If you are done configuring the device, enter **commit** from configuration mode.

Configuring an Inter-AS MS-PW

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

T-PE1

```

set interfaces ge-3/1/0 unit 0 family inet address 192.0.2.1/24
set interfaces ge-3/1/0 unit 0 family mpls

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the T-PE1 router in the inter-AS scenario:

NOTE: Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

```

[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary

```

2. Set the autonomous system number.

```

[edit routing-options]
user@T-PE1# set autonomous-system 1

```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```

[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable

```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
```

```
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier 800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0 target-attachment-identifier
700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection minimum-interval 300
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (ASBR 1) in the inter-AS scenario:

NOTE: Repeat this procedure for the S-PE2 (ASBR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure S-PE1 (ASBR 1) interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls
user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the IBGP group for S-PE1 (ASBR 1) to peer with T-PE1.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 type internal
```

6. Configure the IBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 local-address 10.255.2.1
user@S-PE1# set bgp group to_T-PE1 export next-hop-self
user@S-PE1# set bgp group to_T-PE1 neighbor 10.255.10.1
```

7. Configure the EBGP group for S-PE1 (ASBR 1) to peer with S-PE2 (ASBR 2).

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 type external
```

8. Configure the EBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 local-address 10.255.2.1
user@S-PE1# set bgp group to_S-PE2 peer-as 2
user@S-PE1# set bgp group to_S-PE2 neighbor 10.255.3.1 multihop ttl 1
```

9. Configure OSPF on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

10. Configure LDP on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

11. Define the policy for enabling next-hop-self on S-PE1 (ASBR 1).

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

T-PE1

```
user@T-PE1# show interfaces

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the Routes | 1188](#)
- [Verifying the LDP Database | 1191](#)
- [Checking the MS-PW Connections on T-PE1 | 1192](#)
- [Checking the MS-PW Connections on S-PE1 | 1194](#)
- [Checking the MS-PW Connections on S-PE2 | 1195](#)
- [Checking the MS-PW Connections on T-PE2 | 1197](#)

Confirm that the configuration is working properly.

Verifying the Routes

Purpose

Verify that the expected routes are learned.

Action

From operational mode, run the **show route** command for the **bgp.l2vpn.1**, **ldp.l2vpn.1**, **mpls.0**, and **ms-pw.l2vpn.1** routing tables.

From operational mode, run the **show route table bgp.l2vpn.1** command.

```
user@T-PE1> show route table bgp.l2vpn.1
```

```
bgp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

10.10.10.10:15:700:0.0.2.188:700/160 AD2

```
*[BGP/170] 16:13:11, localpref 100, from 10.255.2.1
  AS path: 2 I, validation-state: unverified
  > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

From operational mode, run the **show route table ldp.l2vpn.1** command.

```
user@T-PE1> show route table ldp.l2vpn.1
```

```
ldp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2

```

      > to 203.0.113.2 via ge-3/1/0.0, Push 300016

```

Meaning

The output shows all the learned routes, including the autodiscovery (AD) routes.

The AD2 prefix format is **RD:SAll-type2**, where:

- **RD** is the route distinguisher value.
- **SAll-type2** is the type 2 source attachment identifier value.

The PW2 prefix format is **Neighbor_Addr:C:PWtype:l2vpn-id:SAll-type2:TAIl-type2**, where:

- **Neighbor_Addr** is the loopback address of neighboring S-PE device.
- **C** indicates if Control Word (CW) is enabled or not.
 - **C** is **CtrlWord** if CW is set.
 - **C** is **NoCtrlWord** if CW is not set.
- **PWtype** indicates the type of the pseudowire.
 - **PWtype** is **4** if it is in Ethernet tagged mode.
 - **PWtype** is **5** if it is Ethernet only.
- **l2vpn-id** is the Layer 2 VPN ID for the MS-PW routing instance.
- **SAll-type2** is the type 2 source attachment identifier value.
- **TAIl-type2** is the type 2 target attachment identifier value.

Verifying the LDP Database

Purpose

Verify the MS-PW labels received by T-PE1 from S-PE1 and sent from T-PE1 to S-PE1.

Action

From operational mode, run the **show ldp database** command.

user@T-PE1> **show ldp database**

```
Input label database, 10.255.10.1:0--10.255.2.1:0
  Label      Prefix
    3        10.255.2.1/32

Troubleshooting

IN THIS SECTION

- [Ping | 1199](#)
- [Bidirectional Forwarding Detection | 1200](#)
- [Traceroute | 1201](#)

To troubleshoot the MS-PW connection, see:

Ping

Problem

How to check the connectivity between the T-PE devices and between a T-PE device and an intermediary device.

Solution

Verify that T-PE1 can ping T-PE2. The **ping mpls l2vpn fec129** command accepts SAs and TAs as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters (**instance**, **local-id**, **remote-id**, **remote-pe-address**).

Checking Connectivity Between T-PE1 and T-PE2

```
user@T-PE1> ping mpls l2vpn fec129 instance FEC129-VPWS local-id 800:800:800 remote-pe-address
10.255.14.1 remote-id 700:700:700
```

```
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2
```

```
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Checking Connectivity Between T-PE1 and S-PE2

user@T-PE1> **ping mpls l2vpn fec129 interface ge-3/1/2 bottom-label-ttl 2**

```
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

Bidirectional Forwarding Detection

Problem

How to use BFD to troubleshoot the MS-PW connection from the T-PE device.

Solution

From operational mode, verify the **show bfd session extensive** command output.

user@T-PE1> **show bfd session extensive**

Address	State	Interface	Detect Time	Transmit Interval	Multiplier

Traceroute

Problem

How to verify that MS-PW was established.

Solution

From operational mode, verify **traceroute** output.

```
user@T-PE1> traceroute mpls l2vpn fec129 interface interface
```

```
Probe options: ttl 64, retries 3, exp 7
```

ttl	Label	Protocol	Address	Previous Hop	Probe Status
1		FEC129	10.255.10.1	(null)	Success
2		FEC129	10.255.2.1	10.255.10.1	Success
3		FEC129	10.255.3.1	10.255.2.1	Success
4		FEC129	10.255.14.1	10.255.2.1	Egress

```

MPLS Stitching For Virtual Machine Connection

IN THIS SECTION

- [When Would I Use Stitching? | 1202](#)
- [How Does MPLS Stitching Work? | 1202](#)
- [How Do I Configure Stitching? | 1203](#)
- [Which Switches Support Stitching? | 1203](#)
- [Q&A | 1203](#)

By using MPLS, the stitching feature of Junos OS provides connectivity between virtual machines that reside either on opposite sides of data center routers or in different data centers. An external controller, programmed in the data-plane, assigns MPLS labels to both virtual machines and servers. Then, the signaled MPLS labels are used between the data center routers, generating static link switched paths (LSPs), resolved over either BGP labeled unicast, RSVP or LDP, to provide the routes dictated by the labels.

When Would I Use Stitching?

There are several ways to connect virtual machines. One option when you have virtual machines on opposite sides of a router (or different data centers) is to use MPLS stitching. A typical topology for using MPLS stitching is shown in [Figure 96 on page 1202](#).

Figure 96: Virtual Machines on Either Side of Routers

The above topology consists of the following MPLS layers: VMs | Servers | ToRs | Router Router | ToRs | Servers | VMs

NOTE: The label on the left is the top of the label stack.

How Does MPLS Stitching Work?

With stitching, the MPLS static allocation of labels demultiplexes incoming traffic onto any device/entity in the next layer in the direction of traffic flow. Essentially, there is a label hierarchy that picks up labels for the correct top-of-rack switch, server, and virtual machine that receives traffic. Static label assignments are done between the top-of-rack switches and the virtual machines.

For example, imagine that traffic is sent from VM1 to VM3 in [Figure 96 on page 1202](#). When traffic exits Server1, its label stack is L1 | L2 | L3 where:

- L1 represents the egress top-of-rack switch ToR1.
- L2 represents the physical server, Server2, towards which the egress-side ToR will forward the traffic.
- L3: represents the virtual machine on Server2 to which the Server2 should deliver the traffic.

Traffic arriving at ToR1 needs to be sent to ToR2. Since ToR1 and ToR2 are not directly connected, traffic must flow from ToR1 to ToR2 using label-switching starting on the outermost (top) label. Stitching has been added to static-LSP functionality to SWAP L1 to a I-BGP label that ToR2 advertises to ToR1. The label stack now must contain another label at the top to enable forwarding of the labeled packets between

ToR1 and ToR2. An L-Top label is added if L-BGP is resolved over RSVP/LDP. If static LSP is resolved over L-BGP, then the top label is swapped with the L-BGP label and there is no L-Top label. When the traffic exits ToR1, the stack is: L-top | L-BGP | L2 | L3.

Traffic from ToR1 to ToR2 is then label switched over any signaled LSP.

When traffic arrives at ToR2, the top label is removed with PHP (popped) and the label stack becomes L-BGP | L2 | L3. Since L-BGP is a implicit null label, ToR2 pops the static LSP label L2 that corresponds to the egress server and then forwards the packet to the egress server using the static-LSP configuration on ToR2, which corresponds to a single-hop implicit-NUL LSP.

The outgoing stack becomes L3 and the next-hop is the egress server Server2.

When traffic arrives at the egress server Server2, Server2 pops L3 and delivers the packet to VM3.

How Do I Configure Stitching?

The new keyword **stitch** has been added under **transit** to resolve the remote next-hop. For example, instead of **set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 next-hop 10.9.82.47**, a top-of-rack switch redirects packets to another top-of-rack switch with **set protocols mpls static-label-switched-path static-to-ToR2 transit 1000000 stitch**. The [show mpls static-lsp](#) command has been extended to show the LSP state as 'InProgress' whenever the LSP is waiting for protocol next-hop resolution by resolver.

See the complete example for stitching at *Using MPLS Stitching with BGP to Connect Virtual Machines* for more information.

Which Switches Support Stitching?

See [Feature Explorer](#) for the list of switches that support the [MPLS Stitching For Virtual Machine Connections](#) feature.

Q&A

Q: Is link and node protection for the next-hop provided by MPLS stitching?

A: Link and node protection for the next-hop of transit LSP stitched to L-BGP LSP are not needed. That is provided by L-BGP LSP.

TDM Pseudowires Overview

A TDM pseudowire acts as Layer 2 circuit or service for T1 and E1 circuit signals across an MPLS packet-switched network. On ACX Series routers, you configure a TDM pseudowire with Structure-Agnostic Time Division Multiplexing (TDM) over Packet (SAToP) on the ACX Series built-in channelized T1 and E1 interfaces. When you configure a TDM pseudowire, the network between the customer edge (CE) routers appears transparent to the CE routers, making it seem that the CE routers are directly connected. With the SAToP configuration on the provider edge (PE) router's T1 and E1 interfaces, the interworking function (IWF) forms a payload (frame) that contains the CE router's T1 and E1 Layer 1 data and control word. This data is transported to the remote PE over the pseudowire. The remote PE removes all the Layer 2 and

MPLS headers added in the network cloud and forwards the control word and the Layer 1 data to the remote IWF, which in turn forwards the data to the remote CE router.

Example: TDM Pseudowire Base Configuration

IN THIS SECTION

- [Requirements | 1204](#)
- [Overview of a TDM Pseudowire Base Configuration | 1204](#)
- [Configuring an TDM Pseudowire | 1204](#)

Requirements

The following is a list of the hardware and software requirements for this configuration.

- One ACX Series router
- Junos OS Release 12.2 or later

Overview of a TDM Pseudowire Base Configuration

The configuration shown here is the base configuration of an TDM pseudowire with T1 framing on an ACX Series router. This configuration is for one provider edge router. To complete the TDM pseudowire configuration, you need to repeat this configuration on an other provider edge router in the Multiprotocol Label Switched (MPLS) network.

Configuring an TDM Pseudowire

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```
set chassis fpc 0 pic 0 framing t1
set interfaces ct1-0/0/0 no-partition interface-type t1
set interfaces t1-0/0/0 encapsulation satop
set interfaces t1-0/0/0 unit 0
set interfaces ge-0/2/0 unit 0 family inet address 20.1.1.2/24
set interfaces ge-0/2/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 70.1.1.1/32
set protocols rsvp interface ge-0/2/0.0
set protocols mpls no-cspf
```

```

set protocols mpls label-switched-path PE1-to-PE2 to 40.1.1.1
set protocols mpls interface ge-0/2/0.0
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/2/0.0
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-0/2/0.0
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id
1

```

NOTE: To configure a TDM pseudowire with E1 framing, include the **e1** statement at the **[edit chassis fpc 0 pic 0 framing]** hierarchy level instead of the **t1** statement shown in this example.

Step-by-Step Procedure

1. Configure the framing format:

```

[edit]
user@host# edit chassis
[edit chassis]
user@host# set fpc 0 pic 0 framing t1

```

2. Create a T1 interface on a channelized T1 interface (**ct1**) and enable full channelization with the **no-partition** statement. On the logical T1 interface, set the Structure-Agnostic TDM over Packet (SAToP) encapsulation mode.

```

[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ct1-0/0/0 no-partition interface-type t1
user@host# set t1-0/0/0 encapsulation satop
user@host# set t1-0/0/0 unit 0

```

3. Create a Gigabit Ethernet interface and enable MPLS on that interface. Create the loopback (**lo0**) interface:

```
[edit interfaces]
user@host# set ge-0/2/0 unit 0 family inet address 20.1.1.2/24
user@host# set ge-0/2/0 unit 0 family mpls
user@host# set lo0 unit 0 family inet address 70.1.1.1/32
```

4. Enable the MPLS and RSVP protocols on the MPLS interface—**ge-0/2/0.0**:

```
[edit]
user@host# edit protocols
[edit protocols]
user@host# set rsvp interface ge-0/2/0.0
user@host# set mpls interface ge-0/2/0.0
```

5. Configure LDP. If you configure RSVP for a pseudowire, you must also configure LDP:

```
[edit protocols]
user@host# set ldp interface ge-0/2/0.0
user@host# set ldp interface lo0.0
```

6. Configure a point-to-point label-switched path (LSP) and disable constrained-path LSP computation:

```
[edit protocols]
user@host# set mpls label-switched-path PE1-to-PE2 to 40.1.1.1
user@host# set mpls no-cspf
```

7. Configure OSPF and enable traffic engineering on the MPLS interface—**ge-0/2/0.0**, and on the loopback (**lo0**) interface:

```
[edit protocols]
user@host# set ospf traffic-engineering
user@host# set ospf area 0.0.0.0 interface ge-0/2/0.0
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
```

8. Uniquely identify a Layer 2 circuit for the TDM pseudowire:

```
[edit protocols]
user@host# set l2circuit neighbor 40.1.1.1 interface t1-0/0/0.0 virtual-circuit-id 1
```

Results

```
[edit]
user@host# show
chassis {
    fpc 0 {
        pic 0 {
            framing t1;
        }
    }
}
interfaces {
    ct1-0/0/0 {
        no-partition interface-type t1;
    }
    t1-0/0/0 {
        encapsulation satop;
        unit 0;
    }
    ge-0/2/0 {
        unit 0 {
            family inet {
                address 20.1.1.2/24;
            }
            family mpls;
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 70.1.1.1/32;
            }
        }
    }
}
protocols {
    rsvp {
        interface ge-0/2/0.0;
```

```

    }
    mpls {
        no-cspf;
        label-switched-path PE1-to-PE2 {
            to 40.1.1.1;
        }
        interface ge-0/2/0.0;
    }
    ospf {
        traffic-engineering;
        area 0.0.0.0 {
            interface ge-0/2/0.0;
            interface lo0.0 {
                passive;
            }
        }
    }
    ldp {
        interface ge-0/2/0.0;
        interface lo0.0;
    }
    l2circuit {
        neighbor 40.1.1.1 {
            interface t1-0/0/0.0 {
                virtual-circuit-id 1;
            }
        }
    }
}

```

Configuring Load Balancing for Ethernet Pseudowires

You can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

NOTE: This feature is supported only on M120, M320, MX Series, and T Series routers.

To configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires, include the **ether-pseudowire** statement at the **[edit forwarding-options hash-key family mpls payload]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ether-pseudowire;
    }
  }
}
```

NOTE: You must also configure either the **label-1** or the **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

You can also configure load balancing for Ethernet pseudowires based on IP information. This functionality provides support for load balancing for Ethernet cross-circuit connect (CCC) connections. To include IP information in the hash key, include the **ip** statement at the **[edit forwarding-options hash-key family mpls payload]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
    (label-1 | no-labels);
    payload {
      ip;
    }
  }
}
```

NOTE: You must also configure either the **label-1** or **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

You can configure load balancing for IPv4 traffic over Ethernet pseudowires to include only Layer 3 IP information in the hash key. To include only Layer 3 IP information, include the **layer-3-only** option at the **[edit forwarding-options family mpls hash-key payload ip]** hierarchy level:

```
[edit forwarding-options]
hash-key {
  family mpls {
```

```

(label-1 | no-labels);
payload {
  ip {
    layer-3-only;
  }
}
}

```

NOTE: You must also configure either the **label-1** or **no-labels** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level.

Configuring Load Balancing Based on MAC Addresses

The hash key mechanism for load-balancing uses Layer 2 media access control (MAC) information such as frame source and destination address. To load-balance traffic based on Layer 2 MAC information, include the **family multiservice** statement at the **[edit forwarding-options hash-key]** hierarchy level:

```

family multiservice {
  destination-mac;
  source-mac;
}

```

To include the destination-address MAC information in the hash key, include the **destination-mac** option. To include the source-address MAC information in the hash key, include the **source-mac** option.

NOTE: Any packets that have the same source and destination address will be sent over the same path.

NOTE: You can configure per-packet load balancing to optimize VPLS traffic flows across multiple paths.

NOTE: Aggregated Ethernet member links will now use the physical MAC address as the source MAC address in 802.3ah OAM packets.

NOTE: ACX Series routers do not support VPLS.

Release History Table

Release	Description
14.1X53	Starting in Junos OS Release 14.1X53 and Junos OS Release 16.1, an Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks.

Configuring Class of Service for MPLS LSPs

IN THIS SECTION

- [Class of Service for MPLS Overview | 1213](#)
- [Configuring the MPLS CoS Values | 1213](#)
- [Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value | 1216](#)

The following sections provide an overview of MPLS class of service (CoS) and describe how to configure the MPLS CoS value:

Class of Service for MPLS Overview

When IP traffic enters an LSP tunnel, the ingress router marks all packets with a CoS value, which is used to place the traffic into a transmission priority queue. On the router, for SDH/SONET and T3 interfaces, each interface has four transmit queues. The CoS value is encoded as part of the MPLS header and remains in the packets until the MPLS header is removed when the packets exit from the egress router. The routers within the LSP utilize the CoS value set at the ingress router. The CoS value is encoded by means of the CoS bits (also known as the EXP or experimental bits). For more information, see [“MPLS Label Allocation” on page 421](#).

MPLS class of service works in conjunction with the router's general CoS functionality. If you do not configure any CoS features, the default general CoS settings are used. For MPLS class of service, you might want to prioritize how the transmit queues are serviced by configuring weighted round-robin, and to configure congestion avoidance using random early detection (RED)..

Configuring the MPLS CoS Values

When traffic enters an LSP tunnel, the CoS value in the MPLS header is set in one of three ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. *Default MPLS EXP Classifier* explains the default MPLS CoS values, and summarizes how the CoS values are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.
- You set an MPLS EXP rewrite rule to override the default behavior.

To set a fixed CoS value on all packets entering the LSP, include the **class-of-service** statement:

```
class-of-service cos-value;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit protocols mpls label-switched-path *path-name*]
- [edit protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit protocols rsvp interface *interface-name* link-protection]
- [edit protocols rsvp interface *interface-name* link-protection bypass *destination*]
- [edit logical-systems *logical-system-name* protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *destination*]

The CoS value set using the **class-of-service** statement at the [edit protocols mpls] hierarchy level supersedes the CoS value set at the [edit class-of-service] hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

The **class-of-service** statement at the [edit protocols mpls label-switched-path] hierarchy level assigns an initial EXP value for the MPLS shim header of packets in the LSP. This value is initialized at the ingress routing device only and overrides the rewrite configuration established for that forwarding class. However, the CoS processing (weighted round robin [WRR] and RED) of packets entering the ingress routing device is not changed by the **class-of-service** statement on an MPLS LSP. Classification is still based on the behavior aggregate (BA) classifier at the [edit class-of-service] hierarchy level or the multifield classifier at the [edit firewall] hierarchy level.

