received from an IBGP peer.

The reason that the inactive path is not selected is displayed in the **Inactive reason** field, in this case, **Interior > Exterior > Exterior via Interior**. The wording of this reason shows the order of preferences applied when the same route is received from two routers. The route received from a strictly internal source (IGP) is preferred first, the route received from an external source (EBGP) is preferred next, and any route which comes from an external source and is received internally (IBGP) is preferred last.

Examine the IGP Cost Selection

Purpose

To examine a route to determine if EBGp is selected over IBGP as the selection criteria for the single, active path.

Action

To examine a route to determine if EBGp is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R6> show route 100.100.4.0 detail
```

```
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
100.100.4.0/24 (2 entries, 1 announced)
  *BGP      Preference: 170/-101
    Source: 10.0.0.4
      Next hop: 10.1.46.1 via so-0/0/1.0, selected
      Protocol next hop: 10.0.0.4 Indirect next hop: 864c000 276
      State: <Active Int Ext>

```

```

AS path: 65001 |
Localpref: 100
Router ID: 10.0.0.2

```

Meaning

The sample output shows that **R6** received two instances of the **100.100.4.0** route: one from **10.0.0.4 (R4)** and one from **10.0.0.2 (R2)**. **R6** selected the path from **R4** as its active route, as indicated by the asterisk (*). The selection is based on the IGP metric, displayed in the **Metric2** field. The route with the lowest IGP metric is preferred. In the example, the path with the lowest IGP metric value is the path from **R4**, with an IGP metric value of 10, while the path from **R2** has an IGP metric of 20. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path was not selected is displayed in the **Inactive reason** field, in this case, **IGP metric**.

Examine the Local Preference Selection

Purpose

To examine a route to determine if local preference is the selection criteria for the single, active path.

Action

To examine a route to determine if local preference is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.1.0 detail
```

```

inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.1.0/24 (2 entries, 1 announced)
    *BGP      Preference: 170/-201
              Source: 10.0.0.2
              Next hop: 10.1.24.1 via so-0/0/3.0, selected
              Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
              State: <Active Int Ext>

```

```

Local AS: 65002 Peer AS: 65002

Next hop: 10.1.45.2 via so-0/0/2.0, selected
State: <Ext>
Inactive reason: Local Preference
Local AS: 65002 Peer AS: 65001
Age: 2w0d 1:28:31      Metric: 10
Task: BGP_65001.10.1.45.2+179
AS path: 65001 I
Localpref: 100
Router ID: 10.0.0.5

```

Meaning

The sample output shows that **R4** received two instances of the **100.100.1.0** route: one from **10.0.0.2 (R2)** and one from **10.1.45.2 (R5)**. **R4** selected the path from **R2** as its active path, as indicated by the asterisk (*). The selection is based on the local preference value contained in the **Localpref** field. The path with the *highest* local preference is preferred. In the example, the path with the higher local preference value is the path from **R2**, 200.

The reason that the route from **R5** is not selected is in the **Inactive reason** field, in this case, **Local Preference**.

Note that the two paths are from the same neighboring network: AS 65001.

Examine the Multiple Exit Discriminator Route Selection

Purpose

To examine a route to determine if the MED is the selection criteria for the single, active path.

Action

To examine a route to determine if the MED is the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.2.0 detail
```

```
inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.2.0/24 (2 entries, 1 announced)
    *BGP      Preference: 170/-101
        Source: 10.0.0.2
        Next hop: 10.1.24.1 via so-0/0/3.0, selected
        Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
        State: <Active Int Ext>
        Local AS: 65002 Peer AS: 65002
        Age: 2:32:01      Metric: 5      Metric2: 10
        Task: BGP_65002.10.0.0.2+179
        Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0
        AS path: 65001 I
        Localpref: 100
        Router ID: 10.0.0.2
    BGP      Preference: 170/-101
        Source: 10.1.45.2
        Next hop: 10.1.45.2 via so-0/0/2.0, selected
        State: <NotBest Ext>
        Inactive reason: Not Best in its group
        Local AS: 65002 Peer AS: 65001
        Age: 2w0d 1:37:58      Metric: 10
        Task: BGP_65001.10.1.45.2+179
        AS path: 65001 I
        Localpref: 100
        Router ID: 10.0.0.5
```

Meaning

The sample output shows that **R4** received two instances of the **100.100.2.0** route: one from **10.0.0.2 (R2)**, and one from **10.1.45.2 (R5)**. **R4** selected the path from **R2** as its active route, as indicated by the asterisk (*). The selection is based on the MED value contained in the **Metric:** field. The path with the lowest MED value is preferred. In the example, the path with the lowest MED value (5) is the path from **R2**. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path is not selected is displayed in the **Inactive reason:** field, in this case, **Not Best in its group**. The wording is used because the Junos OS uses the process of deterministic MED selection, by default.

Examine the EBGp over IBGP Selection

Purpose

To examine a route to determine if EBGp is selected over IBGP as the selection criteria for the single, active path.

Action

To examine a route to determine if EBGp is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

```
user@R4> show route 100.100.3.0 detail
```

```
inet.0: 20 destinations, 24 routes (20 active, 0 holddown, 0 hidden)
100.100.3.0/24 (2 entries, 1 announced)
    *BGP      Preference: 170/-101
        Source: 10.1.45.2
        Next hop: 10.1.45.2 via so-0/0/2.0, selected
        State: <Active Ext>
        Local AS: 65002 Peer AS: 65001
        Age: 5d 0:31:25
        Task: BGP_65001.10.1.45.2+179
        Announcement bits (3): 0-KRT 3-BGP.0.0.0.0+179 4-Resolve inet.0
        AS path: 65001 I
        Localpref: 100
        Router ID: 10.0.0.5
    BGP      Preference: 170/-101
        Source: 10.0.0.2
        Next hop: 10.1.24.1 via so-0/0/3.0, selected
        Protocol next hop: 10.0.0.2 Indirect next hop: 8644000 277
        State: <NotBest Int Ext>
```

Inactive reason: Interior > Exterior > Exterior via Interior

Local AS: 65002 Peer AS: 65002

Age: 2:48:18 Metric2: 10

Task: BGP_65002.10.0.0.2+179

AS path: 65001 I

Localpref: 100

Router ID: 10.0.0.2

Meaning

The sample output shows that **R4** received two instances of the **100.100.3.0** route: one from **10.1.45.2 (R5)** and one from **10.0.0.2 (R2)**. **R4** selected the path from **R5** as its active path, as indicated by the asterisk (*). The selection is based on a preference for routes learned from an EBGp peer over routes learned from an IBGP. **R5** is an EBGp peer.

You can determine if a path is received from an EBGp or IBGP peer by examining the **Local As** and **Peer As** fields. For example, the route from **R5** shows the local AS is 65002 and the peer AS is 65001, indicating that the route is received from an EBGp peer. The route from **R2** shows that both the local and peer AS is 65002, indicating that it is received from an IBGP peer.

The reason that the inactive path is not selected is displayed in the **Inactive reason** field, in this case, **Interior > Exterior > Exterior via Interior**. The wording of this reason shows the order of preferences applied when the same route is received from two routers. The route received from a strictly internal source (IGP) is preferred first, the route received from an external source (EBGP) is preferred next, and any route which comes from an external source and is received internally (IBGP) is preferred last.

Examine the IGP Cost Selection

Purpose

To examine a route to determine if EBGp is selected over IBGP as the selection criteria for the single, active path.

Action

To examine a route to determine if EBGp is selected over IBGP as the selection criteria for the single, active path, enter the following Junos OS CLI operational mode command:

```
user@host> show route destination-prefix < detail >
```

Sample Output

user@R6> show route 100.100.4.0 detail

```
inet.0: 18 destinations, 20 routes (18 active, 0 holddown, 0 hidden)
100.100.4.0/24 (2 entries, 1 announced)

              AS path: 65001 I
              Localpref: 100
              Router ID: 10.0.0.2
```

Meaning

The sample output shows that **R6** received two instances of the **100.100.4.0** route: one from **10.0.0.4 (R4)** and one from **10.0.0.2 (R2)**. **R6** selected the path from **R4** as its active route, as indicated by the asterisk (*). The selection is based on the IGP metric, displayed in the **Metric2** field. The route with the lowest IGP metric is preferred. In the example, the path with the lowest IGP metric value is the path from **R4**, with an IGP metric value of 10, while the path from **R2** has an IGP metric of 20. Note that the two paths are from the same neighboring network: AS 65001.

The reason that the inactive path was not selected is displayed in the **Inactive reason** field, in this case, **IGP metric**.

Examine Routes in the Forwarding Table

Purpose

When you run into problems, such as connectivity problems, you may need to examine routes in the forwarding table to verify that the routing protocol process has relayed the correct information into the forwarding table.

Action

To display the set of routes installed in the forwarding table, enter the following Junos OS CLI operational mode command:

```
user@host> show route forwarding-table
```

Sample Output

```
user@R2> show route forwarding-table
```

```
Routing table: inet
Internet:
Destination          Type RtRef Next hop          Type Index NhRef Netif

[...Output truncated...]

```

Meaning

The sample output shows the network-layer prefixes and their next hops installed in the forwarding table. The output includes the same next-hop information as in the **show route detail** command (the next-hop address and interface name). Additional information includes the destination type, the next-hop type, the number of references to this next hop, and an index into an internal next-hop database. (The internal database contains additional information used by the Packet Forwarding Engine to ensure proper encapsulation of packets sent out an interface. This database is not accessible to the user.

For detailed information about the meanings of the various flags and types fields, see the [Routing Policies, Firewall Filters, and Traffic Policers User Guide](#).

Ping the Egress Router

Purpose

Ping the egress router to confirm that communication over the network is operational.

Action

To ping the egress router, enter the following Junos OS CLI operational mode command:

```
user@host> ping ip-address-interface
```

Sample Output

```

[edit protocols mpls]
user@R1# run ping 10.1.56.1
PING 10.1.56.1 (10.1.56.1): 56 data bytes
64 bytes from 10.1.56.1: icmp_seq=0 ttl=255 time=0.837 ms
64 bytes from 10.1.56.1: icmp_seq=1 ttl=255 time=0.792 ms
64 bytes from 10.1.56.1: icmp_seq=2 ttl=255 time=0.856 ms
^C
--- 10.1.56.1 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.792/0.828/0.856/0.027 ms

```

Meaning

The sample output confirms that communication between router **R1** and the IP address of the relevant interface on router **R5 (10.1.56.1)** is operational.

View the RSVP Log File on Transit Routers

Purpose

Transit router messages that appear in the RSVP log file can help you analyze the problem with an RSVP session. You may need to issue the **clear rsvp session** and **clear log filename** commands to ensure that your records are current. However, if your network is large with many RSVP sessions, this may not be advisable because it may take a while for all sessions to reestablish. However, the **clear rsvp session** command has various options you can include to minimize the effect on your network. For more information about the **clear rsvp session** command, see the *Junos Routing Protocols and Policies Command Reference*.

Action

To view the RSVP log file, enter the following Junos OS CLI operational mode commands:

```
user@host> clear rsvp session (Optional)
user@host> clear log filename (Optional)
user@host> show log filename
```

Sample Output 1

```
user@R3> clear rsvp session

user@R3> clear log rsvp-log

user@R3> show log rsvp-log

Meaning

Sample Output 1 from transit router **R3** shows that **R3 (so-0/0/2.0)** correctly received a Path request message (**recv Path**) from **R1**, and correctly sent the Path message (**send Path**) through interface **so-0/0/3.0** to **R6**. The route record object (**RecRoute**) indicates the list of addresses this Path message transited, in this case, **10.1.36.1** and **10.1.13.1**.

Sample Output 2 from transit router **R6** shows that **R6 (so-0/0/3.0)** correctly received a Path request message (**recv Path**) from **R3**, and correctly sent the Path message (**send Path**) through interface **so-0/0/0** to **R5**. The route record object (**RecRoute**) indicates the list of addresses this Path message transited, in this case, **10.1.56.2**, **10.1.36.1**, and **10.1.13.1**.

With the information above, the focus shifts to egress router **R5** as the source of the problem, with indications that **R5** ignored the RSVP message.

Check the RSVP Log File on the Egress Router

Purpose

After placing an RSVP tracing configuration on router **R5** similar to that on routers **R3** and **R6**, display the RSVP log file for useful information about the problem on router **R5**.

Action

To check the RSVP log file, enter the following Junos OS CLI operational mode command:

```
user@host> show log rsvp-log
```

Sample Output

```

user@R5> show log rsvp-log
Jul 21 10:53:16 R5 clear-log[40071]: logfile cleared

```

```

Jul 21 11:02:37 trace_on: Tracing to "/var/log/rsvp-log" started
Jul 21 11:03:07 RSVP error, send to DISABLED interface ? Hello New
10.1.56.1->10.1.56.2 Len=8  so-0/0/0.0

```

Meaning

The sample output shows that **R5** did not receive the Path message because of a disabled interface, **so-0/0/0.0**.

Determine and Correct the Problem on the Egress Router

Problem

Description: Check the configuration of interface **so-0/0/0.0** on egress router **R5** to determine the reason it was disabled.

Solution

To determine the problem on **R5**, enter the following Junos OS CLI commands:

```

user@R5> show configuration protocols rsvp
user@R5> edit
[edit protocols rsvp]
user@R5# rename interface so-0/0/3 to interface so-0/0/0
user@R5# show
user@R5# commit
user@R5# run show rsvp session ingress detail

```

Sample Output 1

```

user@R5> show configuration protocols rsvp
traceoptions {
  file rsvp-log;
  flag error detail;
  flag path detail;
  flag pathtear detail;
}
interface so-0/0/3.0;      <<< so-0/0/3 incorrectly included
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {

```

```

    disable;
}

```

Sample Output 2

```

[edit protocols rsvp]
user@R5# rename interface so-0/0/3 to interface so-0/0/0

[edit protocols rsvp]
user@R5# show
traceoptions {
    file rsvp-log;
    flag packets detail;
    flag error detail;
}
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

[edit protocols rsvp]
user@R5# commit
commit complete

```

Sample Output 3

```

[edit protocols mpls]
user@R5# run show rsvp session ingress detail
Ingress RSVP: 1 sessions

```

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.0.0.1	10.0.0.5	Up	1	1 FF	-	103104	R5-to-R1

```

Total 1 displayed, Up 1, Down 0
Egress RSVP: 1 sessions

```

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.0.0.5	10.0.0.1	Up	0	1 FF	3	-	R1-to-R5

```

Total 1 displayed, Up 1, Down 0

```

```
Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Meaning

Sample Output 1 from egress router **R5** shows three interfaces configured at the `[edit protocols rsvp]` hierarchy level, none of which is **so-0/0/0.0**. On examination of the network topology, it is apparent that the **so-0/0/0.0** interface was configured incorrectly as **so-0/0/3.0**.

Sample Output 2 shows the correct configuration of interfaces at the `[edit protocols rsvp]` hierarchy level, and the **rename** command issued to correct the configuration error.

Sample Output 3 shows that the RSVP-signaled LSP (**R1-to-R5**) is correctly established after the changes to the RSVP configuration are committed.

Check the Routing CPU Memory Usage

Purpose

Software processes on the router can consume a considerable amount of CPU and memory. The routing protocol process (rpd) can consume enormous amounts of memory to store information needed for the operation of routing and related protocols, such as Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), Intermediate System-to-Intermediate System (ISIS), Resource Reservation Protocol (RSVP), Label Distribution Protocol (LDP), and Multiprotocol Label Switching (MPLS).

To verify the traffic passing through the router and check memory utilization, follow these steps:

1. [Check Overall CPU and Memory Usage | 2439](#)
2. [Check Routing Protocol Process \(rpd\) Memory Usage | 2442](#)
3. [Display Tasks | 2446](#)

Check Overall CPU and Memory Usage

Purpose

You can display exhaustive system process information about software processes that are running on the router and have controlling terminals. This command is equivalent to the UNIX **top** command. However, the UNIX **top** command shows real-time memory usage, with the memory values constantly changing, while the **show system processes extensive** command provides a snapshot of memory usage in a given moment.

Action

To check overall CPU and memory usage, enter the following Junos OS command-line interface (CLI) command:

```
user@host> show system processes extensive
```

Sample Output

```
user@R1> show system processes extensive
```

```
last pid: 5251; load averages: 0.00, 0.00, 0.00 up 4+20:22:16 10:44:41
```

```
58 processes: 1 running, 57 sleeping
```

```
Mem: 57M Active, 54M Inact, 17M Wired, 184K Cache, 35M Buf, 118M Free
```

```
Swap: 512M Total, 512M Free
```

```

Meaning

The sample output shows the amount of virtual memory used by the Routing Engine and software processes. For example, 118 MB of physical memory is free and 512 MB of the swap file is free, indicating that the router is not short of memory. The **processes** field shows that most of the 58 processes are in the **sleeping** state, with 1 in the **running** state. The process or command that is running is the **top** command.

The **commands** column lists the processes that are currently running. For example, the chassis process (chassisd) has a process identifier (**PID**) of 4480, with a current priority (**PRI**) of 2. A lower priority number indicates a higher priority.

The processes are listed according to level of activity, with the most active process at the top of the output. For example, the chassis (chassisd) process is consuming the largest amount of CPU resource at 2.34 percent.