BEST PRACTICE: We recommend configuring all routing devices along the LSP to have the same input classifier for EXP, and, if a rewrite rule is configured, all routing devices should have the same rewrite configuration. Otherwise, traffic at the next LSR might be classified into a different forwarding class, resulting in a different EXP value being written to the EXP header.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that RED will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see *Managing Congestion Using RED Drop Profiles and Packet Loss Priorities*.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 26 on page 1215 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in *Understanding How Forwarding Classes Assign Classes to Output Queues*.

Table 26: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only as they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

To configure class of service (CoS) for Multiprotocol Label Switching (MPLS) packets in a label-switched path (LSP):

1. Specify the CoS value

If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value

For Ethernet interfaces installed on a T Series router or an M320 router with a peer connection to an M Series router or a T Series router, you can rewrite both MPLS CoS and IEEE 802.1p values to a configured value (the MPLS CoS values are also known as the EXP or experimental bits). Rewriting these values allows you to pass the configured value to the Layer 2 VLAN path. To rewrite both the MPLS CoS and IEEE 802.1p values, you must include the EXP and IEEE 802.1p rewrite rules in the class of service interface configuration. The EXP rewrite table is applied when you configure the IEEE 802.1p and EXP rewrite rules.

For information about how to configure the EXP and IEEE 802.1p rewrite rules, see *Rewriting Packet Headers to Ensure Forwarding Behavior*.

Configuring MPLS Rewrite Rules

IN THIS SECTION

- [Rewriting the EXP Bits of All Three Labels of an Outgoing Packet | 1216](#)
- [Rewriting MPLS and IPv4 Packet Headers | 1217](#)

You can apply a number of different rewrite rules to MPLS packets.

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

The following sections describe how you can apply rewrite rules to MPLS packets:

Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

In interprovider, carrier-of-carrier, and complex traffic engineering scenarios, it is sometimes necessary to push three labels on the next hop.

By default, on M Series routers except the M320, the top MPLS EXP label of an outgoing packet is not rewritten when you configure swap-push-push and triple-push operations. You can rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining the class of service (CoS) of an incoming MPLS or non-MPLS packet.

To push three labels on incoming MPLS packets, include the **exp-swap-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-swap-push-push default;
```

To push three labels on incoming non-MPLS packets, include the **exp-push-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-push-push-push default;
```

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Rewriting MPLS and IPv4 Packet Headers

You can apply a rewrite rule to MPLS and IPv4 packet headers simultaneously. This allows you to initialize MPLS EXP and IP precedence bits at LSP ingress. You can configure different rewrite rules depending on whether the traffic is VPN or non-VPN.

To rewrite MPLS and IPv4 packet headers, include the **protocol** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules exp *rewrite-rule-name*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp rewrite-rule-name]
protocol types;
```

Use the **protocol** statement to specify the types of MPLS packets and packet headers to which to apply the rewrite rule. The MPLS packet can be a standard MPLS packet or an MPLS packet with an IPv4 payload. Specify the type of MPLS packet by using the following options:

- **mpls-any**—Applies the rewrite rule to MPLS packets and writes the code point value to MPLS headers.
- **mpls-inet-both**—Applies the rewrite rule to VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series (except T4000 routers) and M320 routers. On M Series routers, except the M320, the **mpls-inet-both** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.
- **mpls-inet-both-non-vpn**—Applies the rewrite rule to any non-VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series and M320 routers. On M Series routers, except the M320, the **mpls-inet-both-non-vpn** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.

For a detailed example on how to configure rewrite rules for MPLS and IPv4 packets and for more information about how to configure class of service, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

Configuring CoS Bits for an MPLS Network

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The [Junos OS Class of Service Configuration Guide](#) explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: The CoS value set using the **class-of-service** statement at the **[edit protocols mpls]** hierarchy level supersedes the CoS value set at the **[edit class-of-service]** hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

Configuring CoS on an MPLS Provider Edge Switch Using IP Over MPLS

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using IP Over MPLS.

This task describes how to create a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE switch. It includes configuring a policer firewall filter and applying it to the customer-edge interface of the ingress PE switch. The policer firewall filter ensures that the amount of traffic forwarded through the MPLS tunnel never exceeds the requested bandwidth allocation.

Before you begin, configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect” on page 73](#).
- Configure one or more provider switches. See [“Configuring MPLS on EX8200 and EX4500 Provider Switches” on page 77](#).

This topic includes:

1. [Configuring CoS | 1219](#)
2. [Configuring an LSP Policer | 1220](#)

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add a forwarding class to this custom DSCP classifier and specify a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-priority loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-priority code-points code-point
```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the customer-edge-interface:

```
[edit firewall]
user@switch# set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
user@switch# set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
user@switch# set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family inet filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the customer-edge interface:

```
[edit interfaces]
user@switch# set ge-2/0/3 unit 0 family inet address 192.168.121.1/16 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Configuring CoS on an MPLS Provider Edge Switch Using Circuit Cross-Connect

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. This topic describes configuring CoS components on a provider edge (PE) switch that is using MPLS over circuit-cross connect (CCC).

NOTE: On EX Series switches other than EX8200 switches, if you are using MPLS over CCC, you can use only one DSCP or IP precedence classifier and only one IEEE 802.1p classifier on the CCC interfaces.

This procedure is for creating a custom DSCP classifier and a custom EXP rewrite rule on the ingress PE. It also includes enabling a policer on the label-switched path (LSP) of the ingress PE to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This topic includes:

1. [Configuring CoS | 1221](#)
2. [Configuring an LSP Policer | 1222](#)

Configuring CoS

To configure CoS on a provider edge switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name import default
```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers dscp classifier-name forwarding-class forwarding-class loss-priority
loss-priority code-points code-point
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class forwarding-class loss-priority loss-priority
code-point code-point
```

4. Bind the DSCP classifier to the CCC interface:

```
[edit ]
```

```
user@switch# set class-of-service interfaces interface unit unit classifier classifier-name
```

5. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces interface unit unit rewrite-rules exp e1
```

Configuring an LSP Policer

To configure an LSP policer:

NOTE: You cannot configure LSP policers on EX8200 switches. EX8200 switches do not support LSP policers.

1. Specify the number of bits per second permitted, on average, for the policer, which will later be applied to the LSP:

```
[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m
```

2. Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

3. Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

4. To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family any filter myfilter term t1 then policer mypolicer
```

5. Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Configuring CoS on Provider Switches of an MPLS Network

You can add class-of-service (CoS) components to your MPLS networks on EX Series switches to achieve end-to-end Differentiated Services to match your specific business requirements. The configuration of CoS components on the provider switches is the same regardless of whether the provider edge (PE) switches are using MPLS over CCC or IP over MPLS.

This task shows how to configure a custom EXP classifier and custom EXP rewrite rule on the provider switch.

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low code-points 010
```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low code-point 111
```

4. On EX8200 switches only, bind the custom EXP rewrite rule to the interface:

```
[edit class-of-service]
user@switch# set class-of-service interfaces ge-0/0/2 unit 0 rewrite-rules exp e1
```

NOTE: You can also configure schedulers and shapers as needed. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

Understanding Using CoS with MPLS Networks on EX Series Switches

IN THIS SECTION

- [EXP Classifiers and EXP rewrite Rules | 1224](#)
- [Guidelines for Using CoS Classifiers on CCCs | 1225](#)
- [Using CoS Classifiers with IP over MPLS | 1225](#)
- [Setting CoS Bits in an MPLS Header | 1226](#)
- [EXP Rewrite Rules | 1227](#)
- [Policer | 1227](#)
- [Schedulers | 1228](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. See *EX Series Switch Software Features Overview* for a complete list of the Junos OS MPLS features that are supported on specific EX Series switches.

Juniper Networks EX Series Ethernet Switches support Differentiated Service Code Point (DSCP) or IP precedence and IEEE 802.1p CoS classifiers on the customer-edge interfaces of the ingress provider edge (PE) switch. DSCP or IP precedence classifiers are used for Layer 3 packets. IEEE 802.1p is used for Layer 2 packets.

When a packet enters a customer-edge interface of the ingress PE switch, the switch associates the packet with a particular CoS servicing level before putting the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch. The CoS value that was embedded in the classifier is translated and encoded in the MPLS header by means of the EXP or experimental bits. EX Series switches enable a default EXP classifier and a default EXP rewrite rule. For more information about EXP classifiers and EXP rewrite rules, see *EXP Classifiers and EXP rewrite Rules*.

This topic includes:

EXP Classifiers and EXP rewrite Rules

EX Series switches enable a default EXP classifier and a default EXP rewrite rule. You can configure a custom EXP classifier and a custom EXP rewrite rule if you prefer. However, the switch supports only one type of EXP classifier (default or custom) and only one EXP rewrite rule (default or custom).

You do not bind the EXP classifier or the EXP rewrite rule to individual interfaces. The switch automatically and implicitly applies the default or the custom EXP classifier and the default or the custom EXP rewrite rule to the appropriate MPLS-enabled interfaces. Because rewrite rules affect only egress interfaces, the switch applies the EXP rewrite rule only to those MPLS interfaces that are transmitting MPLS packets (not to the MPLS interfaces that are receiving the packets).

After traversing the MPLS tunnel, the traffic flows out from the egress provider edge (PE) switch. Before the traffic leaves the egress interface, the egress PE switch copies the EXP bits from the MPLS header to the most significant bits in the original IP packet--- that is, to the IP precedence bits. Note that this is the default behavior only on Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis) that are configured for MPLS.

Guidelines for Using CoS Classifiers on CCCs

When you are configuring CoS for MPLS over circuit cross-connect (CCC), there are some additional guidelines, as follows:

- You *must* explicitly bind a CoS classifier to the CCC interface on the ingress PE switch.
- You *must* use the same DSCP, IP precedence, or IEEE 802.1p classifier on CCC interfaces. However, if the CCC interfaces are on the same switch, you cannot configure both a DSCP and an IP precedence classifier on these interfaces. Thus, if you configure one CCC interface to use a DSCP classifier DSCP1, you cannot configure another CCC interface to use another DSCP classifier DSCP2. All the CCC interfaces on the switch must use the same DSCP (or IP precedence) classifier and the same IEEE 802.1p classifier.
- You *cannot* configure one CCC interface to use a DSCP classifier and another CCC interface to use an IP precedence classifier, because these classifier types overlap.
- You *can* configure one CCC interface to use a DSCP classifier and another CCC interface to use IEEE 802.1p classifier.
- You *can* configure one CCC interface to use both a DSCP and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the DSCP classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.
- You *can* configure one CCC interface to use both an IP precedence and an IEEE 802.1p classifier. If you configure a CCC interface to use both these classifiers, the IP precedence classifier is used for routing Layer 3 packets and the IEEE 802.1p classifier is used for routing Layer 2 packets.

NOTE: These guidelines are not applicable to Juniper Networks EX8200 Ethernet Switches (standalone or Virtual Chassis).

You can define multiple DSCP, IP precedence, and IEEE 802.1p classifiers for the non-CCC interfaces on a switch.

Using CoS Classifiers with IP over MPLS

When you are configuring CoS for IP over MPLS, the customer-edge interface uses the CoS configuration for the switch as the default. You do not have to bind a classifier to the customer-edge interface in this case. There are no restrictions on using multiple DSCP, IP precedence, and IEEE 802.1p classifiers on the same switch.

- You can modify the CoS classifier for a particular interface, but it is not required.

- You can configure a DSCP classifier, DSCP1 on the first interface, another DSCP classifier, DSCP2 on the second interface, and an IP precedence classifier on a third interface, and so forth.

Setting CoS Bits in an MPLS Header

When traffic enters an LSP tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service User Guide (Routers and EX9200 Switches)* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that random early detection (RED) will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see the *Class of Service User Guide (Routers and EX9200 Switches)*.

NOTE: Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 27 on page 1226 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in the *Class of Service User Guide (Routers and EX9200 Switches)*.

Table 27: MPLS CoS Values

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
0	000	0	Not set
1	001	0	Set
2	010	1	Not set
3	011	1	Set

Table 27: MPLS CoS Values (*continued*)

MPLS CoS Value	Bits	Transmit Queue	PLP Bit
4	100	2	Not set
5	101	2	Set
6	110	3	Not set
7	111	3	Set

Because the CoS value is part of the MPLS header, the value is associated with the packets only while they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

NOTE: On EX8200 switches that run MPLS-based Layer 2 virtual private networks (VPNs):

- If you configure an LSP CoS, the EXP bits of the MPLS packet continue to use the same CoS values that are configured at the interface level.
- For Virtual Chassis, if the input and output interfaces are on different line cards, then the loss priority value that you configured on the first line card is not carried to the subsequent line cards. The loss priority for the outgoing traffic from the subsequent line cards is always set to low.

EXP Rewrite Rules

When traffic passes from the customer-edge interface to an MPLS interface, the DSCP, IP precedence, or IEEE 802.1p CoS classifier is translated into the EXP bits within the MPLS header. You cannot disable the default EXP rewrite rule, but you can configure your own custom EXP classifier and a custom EXP rewrite rule. You cannot bind the EXP classifier to individual MPLS interfaces; the switch applies it globally to all the MPLS-enabled interfaces on the switch.

Only one EXP rewrite rule (either default or custom) is supported on a switch. The switch applies it to all the egress interfaces on which MPLS is enabled.. This is, however, not the case with EX8200 switches. With EX8200 switches, you must explicitly apply the rewrite rule on each of the egress interfaces.

Policer

Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. During periods of congestion (when the total rate of queuing packets exceeds the rate of transmission), any new packets being sent to an interface can be dropped because there is no place to store them. You can configure a policer on the ingress PE switch to prevent this:

- If you are using MPLS over CCC, you bind the policer to the LSP. You cannot bind a policer to a CCC interface.
- If you are using IP over MPLS, you bind the policer to the **inet-family** customer-edge interface. You cannot bind a policer to the LSP when you are using IP over MPLS.

NOTE: You cannot configure LSP policers on EX8200 switches.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on EX Series switches. Default schedulers are provided for best-effort and network-control forwarding classes. If you are using assured-forwarding, expedited-forwarding, or any custom forwarding class, we recommend that you configure a scheduler to support that forwarding class. See *Understanding CoS Schedulers*.

Example: Combining CoS with MPLS on EX Series Switches

IN THIS SECTION

- [Requirements | 1229](#)
- [Overview and Topology | 1229](#)
- [Configuring the Local PE Switch | 1231](#)
- [Configuring the Remote PE Switch | 1234](#)
- [Configuring the Provider Switch | 1235](#)
- [Verification | 1236](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion. The CoS value is included within the MPLS label, which is passed through the network, enabling end-to-end CoS across the network.

MPLS services are often used to ensure better performance for low-latency applications such as VoIP and other business-critical functions. These applications place specific demands on a network for successful transmission. CoS gives you the ability to control the mix of bandwidth, delay, jitter, and packet loss while taking advantage of the MPLS labeling mechanism.

This example shows how to configure CoS on an MPLS network that is using a unidirectional circuit cross-connect (CCC) from the ingress provider edge (PE) switch to the egress PE switch. for the customer-edge interface of the ingress provider edge (PE) switch. It describes adding the configuration of CoS components to the ingress PE switch, the egress PE switch, and the core provider switches of the

existing MPLS network. Because of the unidirectional configuration, the DSCP classifier needs to be configured only on the ingress PE switch.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 10.1 or later for EX Series switches
- Three EX Series switches

Before you configure CoS with MPLS, be sure you have:

Configured an MPLS network with two PE switches and one provider switch. See [“Example: Configuring MPLS on EX8200 and EX4500 Switches” on page 41](#). This example assumes that an MPLS network has been configured using a cross circuit-connect (CCC).

Overview and Topology

This example describes adding custom classifiers and custom rewrite rules to switches in an MPLS network that is using MPLS over CCC.

It is a unidirectional configuration. Therefore, you need to configure custom classifiers and custom rewrite rules as follows:

- On the ingress PE switch: custom DSCP classifier and custom EXP rewrite rule
- On the egress PE switch: custom EXP classifier
- On the provider switch: customer EXP classifier and custom EXP rewrite rule

NOTE: You can also configure schedulers and shapers as needed. If you are using **assured-forwarding**, **expedited-forwarding**, or other custom forwarding classes, we recommend that you configure a scheduler to support that forwarding class. See *Defining CoS Schedulers and Scheduler Maps (CLI Procedure)*.

The example creates a custom DSCP classifier (**dscp1**) on the ingress PE switch and binds this classifier to the CCC interface. It includes configuration of a policer on the ingress PE switch. The policer is applied as a filter on the label-switched path (LSP) **lsp_to_pe2_ge1** (created in [“Example: Configuring MPLS on EX8200 and EX4500 Switches” on page 41](#)) to ensure that the amount of traffic forwarded through the LSP never exceeds the requested bandwidth allocation.

This example creates a custom EXP rewrite rule (**exp1**) on the ingress PE switch, specifying a loss-priority and code point to be used for the expedited-forwarding class as the packet travels through the LSP. The switch applies this custom rewrite rule on the core interfaces **ge-0/0/5.0** and **ge-0/0/6.0**, which are the egress interfaces for this switch.

[Table 28 on page 1230](#) shows the CoS configuration components added to the ingress PE switch.

Table 28: CoS Configuration Components on the Ingress PE Switch

Property	Settings	Description
Local PE switch hardware	EX Series switch	PE-1
Policing filter configured and applied to the LSP.	policing filter mypolicer filter myfilter	Name of the rate-limiting policer. Name of the filter, which refers to the policer
Custom DSCP classifier	dscp1	Specifies the name of the custom DSCP classifier
Custom EXP rewrite rule	e1	Name of the custom EXP rewrite rule.
Customer-edge interface	ge-0/0/1.0	Interface that receives packets from devices outside the network. The custom DSCP classifier must be specified on this CCC interface.
Core interfaces	ge-0/0/5.0 and ge-0/0/6.0	Interfaces that transmit MPLS packets to other switches within the MPLS network. The EXP rewrite rule is applied implicitly to these interfaces.

[Table 29 on page 1230](#) shows the CoS configuration components added to the egress PE switch in this example.

Table 29: CoS Configuration Components of the Egress PE Switch

Property	Settings	Description
Remote provider edge switch hardware	EX Series switch	PE-2
Custom EXP classifier	exp1	Name of custom EXP classifier
Customer-edge interface	ge-0/0/1.0	Interface that transmits packets from this network to devices outside the network. No CoS classifier is specified for this interface. A scheduler can be specified.

Table 29: CoS Configuration Components of the Egress PE Switch *(continued)*

Property	Settings	Description
Core interfaces	ge-0/0/7.0 and ge-0/0/8.0	Core interfaces on PE-2 that receive MPLS packets from the provider switch. The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.

[Table 30 on page 1231](#) shows the MPLS configuration components used for the provider switch in this example.

Table 30: CoS Configuration Components of the Provider Switch

Property	Settings	Description
Provider switch hardware	EX Series switch	Transit switch within the MPLS network configuration.
Custom EXP classifier	exp1	Name of the custom EXP classifier.
Custom EXP rewrite rule	e1	Name of the custom EXP rewrite rule.
Core interfaces receiving packets from other MPLS switches.	ge-0/0/5.0 and ge-0/0/6.0	Interfaces that connect the provider switch to the ingress PE switch (PE-1). The EXP classifier is enabled by default on the switch and applied implicitly to these interfaces.
Core interfaces transmitting packets to other switches within the MPLS network.	ge-0/0/7.0 and ge-0/0/8.0	Interfaces that transmit packets to the egress PE (PE-2). The EXP rewrite rule is applied implicitly on these interfaces. Schedulers can also be specified and will be applied to these interfaces.