The memory field (**Mem**) shows the virtual memory managed by the Routing Engine and used by processes. The value in the memory field is in KB and MB, and is broken down as follows:

- **Active**—Memory that is allocated and actually in use by programs.
- **Inact**—Memory that is either allocated but not recently used or memory that was freed by programs. Inactive memory is still mapped in the address space of one or more processes and, therefore, counts toward the resident set size of those processes.
- **Wired**—Memory that is not eligible to be swapped, and is usually used for Routing Engine memory structures or memory physically locked by a process.
- **Cache**—Memory that is not associated with any program and does not need to be swapped before being reused.
- **Buf**—The size of the memory buffer used to hold data recently called from disk.
- **Free**—Memory that is not associated with any programs. Memory freed by a process can become **Inactive**, **Cache**, or **Free**, depending on the method used by the process to free the memory.

When the system is under memory pressure, the pageout process reuses memory from the free, cache, inactive and, if necessary, active pages.

The **Swap** field shows the total swap space available and how much is unused. In the example, the output shows 512 MB of total swap space and 512 MB of free swap space.

Finally, the memory usage of each process is listed. The **SIZE** field indicates the size of the virtual address space, and the **RES** field indicates the amount of the program in physical memory, which is also known as RSS or Resident Set Size. In the sample output, the chassis (chassisd) process has 3728 KB of virtual address space and 1908 KB of physical memory.

Check Routing Protocol Process (rpd) Memory Usage

Purpose

When you notice a lot of memory usage, you can obtain detailed information about the memory utilization of routing tasks to get an idea of what is going on. The routing process (rpd) is the main task that uses Routing Engine memory.

Action

To check routing process memory usage, enter the following Junos OS CLI operational mode commands:

```
user@host> show route summary
user@host> show task memory detail
```

Sample Output

user@host> **show route summary**

```

Autonomous system number: 209
Router ID: 205.175.0.170
inet.0: 179783 destinations, 898393 routes (179771 active, 146 holddown, 157 hidden)

      Direct:      17 routes,      17 active
      Local:      18 routes,      18 active

Meaning

The sample output shows summary statistics about the entries in the routing table (**show route summary** command) and the memory usage breakdown (**show task memory detail** command) for the routing process (rpd). The two commands provide a comprehensive picture of the memory utilization of the routing protocol process.

The **show route summary** command shows the number of routes in the various routing tables. In the sample output, the routing tables represented are **inet.0**, **inet.2**, **inet.3**, **iso.0**, and **mpls.0**. Within each routing table, all of the active, hold-down, and hidden destinations and routes are summarized for all the protocols from which routes are learned. Routes are in the **hold-down** state prior to being declared inactive, and **hidden** routes are not used because of routing policy. Routes in the **hold-down** and **hidden** states are still using memory because they appear in the routing table.

In addition, routes are summarized in the following categories: those directly connected to the network (**Direct**), local routes (**Local**), and routes learned from configured routing protocols, such as BGP and IS-IS.

The **show task memory detail** command lists the data structures within the tasks run by the routing protocol process (rpd). Tasks are enabled depending on the router's configuration. For example, **isis_area_addr** is a data structure resulting from the IS-IS configuration. The **AllocBytes** field indicates the highest amount of memory used by the data structure. For example, the **isis_area_addr** data structure has 544 blocks of allocated memory, each block is allocated a value of 16 bytes, resulting in allocated bytes of 8704. The maximum allocated blocks and bytes are high-water marks for a data structure. For more information on displaying task-related information, see ["Display Tasks" on page 2446](#).

The **Total bytes in use** field shows the total amount of memory used by the routing protocol process (rpd).

Display Tasks

Purpose

You can display information about tasks to further your investigation of a memory problem on the router.

Action

To display a list of tasks that are enabled on the router, enter the following Junos OS CLI operational mode commands:

```
user@host> show task
user@host> show task memory
user@host> show task task-name
```

Sample Output

```
user@R1> show task
```

```

Meaning

The sample output shows a list of routing, routing protocol, and interface tasks that are currently running on the router (**show task**), a summary of memory utilization (**show task memory**), and the memory utilization of a particular task (**show task io**). Tasks can be baseline tasks performed regardless of the router configuration, and other tasks that depend on the router configuration. For example, the **BGP_Group_internal** task is the result of the configuration of BGP on the router, while the **INET6** task is a base task associated with the routing process (rpd).

Each task in the **show task** command output has a priority and a task name. For example, the current priority is 10 for **LMP Client** and 80 for **IF Delete**. A lower number indicates a higher priority.

Some tasks have flags attached to them. For example, the **BGP.0.0.0.0+179** task has two flags, **Accept** and **LowPrio**. The **Accept** flag indicates that the task is waiting for incoming connections, and the **LowPrio** flag indicates that the task will be dispatched to read its socket after other, higher priority tasks. Two additional flags are **Connect**, which indicates that a task is waiting for a connection to complete, and **Delete**, which indicates that a task has been deleted and is being cleaned up.

The **show task io** command shows the statistics gathered for each IO operation. The counters show the following:

- **Reads**—This counter increments when a datagram arrives on a connected socket of the task and the task's read callback is called.
- **Writes**—This counter increments when a connected socket of a task becomes writable and the task's callback is called.
- **Rcvd**—This counter increments when the task calls the Routing Engine to read a datagram from a socket which may or may not be connected.
- **Sent**—This counter increments when a task attempts to read or write a datagram on an existing or nonexisting socket.
- **Drops**—This counter increments when a task attempts to read or write a datagram through the Routing Engine on a prebuilt socket, but the request fails for any reason.

Run Snmpwalk from an NMS System to a Juniper Router

Purpose

Snmpwalk is an SNMP application that you can use to query a MIB for information about the functioning of a router in your network. Snmpwalk uses **GetNext** requests to retrieve the specified information. Object identifiers (OIDs) are used to query the MIB. If the OID argument is not present, Snmpwalk searches MIB-2.

Action

To run Snmpwalk for a specific OID, from a management station that has access to the router, and using a tool such as Snmpwalk, enter the following command:

```
user-nms# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```
user-nms % snmpwalk -Os -M /volume/~mibs -m all tp1 public .1.3.6.1.2.1.4
ipForwarding.0 = forwarding(1)
ipDefaultTTL.0 = 64
ipInReceives.0 = Counter32: 9262713
ipInHdrErrors.0 = Counter32: 0
ipInAddrErrors.0 = Counter32: 0
ipForwDatagrams.0 = Counter32: 614171
ipInUnknownProtos.0 = Counter32: 0
ipInDiscards.0 = Counter32: 0
ipInDelivers.0 = Counter32: 8648408
ipOutRequests.0 = Counter32: 1226483
ipOutDiscards.0 = Counter32: 0
```

```

ipOutNoRoutes.0 = Counter32: 0
ipReasmTimeout.0 = 60
ipReasmReqds.0 = Counter32: 0
ipReasmOKs.0 = Counter32: 0
ipReasmFails.0 = Counter32: 0
ipFragOKs.0 = Counter32: 0
ipFragFails.0 = Counter32: 0
ipFragCreates.0 = Counter32: 0
ipAdEntAddr.10.0.0.1 = IPAddress: 10.0.0.1
ipAdEntAddr.10.1.12.1 = IPAddress: 10.1.12.1
ipAdEntAddr.10.1.15.1 = IPAddress: 10.1.15.1
ipAdEntAddr.10.168.70.143 = IPAddress: 10.168.70.143
[...Output truncated...]

```

Meaning

The sample output shows that the user is on a network management station (**user-nms %**) that has access to the router, **tp1**. In the command, the following options are used:

- **Os**—Deletes all but the last symbolic part of the OID **sysUpTime.0**. For example, Timeticks: (14096763) 1 day, 15:09:27.63.
- **-M**—Compiles the MIB and gives a path or location to the MIBs.
- **-m**—Uses the files in the directory pointed to by the **-M** option.
- **all**—Uses all the files in the directory pointed to by the **-M** option.

In addition, the command includes the hostname **tp1**, the community string **public**, and the OID **.1.3.6.1.2.1.4**.

The OID in this example is from RFC 2096, *IP Forwarding Table MIB*, which displays multipath IP routes that have the same network number but different network masks.

Before you can retrieve SNMP information from a router, you must have the minimum SNMP configuration for that router. Following is the minimum SNMP configuration required:

```

[edit]
snmp {
    community public {
        authorization read-only;
    }
}

```

With this configuration, the system responds to SNMP **Get**, **GetNext**, and **GetBulk** commands that contain the community string **public**.

For more detailed information on configuring SNMP on a router, see the *Junos Network Management Configuration Guide*.

Configure Trace Operations for SNMP

Purpose

Define tracing for SNMP to access more granular information about the packets sent and received through SNMP.

Action

To configure SNMP tracing operations, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit snmp
```

2. Configure trace operations:

```
[edit snmp]
user@R1# set traceoptions flag pdu
```

3. Commit the configuration:

```
user@R1# commit and-quit
commit complete
Exiting configuration mode
```

Sample Output

```
user@R1> show configuration snmp
```

```
view all {
  oid .1 include;
}
view system {
  oid system;
}
community public {
  view all;
  authorization read-only;
```

```

}
community private {
    view system;
    authorization read-write;
}
traceoptions {
    flag pdu;
}

```

Meaning

The sample output shows a configuration for SNMP that includes traceoptions. The **pdu** flag is configured, which results in the generation of SNMP request and response packets. The output for the tracing operation is placed into various log files in the **/var/log** directory.

Protocol-specific tracing operations override any equivalent operations that you specify in the global **traceoptions** statement. If there are no equivalent operations, they supplement the global tracing options. If you do not specify any protocol-specific tracing, the routing protocol inherits all the global tracing operations.

Query a MIB With SNMPGet

Purpose

Send an SNMP request to check that the SNMP configuration is correct.

Action

To query a MIB with **SNMPGet**, enter the following command:

```
user@nms % snmpget hostname community oid
```

Sample Output

```

user-nms % snmpget tp1 public .1.3.6.1.2.1.1.0
system.sysDescr.0 = m7i internet router, kernel 6.0R1.5

user-nms % snmpget tp1 public sysDescr.0
system.sysDescr.0 = m7i internet router, kernel 6.0R1.5

```

Meaning

The sample output shows a query from a network management station (**nms**) for the description of the system running on the router **tp1**. The OID is entered in numerical form in the command line, and a description (**sysDescr.0**) is obtained in the output. You can also use **sysDescr.0** in the command line to obtain the same output.

Check CPU Utilization

Purpose

The enterprise-specific chassis MIB provides information about the router and its components. Within the chassis MIB, the **jnxMIBs** branch contains one main subbranch, **jnxBoxAnatomy**, which in turn contains a section, **jnxOperatingTable**. Within **jnxOperatingTable**, and under the **jnxOperatingEntry**, you can use the **jnxOperatingCPU** object to monitor the CPU on your router. (See [Figure 179 on page 2453](#).)

Figure 179: Chassis MIB Tree

|  |  |  +--jnxRedundancyTable(14)¶
|  |  +--jnxFruTable(15)¶

```

After each object description is a value in parenthesis, such as (1). This value can be used to enter an OID for the specific object. For example, to gather information on the CPU, you can type the object description (**jnxOperatingCPU**) or the OID (**.1.3.6.1.4.1.2636.3.1.13.1.8**).

Action

To check CPU utilization using the Juniper Networks enterprise chassis MIB, from a management station that has access to the router, and using a tool such as Snmpwalk, enter the following command:

```
user-bsd# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```
user-nms % snmpwalk -Os -M /volume/~mibs -m all tp1 public jnxOperatingCPU
jnxOperatingCPU.1.1.1.0 = Gauge32: 0
jnxOperatingCPU.1.1.2.0 = Gauge32: 0

jnxOperatingDescr.6.1.2.0 = CFEB Internet Processor Ilv1
jnxOperatingDescr.7.1.0.0 = FPC @ 0/*/*
jnxOperatingDescr.7.2.0.0 = FPC @ 1/*/*
jnxOperatingDescr.8.1.1.0 = PIC: 4x OC-3 SONET, MM @ 0/0/*
```

```
jnxOperatingDescr.8.2.3.0 = PIC: 1x Tunnel @ 1/2/*
jnxOperatingDescr.8.2.4.0 = PIC: 1x G/E, 1000 BASE-SX @ 1/3/*
jnxOperatingDescr.9.1.0.0 = Routing Engine
jnxOperatingDescr.9.1.1.0 = Routing Engine PCMCIA Card
```

Meaning

The sample output shows the percentage CPU utilization on router, **tp1**. The Routing Engine (**9.1.0.0**) has 6 percent CPU utilization, the two CFEB Internet Processors **Ilv1** (**6.1.1.0** and **6.1.2.0**) have 22 percent each, and the FPCs (**7.1.0.0** and **7.2.0.0**) have 2 percent each. Components with a value of zero indicate that the information is either unavailable or inapplicable.

The output for the **jnxOperatingDesc** object provides a description of the separate instances in the **jnxOperatingCPU** object. For example, **9.1.0.0** represents the Routing Engine.

Check CPU Utilization per Process

Purpose

The standard system application MIB (RFC 2287, *Definitions of System-Level Managed Objects for Applications*), describes a set of managed objects that are restricted to information that can be determined from the system itself. The object **sysAppElmtRunCPU** provides information about applications and associated elements that have run or are currently running on the host system. (See [Figure 180 on page 2456](#).)

```

Meaning

The sample output shows the number of centi-seconds of total system CPU resources consumed by a particular process. For example, the chassis process (**chassisd**, **3.2.2163**) has consumed 3 days, or 33,548,776 centi-seconds of total system CPU resources.

The **sysAppElmtRunName** object retrieves the name of the OID. For example, **sysAppElmtRunCPU.3.2.2163** represents the chassis process.

Retrieve Version Information about Router Software Components

Purpose

RFC 2790, *Host Resources MIB*, describes a set of managed objects that are useful for managing host systems, including routers.

Action

To retrieve version information about software components on the router, from a management station that has access to the router and using a tool, such as Snmpwalk, enter the following command:

```
user-bsd# snmpwalk [common arguments] hostname community object-id
```

Sample Output

```

user-nms % snmpwalk -Os -M /volume/~/.mibs -m all tp1 public.1.3.6.1.2.1.25.6.3hrSWInstalledIndex.2
= 2
hrSWInstalledIndex.3 = 3
hrSWInstalledIndex.4 = 4
hrSWInstalledIndex.5 = 5
hrSWInstalledIndex.6 = 6

```

```

Meaning

The sample output shows the version information for various software components on the router.

Checklist for Displaying Basic Chassis Information

Purpose

[Table 70 on page 2461](#) provides links and commands for displaying basic chassis information, including a list of all Flexible PIC Concentrators (FPCs) and Physical Interface Cards (PICs) installed in the router chassis, the hardware version level, and the serial number.

Action

Table 70: Checklist for Displaying Basic Chassis Information

Task	Command or Action
“Display Basic Chassis Information” on page 2461	<code>show chassis hardware <detail></code>

Display Basic Chassis Information

Purpose

Before you return a router component to Juniper Networks, you must contact the Juniper Networks Technical Assistance Center (JTAC) with the serial number of the failed component and failure information. JTAC will then grant a Return Materials Authorization (RMA).

Action

To display a list of the serial numbers of components installed in the router chassis, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show chassis hardware <detail>
```

Sample Output

```
user@host> show chassis hardware
```

```

SDRAM bank 0	REV 01	710-000099	0003803	64 Mbytes
SDRAM bank 1	REV 01	710-000099	0003847	64 Mbytes
PIC 0	REV 03	750-002914	BC0131	2x OC-3 ATM, MM

Meaning

The sample output is for an M20 and an M40 router. It shows a list of all FPCs and PICs installed in the router chassis, including the hardware version level and serial number.

The **detail** option displays detailed information about hardware, including memory, hardware version level, serial number, and additional information about memory.

If the Routing Engine is identified by a 10- and 16-digit serial number, both numbers are displayed in the output for the **detail** option, and are especially important when processing an RMA for such a Routing Engine. In addition, when you request an RMA for the M40 router, include the **maxicab** serial number.

[Table 71 on page 2463](#) provides a description of all the output fields for the **show chassis hardware** command.

Table 71: Output fields for the show chassis hardware command

Output field	Description
Item	<p>(For M-series routers) Chassis component. Information is displayed about the backplane; power supplies; Routing Engine; maxicab (the connection between the Routing Engine and the backplane, for the M40 router only); System Control Board (SCB), System and Switch Board (SSB), Switching and Forwarding Module (SFM), or Forwarding Engine Board (FEB); Miscellaneous Control Subsystem (MCS) and PFE clock generator (PCG) (for the M160 router only); and each FPC and PIC.</p> <p>(For T-series platforms) Chassis component. Information is displayed about the backplane, power supplies, midplane, Control Board (CB), Connector Interface Panel (CIP), FPC, Front Panel Module (FPM) (craft interface), Power Entry Module (PEM), PIC, SONET Clock Generator (SCG), Small Form-factor Pluggable (SFP) modules, Switch Interface Board (SIB), and Switch Processor Mezzanine Board (SPMB).</p>
Version	Revision level of the chassis component.
Part number	Part number of the chassis component.

Table 71: Output fields for the show chassis hardware command (continued)

Output field	Description
Serial number	Serial number of the chassis component. For all RMAs, the chassis serial number must be provided to JTAC. If the RMA is for the chassis itself, you must obtain the backplane or midplane serial number as well.
Description	Brief description of the hardware item.

NOTE: When you request an RMA, you must also include output from the **show chassis environment** command, the **show version** command, and the troubleshooting output used to identify the failure.

Maintain a Single Configuration File for Both Routing Engines

Purpose

For routers that support multiple Routing Engines, you can specify **re0** and **re1** as group names to ensure that the correct IP addresses are used for each Routing Engine and to maintain a single configuration file for both Routing Engines. It is important that the names of the Routing Engines correspond to a slot position because the names **re0** and **re1** are special group names that you must use for the Routing Engines to recognize which configuration statement to use. Routing Engine 0 must be in slot position 0 and must be named **re0**, and Routing Engine 1 must be in slot position 1 and must be named **re1**.