Configuring the Local PE Switch

CLI Quick Configuration

To quickly configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the local PE switch, copy the following commands and paste them into the switch terminal window of PE-1:

```
[edit]
```

```
set class-of-service classifiers dscp dscp1 import default
```

```

set class-of-service classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority low
code-points 000111
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1
set firewall policer mypolicer if-exceeding bandwidth-limit 500m
set firewall policer mypolicer if-exceeding burst-size-limit 33553920
set firewall policer mypolicer then discard
set firewall family any filter myfilter term t1 then policer mypolicer
set protocols mpls label-switched-path lsp_to_pe2_ge1 to 127.1.1.3 policing filter myfilter

```

Step-by-Step Procedure

To configure a custom DSCP classifier, custom EXP rewrite rule, and a policer on the ingress PE switch:

1. Import the default DSCP classifier classes to the custom DSCP classifier that you are creating:

```

[edit class-of-service]
user@switch# set classifiers dscp dscp1 import default

```

2. Add the expedited-forwarding class to this custom DSCP classifier, specifying a loss priority and code point:

```

[edit class-of-service]
user@switch# set classifiers dscp dscp1 forwarding-class expedited-forwarding loss-priority low
code-points 000111

```

3. Specify the values for the custom EXP rewrite rule, **e1**:

```

[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111

```

4. Bind the DSCP classifier to the CCC interface:

```

[edit ]
user@switch# set class-of-service interfaces ge-0/0/1 unit 0 classifier dscp1

```

5. Specify the number of bits per second permitted, on average, for the firewall policer, which will later be applied to the LSP:

```

[edit firewall]
set policer mypolicer if-exceeding bandwidth-limit 500m

```

- Specify the maximum size permitted for bursts of data that exceed the given bandwidth limit for this policer:

```
[edit firewall policer]
set mypolicer if-exceeding burst-size-limit 33553920
```

- Discard traffic that exceeds the rate limits for this policer:

```
[edit firewall policer]
set mypolicer then discard
```

- To reference the policer, configure a filter term that includes the policer action:

```
[edit firewall]
user@switch# set family any filter myfilter term t1 then policer mypolicer
```

- Apply the filter to the LSP:

```
[edit protocols mpls]
set label-switched-path lsp_to_pe2_ge1 policing filter myfilter
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    dscp dscp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 000111;
      }
    }
  }
}
interfaces {
  ge-0/0/1 {
    unit 0 {
      classifiers {
        dscp dscp1;
      }
    }
  }
}
```

```
rewrite-rules {
  exp e1 {
    forwarding-class expedited-forwarding {
      loss-priority low code-point 111;
    }
  }
}

firewall {
  family any {
    filter myfilter {
      term t1 {
        then policer mypolicer;
      }
    }
  }
  policer mypolicer {
    if-exceeding {
      bandwidth-limit 500m;
      burst-size-limit 33553920;
    }
    then discard;
  }
}
```

Configuring the Remote PE Switch

CLI Quick Configuration

To quickly configure a custom EXP classifier on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE-2:

[edit]

```
set class-of-service classifiers exp exp1 import default
```

```
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Step-by-Step Procedure

To configure a custom EXP classifier on the egress PE switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
```

```
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 010;
      }
    }
  }
}
```

Configuring the Provider Switch

CLI Quick Configuration

To quickly configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch, copy the following commands and paste them into the switch terminal window of the provider switch:

```
[edit]
set class-of-service classifiers exp exp1 import default
set class-of-service classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
set class-of-service rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Step-by-Step Procedure

To configure a custom EXP classifier and a custom EXP rewrite rule on the provider switch:

1. Import the default EXP classifier classes to the custom EXP classifier that you are creating:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 import default
```

2. Add the expedited-forwarding class to this custom EXP classifier, specifying a loss priority and code point:

```
[edit class-of-service]
user@switch# set classifiers exp exp1 forwarding-class expedited-forwarding loss-priority low
code-points 010
```

3. Specify the values for the custom EXP rewrite rule, e1:

```
[edit class-of-service]
user@switch# set rewrite-rules exp e1 forwarding-class expedited-forwarding loss-priority low
code-point 111
```

Results

Display the results of the configuration:

```
[edit]
user@switch# show
class-of-service {
  classifiers {
    exp exp1 {
      import default;
      forwarding-class expedited-forwarding {
        loss-priority low code-points 010;
      }
    }
  }
  rewrite-rules {
    exp e1 {
      forwarding-class expedited-forwarding {
        loss-priority low code-point 111;
      }
    }
  }
}
```

Verification

IN THIS SECTION

- [Verifying That the Policer Firewall Filter Is Operational | 1237](#)
- [Verifying That the CoS Classifiers Are Going to the Right Queue | 1237](#)

- [Verifying the CoS Forwarding Table Mapping | 1241](#)
- [Verifying the Rewrite Rules | 1242](#)

To confirm that the configuration is working properly, perform these tasks:

Verifying That the Policer Firewall Filter Is Operational

Purpose

Verify the operational state of the policer that is configured on the ingress PE switch.

Action

```
user@switch> show firewall
```

```
Filter: myfilter
Policers:
Name                               Packets
mypolicer-t1                       0
```

Meaning

This output shows that the firewall filter **mypolicer** has been created.

Verifying That the CoS Classifiers Are Going to the Right Queue

Purpose

Verify that the CoS classifiers are going to the right queue.

Action

```
user@switch> show class-of-service forwarding-table classifier
```

```
Classifier table index: 7, # entries: 64, Table type: DSCP
Entry #   Code point   Forwarding-class #   PLP
0         000000         0         0

63	111111	3	0

Meaning

This output shows that a new DSCP classifier has been created, index **9346**, on the ingress PE switch (PE-1).

Verifying the CoS Forwarding Table Mapping**Purpose**

For each logical interface, display either the table index of the classifier for a given code point type or the queue number (if it is a fixed classification) in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table classifier mapping
```

Table Index/			
Interface	Index	Q num	Table type
ge-0/0/1.0	92	9346	DSCP

Meaning

The results show that the new DSCP classifier, index number **9346**, is bound to interface **ge-0/0/1.0**.

Verifying the Rewrite Rules

Purpose

Display mapping of the queue number and loss priority to code point value for each rewrite rule as it exists in the forwarding table.

Action

```
user@switch>show class-of-service forwarding-table rewrite-rule
```

```
Rewrite table index: 31, # entries: 4, Table type: DSCP
```

FC#	Low bits	State	High bits	State
0	000000	Enabled	000000	Enabled

```
Rewrite table index: 35, # entries: 4, Table type: IPv4 precedence
```

FC#	Low bits	State	High bits	State
0	000	Enabled	000	Enabled
1	101	Enabled	101	Enabled
2	001	Enabled	001	Enabled
3	110	Enabled	111	Enabled

```
Rewrite table index: 9281, # entries: 1, Table type: EXP
```

FC#	Low bits	State	High bits	State
1	111	Enabled	000	Disabled

Meaning

This output shows that a new EXP classifier with the index number **9281** has been created.

Understanding CoS MPLS EXP Classifiers and Rewrite Rules

IN THIS SECTION

- [EXP Classifiers | 1244](#)
- [EXP Rewrite Rules | 1246](#)
- [Schedulers | 1246](#)

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion by applying packet classifiers and rewrite rules to the MPLS traffic. MPLS classifiers are global and apply to all interfaces configured as **family mpls** interfaces.

When a packet enters a customer-edge interface on the ingress provider edge (PE) switch, the switch associates the packet with a particular CoS servicing level before placing the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch to determine the CoS service level. The CoS value embedded in the classifier is translated and encoded in the MPLS header by means of the experimental (EXP) bits.

EXP classifiers map incoming MPLS packets to a forwarding class and a loss priority, and assign MPLS packets to output queues based on the forwarding class mapping. EXP classifiers are behavior aggregate (BA) classifiers.

EXP rewrite rules change (rewrite) the CoS value of the EXP bits in outgoing packets on the egress queues of the switch so that the new (rewritten) value matches the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

NOTE: On QFX5200, QFX5100, QFX3500, QFX3600, and EX4600 switches, and on QFabric systems, there is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global EXP classifier applies to all MPLS traffic on interfaces configured as **family mpls**.

On QFX10000 switches, there is a no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure EXP classifiers and apply them to logical interfaces configured as **family mpls**. (You cannot apply classifiers to physical interfaces.). You can configure up to 64 EXP classifiers.

There is no default EXP rewrite rule. If you want to rewrite the EXP bit value at the egress interface, you must configure EXP rewrite rules and apply them to logical interfaces.

EXP classifiers and rewrite rules are applied only to interfaces that are configured as **family mpls** (for example, **set interfaces xe-0/0/35 unit 0 family mpls.**)

This topic includes:

EXP Classifiers

On QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, unlike DSCP and IEEE 802.1p BA classifiers, EXP classifiers are global to the switch and apply to all switch interfaces that are configured as **family mpls**. On QFX10000 switches, you apply EXP classifiers to individual logical interfaces, and different interfaces can use different EXP classifiers.

When you configure and apply an EXP classifier, MPLS traffic on all **family mpls** interfaces uses the EXP classifier, even on interfaces that also have a fixed classifier. If an interface has both an EXP classifier and a fixed classifier, the EXP classifier is applied to MPLS traffic and the fixed classifier is applied to all other traffic.

Also unlike DSCP and IEEE 802.1p BA classifiers, there is no default EXP classifier. If you want to classify MPLS traffic based on the EXP bits, you must explicitly configure an EXP classifier and apply it to the switch interfaces. Each EXP classifier has eight entries that correspond to the eight EXP CoS values (0 through 7, which correspond to CoS bits 000 through 111).

You can configure up to 64 EXP classifiers.

However, on QFX5200, QFX5100, EX4600, and legacy CLI switches, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure that classifier as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy level. All switch interfaces configured as **family mpls** use the global EXP classifier to classify MPLS traffic.

On these switches, only one EXP classifier can be configured as the global EXP classifier at any time. If you want to change the global EXP classifier, delete the global EXP classifier configuration (use the **user@switch# delete class-of-service system-defaults classifiers exp** configuration statement), then configure the new global EXP classifier.

QFX10000 switches do not support global EXP classifiers. You can configure one EXP classifier and apply it to multiple logical interfaces, or configure multiple EXP classifiers and apply different EXP classifiers to different logical interfaces.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. (Switches that have a default EXP classifier use the default classifier.) If no EXP classifier and no fixed classifier are applied to the interface, MPLS traffic is treated as best-effort traffic using the 802.1 default untrusted classifier. DSCP classifiers are not applied to MPLS traffic.

On QFX5200, QFX5100, EX4600, and legacy CLI switches, because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier.

NOTE: The switch uses only the outermost label of incoming EXP packets for classification.

NOTE: MPLS packets with 802.1Q tags are not supported.

EXP Rewrite Rules

As MPLS packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. EXP rewrite rules set the value of the EXP CoS bits within the header of the outgoing MPLS packet on **family mpls** interfaces. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table, and writes that CoS value into the packet header, replacing the old CoS value. EXP rewrite rules apply only to MPLS traffic.

EXP rewrite rules apply only to logical interfaces. You cannot apply EXP rewrite rules to physical interfaces.

There are no default EXP rewrite rules. If you want to rewrite the EXP value in MPLS packets, you must configure EXP rewrite rules and apply them to logical interfaces. If no rewrite rules are applied, all MPLS labels that are pushed have a value of zero (0). The EXP value remains unchanged on MPLS labels that are swapped.

You can configure up to 64 EXP rewrite rules, but you can only apply 16 EXP rewrite rules at any time on the switch. On a given logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

You can apply an EXP rewrite rule to an interface that has a DSCP, DSCP IPv6, or IEEE 802.1p rewrite rule. Only MPLS traffic uses the EXP rewrite rule. MPLS traffic does not use DSCP or DSCP IPv6 rewrite rules.

If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on the switch. Default schedulers are provided only for the best-effort, fcoe, no-loss, and network-control default forwarding classes. If you configure a custom forwarding class for MPLS traffic, you need to configure a scheduler to support that forwarding class and provide bandwidth to that forwarding class.

Configuring Rewrite Rules for MPLS EXP Classifiers

You configure EXP rewrite rules to alter CoS values in outgoing MPLS packets on the outbound **family mpls** interfaces of a switch to match the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

To configure an EXP CoS rewrite rule, create the rule by giving it a name and associating it with a forwarding class, loss priority, and code point. This creates a rewrite table. After the rewrite rule is created, enable it on a logical **family mpls** interface. EXP rewrite rules can only be enabled on logical **family mpls** interfaces, not on physical interfaces or on interfaces of other family types. You can also apply an existing EXP rewrite rule on a logical interface.

NOTE: There are no default rewrite rules.

You can configure up to 64 EXP rewrite rules, but you can only use 16 EXP rewrite rules at any time on the switch. On a given **family mpls** logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

NOTE: On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

NOTE: To replace an existing rewrite rule on the interface with a new rewrite rule of the same type, first explicitly remove the existing rewrite rule and then apply the new rule.

To create an EXP rewrite rule for MPLS traffic and enable it on a logical interface:

1. Create an EXP rewrite rule:

```
user@switch# set class-of-service rewrite-rules exp rewrite-rule-name forwarding-class
forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

For example, to configure an EXP rewrite rule named **exp-rr-1** for a forwarding class named **mpls-1** with a loss priority of **low** that rewrites the EXP code point value to **001**:

```
user@switch# set class-of-service rewrite-rules exp exp-rr-1 forwarding-class mpls-1 loss-priority  
low code-points 001
```

2. Apply the rewrite rule to a logical interface:

```
user@switch # set class-of-service interfaces interface-name unit logical-unit rewrite-rules exp  
rewrite-rule-name
```

For example, to apply a rewrite rule named **exp-rr-1** to logical interface **xe-0/0/10.0**:

```
user@switch# set class-of-service interfaces xe-0/0/10 unit 0 rewrite-rules exp exp-rr-1
```

NOTE: In this example, all forwarding classes assigned to port xe-0/0/10 must have rewrite rules. Do not mix forwarding classes that have rewrite rules with forwarding classes that do not have rewrite rules on the same interface.

Configuring CoS Bits for an MPLS Network

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service User Guide (Routers and EX9200 Switches)* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

NOTE: The CoS value set using the **class-of-service** statement at the **[edit protocols mpls]** hierarchy level supersedes the CoS value set at the **[edit class-of-service]** hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]  
user@switch# set class-of-service cos-value
```

Configuring a Global MPLS EXP Classifier

EXP packet classification associates incoming packets with a particular MPLS CoS servicing level. EXP behavior aggregate (BA) classifiers examine the MPLS EXP value in the packet header to determine the CoS settings applied to the packet. EXP BA classifiers allow you to set the forwarding class and loss priority of an MPLS packet based on the incoming CoS value.

You can configure up to 64 EXP classifiers, however, the switch uses only one MPLS EXP classifier as a global classifier, which is applied only on interfaces configured as **family mpls**. All **family mpls** switch interfaces use the global EXP classifier to classify MPLS traffic.

There is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global classifier applies to all MPLS traffic on all **family mpls** interfaces.

If a global EXP classifier is configured, MPLS traffic on **family mpls** interfaces uses the EXP classifier. If a global EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

To configure an MPLS EXP classifier using the CLI:

1. Create an EXP classifier and associate it with a forwarding class, a loss priority, and a code point:

```
[edit class-of-service classifiers]
user@switch# set (dscp | ieee-802.1 | exp) classifier-name forwarding-class forwarding-class-name
loss-priority level code-points [aliases] [bit-patterns]
```

2. Apply the EXP classifier to the switch interfaces:

```
[edit class-of-service]
user@switch# set system-defaults classifiers exp classifier-name
```

Introduction to GMPLS

Traditional MPLS is designed to carry Layer 3 IP traffic using established IP-based paths and associating these paths with arbitrarily assigned labels. These labels can be configured explicitly by a network administrator, or can be dynamically assigned by means of a protocol such as LDP or RSVP.

GMPLS generalizes MPLS in that it defines labels for switching varying types of Layer 1, Layer 2, or Layer 3 traffic. GMPLS nodes can have links with one or more of the following switching capabilities:

- Fiber-switched capable (FSC)
- Lambda-switched capable (LSC)
- Time-division multiplexing (TDM) switched-capable (TSC)
- Packet-switched capable (PSC)

Label-switched paths (LSPs) must start and end on links with the same switching capability. For example, routers can establish packet-switched LSPs with other routers. The LSPs might be carried over a TDM-switched LSP between SONET add/drop multiplexers (ADMs), which in turn might be carried over a lambda-switched LSP.

The result of this extension of the MPLS protocol is an expansion in the number of devices that can participate in label switching. Lower-layer devices, such as OXCs and SONET ADMs, can now participate in GMPLS signaling and set up paths to transfer data. A router can participate in signaling optical paths across a transport network.

Two service models determine the visibility that a client node (a router, for example) has into the optical core or transport network. The first is through a user-to-network interface (UNI), which is often referred to as the overlay model. The second is known as the peer model. Juniper Networks supports both models.

NOTE: There is not necessarily a one-to-one correspondence between a physical interface and a GMPLS interface. If a GMPLS connection uses a nonchannelized physical connector, the GMPLS label can use the physical port ID. However, the label for channelized interfaces often is based on a channel or time slot. Consequently, it is best to refer to GMPLS labels as identifiers for a resource on a traffic engineering link.

To establish LSPs, GMPLS uses the following mechanisms:

- An out-of-band control channel and a data channel—RSVP messages for LSP setup are sent over an out-of-band control network. Once the LSP setup is complete and the path is provisioned, the data channel is up and can be used to carry traffic. The Link Management Protocol (LMP) is used to define and manage the data channels between a pair of nodes. You can optionally use LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- RSVP-TE extensions for GMPLS—RSVP-TE is already designed to signal the setup of packet LSPs. This has been extended for GMPLS to be able to request path setup for various kinds of LSPs (nonpacket) and request labels like wavelengths, time slots, and fibers as label objects.
- Bidirectional LSPs—Data can travel both ways between GMPLS devices over a single path, so nonpacket LSPs are signaled to be bidirectional.

GMPLS Terms and Acronyms

F

Forwarding adjacency A forwarding path for sending data between GMPLS-enabled devices.

G

Generalized MPLS (GMPLS) An extension to MPLS that allows data from multiple layers to be switched over label-switched paths (LSPs). GMPLS LSP connections are possible between similar Layer 1, Layer 2, and Layer 3 devices.

GMPLS label Layer 3 identifiers, fiber port, time-division multiplexing (TDM) time slot, or dense wavelength-division multiplexing (DWDM) wavelength of a GMPLS-enabled device used as a next-hop identifier.

GMPLS LSP types The four types of GMPLS LSPs are:

- Fiber-switched capable (FSC)—LSPs are switched between two fiber-based devices, such optical cross-connects (OXC) that operate at the level of individual fibers.
- Lambda-switched capable (LSC)—LSPs are switched between two DWDM devices, such as such as OXC that operate at the level of individual wavelengths.
- TDM-switched capable (TDM)—LSPs are switched between two TDM devices, such as SONET ADMs.
- Packet-switched capable (PSC)—LSPs are switched between two packet-based devices, such as routers or ATM switches.

L

Link Management Protocol A protocol used to define a forwarding adjacency between peers and to maintain and allocate resources on the traffic engineering links.

T

Traffic engineering link A logical connection between GMPLS-enabled devices. Traffic engineering links can have addresses or IDs and are associated with certain resources or interfaces. They also have certain attributes (encoding-type, switching capability, bandwidth, and so on). The logical addresses can be routable, although this is not required because they are acting as link identifiers. Each traffic engineering link represents a forwarding adjacency between a pair of devices.

GMPLS Operation

The basic functionality of GMPLS requires close interaction between RSVP and LMP. It works in the following sequence:

1. LMP notifies RSVP of the new entities:
 - Traffic engineering link (forwarding adjacency)

- Resources available for the traffic engineering link
 - Control peer
2. GMPLS extracts the LSP attributes from the configuration and requests RSVP to signal one or more specific paths, which are specified by the traffic engineering link addresses.
 3. RSVP determines the local traffic engineering link, corresponding control adjacency and active control channel, and transmission parameters (such as IP destination). It requests that LMP allocate a resource from the traffic engineering link with the specified attributes. If LMP finds a resource matching the attributes, label allocation succeeds. RSVP sends a PathMsg hop by hop until it reaches the target router.
 4. When the target router receives the PathMsg, RSVP again requests that LMP allocate a resource based on the signaled parameters. If label allocation succeeds, the router sends back a ResvMsg.
 5. If the signaling is successful, a bidirectional optical path is provisioned.

GMPLS and OSPF

You can configure OSPF for GMPLS. OSPF is an interior gateway protocol (IGP) that routes packets within a single autonomous system (AS). OSPF uses link-state information to make routing decisions.

GMPLS and CSPF

GMPLS introduces extra constraints for computing paths for GMPLS LSPs that use CSPF. These additional constraints affect the following link attributes:

- Signal type (minimum LSP bandwidth)
- Encoding type
- Switching type

These new constraints are populated in the traffic engineering database with the exchange of an interface-switching capability descriptor type, length, value (TLV) through an IGP.

The ignored constraints that are exchanged through the interface switching capability descriptor include:

- Maximum LSP bandwidth
- Maximum transmission unit (MTU)

The CSPF path computation is the same as in non-GMPLS environments, except that the links are also limited by GMPLS constraints.

Each link can have multiple interface-switching capability descriptors. All the descriptors are checked before a link is rejected.

The constraints are checked in the following order:

1. The signal type configured for the GMPLS LSP signifies the amount of bandwidth requested. If the desired bandwidth is less than the minimum LSP bandwidth, the interface-switching descriptor is rejected.
2. The encoding type of the link for the ingress and the egress interfaces should match. The encoding type is selected and stored at the ingress node after all the constraints are satisfied by the link and is used to select the link on the egress node.
3. The switching type of the links of the intermediate switches should match that of the GMPLS LSP specified in the configuration.