To maintain a single configuration file for both Routing Engines, follow these steps:

1. [Configure the New Group | 2464](#)
2. [Apply the New Group | 2466](#)

Configure the New Group

Purpose

Each **re0** or **re1** group typically contains, at a minimum, the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Action

To configure the **re0** and **re1** groups, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]  
user@host# edit groups
```

2. Configure the group:

```
[edit groups]  
user@host# set group-name
```

For example:

```
[edit groups]  
user@host# set re0
```

3. To configure the management interface, go to the following hierarchy level:

```
[edit groups]  
user@host# edit groups re0
```

4. Include the following statement:

```
[edit groups re0]  
user@host# set interfaces interface-name unit unit family inet address address
```

For example:

```
[edit groups re0]  
user@host# set interfaces fxp0 unit 0 family inet address 1.1.1.1/24
```

5. To configure the hostname, go to the following hierarchy level:

```
[edit groups re0]  
user@host# edit groups re0 system
```

6. Include the following statement:

```
[edit groups re0 system]  
user@host# set host-name hostname
```

For example:

```
[edit groups re0 system]
user@host# set host-name foo-re0
```

7. Verify the configuration:

```
[edit groups re0]
user@host# show
re0 {
  system {
    host-name foo-re0;
  }
  interfaces {
    fxp0 {
      unit 0 {
        family inet {
          address 1.1.1.1/24;
        }
      }
    }
  }
}
```

8. Commit the configuration:

```
user@host# commit
```

9. Repeat Step 1 through Step 8 for the **re1** group.

Meaning

The sample output in Step 7 shows that the **re0** group contains the minimum configuration for a group, the hostname, and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Apply the New Group

Action

To apply the **re0** group to maintain a single configuration file for both Routing Engines, follow these steps:

1. In configuration mode, go to the top hierarchy level and include the following statement:

```
user@host# [edit]
```

```
user@host# set apply-groups group-name
```

For example:

```
user@host# [edit]
```

```
user@host# set apply-groups re0
```

2. Verify the configuration:

```
user@host# show
```

```
groups {
  re0 {
    system {
      host-name foo-re0;
    }
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address 1.1.1.1/24;
          }
        }
      }
    }
  }
  re1 {
    system {
      host-name foo-re1;
    }
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address 1.1.1.2/24;
          }
        }
      }
    }
  }
}
```

```
apply-groups [ re0 re1 ];
```

3. Commit the configuration:

```
user@host# commit
```

Meaning

The sample output shows that each group, **re0** and **re1**, has its own IP address that is used for each Routing Engine to maintain a single configuration file.

Configure the New Group

Purpose

Each **re0** or **re1** group typically contains, at a minimum, the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Action

To configure the **re0** and **re1** groups, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit groups
```

2. Configure the group:

```
[edit groups]
user@host# set group-name
```

For example:

```
[edit groups]
user@host# set re0
```

3. To configure the management interface, go to the following hierarchy level:

```
[edit groups]
user@host# edit groups re0
```

4. Include the following statement:

```
[edit groups re0]
user@host# set interfaces interface-name unit unit family inet address address
```

For example:

```
[edit groups re0]
user@host# set interfaces fxp0 unit 0 family inet address 1.1.1.1/24
```

5. To configure the hostname, go to the following hierarchy level:

```
[edit groups re0]
user@host# edit groups re0 system
```

6. Include the following statement:

```
[edit groups re0 system]
user@host# set host-name hostname
```

For example:

```
[edit groups re0 system]
user@host# set host-name foo-re0
```

7. Verify the configuration:

```
[edit groups re0]
user@host# show
re0 {
  system {
    host-name foo-re0;
  }
  interfaces {
    fxp0 {
      unit 0 {
        family inet {
          address 1.1.1.1/24;
        }
      }
    }
  }
}
```

8. Commit the configuration:

```
user@host# commit
```

9. Repeat Step 1 through Step 8 for the **re1** group.

Meaning

The sample output in Step 7 shows that the **re0** group contains the minimum configuration for a group, the hostname, and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group must also contain the configuration for the backup router and static routes.

Apply the New Group

Action

To apply the **re0** group to maintain a single configuration file for both Routing Engines, follow these steps:

1. In configuration mode, go to the top hierarchy level and include the following statement:

```
user@host# [edit]
```

```
user@host# set apply-groups group-name
```

For example:

```
user@host# [edit]
```

```
user@host# set apply-groups re0
```

2. Verify the configuration:

```
user@host# show
```

```
groups {
  re0 {
    system {
      host-name foo-re0;
    }
    interfaces {
      fxp0 {
```

```

        unit 0 {
            family inet {
                address 1.1.1.1/24;
            }
        }
    }
}
re1 {
    system {
        host-name foo-re1;
    }
    interfaces {
        fxp0 {
            unit 0 {
                family inet {
                    address 1.1.1.2/24;
                }
            }
        }
    }
}
}
}
apply-groups [ re0 re1 ];

```

3. Commit the configuration:

```
user@host# commit
```

Meaning

The sample output shows that each group, **re0** and **re1**, has its own IP address that is used for each Routing Engine to maintain a single configuration file.

Viewing Files and Directories on a Device Running Junos OS

IN THIS SECTION

- [Directories on the Device | 2472](#)
- [Listing Files and Directories | 2473](#)
- [Specifying Filenames and URLs | 2476](#)

Junos OS stores information in files on the device, including configuration files, log files, and device software files. This topic shows some examples of operational commands that you can use to view files and directories on a device running Junos OS.

Sections include:

Directories on the Device

The following table lists some standard directories on a device running Junos OS.

Table 72: Directories on the Device

Directory	Description
<code>/config</code>	This directory is located on the device's router's internal flash drive. It contains the active configuration (juniper.conf) and rollback files 1, 2, and 3.
<code>/var/db/config</code>	This directory is located on the router's device's hard drive and contains rollback files 4 through 49.
<code>/var/tmp</code>	This directory is located on the device's hard drive. It holds core files from the various processes on the Routing Engines. Core files are generated when a particular process crashes and are used by Juniper Networks engineers to diagnose the reason for failure.
<code>/var/log</code>	This directory is located on the device's hard drive. It contains files generated by both the device's logging function as well as the traceoptions command.

Table 72: Directories on the Device (*continued*)

Directory	Description
/var/home	This directory is located on the device's hard drive. It contains a subdirectory for each configured user on the device. These individual user directories are the default file location for many Junos OS commands.
/altroot	This directory is located on the device's hard drive and contains a copy of the root file structure from the internal flash drive. This directory is used in certain disaster recovery modes where the internal flash drive is not operational.
/altconfig	This directory is located on the device's hard drive and contains a copy of the /config file structure from the internal flash drive. This directory is also used in certain disaster recovery modes when the internal flash drive is not operational.

Listing Files and Directories

You can view the device's directory structure as well as individual files by issuing the **file** command in operational mode.

1. To get help about the **file** command, type the following:

```

user@host> file ?
Possible completions:
  <[Enter]>      Execute this command
  archive        Archives files from the system
  checksum       Calculate file checksum
  compare        Compare files
  copy           Copy files (local or remote)
  delete         Delete files from the system
  list           List file information
  rename         Rename files
  show           Show file contents
  source-address Local address to use in originating the connection
  |             Pipe through a command
user@host> file

```

Help shows that the **file** command includes several options for manipulating files.

2. Use the **list** option to see the directory structure of the device. For example, to show the files located in your home directory on the device:

```
user@host> file list
.ssh/
common
```

The default directory for the **file list** command is the home directory of the user logged in to the device. In fact, the user's home directory is the default directory for most of Junos OS commands requiring a filename.

3. To view the contents of other file directories, specify the directory location. For example:

```
user@host> file list /config
juniper.conf
juniper.conf.1.gz
juniper.conf.2.gz
juniper.conf.3.gz
```

4. You can also use the device's context-sensitive help system to locate a directory. For example:

```
user@host> file list /?
Possible completions:
  <[Enter]>          Execute this command
  <path>             Path to list

...

```

Specifying Filenames and URLs

In some CLI commands and configuration statements—including **file copy**, **file archive**, **load**, **save**, **set system login user *username* authentication load-key-file**, and **request system software add**—you can include a filename. On a routing matrix, you can include chassis information as part of the filename (for example, **lcc0**, **lcc0-re0**, or **lcc0-re1**).

You can specify a filename or URL in one of the following ways:

- **filename**—File in the user's current directory on the local flash drive. You can use wildcards to specify multiple source files or a single destination file. Wildcards are not supported in Hypertext Transfer Protocol (HTTP) or FTP.

NOTE: Wildcards are supported only by the **file (compare | copy | delete | list | rename | show)** commands. When you issue the **file show** command with a wildcard, it must resolve to one filename.

- **path/filename**—File on the local flash disk.
- **/var/filename** or **/var/path/filename**—File on the local hard disk. You can also specify a file on a local Routing Engine for a specific T640 router on a routing matrix:

```
user@host> file delete lcc0-re0:/var/tmp/junk
```

- **a:filename** or **a:path/filename**—File on the local drive. The default path is / (the root-level directory). The removable media can be in MS-DOS or UNIX (UFS) format.
- **hostname:/path/filename**, **hostname:filename**, **hostname:path/filename**, or **scp://hostname/path/filename**—File on an **scp/ssh** client. This form is not available in the worldwide version of Junos OS. The default path is the user's home directory on the remote system. You can also specify **hostname** as **username@hostname**.

- **ftp://hostname/path/filename**—File on an FTP server. You can also specify **hostname** as **username@hostname** or **username:password@hostname**. The default path is the user's home directory. To specify an absolute path, the path must start with **%2F**; for example, **ftp://hostname/%2Fpath/filename**. To have the system prompt you for the password, specify **prompt** in place of the password. If a password is required, and you do not specify the password or **prompt**, an error message is displayed:

```
user@host> file copy ftp://username@ftp.hostname.net//filename
```

```
file copy ftp.hostname.net: Not logged in.
```

```
user@host> file copy ftp://username:prompt@ftp.hostname.net//filename
```

```
Password for username@ftp.hostname.net:
```

- **http://hostname/path/filename**—File on an HTTP server. You can also specify **hostname** as **username@hostname** or **username:password@hostname**. If a password is required and you omit it, you are prompted for it.
- **re0:/path/filename** or **re1:/path/filename**—File on a local Routing Engine. You can also specify a file on a local Routing Engine for a specific T640 router on a routing matrix:

```
user@host> show log lcc0-re1:chassisd
```

Display File Contents

Purpose

To display the contents of a file on the local router.

Action

To display the contents of a file on the local router, use the following CLI operational mode command:

```
user@host> file show filename
```

Sample Output

```
user@host> file show /var/log/messages
```

```

Apr 13 21:00:08 romney /kernel: so-1/1/2: loopback suspected; going to standby.
Apr 13 21:00:40 romney /kernel: so-1/1/2: loopback suspected; going to standby.
Apr 13 21:02:48 romney last message repeated 4 times
Apr 13 21:07:04 romney last message repeated 8 times
Apr 13 21:07:13 romney /kernel: so-1/1/0: Clearing SONET alarm(s) RDI-P
Apr 13 21:07:29 romney /kernel: so-1/1/0: Asserting SONET alarm(s) RDI-P
Apr 13 21:07:36 romney /kernel: so-1/1/2: loopback suspected; going to standby.
Apr 13 21:08:08 romney /kernel: so-1/1/2: loopback suspected; going to standby.
...Output truncated...

```

Meaning

The sample output shows the contents of the `/var/log/messages` file.

Rename a File on a Router

Action

To rename a file on the local router, use the following CLI operational mode command:

```
user@host> file rename source destination
```

Sample Output

```
user@host> file list /var/tmp
```

```

dcd.core
rpd.core
snmpd.core

```

```
user@host> file rename /var/tmp/dcd.core /var/tmp/dcd.core.990413
```

```
user@host> file list /var/tmp
```

```

dcd.core.990413
rpd.core
snmpd.core

```

Meaning

The sample output shows that the **dcd.core** file was renamed to **dcd.core.990413**. The original name of the file is the *source* and the new name for the file is the *destination*.

Delete a File on a Router

Action

To delete a file on the local router, use the following CLI operational mode command:

```
user@host> file delete filename
```

Sample Output

```
user@host> file list /var/tmp
```

```
dcd.core  
rpd.core  
snmpd.core
```

```
user@host> file delete /var/tmp/snmpd.core
```

```
user@host> file list /var/tmp
```

```
dcd.core  
rpd.core
```

Meaning

The sample output shows that the **snmpd.core** file was deleted.

Check the Time on a Router

Purpose

Display the current time on a router and display information about how long the router, router software, and routing protocols have been running.

Action

To check time on a router, use the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show system uptime
```

Sample Output

```
user@host> show system uptime
```

```
Current time:      1998-10-13 19:45:47 UTC
System booted:     1998-10-12 20:51:41 UTC (22:54:06 ago)
Protocols started: 1998-10-13 19:33:45 UTC (00:12:02 ago)
Last configured:   1998-10-13 19:33:45 UTC (00:12:02 ago) by abc
12:45PM up 22:54, 2 users, load averages: 0.07, 0.02, 0.01
```

Meaning

The sample output shows the current system time in UTC, the date and time when the router was last booted and how long it has been running, when the routing protocols were last started and how long they have been running, when a configuration was last committed, and the name of the user who issued the last **commit** command. If a different time zone is configured, the output shows that time zone. For information on configuring the time zone, see the *Junos System Basics Configuration Guide*.

The sample output shows that the current time is 12:45 PM, the router has been operational for 22:54 hours, and two users are logged in to the router. The output also shows that the load average is 0.07 seconds for the last minute, 0.02 seconds for the last 5 minutes, and 0.01 seconds for the last 15 minutes.

Check for Users in Configuration Mode

Purpose

Before you change the configuration or commit a candidate configuration, it is a good idea to check for users in configuration mode.

Action

To display users currently editing the configuration, follow these steps:

1. To enter configuration mode, type the following command:

```
user@host> edit
```

2. Enter the following configuration mode command:

```
[edit]
user@host# status
```

For example:

```
user@host> show system users
```

```
4:58PM PST up 5 days, 9:52, 5 users, load averages: 0.01, 0.01, 0.00
USER      TTY      FROM            LOGIN@   IDLE   WHAT
mwazna    p0       bigpunk.juniper.net 4:58PM   -    -cli (cli)
jgchan    p1       bigpunk.juniper.net 2:25PM   2:32 -csh (csh)
jgchan    p2       bigpunk.juniper.net 2:35PM   2:18 cli
taffy     p3       bigpunk.juniper.net 3:28PM   5    -cli (cli)
tmauro    p4       bigpunk.juniper.net 4:16PM   37   cli
```

Sample Output

Meaning

The sample output lists the users who are currently logged in to the router. Five users are logged in to the router, with one user logged in twice, **jgchan**. Each user is logged in through a different terminal (**TTY**—**p0**, **p1**, **p2**, **p3**, and **p4**) from the system **bigpunk.juniper.net**. A hyphen in the **FROM** field indicates that the user logged in through the console.

Additional information includes the time when the user logged in (**LOGIN**), the amount of time the user is not active on the router (**IDLE**), and the processes that the user is running (**WHAT**). In this example, the users are running the command-line interface (**cli**) and the UNIX-level shell (**csh**).

Check the Commands That Users Are Entering

Purpose

A common set of operations you can check is when users log in to the router and the CLI commands they issue.

To check the commands that users are entering, follow these steps:

1. [Configure the Log File for Tracking CLI Commands | 2482](#)
2. [Display the Configured Log File | 2483](#)

Configure the Log File for Tracking CLI Commands

Action

To configure the log file for tracking CLI commands, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit system syslog
```

2. Configure the log file:

```
[edit system syslog]
user@host# edit file filename
```

For example:

```
[edit system syslog]
user@host# edit file cli-commands
```

3. Configure the interactive-commands facility and severity level:

```
[edit system syslog filename]
user@host# set interactive-commands info
```

4. Verify the configuration:

```
[edit system syslog]
user@host# show
file cli-commands {
    interactive-commands info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Meaning

The configuration example shows that the log file **cli-commands** is configured with the **interactive-commands** facility at the **info** severity level. [Table 73 on page 2483](#) lists and describes the severity levels.

Table 73: Severity Levels

Severity Level	Description
info	Log all top-level CLI commands, including the configure command, and all configuration mode commands.
notice	Log the configuration mode commands rollback and commit .
warning	Log when any software process restarts.

Display the Configured Log File

Purpose

To display the log file in configuration mode, enter the following command:

Action

```
[edit system syslog]
user@host# run show log filename
```

For example:

```
[edit system syslog]
user@host# run show log cli-commands
```

Sample Output

```
[edit system syslog]
user@host# run show log cli-commands

interactive-commands info '
Sep 16 14:32:15  nut mgd[3442]: UI_CMDLINE_READ_LINE: User 'user', command 'run
show log cli-commands '

```

Meaning

The sample output shows the CLI commands that were entered since the log file was configured.

Configure the Log File for Tracking CLI Commands

Action

To configure the log file for tracking CLI commands, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```

[edit]
user@host# edit system syslog

```

2. Configure the log file:

```

[edit system syslog]
user@host# edit file filename

```

For example:

```

[edit system syslog]
user@host# edit file cli-commands

```

3. Configure the interactive-commands facility and severity level:

```

[edit system syslog filename]
user@host# set interactive-commands info