GMPLS Features

The Junos OS includes the following GMPLS functionality:

- An out-of-band control plane makes it possible to signal LSP path setup.
- RSVP-TE extensions support additional objects beyond Layer 3 packets, such as ports, time slots, and wavelengths.
- The LMP protocol creates and maintains a database of traffic engineering links and peer information. Only the static version of this protocol is supported in the Junos OS. You can optionally configure LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- Bidirectional LSPs are required between devices.
- Several GMPLS label types that are defined in RFC 3471, *Generalized MPLS—Signaling Functional Description*, such as MPLS, Generalized, SONET/SDH, Suggested, and Upstream, are supported. Generalized labels do not contain a type field, because the nodes should know from the context of their connection what type of label to expect.
- Traffic parameters facilitate GMPLS bandwidth encoding and SONET/SDH formatting.
- Other supported attributes include interface identification and errored interface identification, user-to-network (UNI)-style signaling, and secondary LSP paths.

Configuring MPLS Paths for GMPLS

As part of the configuration for GMPLS, you need to establish an MPLS path for each unique device connected through GMPLS. Configure the traffic engineering link remote address as the address at the **[edit protocols mpls path path-name]** hierarchy level. Constrained Shortest Path First (CSPF) is supported so you can choose either the **strict** or **loose** option with the address.

See *LMP Configuration Overview* for information about how to obtain a traffic engineering link remote address.

To configure the MPLS path, include the **path** statement at the **[edit protocols mpls]** hierarchy level:

```
[edit protocols mpls]
path path-name {
    next-hop-address (strict | loose);
}
```

For information about how to configure MPLS paths, see [“Creating Named Paths” on page 487](#).

Tracing LMP Traffic

To trace LMP protocol traffic, include the **traceoptions** statement at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`.

The following trace flags display the operations associated with the sending and receiving of various LMP messages:

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel
- **init**—Output from the initialization messages
- **packets**—Trace all packets other than hello packets on any LMP control channel
- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols
- **server**—Server processing operations
- **show**—Servicing operations for **show** commands
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

Each flag can carry one or more of the following flag modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

Configuring MPLS LSPs for GMPLS

IN THIS SECTION

- [Configuring the Encoding Type | 1257](#)
- [Configuring the GPID | 1258](#)
- [Configuring the Signal Bandwidth Type | 1258](#)
- [Configuring GMPLS Bidirectional LSPs | 1259](#)
- [Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS | 1259](#)

To enable the proper GMPLS switching parameters, configure the label-switched path (LSP) attributes that are appropriate for your network connection. The default value for **switching-type** is **psc-1**, which is also appropriate for standard MPLS.

To configure the LSP attributes, include the **lsp-attributes** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name]
lsp-attributes {
  encoding-type type;
  gpipid gpipid;
  signal-bandwidth type;
  switching-type type;
}
```

If you include the **no-cspf** statement in the label-switched path configuration, you must also configure primary and secondary paths, or the configuration cannot be committed.

The following sections describe how to configure each of the LSP attributes for a GMPLS LSP:

Configuring the Encoding Type

You need to specify the encoding type of the payload carried by the LSP. It can be any of the following:

- **ethernet**—Ethernet
- **packet**—Packet
- **pdh**—Plesiochronous digital hierarchy (PDH)
- **sonet-sdh**—SONET/SDH

The default value is **packet**.

To configure the encoding type, include the **encoding-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
encoding-type type;
```

Configuring the GPID

You need to specify the type of payload carried by the LSP. The payload is the type of packet underneath the MPLS label. The payload is specified by the generalized payload identifier (GPID).

You can specify the GPID with any of the following values:

- **hdlc**—High-Level Data Link Control (HDLC)
- **ethernet**—Ethernet
- **ipv4**—IP version 4 (default)
- **pos-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-scrambling-crc-32**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-32**—For interoperability with other vendors' equipment
- **ppp**—Point-to-Point Protocol (PPP)

To configure the GPID, include the **gpipid** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
gpipid gpipid;
```

Configuring the Signal Bandwidth Type

The signal bandwidth type is the encoding used for path computation and admission control. To configure the signal bandwidth type, include the **signal-bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  signal-bandwidth type;
```

Configuring GMPLS Bidirectional LSPs

Because MPLS and GMPLS use the same configuration hierarchy for LSPs, it is helpful to know which LSP attributes control LSP functionality. Standard MPLS packet-switched LSPs are unidirectional, whereas GMPLS nonpacket LSPs are bidirectional.

If you use the default packet-switching type of **psc-1**, your LSP becomes unidirectional. To enable a GMPLS bidirectional LSP, you must select a non-packet-switching type option, such as **lambda**, **fiber**, or **ethernet**. Include the **switching-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  switching-type (lambda | fiber | ethernet);
```

Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS

By setting the A-bit in the Admin Status object, you can enable nonpacket GMPLS LSPs to establish paths through routers that run Junos. When an ingress router sends an RSVP PATH message with the Admin Status A-bit set, an external device (not a router running the Junos OS) can either perform a Layer 1 path setup test or help bring up an optical cross-connect.

When set, the A-bit in the Admin Status object indicates the administrative down status for a GMPLS LSP. This feature is used specifically by nonpacket GMPLS LSPs. It does not affect control path setup or data forwarding for packet LSPs.

Junos does not distinguish between the control path setup and data path setup. Other nodes along the network path use RSVP PATH signaling using the A-bit in a meaningful way.

To configure the Admin Status object for a GMPLS LSP, include the **admin-down** statement:

```
admin-down;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]**

Gracefully Tearing Down GMPLS LSPs

IN THIS SECTION

- [Temporarily Deleting GMPLS LSPs | 1260](#)
- [Permanently Deleting GMPLS LSPs | 1260](#)
- [Configuring the Graceful Deletion Timeout Interval | 1261](#)

You can gracefully tear down nonpacket GMPLS LSPs. An LSP that is torn down abruptly, a common process in a packet-switched network, can cause stability problems in nonpacket-switched networks. To maintain the stability of nonpacket-switched networks, it might be necessary to tear down LSPs gracefully.

The following sections describe how to tear down GMPLS LSPs gracefully:

Temporarily Deleting GMPLS LSPs

You can gracefully tear down a GMPLS LSP using the **clear rsvp session gracefully** command.

This command gracefully tears down an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin Status object is signaled along the path to the endpoint of the LSP. During the second pass, the LSP is taken down. Using this command, the LSP is taken down temporarily. After the appropriate interval, the GMPLS LSP is resignaled and then reestablished.

The **clear rsvp session gracefully** command has the following properties:

- It only works on the ingress and egress routers of an RSVP session. If used on a transit router, it has the same behavior as the **clear rsvp session** command.
- It only works for nonpacket LSPs. If used with packet LSPs, it has the same behavior as the **clear rsvp session** command.

For more information, see the [CLI Explorer](#).

Permanently Deleting GMPLS LSPs

When you disable an LSP in the configuration, the LSP is permanently deleted. By configuring the **disable** statement, you can disable a GMPLS LSP permanently. If the LSP being disabled is a nonpacket LSP, then the graceful LSP tear-down procedures that use the Admin Status object are used. If the LSP being disabled is a packet LSP, then the regular signaling procedures for LSP deletion are used.

To disable a GMPLS LSP, include the **disable** statement at any of the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**—Disable the LSP.
- **[edit protocols link-management *te-link* *te-link-name*]**—Disable a traffic engineering link.

- **[edit protocols link-management [te-link](#) *te-link-name* [interface](#) *interface-name*]**—Disable an interface used by a traffic engineering link.

Configuring the Graceful Deletion Timeout Interval

The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.

The ingress router initiates the graceful deletion procedure by sending the Admin Status object in the path message with the **D** bit set. The ingress router expects to receive an Resv message with the **D** bit set from the egress router. If the ingress router does not receive this message within the time specified by the graceful deletion timeout interval, it initiates a forced tear-down of the LSP by sending a PathTear message.