```

4. Verify the configuration:

```

[edit system syslog]

```

```
user@host# show
file cli-commands {
    interactive-commands info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Meaning

The configuration example shows that the log file **cli-commands** is configured with the **interactive-commands** facility at the **info** severity level. [Table 73 on page 2483](#) lists and describes the severity levels.

Table 74: Severity Levels

Severity Level	Description
info	Log all top-level CLI commands, including the configure command, and all configuration mode commands.
notice	Log the configuration mode commands rollback and commit .
warning	Log when any software process restarts.

Check When the Last Configuration Change Occurred

Purpose

When a problem occurs on a router, it is a good idea to check when the last configuration change was made because it may have had some influence on the problem.

To check when the last configuration change occurred, follow these steps:

- 1. [Configure Configuration Change Tracking | 2485](#)
- 2. [Display the Configured Log File | 2486](#)

Configure Configuration Change Tracking

Action

To configure this type of logging, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]  
user@host# edit system syslog
```

2. Configure the log file:

```
[edit system syslog]  
user@host# edit file filename
```

For example:

```
[edit system syslog]  
user@host# edit file mw-configuration-changes
```

3. Configure the change-log facility and severity level:

```
[edit system syslog filename]  
user@host# set change-log info
```

4. Verify the configuration:

```
[edit system syslog]  
user@host# show  
file mw-configuration-changes {  
    change-log info;  
}
```

5. Commit the configuration:

```
user@host# commit
```

Display the Configured Log File

Purpose

To display the log file in configuration mode.

Action

To display the log file in configuration mode, enter the following command:

```
[edit system syslog]
```

```
user@host# run show log filename
```

For example:

```
[edit system syslog]
user@host# run show log mw-configuration-changes
```

Sample Output

```
[edit system syslog]
user@host# run show log mw-configuration-changes
Sep 17 07:03:22  nut mgd[7793]: UI_CFG_AUDIT_OTHER: User 'root' override:

domain-search] "englab.company.net"
Sep 17 07:07:22  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [system
domain-search] "company.net"
Sep 17 07:07:22  nut mgd[2751]: UI_CFG_AUDIT_OTHER: User 'root' set: [system
domain-search] "jnpr.net"
```

Meaning

The sample output shows the contents of the log file and that the last configuration change was on September 17 at 07:07:22.

Configure Configuration Change Tracking

Action

To configure this type of logging, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit system syslog
```

2. Configure the log file:

```
[edit system syslog]
user@host# edit file filename
```

For example:

```
[edit system syslog]
user@host# edit file mw-configuration-changes
```

3. Configure the change-log facility and severity level:

```
[edit system syslog filename]
user@host# set change-log info
```

4. Verify the configuration:

```
[edit system syslog]
user@host# show
file mw-configuration-changes {
    change-log info;
}
```

5. Commit the configuration:

```
user@host# commit
```

Display a Log File

Purpose

To look at a log or trace file.

Action

To look at a log or trace file, use the following Junos OS CLI operational mode command:

```
user@host> show log filename
```

Sample Output

user@host> **show log messages**

```
Sep 10 07:00:00 host newsyslog[7249]: logfile turned over
Sep 10 07:01:49 host rpd[6451]: bgp_listen_accept: Connection attempt from

Sep 10 07:21:33 host rpd[6451]: bgp_listen_accept: Connection attempt from
unconfigured neighbor:
```

Meaning

The sample output shows the **rpd** log messages in the **messages** file for September 10 from 7:00 to 7:21 AM.

NOTE: Local log files are saved in the **/var/log** directory.

Configure IS-IS-Specific Options

Purpose

When unexpected events or problems occur, or if you want to diagnose IS-IS adjacency establishment issues, you can view more detailed information by configuring options specific to IS-IS.

To configure IS-IS options, follow these steps:

1. [Displaying Detailed IS-IS Protocol Information | 2490](#)
2. [Displaying Sent or Received IS-IS Protocol Packets | 2493](#)
3. [Analyzing IS-IS Link-State PDUs in Detail | 2495](#)

Displaying Detailed IS-IS Protocol Information

Action

To trace IS-IS messages in detail, follow these steps:

1. Configure the flag to display detailed IS-IS protocol messages.

```
[edit protocols isis traceoptions]  
user@host# set flag hello detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]  
user@host# show  
file isislog size 10k files 10;  
flag hello detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
```

```

Nov 29 23:17:50 trace_on: Tracing to "/var/log/isislog" started

Understanding IS-IS Areas to Divide an Autonomous System into Smaller Groups

Example: Configuring a Multi-Level IS-IS Topology to Control Interarea Flooding

Displaying Sent or Received IS-IS Protocol Packets

To configure the tracing for only sent or received IS-IS protocol packets, follow these steps:

1. Configure the flag to display sent, received, or both sent and received packets.

```
[edit protocols isis traceoptions]
user@host# set flag hello send
```

or

```
[edit protocols isis traceoptions]  
user@host# set flag hello receive
```

or

```
[edit protocols isis traceoptions]  
user@host# set flag hello
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]  
user@host# show  
file isislog size 10k files 10;  
flag hello send;
```

or

```
[edit protocols isis traceoptions]  
user@host# show  
file isislog size 10k files 10;  
flag hello receive;
```

or

```
[edit protocols isis traceoptions]  
user@host# show  
file isislog size 10k files 10;  
flag hello send receive;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
Sep 27 18:17:01 ISIS periodic xmit to 01:80:c2:00:00:15 (IFL 2)
Sep 27 18:17:01 ISIS periodic xmit to 01:80:c2:00:00:14 (IFL 2)
Sep 27 18:17:03 ISIS periodic xmit to 01:80:c2:00:00:15 (IFL 2)
Sep 27 18:17:04 ISIS periodic xmit to 01:80:c2:00:00:14 (IFL 2)
Sep 27 18:17:06 ISIS L2 hello from 0000.0000.0008 (IFL 2) absorbed

Analyzing IS-IS Link-State PDUs in Detail

To analyze IS-IS link-state PDUs in detail, follow these steps:

1. Configure IS-IS open messages.

```
[edit protocols isis traceoptions]
user@host# set flag lsp detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 5m world-readable;
flag error;
flag lsp detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog

Displaying Detailed IS-IS Protocol Information

Action

To trace IS-IS messages in detail, follow these steps:

1. Configure the flag to display detailed IS-IS protocol messages.

```
[edit protocols isis traceoptions]  
user@host# set flag hello detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]  
user@host# show  
file isislog size 10k files 10;  
flag hello detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog
```

```
Nov 29 23:17:50 trace_on: Tracing to "/var/log/isislog" started  
Nov 29 23:17:50 Sending PTP IIH on so-1/1/1.0

Analyzing IS-IS Link-State PDUs in Detail

To analyze IS-IS link-state PDUs in detail, follow these steps:

1. Configure IS-IS open messages.

```
[edit protocols isis traceoptions]
user@host# set flag lsp detail
```

2. Verify the configuration.

```
user@host# show
```

For example:

```
[edit protocols isis traceoptions]
user@host# show
file isislog size 5m world-readable;
```

```
flag error;
flag lsp detail;
```

3. Commit the configuration.

```
user@host# commit
```

4. View the contents of the file containing the detailed messages.

```
user@host# run show log filename
```

For example:

```
user@host# run show log isislog

RELATED DOCUMENTATION

Understanding IS-IS Areas to Divide an Autonomous System into Smaller Groups

Example: Configuring a Multi-Level IS-IS Topology to Control Interarea Flooding

Configure OSPF-Specific Options

Purpose

When unexpected events or problems occur, or if you want to diagnose OSPF neighbor establishment issues, you can view more detailed information by configuring options specific to OSPF.