To configure the graceful deletion timeout interval, include the **graceful-deletion-timeout** statement at the **[edit protocols rsvp]** hierarchy level. You can configure a time between 1 through 300 seconds. The default value is 30 seconds.

```
graceful-deletion-timeout seconds;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

You can use the **show rsvp version** command to determine the current value configured for the graceful deletion timeout.

GMPLS RSVP-TE VLAN LSP Signaling Overview

IN THIS SECTION

- [Supported and Unsupported Features | 1267](#)

Understanding GMPLS RSVP-TE Signaling

Signaling is the process of exchanging messages within the control plane to set up, maintain, modify, and terminate data paths (label-switched paths (LSPs)) in the data plane. Generalized MPLS (GMPLS) is a protocol suite that extends the existing control plane of MPLS to manage further classes of interfaces and to support other forms of label switching, such as time-division multiplexing (TDM), fiber (port), Lambda, and so on.

GMPLS extends intelligent IP/MPLS connections from Layer 2 and Layer 3 all the way to Layer 1 optical devices. Unlike MPLS, which is supported mainly by routers and switches, GMPLS can also be supported by optical platforms, including SONET/SDH, optical cross-connects (OXCs), and dense wave division multiplexing (DWDM).

In addition to labels, which are primarily used to forward data in MPLS, other physical entries, such as wavelengths, time slots, and fibers can be used as label objects to forward data in GMPLS, thereby leveraging the existing control plane mechanisms to signal different kinds of LSPs. GMPLS uses RSVP-TE to be able to request the other label objects to signal the various kinds of LSPs (nonpacket). Bidirectional LSPs and an out-of-band control channel and a data channel using the Link Management Protocol (LMP) are the other mechanisms that are used by GMPLS to establish LSPs.

Need for GMPLS RSVP-TE VLAN LSP Signaling

The traditional Layer 2 point-to-point services use Layer 2 circuits and Layer 2 VPN technologies that are based on LDP and BGP. In the traditional deployment, the customer edge (CE) devices do not participate in the signaling of the Layer 2 service. The provider edge (PE) devices manage and provision the Layer 2 service to provide end-to-end connectivity between the CE devices.

One of the biggest challenges of having the PE devices provision the Layer 2 services for each Layer 2 circuit between a pair of CE devices is the network management burden on the provider network.

[Figure 97 on page 1263](#) illustrates how the Layer 2 service is set up and used by the CE routers in a LDP/BGP-based Layer 2 VPN technology. Two CE routers CE1 and CE2 are connected to a provider MPLS network through the PE routers PE1 and PE2 respectively. The CE routers are connected to the PE routers by Ethernet links. Routers CE1 and CE2 are configured with VLAN1 and VLAN2 logical Layer 3 interfaces, so they appear to be directly connected. Routers PE1 and PE2 are configured with Layer 2 circuit (pseudowire) to carry the Layer 2 VLAN traffic between the CE routers. The PE routers use packet MPLS LSPs within the provider MPLS network to carry the Layer 2 VLAN traffic.

Figure 97: Traditional Layer 2 Point-to-Point Services

With the introduction of GMPLS-based VLAN LSP signaling, the need for the PE (also called server-layer) network to provision each individual Layer 2 connection between the CE (also called client) devices is minimized. The client router requests the server-layer router to which it is directly connected, for setting up the Layer 2 service to connect with a remote client router through GMPLS signaling.

The server-layer devices extend the signaling through the server-layer network to connect with the remote client routers. In the process, the server-layer device sets up the data plane for the Layer 2 service at the server-client border, and sets up the data plane for carrying the Layer 2 traffic within the server-layer network. With the Layer 2 service setup, the client routers can run IP/MPLS directly on top of the Layer 2 service and have IP/MPLS adjacency with each other.

In addition to reducing the provisioning activity needed on the server-layer devices, GMPLS signaling also provides the client routers with the flexibility of bringing up the Layer 2 circuits on an on-demand basis without depending on the server-layer administration for the provisioning of the Layer 2 service.

Using the same topology as in Figure 1, [Figure 98 on page 1263](#) illustrates how the Layer 2 service is set up and used by the client routers in GMPLS RSVP-TE-based Layer 2 VPN technology.

Figure 98: GMPLS RSVP-TE VLAN LSP

In [Figure 98 on page 1263](#), instead of configuring a pseudowire to carry the Layer 2 VLAN traffic between the client routers, Routers PE1 and PE2 are configured with an IP-based communication channel and other GMPLS-specific configurations (identification of Ethernet links as TE-links) for allowing the exchange of GMPLS RSVP-TE signaling messages with the client routers. Routers CE1 and CE2 are also configured with an IP-based communication channel and relevant GMPLS configuration for exchanging the GMPLS RSVP-TE signaling messages with the server-layer routers. Routers CE1 and CE2 establish an IP/MPLS adjacency on top of this Layer 2 service.

GMPLS RSVP-TE VLAN LSP Signaling Functionality

Based on [Figure 98 on page 1263](#), the client router establishes the Layer 2 service in the server-layer network as follows:

1. Router CE1 initiates GMPLS RSVP-TE signaling with Router PE1. In this signaling message, Router CE1 indicates the VLAN on the Ethernet link for which it needs the Layer 2 service and the remote CE router, Router CE2, with which the VLAN should be connected.

Router CE1 also indicates the remote PE router, Router PE2, to which Router CE2 is connected, and the exact Ethernet link connecting Router CE2 to Router PE2 on which the Layer 2 service is required in the signaling message.
2. Router PE1 uses the information from Router CE1 in the signaling message and determines the remote PE router, Router PE2, with which Router CE2 is attached. Router PE1 then establishes a packet MPLS LSP (associated bidirectional) through the server-layer MPLS network for carrying the VLAN traffic and then passes the GMPLS RSVP-TE signaling message to Router PE2 using the LSP hierarchy mechanism.
3. Router PE2 propagates the GMPLS RSVP-TE signaling message to Router CE2 with the VLAN to be used on the PE2-CE2 Ethernet link.
4. Router CE2 responds with an acknowledgment to the GMPLS RSVP-TE signaling message to Router PE2. Router PE2 then propagates it to Router PE1, which in turn propagates it to Router CE1.
5. As part of this message propagation, Routers PE1 and PE2 set up the forwarding plane to enable bidirectional flow of VLAN Layer 2 traffic between Routers CE1 and CE2.

LSP Hierarchy with GMPLS RSVP-TE VLAN LSP

The Layer 2 service in GMPLS RSVP-TE VLAN LSP signaling is brought up using a hierarchy mechanism in which two different RSVP LSPs are created for the Layer 2 service:

- An end-to-end VLAN LSP that has state information at the client and server-layer routers.
- An associated bidirectional packet transport LSP that is present in the server-layer routers (PE and P) of the server-layer network.

The LSP hierarchy avoids sharing information about technology-specific LSP characteristics with the core nodes of the server-layer network. This solution cleanly separates the VLAN LSP state and the transport LSP state, and ensures that the VLAN LSP state is only present on the nodes (PE, CE) where it is needed.

Path Specification for GMPLS RSVP-TE VLAN LSP

The path for the GMPLS RSVP-TE LSP is configured as an Explicit Route Object (ERO) at the initiating client router. As this LSP traverses different network domains (initiating, terminating at client network, and traversing the server-layer network), the LSP setup falls under the category of an interdomain LSP setup. In an interdomain scenario, one network domain generally does not have full visibility into the

topology of the other network domain. Hence, the ERO that gets configured at the initiating client router does not have full hop information for the server-layer portion. This feature requires that the ERO configured at the CE router has three hops, with the first hop being a strict hop identifying the CE1-PE1 Ethernet link, the second hop being a loose hop identifying the egress PE router (PE2), and the third hop being a strict hop identifying the CE2-PE2 Ethernet link.

GMPLS RSVP-TE VLAN LSP Configuration

The configuration required to set up a GMPLS VLAN LSP at the client and server routers uses the existing GMPLS configuration model with some extensions. The Junos OS GMPLS configuration model for nonpacket LSPs is targeted toward bringing the physical interfaces up and running through GMPLS RSVP-TE signaling, whereas signaling a GMPLS RSVP-TE VLAN LSP aims at bringing up individual VLANs on top of a physical interface. The **ethernet-vlan** configuration statement under the **[edit protocols link-management te-link]** hierarchy enables this.

The client router has physical interfaces connected to a server network, and the server network provides a point-to-point connection between two client routers over the attached physical interfaces. The physical interface is brought into an operational state by GMPLS RSVP-TE as follows:

1. The client router maintains a routing or signaling adjacency with the server network node to which the physical interface is connected, typically through a control channel different from the physical interface, because the physical interface itself is brought up and running only after the signaling.
2. The client router and the server network node identify the physical interfaces connecting them using the TE-link mechanism.
3. The client router and the server network node use the TE-link identifier (IP address) as the GMPLS RSVP hop and the physical interface identifier as the GMPLS label values in the GMPLS RSVP-TE signaling messages to bring the physical interface into an operational state.

In the existing GMPLS configuration, the server and client network nodes use the **protocols link-management peer *peer-name*** configuration statement to specify the adjacent peer node. Because a client router can have one or more physical interfaces connected to the server network node, these physical interfaces are grouped and identified by an IP address through the **protocols link-management te-link *link-name*** configuration statement. The TE-link is assigned a local IP address, a remote IP address, and a list of physical interfaces. The TE-link is then associated with the **protocols link-management peer *peer-name* te-link *te-link-list*** configuration statement.

The out-of-band control channel that is required for exchanging signaling messages is specified using the **protocols link-management peer *peer-name* control-channel *interface-name*** configuration statement. The existence of the server or client network node is made visible to the RSVP and IGP (OSPF) protocols through the **peer-interface *interface-name*** configuration statement under the **[edit protocols rsvp]** and **[edit protocols ospf]** hierarchy levels.

In the existing GMPLS configuration, the label (upstream label and resv label) that is carried in the signaling message is an integer identifier that identifies the physical interface that is required to be brought up. As the label is used to identify the physical interface, the existing GMPLS configuration allows multiple

interfaces to be grouped under a single TE-link. In the existing GMPLS configuration, there is sufficient information in the GMPLS RSVP-TE signaling message, such as TE-link address and label value, to identify the physical interface that is required to be brought up. In contrast, for GMPLS RSVP-TE VLAN LSP configuration, the VLAN ID value is used as the label in the signaling message.

In the GMPLS RSVP-TE VLAN LSP configuration, if multiple interfaces are allowed to be configured under a single TE-link, using VLAN ID as the label value in the signaling message can cause ambiguity as to which physical interface on which the VLAN has to be provisioned. Therefore, the TE-link is configured with the **ethernet-vlan** configuration statement, if the number of physical interfaces that can be configured under the TE-link is restricted to only one.

In the existing GMPLS configuration, the bandwidth for a nonpacket LSP is a discrete quantity that corresponds to the bandwidth of the physical interface that needs to be brought up. So, the GMPLS LSP configuration does not allow any bandwidth to be specified, but allows the bandwidth to be specified only through the **signal-bandwidth** configuration statement under the **[protocols mpls label-switched-path lsp-name lsp-attributes]** hierarchy level. In the GMPLS VLAN LSP configuration, bandwidth is specified similar to that of a packet LSP. In the GMPLS VLAN LSP configuration, the **bandwidth** option is supported and **signal-bandwidth** is not supported.

Associated Bidirectional Packet LSP

The GMPLS RSVP-TE VLAN LSP is carried on an associated bidirectional transport LSP within the server-layer network, which is a single-sided provisioned LSP. The transport LSP signaling is initiated as a unidirectional LSP from the source router to the destination router in the forward direction, and the destination router in turn initiates the signaling of the unidirectional LSP in the reverse direction back to the source router.

Make-Before-Break for Associated Bidirectional Packet and GMPLS RSVP-TE VLAN LSP

The make-before-break support for an associated bidirectional transport LSP follows a similar model, where the destination router for the forward direction of the bidirectional LSP does not perform any make-before-break operations on the reverse direction of the bidirectional LSP. It is the source router (initiator of the associated bidirectional LSP) that initiates the make-before-break newer instance of the associated bidirectional LSP, and the destination router in turn initiates the make-before-break newer instance in the other direction.

For instance, in [Figure 98 on page 1263](#), the unidirectional transport LSP is initiated from Router PE1 to Router PE2 in the forwarding direction, and in turn Router PE2 initiates the transport LSP to Router PE1 in the reverse direction. When a make-before-break instance occurs, only Router PE1 as the initiating client router can establish a new instance of the associated bidirectional LSP. Router PE2 in turn initiates the make-before-break newer instance in the reverse direction.

The make-before-break support for the associated bidirectional transport LSP is used only in scenarios where the transport LSP gets into a state of being locally protected due to link or node failure on the path of the LSP. The GMPLS RSVP-TE VLAN LSP uses the make-before-break mechanism for adjusting seamless bandwidth changes.

NOTE: Periodic re-optimization is not enabled for the associated bidirectional transport LSPs.

The newer make-before-break instance of the GMPLS VLAN LSP is supported under the following constraints:

- It should originate from the same client router as the older instance and be destined to the same client router as the older instance.
- It should use the same server-client links at both the server-client ends as the older instance.
- It should use the same VLAN label at the server-client links as the older instance.
- The GMPLS VLAN LSP should be configured as **adaptive** when the bandwidth change is initiated from the CLI, or else the current instance of the VLAN LSP is torn down and a new VLAN LSP instance is established.

The make-before-break operation for the GMPLS VLAN LSP on the server-layer edge router is rejected if these constraints are not met.

On the server-layer edge routers, when a make-before-break instance of the GMPLS VLAN LSP is seen, a completely new, separate associated bidirectional transport LSP is created to support this make-before-break instance. The existing associated bidirectional LSP (supporting the older instance) is not triggered to initiate a make-before-break instance at the transport LSP level. An implication of this choice (of initiating a new transport LSP) is that at the server-layer resource/bandwidth sharing does not happen when a make-before-break operation is performed for the GMPLS VLAN LSP.

Supported and Unsupported Features

Junos OS supports the following features with the GMPLS RSVP-TE VLAN LSP:

- Request for specific bandwidth and local protection for the VLAN LSP on the client router to the server-layer router.
- Nonstop active routing (NSR) support for the GMPLS VLAN LSP at the client routers, server-layer edge routers, and associated bidirectional transport LSP at the server-layer edge routers.
- Multichassis support.

Junos OS does **not** support the following GMPLS RSVP-TE VLAN LSP functionality:

- Graceful restart support for associated bidirectional packet LSP and GMPLS VLAN LSP.
- End-to-end path computation for GMPLS VLAN LSP using CSPF algorithm at the client router.
- Non-CSPF routing-based discovery of next-hop routers by the different client, server-layer edge routers.
- Automatic provisioning of the client Layer 3 VLAN interfaces upon the successful setup of the VLAN LSP at the client routers.
- MPLS OAM (LSP-ping, BFD).

- Packet MPLS applications, such as next-hop in static route and in IGP shortcuts.
- Local cross connect mechanism, where a client router connects to a remote client router which is connected to the same server router.
- Junos OS Services Framework.
- IPv6 support.
- Logical systems.
- Aggregated Ethernet/SONET/IRB interfaces at the server-client link.

Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling

IN THIS SECTION

- [Requirements | 1268](#)
- [Overview | 1269](#)
- [Configuration | 1275](#)
- [Verification | 1289](#)

This example shows how to configure GMPLS RSVP-TE VLAN LSP signaling on the client routers to enable one client router to connect with a remote client router through a server-layer network using the LSP hierarchy. This enables the client routers to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network.

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, and PTX Series Packet Transport Routers
- Junos OS Release 14.2 or later running on the client routers and server-layer edge routers

Before you begin:

1. Configure the device interfaces.
2. Configure the interface-associated VLANs.
3. Configure the following routing protocols:
 - RSVP

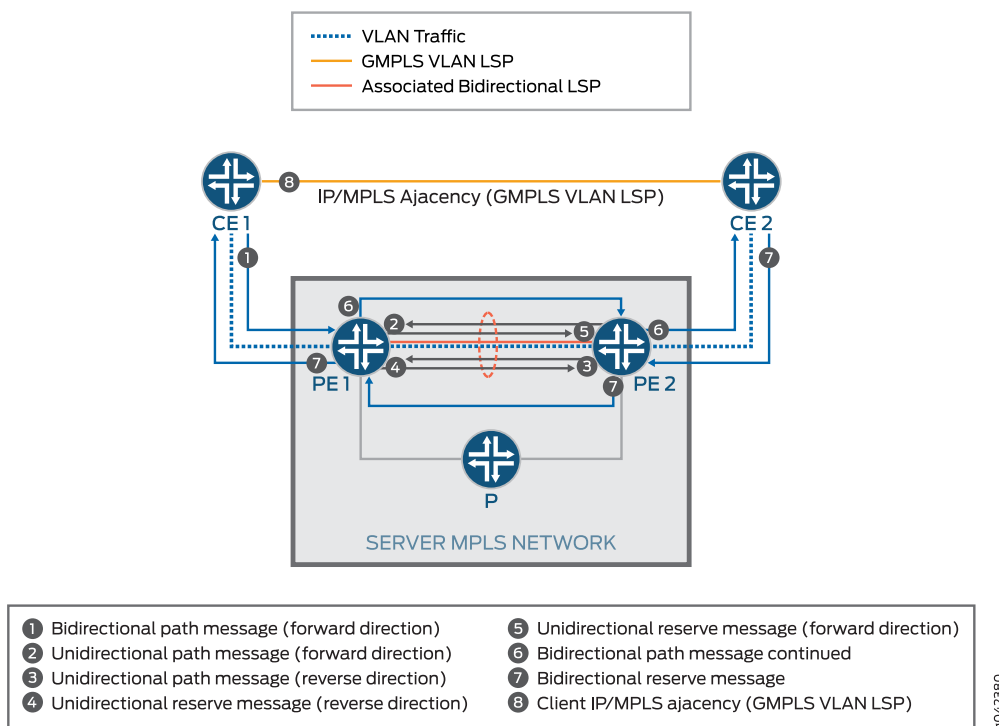

- MPLS
- LMP

Overview

Starting with Junos OS Release 14.2, the Layer 2 services between two client routers across an external/third-party server-layer network are set up by the client routers on an on-demand basis through GMPLS RSVP-TE signaling. This feature provides the client routers the flexibility to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network. In traditional Layer 2 VPN technology based on LDP and BGP, the provider network handled the provisioning activity for each Layer 2 circuit established between two client routers.

Figure 99 on page 1269 illustrates the setting up and signaling of the GMPLS VLAN LSP between two client routers, CE1 and CE2, across a server-layer network with two server-layer edge routers, PE1 and PE2, and one server-layer core router, P.

Figure 99: Setting Up a GMPLS VLAN LSP

The signaling of GMPLS VLAN LSP is executed as follows:

1. Initiating GMPLS VLAN LSP at CE1

Router CE1 initiates the GMPLS VLAN LSP setup by sending the GMPLS RSVP-TE path message to Router PE1. The signaling between CE1 and PE1 is over an out-of-band control channel, which is a separate control VLAN configured on the Ethernet link connecting the two routers.

The GMPLS RSVP-TE path message initiated by Router CE1 is used to perform the following:

- a. Identify the Ethernet link on which the VLAN is active.
- b. Abstract the Ethernet link as a TE-link and assign an IP address to identify the Ethernet link.
- c. Allocate a VLAN ID from the pool of free VLANs managed by Router CE1 for every Ethernet link connecting Router PE1 to the identified Ethernet link.

This VLAN ID can also be used for the GMPLS VLAN LSP at the CE2-PE2 Ethernet link.

- d. Identify the VLAN for which the Layer 2 service is required to be set up using the allocated VLAN ID as the upstream label object and the upstream direction label value.
- e. Include an ERO object that helps Router PE1 in establishing the VLAN LSP through the server-layer network to the remote client router, CE2. The ERO object in the path message includes three hops:
 - First hop—Strict hop identifying the initiating client-server Ethernet link, PE1-CE1.
 - Second hop—Loose hop identifying the remote server-layer router, PE2.
 - Third hop—Strict hop identifying the remote client-server Ethernet link, PE2-CE2.
- f. Include the bandwidth required for the GMPLS VLAN LSP.
- g. Include any local-protection required within the server-layer network for the VLAN LSP.

2. Initiating Associated Bidirectional Transport LSP at PE1

After Router PE1 receives the path message from Router CE1, the message is validated to check the availability of the Ethernet link and VLAN ID. In the server-layer network, the Layer 2 services between the server-layer routers, PE1 and PE2, are provided at the data plane in a manner similar to Layer 2 circuits. Router PE1 brings up a transport LSP to Router PE2 and then extends the GMPLS VLAN LSP as a hierarchical LSP running on top of the PE1-PE2 transport LSP. The PE1-PE2 transport LSP is a packet LSP and is bidirectional in nature. This is because the GMPLS VLAN LSP is bidirectional and each server-layer router needs to be able to do the following:

- Receive traffic from the server-client Ethernet link (for example, the PE1-CE1 link) and send it to the remote server-layer router, PE2.
- Receive traffic from remote Router PE2 and send it on the PE1-CE1 Ethernet link.

For each GMPLS VLAN LSP, a packet transport LSP is set up within the server-layer network. The transport LSP is exclusively used to carry traffic of the GMPLS VLAN LSP for which it was created. The

transport LSP is dynamically created at the time of receiving the GMPLS VLAN LSP; thus, no configuration is required to trigger its creation. The transport LSP established for the VLAN LSP inherits the bandwidth and the local-protection attributes from the VLAN LSP.

Router PE1 signals the PE1-PE2 transport LSP to Router PE2. Router PE1 determines the destination for the transport LSP from the loose hop specified in the ERO object of the GMPLS RSVP-TE path message from Router CE1 and then signals the VLAN LSP. However, if the PE1-PE2 transport LSP fails to establish, Router PE1 sends back a path error message to Router CE1, and the GMPLS VLAN LSP is not established as well.

3. Setting Up the Associated Bidirectional Transport LSP Between the Server-Layer Routers

The associated bidirectional LSP between routers PE1 and PE2 consists of two unidirectional packet LSPs:

- PE1-to-PE2
- PE2-to-PE1

Router PE1 initiates signaling of a unidirectional packet LSP to Router PE2. This unidirectional packet LSP constitutes the forward direction (PE1-to-PE2) of the associated bidirectional LSP, and the path message carries the Extended Association Object indicating this is a single-sided provisioning model. On receiving the path message for the LSP, Router PE2 responds with a Resv message and triggers the signaling of a unidirectional packet LSP to Router PE1 with the same path as (PE1-to-PE2) in the reverse direction. This unidirectional packet LSP uses the PE2-to-PE1 direction of the associated bidirectional LSP, and this path message carries the same Extended Association Object seen in the PE1-to-PE2 path message.

When Router PE1 receives the Resv message for the PE1-to-PE2 unidirectional LSP and the path message for the PE2-to-PE1 unidirectional LSP, PE1 binds the PE1-to-PE2 and PE2-to-PE1 unidirectional LSPs by matching the Extended Association Objects carried in the respective path messages. For the path message for the PE2-to-PE1 unidirectional LSP, Router PE1 responds with the Resv Message. On receiving the Resv message for the PE1-to-PE2 LSP and the path message for the PE2-to-PE1 LSP, Router PE1 has established the associated bidirectional packet transport LSP.

4. Setting Up the GMPLS VLAN LSP at Router PE1

After successfully establishing the transport LSP, Router PE1 triggers the signaling of the GMPLS VLAN LSP. Router PE1 sends the GMPLS RSVP-TE path message corresponding to the VLAN LSP directly to Router PE2, which is bidirectional in nature and includes the upstream label object.

Router PE2 is not aware of the association between the transport LSP and the VLAN LSP. This association is indicated to Router PE2 by Router PE1.

5. Setting Up the GMPLS VLAN LSP at Router PE2

On receiving the VLAN LSP path message from Router PE1, Router PE2 verifies the availability of the transport LSP. If the transport LSP is not available or the LSP setup is in progress, the VLAN LSP processing is put on hold. When the transport LSP is available, Router PE2 processes the VLAN LSP path message. The ERO object in this path message indicates that the next hop is a strict hop identifying the PE2-to-CE2 Ethernet link. The ERO object can indicate the VLAN ID to be used on the PE2-to-CE2 Ethernet link by Router PE2.

Router PE2 appropriately allocates the VLAN ID to be sent as the upstream label in the VLAN LSP path message to Router CE2, and sends it through an out-of-band control channel.

6. Processing the GMPLS VLAN LSP at Router CE2

On receiving the GMPLS RSVP-TE LSP from Router PE2, Router CE2 validates the availability of VLAN ID for allocation on the PE2-to-CE2 link. Router CE2 then allocates the VLAN ID for this VLAN LSP and sends back a Resv message to Router PE2 with the VLAN ID as the label object in the Resv message.

7. Processing the GMPLS VLAN LSP at Router PE2

On receiving the Resv message from Router CE2, Router PE2 validates that the label object in the Resv message has the same VLAN ID as in the path message. Router PE2 then allocates a 20-bit MPLS label, which is included in the Resv message sent to Router PE1.

Router PE2 then programs the forwarding plane with the entries to provide the Layer 2 service functionality.

NOTE: For all the VLAN IDs that can be allocated as labels on the PE1-to-CE1 and PE2-CE2 Ethernet links, you must manually configure logical interfaces for circuit cross-connect (CCC) purposes on the server-layer edge routers and not for other families, such as IPv4, IPv6, or MPLS.

8. Processing the GMPLS VLAN LSP at Router PE1

On receiving the Resv message for the VLAN LSP from Router PE2, Router PE1 sends a Resv message to Router CE1 with the same VLAN ID it received as the upstream label from Router CE1. Router PE1 programs the forwarding plane with the entries to provide the Layer 2 service functionality as Router PE2.

9. Processing the GMPLS VLAN LSP at Router CE1

On receiving the Resv message from Router PE1, Router CE1 validates that the VLAN ID received in the Resv message matches the VLAN ID in the upstream label in the path message it sent. This completes the setup of the GMPLS VLAN LSP from Router CE1 to Router CE2.

NOTE:

- The GMPLS VLAN LSP setup does not result in the addition of any forwarding plane entries at the client routers, CE1 and CE2. Only the server-layer routers, PE1 and PE2, add the forwarding plane entries for the GMPLS VLAN LSP.
- There is no routing information exchange between the client and the server-layer routers. The client and server-layer routers do not exchange their network topology information with each other.

10. Accounting for Bandwidth of the GMPLS VLAN LSP

On successfully setting up the GMPLS VLAN LSP, both the client and server-layer routers reduce the amount of available bandwidth on the server-client Ethernet links by the bandwidth amount allocated for the GMPLS VLAN LSP. This bandwidth accounting information is used for admission control purposes when additional GMPLS VLAN LSPs are brought up on the server-client Ethernet links.

11. Using GMPLS VLAN LSP by the Client Routers

After successfully setting up the GMPLS VLAN LSP, the client routers – CE1 and CE2 – need to be manually configured with the VLAN logical interface on top of the server-client Ethernet links with the signaled VLAN ID. This logical interface needs to be configured with the IP address and needs to be included in the IGP protocol. As a result of this configuration, Routers CE1 and CE2 establish IGP adjacency and exchange data traffic over the Layer 2 service established through the GMPLS signaling.

[Figure 100 on page 1274](#) illustrates the data traffic flow of the GMPLS VLAN LSP from Router CE1 to Router CE2 after the LSP setup is complete and the necessary CE1-to-CE2 IGP/MPLS adjacency has been established. The server-layer transport LSP originates from Router PE1, traverses a single server-layer core router, Router P, and reaches Router PE2. The server-layer transport LSP is shown as a penultimate-hop pop LSP, where Router P pops off the transport LSP label, and only the service label is present on the P-to-PE2 link.

Figure 100: Data Traffic Flow of GMPLS VLAN LSP

Topology

In [Figure 101 on page 1274](#), GMPLS RSVP-TE VLAN LSP signaling is used to establish the Layer 2 services between the client routers, Router CE1 and Router CE2. The server routers, Router PE1 and Router PE2, have a GRE tunnel established with each of the directly connected client routers. Routers P1 and P2 are also server routers in the server-layer network.

Figure 101: Configuring GMPLS RSVP-TE VLAN LSP Signaling

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring the Client Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router CE1:

NOTE: Repeat this procedure for Router CE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router CE1 to Router PE1.

```

[edit interfaces]
user@CE1# set ge-0/0/0 vlan-tagging

```

2. Configure the control VLAN for the ge-0/0/0 interface.

```

[edit interfaces]
user@CE1# set ge-0/0/0 unit 1 vlan-id 1
user@CE1# set ge-0/0/0 unit 1 family inet address 1.1.1.1/30
user@CE1# set ge-0/0/0 unit 1 family mpls

```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@CE1# set ge-0/0/0 unit 10 vlan-id 10
user@CE1# set ge-0/0/0 unit 10 family inet address 10.10.10.1/24
user@CE1# set ge-0/0/0 unit 10 family mpls
```

4. Configure the GRE tunnel as the controlling interface for Router CE1.

```
[edit interfaces]
user@CE1# set gre unit 0 tunnel source 1.1.1.1
user@CE1# set gre unit 0 tunnel destination 1.1.1.2
user@CE1# set gre unit 0 family inet address 10.35.100.25/30
```

5. Configure the loopback interface of Router CE1.

```
[edit interfaces]
user@CE1# set lo0 unit 0 family inet address 10.255.10.1/32
```

6. Configure the loopback address of Router CE1 as its router ID.

```
[edit routing-options]
user@CE1# set router-id 10.255.10.1
```

7. Enable RSVP on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set rsvp interface all
user@CE1# set rsvp interface fxp0.0 disable
```

8. Configure the RSVP peer interface for Router CE1.

```
[edit protocols]
user@CE1# set rsvp peer-interface PE1
```

9. Disable automatic path computation for label-switched paths (LSPs).

```
[edit protocols]
```

```
user@CE1# set mpls no-cspf
```

10. Configure the LSP to connect Router CE1 to Router CE2.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 from 10.255.10.1
user@CE1# set mpls label-switched-path CE1-to-CE2 to 10.255.10.6
```

11. Configure the CE1-to-CE2 LSP attributes.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes switching-type ethernet-vlan
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes upstream-label vlan-id 10
user@CE1# set mpls label-switched-path CE1-to-CE2 bandwidth 100m
```

12. Configure the CE1-to-CE2 LSP path and path parameters.

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 primary path1
user@CE1# set mpls path path1 10.35.1.2 strict
user@CE1# set mpls path path1 10.255.10.5 loose
user@CE1# set mpls path path1 10.36.1.1 strict
```

13. Enable MPLS on all the interfaces of Router CE1, excluding the management interface.

```
[edit protocols]
user@CE1# set mpls interface all
user@CE1# set mpls interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@CE1# set link-management te-link link10 local-address 10.35.1.1
user@CE1# set link-management te-link link10 remote-address 10.35.1.2
```

15. Enable setting up of Layer 2 VLAN LSP on the link10 traffic engineering link.

```
[edit protocols]
```

```
user@CE1# set link-management te-link link10 ethernet-vlan
```

16. Configure the Router CE1 interface as the member interface of the link10 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link10 interface ge-0/0/0
```

17. Configure Router PE1 as the Link Management Protocol (LMP) peer for Router CE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer PE1 address 10.255.10.2
user@CE1# set link-management peer PE1 control-channel gre.0
user@CE1# set link-management peer PE1 te-link link10
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-0/0/0 {
  vlan-tagging;
  unit 1 {
    vlan-id 1;
    family inet {
      address 1.1.1.1/30;
    }
    family mpls;
  }
  unit 10 {
    vlan-id 10;
    family inet {
      address 10.10.10.1/24;
    }
    family mpls;
  }
}

```

Configuring the Server Router

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router PE1 to Router CE1.

```

[edit interfaces]
user@PE1# set ge-0/0/0 vlan-tagging
user@PE1# set ge-0/0/0 encapsulation flexible-ethernet-services

```

2. Configure the control VLAN for the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 1 vlan-id 1
user@PE1# set ge-0/0/0 unit 1 family inet address 1.1.1.2/30
user@PE1# set ge-0/0/0 unit 1 family mpls
```

3. Configure the LSP VLAN on the ge-0/0/0 interface.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 10 encapsulation vlan-ccc
user@PE1# set ge-0/0/0 unit 10 vlan-id 10
```

4. Configure the interface connecting Router PE1 to the core routers (Router P1 and Router P2).

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 70.70.70.1/30
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 20.20.20.1/30
user@PE1# set ge-0/0/2 unit 0 family mpls
```

5. Configure the GRE tunnel as the controlling interface for Router PE1.

```
[edit interfaces]
user@PE1# set gre unit 0 tunnel source 1.1.1.2
user@PE1# set gre unit 0 tunnel destination 1.1.1.1
user@PE1# set gre unit 0 family inet address 10.35.100.26/30
```

6. Configure the loopback interface of Router PE1.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.10.2/32
```

7. Configure the loopback address of Router PE1 as its router ID.

```
[edit routing-options]
user@PE1# set router-id 10.255.10.2
```

8. Configure an associated bidirectional LSP, and enable unidirectional reverse LSP setup for single-sided provisioned forward LSP.

```
[edit protocols]
user@PE1# set rsdp associated-bidirectional-lsp single-sided-provisioning
```

9. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsdp interface all
user@PE1# set rsdp interface fxp0.0 disable
```

10. Configure the RSVP peer interface for Router PE1, and enable dynamic setup of bidirectional packet LSP for transporting nonpacket GMPLS LSP.

```
[edit protocols]
user@PE1# set rsdp peer-interface CE1 dynamic-bidirectional-transport
```

11. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

12. Configure OSPF with traffic engineering capabilities.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

13. Enable OSPF area 0 on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.

```
[edit protocols]
user@PE1# set link-management te-link link1 local-address 10.35.1.2
user@PE1# set link-management te-link link1 remote-address 10.35.1.1
```

15. Enable setting up of a Layer 2 VLAN LSP for a specific range of VLANs on the link1 traffic engineering link.

```
[edit protocols]
user@PE1# set link-management te-link link1 ethernet-vlan vlan-id-range 1-1000
```

16. Configure the Router PE1 interface as the member interface of the link1 traffic engineering link.

```
[edit protocols]
user@CE1# set link-management te-link link1 interface ge-0/0/0
```

17. Configure Router CE1 as the LMP peer for Router PE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer CE1 address 10.255.10.1
user@CE1# set link-management peer CE1 control-channel gre.0
user@CE1# set link-management peer CE1 te-link link1
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
  vlan-tagging;
  encapsulation flexible-ethernet-services;
  unit 1 {
    vlan-id 1;
    family inet {
      address 1.1.1.2/30;
    }
    family mpls;
  }
  unit 10 {
    encapsulation vlan-ccc;
    vlan-id 10;
  }
}
ge-0/0/1 {
  unit 0 {
```

```

        family inet {
            address 70.70.70.1/30;
        }
        family mpls;
    }
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 20.20.20.1/30;
        }
        family mpls;
    }
}
gre {
    unit 0 {
        tunnel {
            source 1.1.1.2;
            destination 1.1.1.1;
        }
        family inet {
            address 10.35.100.26/30;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.10.2/32;
        }
    }
}

```

```

user@PE1# show routing-options

            vlan-id-range 1-1000;
        }
        interface ge-0/0/0;
    }
    peer CE1 {
        address 10.255.10.1;
        control-channel gre.0;
        te-link link1;
    }
}

```

Verification

IN THIS SECTION

- [Verifying the Traffic Engineering Link Status on the Client Routers | 1290](#)
- [Verifying the RSVP Session Status on the Client Routers | 1291](#)
- [Verifying the LSP Status on the Server Router | 1292](#)

- [Verifying the CCC Entries in the MPLS Routing Table of the Server Routers | 1293](#)
- [Verifying End-to-End Connectivity | 1294](#)

Confirm that the configuration is working properly.

Verifying the Traffic Engineering Link Status on the Client Routers

Purpose

Verify the status of the traffic engineering link configured between Router CE1 and Router CE2.

Action

From operational mode, run the **show link-management** and the **show link-management te-link detail** commands.

```
user@CE1> show link-management
```

```
Peer name: PE1, System identifier: 50740
State: Up, Control address: 10.255.10.2
Hello interval: 150, Hello dead interval: 500
  Control-channel      State
  gre.0                Active
TE links:
  link10

TE link name: link10, State: Up
  Local identifier: 65075, Remote identifier: 0, Local address: 10.35.1.1, Remote
address: 10.35.1.2, Encoding: Ethernet, Switching: EVPL, Minimum bandwidth: 0bps,

  Maximum bandwidth: 1000Mbps, Total bandwidth: 1000Mbps, Available bandwidth:
900Mbps
  Name                  State Local ID Remote ID      Bandwidth Used
  LSP-name
  ge-0/0/0              Up          54183         0          1000Mbps Yes
  CE1-to-CE2
```

```
user@CE1> show link-management te-link detail
```

```

address: 10.36.1.2, Encoding: Ethernet, Switching: EVPL, Minimum bandwidth: 0bps,

Maximum bandwidth: 1000Mbps, Total bandwidth: 1000Mbps, Available bandwidth:
900Mbps

```

Name	State	Local ID	Remote ID	Bandwidth	Used
LSP-name					
ge-0/0/0	Up	54183	0	1000Mbps	Yes
CE1-to-CE2					

Meaning

The Link Management Protocol (LMP) peering has been established between the client routers, and the traffic engineering link is up on both Routers CE1 and CE2.

Verifying the RSVP Session Status on the Client Routers

Purpose

Verify the status of the RSVP sessions between Router CE1 and Router CE2.

Action

From operational mode, run the **show rsvp session** command.

```
user@CE1> show rsvp session
```

Ingress RSVP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.255.10.6	10.255.10.1	Up	0	1 FF	-	10	CE1-to-CE2 Bidir

Total 1 displayed, Up 1, Down 0

Egress RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

```
user@CE2> show rsvp session
```

Ingress RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Egress RSVP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
10.255.10.6	10.255.10.1	Up	0	1 FF	10	-	CE1-to-CE2 Bidir

Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning

The RSVP sessions are established between the ingress router, Router CE1, and the egress router, Router CE2.

Verifying the LSP Status on the Server Router

Purpose

Verify the status of the MPLS LSP on Router PE1.

Action

From operational mode, run the **show mpls lsp** command.

```
user@PE1> show mpls lsp
```

```
Ingress LSP: 1 sessions
To          From          State Rt P    ActivePath    LSPname
10.255.10.5  10.255.10.2    Up    0  *
vlan:0:10:8176:10.255.10.2->10.255.10.5 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
10.255.10.2  10.255.10.5    Up    0  1 FF      3      -
vlan:0:10:8176:10.255.10.2->10.255.10.5:rev
Total 1 displayed, Up 1, Down 0

Transit LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
10.255.10.6  10.255.10.1    Up    0  1 FF      10     299808 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0
```

Meaning

The CE1-to-CE2 LSP is established, and the output displays the LSP attributes.

Verifying the CCC Entries in the MPLS Routing Table of the Server Routers

Purpose

Verify the circuit cross-connect (CCC) interface entries in the MPLS routing table.

Action

From operational mode, run the **show route table mpls.0** and the **show route forwarding-table ccc ccc-interface** commands.

```
user@PE1> show route table mpls.0
```

```
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 1d 22:14:51, metric 1
            Receive
1          *[MPLS/0] 1d 22:14:51, metric 1
            Receive
2          *[MPLS/0] 1d 22:14:51, metric 1
            Receive
13         *[MPLS/0] 1d 22:14:51, metric 1
```

```

                Receive
299824          *[RSVP/7/1] 17:32:07, metric 1
                > via ge-0/0/0.10, Pop
ge-0/0/0.10    *[RSVP/7/1] 17:32:07, metric 1
                > to 20.20.20.2 via ge-0/0/2.0, label-switched-path CE1-to-CE2

```

```
user@PE1> show route forwarding-table ccc ge-0/0/0.10
```

```

Routing table: default.mpls
MPLS:
Destination      Type RtRef Next hop                Type Index   NhRef Netif
ge-0/0/0.10      (CCC) user      0 20.20.20.2          Push 299808, Push 299872(top)
581              2 ge-0/0/2.0

Routing table: __mpls-oam__.mpls
MPLS:
Destination      Type RtRef Next hop                Type Index   NhRef Netif
default          perm      0                               dscd      534      1

```

Meaning

The output displays the CCC interface that is the client-router-facing interface and the next-hop details for that interface.

Verifying End-to-End Connectivity

Purpose

Verify the connectivity between Router CE1 and the remote client router, Router CE2.

Action

From operational mode, run the **ping** command.

```
user@CE1> ping 10.10.10.2
```

```

PING 10.10.10.2 (10.10.10.2): 56 data bytes
64 bytes from 10.10.10.2: icmp_seq=0 ttl=64 time=15.113 ms
64 bytes from 10.10.10.2: icmp_seq=1 ttl=64 time=13.353 ms
64 bytes from 10.10.10.2: icmp_seq=2 ttl=64 time=13.769 ms
64 bytes from 10.10.10.2: icmp_seq=3 ttl=64 time=10.341 ms
64 bytes from 10.10.10.2: icmp_seq=4 ttl=64 time=12.597 ms
^C
--- 10.10.10.2 ping statistics ---

```

```
5 packets transmitted, 5 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 10.341/13.035/15.113/1.575 ms
```

Meaning

The ping from Router CE1 to Router CE2 is successful.

TCC and Layer 2.5 Switching Overview

Translational cross-connect (TCC) allows you to forward traffic between a variety of Layer 2 protocols or circuits. It is similar to its predecessor, CCC. However, while CCC requires the same Layer 2 encapsulations on both sides of a router (such as Point-to-Point Protocol [PPP] or Frame Relay-to-Frame Relay), TCC lets you connect different types of Layer 2 protocols interchangeably. With TCC, combinations such as PPP-to-ATM and Ethernet-to-Frame Relay cross-connections are possible. Also, TCC can be used to create Layer 2.5 VPNs and Layer 2.5 circuits.

Consider a sample topology ([Figure 102 on page 1298](#)) in which you can configure a full-duplex Layer 2.5 translational cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the TCC interface. In this topology, Router B strips all PPP encapsulation data from frames arriving from Router A and adds ATM encapsulation data before the frames are sent to Router C. All Layer 2 negotiations are terminated at the interconnecting router (Router B).

Figure 102: Sample Translation Cross-Connect Topology

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, time-to-live (TTL) decrementing, or protocol handling, is performed. Currently, TCC is supported in IPv4, ISO, and MPLS.

Ethernet TCC is supported on interfaces that carry IPv4 traffic only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC and extended VLAN CCC are not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC and extended VLAN TCC are not supported.

Configuring VLAN TCC Encapsulation

VLAN TCC encapsulation allows circuits to have different media on either side of the forwarding path. VLAN TCC encapsulation supports TPID 0x8100 only. You must include configuration statements at the logical and physical interface hierarchy levels.

Starting in Junos OS Release 20.1R1, aggregated Ethernet interfaces support VLAN translational cross-connect (TCC) encapsulation. For configuring VLAN TCC encapsulation, you must have the member links of aggregated Ethernet with VLAN TCC encapsulation supported hardware.

NOTE: MX series routers does not perform any external commit check for member links of aggregated interfaces for the VLAN TCC encapsulation supported hardware.

To configure VLAN TCC encapsulation, include the **encapsulation** statement and specify the **vlan-tcc** option:

```
[edit interfaces interface-name unit logical-unit-number]
encapsulation vlan-tcc;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

Additionally, configure the logical interface by including the **proxy** and **remote** statements:

```
proxy {
  inet-address;
}
remote {
  (inet-address | mac-address);
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family tcc]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family tcc]

The proxy address is the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy.

The remote address is the IP or MAC address of the remote router. The **remote** statement provides ARP capability from the TCC switching router to the Ethernet neighbor. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

When VLAN TCC encapsulation is configured on the logical interface, you also must specify flexible Ethernet services on the physical interface. To specify flexible Ethernet services, include the **encapsulation** statement at the [edit interfaces *interface-name*] hierarchy level and specify the **flexible-ethernet-services** option:

```
[edit interfaces interface-name]
encapsulation flexible-ethernet-services;
```

Extended VLAN TCC encapsulation supports TPIDs 0x8100 and 0x9901. Extended VLAN TCC is specified at the physical interface level. When configured, all units on that interface must use VLAN TCC encapsulation, and no explicit configuration is needed on logical interfaces.

One-port Gigabit Ethernet, 2-port Gigabit Ethernet, and 4-port Fast Ethernet PICs with VLAN tagging enabled can use VLAN TCC encapsulation. To configure the encapsulation on a physical interface, include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level and specify the **extended-vlan-tcc** option:

```
[edit interfaces interface-name]  
encapsulation extended-vlan-tcc;
```

For VLAN TCC encapsulation, all VLAN IDs from 1 through 1024 are valid. VLAN ID 0 is reserved for tagging the priority of frames.

Extended VLAN TCC is not supported on 4-port Gigabit Ethernet PICs.

Configuring Translation Cross-Connect Interface Switching

To configure a full-duplex Layer 2.5 translation cross-connect between two routers (A and C), you can configure a Juniper Networks router (Router B) as the TCC interface. Ethernet TCC encapsulation provides an Ethernet wide area circuit for interconnecting IP traffic. Consider the topology in [Figure 103 on page 1300](#) where the Router A-to-Router B circuit is PPP, and the Router B-to-Router C circuit accepts packets carrying standard TPID values.

Figure 103: Sample Topology of Layer 2.5 Translational Cross-Connect

If traffic flows from Router A to Router C, the Junos OS strips all PPP encapsulation data from incoming packets and adds Ethernet encapsulation data before forwarding the packets. If traffic flows from Router C to Router A, the Junos OS strips all Ethernet encapsulation data from incoming packets and adds PPP encapsulation data before forwarding the packets.

To configure the router as the translational cross-connect interface:

1. In the configuration mode, at the **[edit]** hierarchy level, first configure the interface that is connected to Router A.

```
[edit]  
user@host# edit interfaces interface-name
```

2. (Optional) Specify the description of the interface. For example, you could specify the interface name on Router A that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

3. Specify the encapsulation. If the Router A to Router B circuit is PPP, then specify **ppp-tcc** as the encapsulation. If the Router A to Router B circuit is frame relay, specify **frame-relay-tcc**.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

4. In the configuration mode, at the **[edit]** hierarchy level, first configure the interface that is connected to Router C.

```
[edit]
user@host# edit interfaces interface-name
```

5. (Optional) Specify the description of this interface. For example, you could specify the interface name on Router C that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

6. Specify the encapsulation. If the Router B to Router C circuit is Ethernet, then specify **ethernet-tcc** as the encapsulation. If the Router B to Router C circuit is ATM, specify **atm-tcc-vc-mux**.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

7. Specify the IP address or MAC address of the remote router to provide address resolution protocol (ARP) for the TCC router's Ethernet-based neighbor using the **remote** statement. You must specify the statement at the **[edit interfaces interface-name unit unit-number family tcc]** hierarchy level. You can also specify the MAC address of the remote router instead of the IP address. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

```
[edit interfaces interface-name]
user@host# set unit 0 family family remote inet-address ip-address
```

8. Specify the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy using the **proxy** statement. You must specify the statement at the **[edit interfaces interface-name unit unit-number family tcc]** hierarchy level.

```
[edit interfaces interface-name]
user@host# set unit 0 family family proxy inet-address ip-address
```

To verify the TCC connection, use the **show connections** command on TCC router.

CCC Overview

Circuit cross-connect (CCC) allows you to configure transparent connections between two circuits, where a circuit can be a Frame Relay data-link connection identifier (DLCI), an Asynchronous Transfer Mode (ATM) virtual circuit (VC), a Point-to-Point Protocol (PPP) interface, a Cisco High-Level Data Link Control (HDLC) interface, or an MPLS label-switched path (LSP). Using CCC, packets from the source circuit are delivered to the destination circuit with, at most, the Layer 2 address being changed. No other processing—such as header checksums, time-to-live (TTL) decrementing, or protocol processing—is done.

NOTE: The QFX10000 Series switches do not support ATM virtual circuits.

CCC circuits fall into two categories: logical interfaces, which include DLCIs, VCs, virtual local area network (VLAN) IDs, PPP and Cisco HDLC interfaces, and LSPs. The two circuit categories provide three types of cross-connect:

- Layer 2 switching—Cross-connects between logical interfaces provide what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.
- MPLS tunneling—Cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit.
- LSP stitching—Cross-connects between LSPs provide a way to “stitch” together two label-switched paths, including paths that fall in two different traffic engineering database areas.

For Layer 2 switching and MPLS tunneling, the cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first. For LSP stitching, the cross-connect is unidirectional.

Understanding Carrier-of-Carriers VPNs

IN THIS SECTION

- [Internet Service Provider as the Customer | 1305](#)
- [VPN Service Provider as the Customer | 1305](#)

The customer of a VPN service provider might be a service provider for the end customer. The following are the two main types of carrier-of-carriers VPNs (as described in RFC 4364):

- [“Internet Service Provider as the Customer” on page 1305](#)—The VPN customer is an ISP that uses the VPN service provider’s network to connect its geographically disparate regional networks. The customer does not have to configure MPLS within its regional networks.
- [“VPN Service Provider as the Customer” on page 1305](#)—The VPN customer is itself a VPN service provider offering VPN service to its customers. The carrier-of-carriers VPN service customer relies on the backbone VPN service provider for inter-site connectivity. The customer VPN service provider is required to run MPLS within its regional networks.

[Figure 104 on page 1304](#) illustrates the network architecture used for a carrier-of-carriers VPN service.

Figure 104: Carrier-of-Carriers VPN Architecture

8017197

This topic covers the following:

Internet Service Provider as the Customer

In this type of carrier-of-carriers VPN configuration, ISP A configures its network to provide Internet service to ISP B. ISP B provides the connection to the customer wanting Internet service, but the actual Internet service is provided by ISP A.

This type of carrier-of-carriers VPN configuration has the following characteristics:

- The carrier-of-carriers VPN service customer (ISP B) does not need to configure MPLS on its network.
- The carrier-of-carriers VPN service provider (ISP A) must configure MPLS on its network.
- MPLS must also be configured on the CE routers and PE routers connected together in the carrier-of-carriers VPN service customer's and carrier-of-carriers VPN service provider's networks.

VPN Service Provider as the Customer

A VPN service provider can have customers that are themselves VPN service providers. In this type of configuration, also called a hierarchical or recursive VPN, the customer VPN service provider's VPN-IPv4 routes are considered external routes, and the backbone VPN service provider does not import them into its VRF table. The backbone VPN service provider imports only the customer VPN service provider's internal routes into its VRF table.

The similarities and differences between interprovider and carrier-of-carriers VPNs are shown in [Table 31 on page 1305](#).

Table 31: Comparison of Interprovider and Carrier-of-Carriers VPNs

Feature	ISP Customer	VPN Service Provider Customer
Customer edge device	AS border router	PE router
IBGP sessions	Carry IPv4 routes	Carry external VPN-IPv4 routes with associated labels
Forwarding within the customer network	MPLS is optional	MPLS is required

Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

Understanding Interprovider and Carrier-of-Carriers VPNs

All interprovider and carrier-of-carriers VPNs share the following characteristics:

- Each interprovider or carrier-of-carriers VPN customer must distinguish between internal and external customer routes.

- Internal customer routes must be maintained by the VPN service provider in its PE routers.
- External customer routes are carried only by the customer's routing platforms, not by the VPN service provider's routing platforms.

The key difference between interprovider and carrier-of-carriers VPNs is whether the customer sites belong to the same AS or to separate ASs:

- *Interprovider VPNs*—The customer sites belong to different ASs. You need to configure EBGp to exchange the customer's external routes.
- [“Understanding Carrier-of-Carriers VPNs” on page 1303](#)—The customer sites belong to the same AS. You need to configure IBGP to exchange the customer's external routes.

In general, each service provider in a VPN hierarchy is required to maintain its own internal routes in its P routers, and the internal routes of its customers in its PE routers. By recursively applying this rule, it is possible to create a hierarchy of VPNs.

The following are definitions of the types of PE routers specific to interprovider and carrier-of-carriers VPNs:

- The AS border router is located at the AS border and handles traffic leaving and entering the AS.
- The end PE router is the PE router in the customer VPN; it is connected to the CE router at the end customer's site.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 Circuit

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 circuit on the switch to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on Provider Switches” on page 62](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 circuit:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
```

```

user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address

```

4. Enable the MPLS protocol with CSPF disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```

[edit protocols]
user@switch# set mpls no-cspf

```

5. Configure the customer edge interface as a Layer 2 circuit from the local PE switch to the other PE switch:

```

[edit protocols]
user@switch# set l2circuit neighbor address interface interface-name virtual-circuit-id identifier

```

TIP: Use the switch address of the other switch as the neighbor address.

6. Configure MPLS on the core interfaces:

```

[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name

```

7. Configure LDP on the loopback interface and the core interfaces:

```

[edit protocols]
user@switch# set ldp interface lo0.0
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name
user@switch# set ldp interface interface-name

```

8. Configure **family mpls** on the logical units of the core interfaces:

```

[edit]

```

```

user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls

```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```

[edit]
user@switch# set interfaces interface-name vlan-tagging

```

10. Configure the customer edge interface to use VLAN CCC encapsulation:

```

[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc

```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit 0. The logical unit number must be 1 or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```

[edit ]
user@switch# set interfaces interface-name logical-unit-number vlan-id vlan-id

```

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: For EX Series switches, you must use the same type of switch for the other PE switch.