To configure OSPF options, follow these steps:

1. [Diagnose OSPF Session Establishment Problems | 2504](#)
2. [Analyze OSPF Link-State Advertisement Packets in Detail | 2509](#)

Diagnose OSPF Session Establishment Problems

Action

To trace OSPF messages in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols ospf traceoptions
```

2. Configure OSPF hello messages:

```
[edit protocols ospf traceoptions]
user@host# set flag hello detail
```

3. Verify the configuration:

```
user@host# show
```

For example:

```
[edit protocols ospf traceoptions]
user@host# show
file ospf size 5m world-readable;
flag hello detail;
```

4. Commit the configuration:

```
user@host# commit
```

5. View the contents of the file containing the detailed messages:

```
user@host# run show log filename
```

For example:

```
user@host# run show log ospf
```

```

Analyze OSPF Link-State Advertisement Packets in Detail

Action

To analyze OSPF link-state advertisement packets in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols ospf traceoptions
```

2. Configure OSPF link-state packages:

```
[edit protocols ospf traceoptions]
user@host# set flag lsa-update detail
```

3. Verify the configuration:

```
user@host# show
```

For example:

```
[edit protocols ospf traceoptions]
user@host# show
file ospf size 5m world-readable;
flag hello detail;
flag lsa-update detail;
```

4. Commit the configuration:

```
user@host# commit
```

5. View the contents of the file containing the detailed messages:

```
user@host# run show log filename
```

For example:

```
user@host# run show log ospf
```

```
Dec 2 16:23:47 OSPF sent LSUpdate (4) -> 224.0.0.5 (so-1/1/0.0) ec 2 16:23:47
Version 2, length 196, ID 10.0.0.6, area 0.0.0.0

Analyze OSPF Link-State Advertisement Packets in Detail

Action

To analyze OSPF link-state advertisement packets in detail, follow these steps:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@host# edit protocols ospf traceoptions
```

2. Configure OSPF link-state packages:

```
[edit protocols ospf traceoptions]
user@host# set flag lsa-update detail
```

3. Verify the configuration:

```
user@host# show
```

For example:

```
[edit protocols ospf traceoptions]
user@host# show
file ospf size 5m world-readable;
flag hello detail;
flag lsa-update detail;
```

4. Commit the configuration:

```
user@host# commit
```

5. View the contents of the file containing the detailed messages:

```
user@host# run show log filename
```

For example:

```
user@host# run show log ospf
```

```
Dec 2 16:23:47 OSPF sent LSUpdate (4) -> 224.0.0.5 (so-1/1/0.0) ec 2 16:23:47
Version 2, length 196, ID 10.0.0.6, area 0.0.0.0

```

Chassis

Chassis dimensions are listed in the physical specifications table for each router. For more information about chassis dimensions, see the router platform-specific hardware guide.

Each Juniper Networks router features a rigid sheet metal chassis that houses all of the router components. The chassis are designed to install into a variety of racks, including standard 19-inch equipment racks, telco center-mount racks, and four-post racks and cabinets. See [Table 79 on page 2518](#) for the maximum number of each router type that can be installed into a rack. Each chassis includes mounting ears or support posts to facilitate rack mounting, and one or more points for connecting an electrostatic discharge (ESD) wrist strap for use when servicing the router.

Table 79: Maximum Number of Routers per Rack

Router or Routing Node	Maximum in Standard Rack
T640	2
T320	3
M160	2
M40e	2
M40	2
M20	5
M5 and M10	14

Each chassis includes a midplane (called the backplane on an M40 router). The midplane transfers data packets to and from the FPCs, distributes power to router components, and provides signal connectivity to the router components for system monitoring and control.

Physical Interface Cards

Juniper Networks M-series routers and T-series platforms use PICs to connect to a wide variety of network media. PICs receive incoming packets from the network and transmit outgoing packets to the network, performing framing and line-speed signaling for their specific media type. Before transmitting outgoing data packets, the PICs encapsulate the packets received from the FPCs. Each PIC is equipped with an ASIC that performs control functions specific to the PIC's media type. For information about PICs, see the specific PIC guide.

Routing Engine

The Routing Engine consists of an Intel-based PCI platform running the Junos OS. The Routing Engine maintains the routing tables used by the router in which it is installed and controls the routing protocols on the router. The T640 routing node, and the T320, M160, M40e, and M20 routers support up to two Routing Engines, while the M40, M10, and M5 routers support a single Routing Engine.

Each Routing Engine consists of a CPU; SDRAM for storage of the routing and forwarding tables and other processes; a compact flash disk for primary storage of software images, configuration files, and microcode;

a hard disk for secondary storage; a PC card slot (on some M40 routers, a floppy disk) for storage of software upgrades; and interfaces for out-of-band management access.

Compare Information Logged Before and After the Reinstall

Purpose

Compare the operation of the system before and after the reinstall to ensure that everything is working as expected.

Action

To obtain system information, use the following commands:

```
user@host> show version
user@host> show chassis hardware
user@host> show chassis environment
user@host> show system boot-messages
user@host> show configuration
user@host> show interface terse
user@host> show bgp summary
user@host> show isis adjacency brief
user@host> show ospf neighbor brief
user@host> show system storage
```

Compare the information from these commands with the information you obtained before the reinstall.

Back Up the New Software

Purpose

After a week or so, when you are satisfied that the new software is running successfully, we recommend that you back up the reinstalled software.

Action

To back up the reinstalled software, use the following Junos OS CLI operational mode command:

```
user@host> request system snapshot
```

The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Monitor Hardware Components

Purpose

NOTE: If the System Control Board (SCB), System and Switch Board (SSB), or Forwarding Engine Board (FEB) is not running, information about chassis components is not available through the command-line interface (CLI).

Action

To use the CLI to monitor Juniper Networks routers, follow these steps:

1. Log in to the router. The CLI operational mode prompt (>) appears.

If the operational mode prompt does not appear when you log in to the router, type **cli** to start the Junos OS and enter operational mode. The prompt changes to **>**, indicating that you are in operational mode.

2. Use one of the operational mode CLI commands listed in *Operational Mode CLI Commands for Router Monitoring* to monitor router hardware.

Log Software Version Information

Purpose

To log the Junos OS version information.

Action

To log the Junos OS version information, use the following Junos OS CLI operational mode command:

```
user@host> show version
```

Sample Output

```
user@host> show version
```

```

- [Flexible PIC Concentrators | 2523](#)

- Physical Interface Cards | 2523
- Routing Engine | 2523
- Power Supplies | 2523
- Cooling System | 2524

Each Juniper Networks router consists of a chassis and a set of components, including FPCs, PICs, Routing Engines, power supplies, cooling system, and cable management system. Many of the components are field-replaceable units. The following major components are discussed in this topic:

Chassis

Chassis dimensions are listed in the physical specifications table for each router. For more information about chassis dimensions, see the router platform-specific hardware guide.

Each Juniper Networks router features a rigid sheet metal chassis that houses all of the router components. The chassis are designed to install into a variety of racks, including standard 19-inch equipment racks, telco center-mount racks, and four-post racks and cabinets. See [Table 79 on page 2518](#) for the maximum number of each router type that can be installed into a rack. Each chassis includes mounting ears or support posts to facilitate rack mounting, and one or more points for connecting an electrostatic discharge (ESD) wrist strap for use when servicing the router.

Table 80: Maximum Number of Routers per Rack

Router or Routing Node	Maximum in Standard Rack
T640	2
T320	3
M160	2
M40e	2
M40	2
M20	5
M5 and M10	14

Each chassis includes a midplane (called the backplane on an M40 router). The midplane transfers data packets to and from the FPCs, distributes power to router components, and provides signal connectivity to the router components for system monitoring and control.

Flexible PIC Concentrators

The FPCs house the PICs used in the router and connect them to other router components. FPCs install into the front of the router in either a vertical or horizontal orientation, depending on the router. A compatible FPC can be installed into any available FPC slot, regardless of the PICs it contains. If a slot is not occupied by an FPC, a blank FPC panel must be installed to shield the empty slot and allow cooling air to circulate properly through the FPC card cage. For information about FPCs, see the specific hardware guide.

Physical Interface Cards

Juniper Networks M-series routers and T-series platforms use PICs to connect to a wide variety of network media. PICs receive incoming packets from the network and transmit outgoing packets to the network, performing framing and line-speed signaling for their specific media type. Before transmitting outgoing data packets, the PICs encapsulate the packets received from the FPCs. Each PIC is equipped with an ASIC that performs control functions specific to the PIC's media type. For information about PICs, see the specific PIC guide.

Routing Engine

The Routing Engine consists of an Intel-based PCI platform running the Junos OS. The Routing Engine maintains the routing tables used by the router in which it is installed and controls the routing protocols on the router. The T640 routing node, and the T320, M160, M40e, and M20 routers support up to two Routing Engines, while the M40, M10, and M5 routers support a single Routing Engine.

Each Routing Engine consists of a CPU; SDRAM for storage of the routing and forwarding tables and other processes; a compact flash disk for primary storage of software images, configuration files, and microcode; a hard disk for secondary storage; a PC card slot (on some M40 routers, a floppy disk) for storage of software upgrades; and interfaces for out-of-band management access.

Power Supplies

Each Juniper Networks M-series router, T-series platform, or MX-series router has one to four load-sharing power supplies depending on the platform. If a power supply in a redundant configuration is removed or fails, the other power supplies assume the electrical load. For more information about the power supplies in each router, see the router platform-specific hardware guide.

The power supplies are connected to the router midplane, which distributes the different output voltages throughout the router and its components. Some routers can operate using either AC or DC power; other

routers operate with DC power only. For information about the type of power used by each router, see the platform-specific hardware guide.

Cooling System

Each Juniper Networks M-series router and T-series platform features a cooling system designed to keep all router components within recommended operating temperature limits. If one component of the cooling system fails or is removed, the system automatically adjusts the speed of the remaining components to keep the temperature within the acceptable range. The cooling system for each router is unique and can consist of fans, impellers, and air filters. For information about the cooling system components of each router, see the “Major Hardware Components” table in the router platform-specific hardware guide.