VLAN CCC Encapsulation on Transport Side of Pseudowire Client Logical Interfaces Overview

Currently, Junos OS does not allow the same VLAN ID to be configured on more than one logical interface under the same pseudowire client physical interface. To support **vlan-ccc** encapsulation on transport pseudowire service (PS) interface on the provider edge (PE) device, this restriction is removed and you can configure the same VLAN ID on more than one logical interface.

The primary reason to configure **vlan-ccc** on the transport PS interface is interoperability with the existing access and aggregate devices in the network. Currently, Junos OS supports **ethernet-ccc** encapsulation on the transport PS interface. Typically, while establishing a pseudowire connection, the access device initiates a VLAN-based pseudowire (also known as VLAN-tagged mode), and a PE router signals the Ethernet mode VLAN back to the access device. For this type of pseudowire connection to be established, you can use the **ignore-encapsulation-mismatch** statement. However, the Junos OS device (access device) might not support the **ignore-encapsulation-mismatch** statement and, as a result, the pseudowire connection is not formed. When the **ignore-encapsulation-mismatch** statement is not supported on the access device, you can configure **vlan-ccc** between the nodes to form a pseudowire connection.

The forwarding data path is not changed with the new **vlan-ccc** encapsulation on the transport PS interface and the behavior similar to that when the **ethernet-ccc** encapsulation is configured on the transport PS interface. The transport PS interface either encapsulates or de-encapsulate the outer Layer 2 header and MPLS headers on the transmitted or received packets on the WAN port. Inner Ethernet or VLAN headers of the packet are handled on pseudowire client service logical interfaces. You must configure pseudowire client service logical interfaces with appropriate VLAN IDs or VLAN tags.

The following sections provides details, along with a sample configuration, about pseudowire configuration from both access and aggregation nodes.

Pseudowire Configuration from Access Node

These pseudowires are set up using VLANs from the access node for customer devices attached to the Layer 2 circuit configured on access and PE routers with customer VLANs (C-VLANs). The ingress traffic (from the access node side) on the PE router is single VLAN tagged (inner Ethernet header), and thus the service logical interfaces must be configured with the same VLAN IDs corresponding to the C-VLAN IDs attached to the access node.

[Figure 105 on page 1311](#) provides the details of a transport PS interface from an access node (access node).

Figure 105: Pseudowire Client Transport Logical Interface from Access Node

The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an access node:

```

interfaces {
  ps0 {
    anchor-point lt-3;
    unit 0 {
      encapsulation VLAN-ccc;
      VLAN ID 100;
    }
    unit 1 {
      VLAN ID 100;
      family inet;
    }
  }
}

```

Pseudowire Configuration from Aggregation Node

In this case, the aggregation node processes a stacked VLAN (also known as Q-in-Q). The pseudowire originates from aggregation node and terminates on a PE router. The aggregation node pushes the service VLAN (S-VLAN) tag, and the PE router is expected to operate on two VLAN tags—the outer VLAN tag corresponds to an S-VLAN and the inner VLAN tag corresponds to a C-VLAN. The VLAN ID configured on the transport PS interface at the PE router must match the VLAN tag of the S-VLAN. On the pseudowire client service logical interface, the outer VLAN tag must be configured to match the S-VLAN and the inner VLAN tag must be configured to match the C-VLAN.

[Figure 106 on page 1312](#) provides the details of a transport PS interface from an aggregation node.

Figure 106: Pseudowire Client Transport Logical Interface from Aggregation Node

The following example shows the configuration of a pseudowire client logical interface configuration on a PE router from an aggregation node:

```

interfaces {
  ps0 {
    anchor-point lt-3;
    unit 0 {
      encapsulation VLAN-ccc;
      VLAN ID 500;
    }
    unit 1 {
      VLAN tags {
        outer 500;
        inner 100;
      }
    }
    unit 2 {
      VLAN tags {
        outer 500;
        inner 200;
      }
    }
  }
}

```

Transmitting Nonstandard BPDUs

CCC protocol (and Layer 2 Circuit and Layer 2 VPN) configurations can transmit nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment. This is the default behavior on all supported PICs and requires no additional configuration.

The following PICs are supported on M320 and T Series routers:

- 1-port Gigabit Ethernet PIC
- 2-port Gigabit Ethernet PIC
- 4-port Gigabit Ethernet PIC
- 10-port Gigabit Ethernet PIC

TCC Overview

Translational cross-connect (TCC) is a switching concept that enables you to establish interconnections between a variety of Layer 2 protocols or circuits. It is similar to CCC. However, whereas CCC requires the same Layer 2 encapsulations on each side of a Juniper Networks router (such as PPP-to-PPP or Frame Relay-to-Frame Relay), TCC enables you to connect different types of Layer 2 protocols interchangeably. When you use TCC, combinations such as PPP-to-ATM (see [Figure 107 on page 1313](#)) and Ethernet-to-Frame Relay connections are possible.

Figure 107: TCC Example

The Layer 2 circuits and encapsulation types that can be interconnected by TCC are:

- Ethernet
- Extended VLANs
- PPP
- HDLC
- ATM
- Frame Relay

TCC works by removing the Layer 2 header when frames enter the router and adding a different Layer 2 header on the frames before they leave the router. In [Figure 107 on page 1313](#), the PPP encapsulation is stripped from the frames arriving at Router B, and the ATM encapsulation is added before the frames are sent to Router C.

Note that all control traffic is terminated at the interconnecting router (Router B). Examples of traffic controllers include the Link Control Protocol (LCP) and the Network Control Protocol (NCP) for PPP, keepalives for HDLC, and Local Management Interface (LMI) for Frame Relay.

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, TTL decrementing, or protocol handling is performed. TCC is supported for IPv4 only.

Address Resolution Protocol (APR) packet policing on TCC Ethernet interfaces is effective for releases 10.4 and onwards.

You can configure TCC for interface switching and for Layer 2 VPNs. For more information about using TCC for virtual private networks (VPNs), see the *Junos OS VPNs Library for Routing Devices*.

Configuring Layer 2 Switching Cross-Connects Using CCC

IN THIS SECTION

- [Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects | 1315](#)
- [Configuring the CCC Connection for Layer 2 Switching Cross-Connects | 1320](#)
- [Configuring MPLS for Layer 2 Switching Cross-Connects | 1320](#)
- [Example: Configuring a Layer 2 Switching Cross-Connect | 1321](#)
- [Configuring Layer 2 Switching Cross-Connect on ACX5440 | 1323](#)

Layer 2 switching cross-connects join logical interfaces to form what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.

[Figure 108 on page 1315](#) illustrates a Layer 2 switching cross-connect. In this topology, Router A and Router C have Frame Relay connections to Router B, which is a Juniper Networks router. Circuit cross-connect (CCC) allows you to configure Router B to act as a Frame Relay (Layer 2) switch.

To configure Router B to act as a Frame Relay switch, you configure a circuit from Router A to Router C that passes through Router B, effectively configuring Router B as a Frame Relay switch with respect to these routers. This configuration allows Router B to transparently switch packets (frames) between Router A and Router C without regard to the packets' contents or the Layer 3 protocols. The only processing that Router B performs is to translate DLCI 600 to 750.

Figure 108: Layer 2 Switching Cross-Connect

If the Router A-to-Router B and Router B-to-Router C circuits were PPP, for example, the Link Control Protocol and Network Control Protocol exchanges occur between Router A and Router C. These messages are handled transparently by Router B, allowing Router A and Router C to use various PPP options (such as header or address compression and authentication) that Router B might not support. Similarly, Router A and Router C exchange keepalives, providing circuit-to-circuit connectivity status.

You can configure Layer 2 switching cross-connects on PPP, Cisco HDLC, Frame Relay, Ethernet, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

To configure Layer 2 switching cross-connects, you must configure the following on the router that is acting as the switch (Router B in [Figure 108 on page 1315](#)):

Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects

IN THIS SECTION

- [Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects | 1316](#)
- [Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects | 1316](#)
- [Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects | 1317](#)
- [Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects | 1318](#)
- [Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects | 1319](#)
- [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects | 1319](#)

To configure Layer 2 switching cross-connects, configure the CCC encapsulation on the router that is acting as the switch (Router B in [Figure 108 on page 1315](#)).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the **family** statement at the `[edit interfaces interface-name unit logical-unit-number]` hierarchy level.

For instructions for configuring the encapsulation for Layer 2 switching cross-connects, see the following sections:

Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects

For ATM circuits, specify the encapsulation when configuring the virtual circuit (VC). Configure each VC as a circuit or a regular logical interface by including the following statements:

```
at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    encapsulation encapsulation-type;
    point-to-point; # Default interface type
    vci vpi-identifier.vci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects

For Ethernet circuits, specify **ethernet-ccc** in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must also configure a logical interface (unit 0).

Ethernet interfaces with standard Tag Protocol Identifier (TPID) tagging can use Ethernet CCC encapsulation. On M Series Multiservice Edge Routers, except the M320, one-port Gigabit Ethernet, two-port Gigabit Ethernet, four-port Gigabit Ethernet, and four-port Fast Ethernet PICs can use Ethernet CCC encapsulation. On T Series Core Routers and M320 routers, one-port Gigabit Ethernet and two-port Gigabit Ethernet PICs installed in FPC2 can use Ethernet CCC encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.

```
fe-fpc/pic/port {
  encapsulation ethernet-ccc;
  unit 0;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects

An Ethernet virtual LAN (VLAN) circuit can be configured using either the **vlan-ccc** or **extended-vlan-ccc** encapsulation. If you configure the **extended-vlan-ccc** encapsulation on the physical interface, you cannot configure the **inet** family on the logical interfaces. Only the **ccc** family is allowed. If you configure the **vlan-ccc** encapsulation on the physical interface, both the **inet** and **ccc** families are supported on the logical interfaces. Ethernet interfaces in VLAN mode can have multiple logical interfaces.

For encapsulation type **vlan-ccc**, VLAN IDs from 512 through 4094 are reserved for CCC VLANs. For the **extended-vlan-ccc** encapsulation type, all VLAN IDs 1 and higher are valid. VLAN ID 0 is reserved for tagging the priority of frames.

NOTE: Some vendors use the proprietary TPIDs 0x9100 and 0x9901 to encapsulate a VLAN-tagged packet into a VLAN-CCC tunnel to interconnect a geographically separated metro Ethernet network. By configuring the **extended-vlan-ccc** encapsulation type, a Juniper Networks router can accept all three TPIDs (0x8100, 0x9100, and 0x9901).

Configure an Ethernet VLAN circuit with the **vlan-ccc** encapsulation as follows:

```
interfaces {
  type-fpc/pic/port {
    vlan-tagging;
    encapsulation vlan-ccc;
    unit logical-unit-number {
      encapsulation vlan-ccc;
      vlan-id vlan-id;
    }
  }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems logical-system-name interfaces]**

Configure an Ethernet VLAN circuit with the **extended-vlan-ccc** encapsulation statement as follows:

```
interfaces {
  type-fpc/pic/port {
    vlan-tagging;
    encapsulation extended-vlan-ccc;
    unit logical-unit-number {
      vlan-id vlan-id;
    }
  }
}
```

```

        family ccc;
    }
}

```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Whether you configure the encapsulation as **vlan-ccc** or **extended-vlan-ccc**, you must enable VLAN tagging by including the **vlan-tagging** statement.

Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects

You can configure aggregated Ethernet interfaces for CCC connections and for Layer 2 virtual private networks (VPNs).

Aggregated Ethernet interfaces configured with VLAN tagging can be configured with multiple logical interfaces. The only encapsulation available for aggregated Ethernet logical interfaces is **vlan-ccc**. When you configure the **vlan-id** statement, you are limited to VLAN IDs 512 through 4094.

Aggregated Ethernet interfaces configured without VLAN tagging can be configured only with the **ethernet-ccc** encapsulation. All untagged Ethernet packets received are forwarded based on the CCC parameters.

To configure aggregated Ethernet interfaces for CCC connections, include the **ae0** statement at the **[edit interfaces]** hierarchy level:

```

[edit interfaces]
ae0 {
    encapsulation (ethernet-ccc | extended-vlan-ccc | vlan-ccc);
    vlan-tagging;
    aggregated-ether-options {
        minimum-links links;
        link-speed speed;
    }
    unit logical-unit-number {
        encapsulation vlan-ccc;
        vlan-id identifier;
        family ccc;
    }
}

```

Be aware of the following limitations when configuring CCC connections over aggregated Ethernet interfaces:

- If you configured load balancing between child links, be aware that a different hash key is used to distribute packets among the child links. Standard aggregated interfaces have family inet configured. An IP version 4 (IPv4) hash key (based on the Layer 3 information) is used to distribute packets among the child links. A CCC connection over an aggregated Ethernet interface has family ccc configured instead. Instead of an IPv4 hash key, an MPLS hash key (based on the destination media access control [MAC] address) is used to distributed packets among the child links.
- The extended-vlan-ccc encapsulation is not supported on the 12-port Fast Ethernet PIC and the 48-port Fast Ethernet PIC.
- The Junos OS does not support the Link Aggregation Control Protocol (LACP) when an aggregated interface is configured as a VLAN (with vlan-ccc encapsulation). LACP can be configured only when the aggregated interface is configured with the ethernet-ccc encapsulation.

For more information about how to configure aggregated Ethernet interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects

For Frame Relay circuits, specify the encapsulation when configuring the DLCI. Configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be from 1 through 511. For CCC interfaces, it must be from 512 through 4094.

```

interfaces {
  type-fpc/pic/port {
    unit logical-unit-number {
      dlci dlci-identifier;
      encapsulation encapsulation-type;
      point-to-point; # Default interface type
    }
  }
}

```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects

For PPP and Cisco HDLC circuits, specify the encapsulation in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must configure a logical interface (unit 0).

```

interfaces type-fpc/pic/port {
  encapsulation encapsulation-type;
}

```

```

    unit 0;
}

```

You can configure these statements at the following hierarchy levels:

- [edit interfaces *type-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *type-fpc/pic/port*]

Configuring the CCC Connection for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, define the connection between the two circuits by including the **interface-switch** statement. You configure this connection on the router that is acting as the switch (Router B in [Figure 108 on page 1315](#)). The connection joins the interface that comes from the circuit's source to the interface that leads to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

```

interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
}

```

You can include this statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Configuring MPLS for Layer 2 Switching Cross-Connects

For Layer 2 switching cross-connects to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```

family mpls;

```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```

mpls {
  interface interface-name; # Required to enable MPLS on the interface
}

```

You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

Example: Configuring a Layer 2 Switching Cross-Connect

Configure a full-duplex Layer 2 switching cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the virtual switch. See the topology in [Figure 109 on page 1321](#) and [Figure 110 on page 1322](#).

Figure 109: Topology of a Frame Relay Layer 2 Switching Cross-Connect

```

[edit]
interfaces {
  so-1/0/0 {
    encapsulation frame-relay-ccc;
    unit 1 {
      point-to-point;
      encapsulation frame-relay-ccc;
      dlci 600;
    }
  }
  so-2/0/0 {
    encapsulation frame-relay-ccc;
    unit 2 {
      point-to-point;
      encapsulation frame-relay-ccc;
      dlci 750;
    }
  }
}
protocols {
  connections {
    interface-switch router-a-to-router-c {

```

```

        interface so-1/0/0.1;
        interface so-2/0/0.2;
    }
}
mpls {
    interface all;
}
}

```

Figure 110: Sample Topology of a VLAN Layer 2 Switching Cross-Connect

[edit]
interfaces {
    ge-2/1/0 {
        vlan-tagging;
        encapsulation vlan-ccc;
        unit 0 {
            encapsulation vlan-ccc;
            vlan-id 600;
        }
    }
    ge-2/2/0 {
        vlan-tagging;
        encapsulation vlan-ccc;
        unit 0 {
            encapsulation vlan-ccc;
            vlan-id 600;
        }
        unit 1 {
            family inet {
                vlan-id 1;
                address 10.9.200.1/24;
            }
        }
    }
}
protocols {
    mpls {

```

```

interface all;
}
connections {
  interface-switch layer2-sw {
    interface ge-2/1/0.0;
    interface ge-2/2/0.0;
  }
}
}

```

Configuring Layer 2 Switching Cross-Connect on ACX5440

Starting in Junos OS Release 19.3R1, you can leverage the hardware support available for cross-connects on the ACX5448 device with the Layer 2 local switching functionality using certain models. With this support, you can provide the EVP and Ethernet Virtual Private Line (EVPL) services..

Local-switching with the following forwarding models are supported:

- VLAN-CCC (logical interface-level local-switching) without any map.
- VLAN-CCC (logical interface-level local-switching) with the following vlan-maps:
 - Push 0x8100.pushVLAN (QinQ type)
 - Swap 0x8100.swapVLAN
- Aggregated Ethernet (AE) static interfaces.
- AE interfaces with LACP, load-balance all active mode.
- Local-switching end-interface support for AE or LAG interface (one non-AE interface and other AE interface).
- Local-switching both interface as AE or LAG interfaces.

To enable Layer 2 local switching on the ACX5448 device, you can use the existing configuration statements for Layer 2 circuits. For example,

```

[edit protocols l2circuit]
local-switching {
  interface interface1 {
    end-interface interface3;
    ignore-encapsulation-mismatch;
    ignore-mtu-mismatch;
  }
}

```

Configuring MPLS LSP Tunnel Cross-Connects Using CCC

IN THIS SECTION

- [Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects | 1325](#)
- [Configuring the CCC Connection for LSP Tunnel Cross-Connects | 1327](#)
- [Example: Configuring an LSP Tunnel Cross-Connect | 1327](#)

MPLS tunnel cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit. The topology in [Figure 111 on page 1324](#) illustrates an MPLS LSP tunnel cross-connect. In this topology, two separate networks, in this case ATM access networks, are connected through an IP backbone. CCC allows you to establish an LSP tunnel between the two domains. With LSP tunneling, you tunnel the ATM traffic from one network across a SONET backbone to the second network by using an MPLS LSP.

Figure 111: MPLS Tunnel Cross-Connect

When traffic from Router A (VC 234) reaches Router B, it is encapsulated and placed into an LSP, which is sent through the backbone to Router C. At Router C, the label is removed, and the packets are placed onto the ATM permanent virtual circuit (PVC) (VC 591) and sent to Router D. Similarly, traffic from Router D (VC 591) is sent over an LSP to Router B, then placed on VC 234 to Router A.

You can configure LSP tunnel cross-connect on PPP, Cisco HDLC, Frame Relay, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

When you use MPLS tunnel cross-connects to support IS-IS, you must ensure that the LSP's maximum transmission unit (MTU) can, at a minimum, accommodate a 1492-octet IS-IS protocol data unit (PDU) in addition to the link-level overhead associated with the technology being connected.

For the tunnel cross-connects to work, the IS-IS frame size on the edge routers (Routers A and D in [Figure 112 on page 1327](#)) must be smaller than the LSP's MTU.

NOTE: Frame size values do not include the frame check sequence (FCS) or delimiting flags.

To determine the LSP MTU required to support IS-IS, use the following calculation:

$$\text{IS-IS MTU (minimum 1492, default 1497) + frame overhead + 4 (MPLS shim header) = Minimum LSP MTU}$$

The framing overhead varies based on the encapsulation being used. The following lists the IS-IS encapsulation overhead values for various encapsulations:

- ATM
 - AAL5 multiplex—8 bytes (RFC 1483)
 - VC multiplex—0 bytes
- Frame Relay
 - Multiprotocol—2 bytes (RFCs 1490 and 2427)
 - VC multiplex—0 bytes
- HDLC—4 bytes
- PPP—4 bytes
- VLAN—21 bytes (802.3/LLC)

For IS-IS to work over VLAN-CCC, the LSP's MTU must be at least 1513 bytes (or 1518 for 1497-byte PDUs). If you increase the size of a Fast Ethernet MTU above the default of 1500 bytes, you might need to explicitly configure jumbo frames on intervening equipment.

To modify the MTU, include the **mtu** statement when configuring the logical interface family at the **[edit interfaces interface-name unit logical-unit-number encapsulation family]** hierarchy level. For more information about setting the MTU, see the *Junos OS Network Interfaces Library for Routing Devices*.

To configure an LSP tunnel cross-connect, you must configure the following on the interdomain router (Router B in [Figure 112 on page 1327](#)):

Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, you must configure the CCC encapsulation on the ingress and egress routers (Router B and Router C, respectively, in [Figure 112 on page 1327](#)).

NOTE: You cannot configure families on CCC interfaces; that is, you cannot include the **family** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level.

For PPP or Cisco HDLC circuits, include the **encapsulation** statement to configure the entire physical device. For these circuits to work, you must configure logical unit 0 on the interface.

```

type-fpc/pic/port {
  encapsulation (ppp-ccc | cisco-hdlc-ccc);
  unit 0;
}

```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

For ATM circuits, specify the encapsulation when configuring the VC by including the following statements. For each VC, you configure whether it is a circuit or a regular logical interface.

```

at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    point-to-point; # Default interface type
    encapsulation atm-ccc-vc-mux;
    vci vpi-identifier.vci-identifier;
  }
}

```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

For Frame Relay circuits, include the following statements to specify the encapsulation when configuring the DLCI. For each DLCI, you configure whether it is a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range 1 through 511. For CCC interfaces, it must be in the range 512 through 1022.

```

type-fpc/pic/port {
  encapsulation frame-relay-ccc;
  unit logical-unit-number {
    point-to-point; # default interface type
    encapsulation frame-relay-ccc;
    dlci dlci-identifier;
  }
}

```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For more information about the **encapsulation** statement, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring the CCC Connection for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, include the **remote-interface-switch** statement to define the connection between the two circuits on the ingress and egress routers (Router B and Router C, respectively, in [Figure 112 on page 1327](#)). The connection joins the interface or LSP that comes from the circuit's source to the interface or LSP that leads to the circuit's destination. When you specify the interface name, include the logical portion of the name, which corresponds to the logical unit number. For the cross-connect to be bidirectional, you must configure cross-connects on two routers.

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    transmit-lsp label-switched-path;
    receive-lsp label-switched-path;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Example: Configuring an LSP Tunnel Cross-Connect

Configure a full-duplex MPLS LSP tunnel cross-connect from Router A to Router D, passing through Router B and Router C. See the topology in [Figure 112 on page 1327](#).

Figure 112: Example Topology of MPLS LSP Tunnel Cross-Connect

On Router B:

```
[edit]
interfaces {
    at-7/1/1 {
        atm-options {
```

```

        vpi 1 maximum-vcs 600;
    }
    unit 1 {
        point-to-point; # default interface type
        encapsulation atm-ccc-vc-mux;
        vci 1.234;
    }
}
protocols {
    connections {
        remote-interface-switch router-b-to-router-c {
            interface at-7/1/1.1;
            transmit-lsp lsp1;
            receive-lsp lsp2;
        }
    }
}

```

On Router C:

```

[edit]
interfaces {
    at-3/0/0 {
        atm-options {
            vpi 2 maximum-vcs 600;
        }
        unit 2 {
            point-to-point; # default interface type
            encapsulation atm-ccc-vc-mux;
            vci 2.591;
        }
    }
}
protocols {
    connections {
        remote-interface-switch router-b-to-router-c {
            interface at-3/0/0.2;
            transmit-lsp lsp2;
            receive-lsp lsp1;
        }
    }
}

```

Configuring TCC

IN THIS SECTION

- [Configuring the Encapsulation for Layer 2 Switching TCCs | 1329](#)
- [Configuring the Connection for Layer 2 Switching TCCs | 1333](#)
- [Configuring MPLS for Layer 2 Switching TCCs | 1334](#)

This section describes how to configure translational cross-connect (TCC).

To configure TCC, you must perform the following tasks on the router that is acting as the switch:

Configuring the Encapsulation for Layer 2 Switching TCCs

IN THIS SECTION

- [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs | 1330](#)
- [Configuring ATM Encapsulation for Layer 2 Switching TCCs | 1330](#)
- [Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs | 1330](#)
- [Configuring Ethernet Encapsulation for Layer 2 Switching TCCs | 1331](#)
- [Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs | 1332](#)
- [Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations | 1333](#)

To configure a Layer 2 switching TCC, specify the TCC encapsulation on the desired interfaces of the router that is acting as the switch.

NOTE: You cannot configure standard protocol families on TCC or CCC interfaces. Only the CCC family is allowed on CCC interfaces, and only the TCC family is allowed on TCC interfaces.

For Ethernet circuits and Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 1333](#).

Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs

For PPP and Cisco HDLC circuits, configure the encapsulation type for the entire physical device by specifying the appropriate value for the **encapsulation** statement. For these circuits to work, you must also configure the logical interface **unit 0**.

```
encapsulation (ppp-tcc | cisco-hdlc-tcc);
unit 0{...}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

Configuring ATM Encapsulation for Layer 2 Switching TCCs

For ATM circuits, configure the encapsulation type by specifying the appropriate value for the **encapsulation** statement in the virtual circuit (VC) configuration. Specify whether each VC is a circuit or a regular logical interface.

```
atm-options {
  vpi vpi-identifier maximum-vcs maximum-vcs;
}
unit logical-unit-number {
  encapsulation (atm-tcc-vc-mux | atm-tcc-snap);
  point-to-point;
  vci vpi-identifier.vci-identifier;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *at-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *at-fpc/pic/port*]

Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs

For Frame Relay circuits, configure the encapsulation type by specifying the value **frame-relay-tcc** for the **encapsulation** statement when configuring the data-link connection identifier (DLCI). You configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range from 1 through 511, but for TCC and CCC interfaces it must be in the range from 512 through 1022.

```
encapsulation frame-relay-tcc;
unit logical-unit-number {
  dlci dlci-identifier;
  encapsulation frame-relay-tcc;
```

```
point-to-point;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

Configuring Ethernet Encapsulation for Layer 2 Switching TCCs

For Ethernet TCC circuits, configuring the encapsulation type for the entire physical device by specifying the value **ethernet-tcc** for the **encapsulation** statement.

You must also specify static values for a remote address and a proxy address at the [edit interfaces *interface-name* unit *unit-number* family *tcc*] or [edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family *tcc*] hierarchy level.

The remote address is associated with the TCC switching router's Ethernet neighbor; in the **remote** statement you must specify both the IP address and the media access control (MAC) address of the Ethernet neighbor. The proxy address is associated with the TCC router's other neighbor connected by the unlike link; in the **proxy** statement you must specify the IP address of the non-Ethernet neighbor.

You can configure Ethernet TCC encapsulation for the interfaces on 1-port Gigabit Ethernet, 2-port Gigabit Ethernet, 4-port Fast Ethernet, and 4-port Gigabit Ethernet PICs.

```
encapsulation ethernet-tcc;
unit logical-unit-number {
  family tcc {
    proxy {
      inet-address ip-address;
    }
    remote {
      inet-address ip-address;
      mac-address mac-address;
    }
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces (fe | ge)-*fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces (fe | ge)-*fpc/pic/port*]

NOTE: For Ethernet circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 1333](#).

Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs

For Ethernet extended VLAN circuits, configure the encapsulation type for the entire physical device by specifying the value **extended-vlan-tcc** for the **encapsulation** statement.

You must also enable VLAN tagging. Ethernet interfaces in VLAN mode can have multiple logical interfaces. With encapsulation type **extended-vlan-tcc**, all VLAN IDs from 0 through 4094 are valid, up to a maximum of 1024 VLANs. As with Ethernet circuits, you must also specify a proxy address and a remote address at the **[edit interfaces *interface-name* unit *logical-unit-number* family tcc]** or **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family tcc]** hierarchy level (see [“Configuring Ethernet Encapsulation for Layer 2 Switching TCCs” on page 1331](#)).

```
encapsulation extended-vlan-tcc;
vlan-tagging;
unit logical-unit-number {
    vlan-id identifier;
    family tcc;
    proxy {
        inet-address ip-address;
    }
    remote {
        inet-address ip-address;
        mac-address mac-address;
    }
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces *interface-name*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name*]**

NOTE: For Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 1333](#).

Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations

For Ethernet and Ethernet extended VLAN circuits with TCC encapsulation, you must also configure ARP. Because TCC simply removes one Layer 2 header and adds another, the default form of dynamic ARP is not supported; you must configure static ARP.

Because remote and proxy addresses are specified on the router performing TCC switching, you must apply the static ARP statement to the Ethernet-type interfaces of the routers that connect to the TCC-switched router. The **arp** statement must specify the IP address and the MAC address of the remotely connected neighbor by use of the unlike Layer 2 protocol on the far side of the TCC switching router.

```
arp ip-address mac mac-address;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family inet address *ip-address*]

Configuring the Connection for Layer 2 Switching TCCs

You must configure the connection between the two circuits of the Layer 2 switching TCC on the router acting as the switch. The connection joins the interface coming from the circuit's source to the interface leading to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted from the second interface, and those received on the second interface are transmitted from the first.

To configure a connection for a local interface switch, include the following statements:

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
lsp-switch connection-name {
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

To configure a connection for a remote interface switch, include the following statements:

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

Configuring MPLS for Layer 2 Switching TCCs

For a Layer 2 switching TCC to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
    interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

NOTE: MPLS LSP link protection does not support TCC.

CCC and TCC Graceful Restart

CCC and TCC graceful restart allows Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the PE routers and P routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

[Figure 113 on page 1335](#) illustrates how graceful restart might work on a CCC connection between two CE routers.

Figure 113: Remote Interface Switch Connecting Two CE Routers Using CCC

PE Router A is the ingress for the transmit LSP from PE Router A to PE Router B and the egress for the receive LSP from PE Router B to PE Router A. With RSVP graceful restart enabled on all the PE and P routers, the following occurs when PE router A restarts:

- PE Router A preserves the forwarding state associated with the CCC routes (those from CCC to MPLS and from MPLS to CCC).
- Traffic flows without disruption from CE router to CE router.
- After the restart, PE Router A preserves the label for the LSP for which PE Router A is the egress (the receive LSP, for example). The transmit LSP from PE Router A to PE Router B can derive new label mappings, but should not cause any traffic disruption.

Configuring CCC and TCC Graceful Restart

To enable CCC and TCC graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

Configuring an MPLS-Based VLAN CCC Using the Connection Method (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based connection using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on EX8200 and EX4500 Provider Switches” on page 77](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based connections:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
```

```
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
```

4. Enable the MPLS protocol with **cspf** disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

6. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

7. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit 0.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
user@switch# set interfaces interface-name logical-unit-number bbrbhadran vlan-id
```

8. Define the label switched path (LSP):

```
[edit protocols]
user@switch# set mpls label-switched-path lsp-name from address
user@switch# set mpls label-switched-path lsp-name to address
```

TIP: You will need to use the specified LSP name again when configuring the CCC.

9. Configure the connection between the two circuits in the CCC connection

```
[edit protocols]
user@switch# set connections remote-interface-switch interface-switch interface local-interface
user@switch# set connections remote-interface-switch interface-switch transmit-lsp destination-lsp
user@switch# set connections remote-interface-switch interface-switch receive-lsp source-lsp
```

Configuring CCC Switching for Point-to-Multipoint LSPs

IN THIS SECTION

- [Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers | 1339](#)
- [Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers | 1339](#)
- [Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers | 1339](#)

You can configure circuit cross-connect (CCC) between two circuits to switch traffic from interfaces to point-to-multipoint LSPs. This feature is useful for handling multicast or broadcast traffic (for example, a digital video stream).

To configure CCC switching for point-to-multipoint LSPs, you do the following:

- On the ingress provider edge (PE) router, you configure CCC to switch traffic from an incoming interface to a point-to-multipoint LSP.
- On the egress PE, you configure CCC to switch traffic from an incoming point-to-multipoint LSP to an outgoing interface.

The CCC connection for point-to-multipoint LSPs is unidirectional.

For more information about point-to-multipoint LSPs, see [“Point-to-Multipoint LSPs Overview” on page 656](#).

To configure a CCC connection for a point-to-multipoint LSP, complete the steps in the following sections:

Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers

To configure the ingress PE router with a CCC switch for a point-to-multipoint LSP, include the **p2mp-transmit-switch** statement:

```
p2mp-transmit-switch switch-name {
    input-interface input-interface-name.unit-number;
    transmit-p2mp-lsp transmitting-lsp;
}
```

You can include the **p2mp-transmit-switch** statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

switch-name specifies the name of the ingress CCC switch.

input-interface *input-interface-name.unit-number* specifies the name of the ingress interface.

transmit-p2mp-lsp *transmitting-lsp* specifies the name of the transmitting point-to-multipoint LSP.

Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers

In addition to configuring an incoming CCC interface to a point-to-multipoint LSP on an ingress PE router, you can also configure CCC to switch traffic on an incoming CCC interface to one or more outgoing CCC interfaces by configuring output interfaces as local receivers.

To configure output interfaces, include the **output-interface** statement at the [edit protocols connections **p2mp-transmit-switch p2mp-transmit-switch-name**] hierarchy level.

```
[edit protocols connections]
p2mp-transmit-switch pc-ccc {
    input-interface fe-1/3/1.0;
    transmit-p2mp-lsp myp2mp;
    output-interface [fe-1/3/2.0 fe-1/3/3.0];
}
```

You can configure one or more output interfaces as local receivers on the ingress PE router using this statement.

Use the **show connections p2mp-transmit-switch (extensive | history | status)**, **show route ccc <interface-name> (detail | extensive)**, and **show route forwarding-table ccc <interface-name> (detail | extensive)** commands to view details of the local receiving interfaces on the ingress PE router.

Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers

To configure the CCC switch for a point-to-multipoint LSP on the egress PE router, include the **p2mp-receive-switch** statement.

```
p2mp-receive-switch switch-name {
    output-interface [ output-interface-name.unit-number ];
    receive-p2mp-lsp receptive-lsp;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

switch-name specifies the name of the egress CCC switch.

output-interface [*output-interface-name.unit-number*] specifies the name of one or more egress interfaces.

receive-p2mp-lsp *receptive-lsp* specifies the name of the receptive point-to-multipoint LSP.

Configuring an MPLS-Based VLAN CCC Using a Layer 2 VPN (CLI Procedure)

You can configure an 802.1Q VLAN as an MPLS-based Layer 2 virtual private network (VPN) using EX8200 and EX4500 switches to interconnect multiple customer sites with Layer 2 technology.

This topic describes configuring provider edge (PE) switches in an MPLS network using a circuit cross-connect (CCC) on a tagged VLAN interface (802.1Q VLAN) rather than a simple interface.

NOTE: You do not need to make any changes to existing provider switches in your MPLS network to support this type of configuration. For information on configuring provider switches, see [“Configuring MPLS on EX8200 and EX4500 Provider Switches” on page 77](#).

NOTE: You can send any kind of traffic over a CCC, including nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment.

NOTE: If you configure a physical interface as VLAN-tagged and with the vlan-ccc encapsulation, you cannot configure the associated logical interfaces with the inet family. Doing so could cause the logical interfaces to drop packets.

To configure a PE switch with a VLAN CCC and an MPLS-based Layer 2 VPN:

1. Configure OSPF (or IS-IS) on the loopback (or switch address) and core interfaces:

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
user@switch# set ospf area 0.0.0.0 interface interface-name
```

2. Enable traffic engineering for the routing protocol:

```
[edit protocols]
user@switch# set ospf traffic-engineering
```

3. Configure an IP address for the loopback interface and for the core interfaces:

```
[edit]
user@switch# set interfaces lo0 unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
user@switch# set interfaces interface-name unit logical-unit-number family inet address address
```

4. Enable the MPLS protocol with **cspf** disabled:

NOTE: CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. You need to disable CSPF for link protection to function properly on interarea paths.

```
[edit protocols]
user@switch# set mpls no-cspf
```

5. Define the label switched path (LSP):

```
[edit protocols]
user@switch# set mpls label-switched-path lsp_name to address
```

TIP: You will need to use the specified LSP name again when configuring the CCC.

6. Configure MPLS on the core interfaces:

```
[edit protocols]
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
user@switch# set mpls interface interface-name
```

7. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
user@switch# set rsvp interface interface-name
```

8. Configure **family mpls** on the logical units of the core interfaces:

```
[edit]
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
user@switch# set interfaces interface-name unit logical-unit-number family mpls
```

NOTE: You can enable **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

9. Enable VLAN tagging on the customer edge interface of the local PE switch:

```
[edit]
user@switch# set interfaces interface-name vlan-tagging
```

10. Configure the customer edge interface to use encapsulation **vlan-ccc**:

```
[edit]
user@switch# set interfaces interface-name encapsulation vlan-ccc
```

11. Configure the logical unit of the customer edge interface with a VLAN ID:

NOTE: The VLAN ID cannot be configured on logical interface unit 0. The logical unit number must be 1 or higher.

The same VLAN ID must be used when configuring the customer edge interface on the other PE switch.

```
[edit ]
```

```
user@switch# set interfaces interface-name logical-unit-number vlan-id vlan-id
```

12. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```
[edit protocols bgp]
```

```
user@switchPE1# set local-address address family l2vpn signaling
```

13. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
```

```
user@switchPE1# set group ibgp type internal
```

14. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:

```
[edit protocols bgp]
```

```
user@switchPE1# set neighbor address
```

15. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
```

```
user@switchPE1# set routing-instance-name instance-type l2vpn
```

16. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
```

```
user@switchPE1# set routing-instance-name interface interface-name
```

17. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
```

```
user@switchPE1# set routing-instance-name route-distinguisher address
```

18. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name vrf-target community
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

19. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn encapsulation-type ethernet-vlan
```

20. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols interface interface-name description description
```

21. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@switchPE1# set routing-instance-name protocols l2vpn site site-name site-identifier identifier
remote-site-id identifier
```

NOTE: The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured on the other PE switch.

When you have completed configuring one PE switch, follow the same procedures to configure the other PE switch.

NOTE: You must use the same type of switch for the other PE switch. You cannot use an EX8200 as one PE switch and use an EX3200 or EX4200 as the other PE switch.

Release History Table

Release	Description
20.1R1	Starting in Junos OS Release 20.1R1, aggregated Ethernet interfaces support VLAN translational cross-connect (TCC) encapsulation.
19.3R1	Starting in Junos OS Release 19.3R1, you can leverage the hardware support available for cross-connects on the ACX5448 device with the Layer 2 local switching functionality using certain models. With this support, you can provide the EVP and Ethernet Virtual Private Line (EVPL) services.
17.1R1	Support for VPN service as the customer is supported on QFX10000 switches starting with Junos OS Release 17.1R1.

PCEP Overview

A Path Computation Element (PCE) is an entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints.

A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE. The Path Computation Element Protocol (PCEP) enables communications between a PCC and a PCE, or between two PCEs (defined in RFC 5440).

PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain traffic engineered LSPs (TE LSPs). It provides a mechanism for a PCE to perform path computation for a PCC's external LSPs. The PCEP interactions include LSP status reports sent by the PCC to the PCE, and PCE updates for the external LSPs.

Figure 114 on page 1348 illustrates the role of PCEP in the client-side implementation of a stateful PCE architecture in an MPLS RSVP-TE enabled network.

Figure 114: PCEP Session

A TCP-based PCEP session connects a PCC to an external PCE. The PCC initiates the PCEP session and stays connected to the PCE for the duration of the PCEP session. During the PCEP session, the PCC requests LSP parameters from the stateful PCE. On receiving one or more LSP parameters from the PCE, the PCC re-signals the TE LSP. When the PCEP session is terminated, the underlying TCP connection is closed immediately, and the PCC attempts to re-establish the PCEP session.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between a PCC and a stateful PCE—When an active stateful PCE connection is detected, a PCC tries to delegate all LSPs to this PCE in a procedure called LSP state synchronization. PCEP enables synchronization of the PCC LSP state to the PCE.
- Delegation of control over LSP tunnels to a stateful PCE—An active stateful PCE controls one or more LSP attributes for computing paths, such as bandwidth, path (ERO), and priority (setup and hold). PCEP enables such delegation of LSPs for path computation.
- Stateful PCE control of timing and sequence of path computations within and across PCEP sessions—An active stateful PCE modifies one or more LSP attributes, such as bandwidth, path (ERO), and priority (setup and hold). PCEP communicates these new LSP attributes from the PCE to the PCC, after which the PCC re-signals the LSP in the specified path.

Understanding MPLS RSVP-TE

Traffic engineering (TE) deals with performance optimization of operational networks, mainly mapping traffic flows onto an existing physical topology. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

For traffic engineering in large, dense networks, MPLS capabilities can be implemented because they potentially provide most of the functionality available from an overlay model, in an integrated manner, and at a lower cost than the currently competing alternatives. The primary reason for implementing MPLS traffic engineering is to control paths along which traffic flows through a network. The main advantage of implementing MPLS traffic engineering is that it provides a combination of the traffic engineering capabilities of ATM, along with the class-of-service (CoS) differentiation of IP.

In an MPLS network, data plane information is forwarded using label switching. A packet arriving on a provider edge (PE) router from the customer edge (CE) router has labels applied to it, and it is then forwarded to the egress PE router. The labels are removed at the egress router and it is then forwarded out to the

appropriate destination as an IP packet. The label-switching routers (LSRs) in the MPLS domain use label distribution protocols to communicate the meaning of labels used to forward traffic between and through the LSRs. RSVP-TE is one such label distribution protocol that enables an LSR peer to learn about the label mappings of other peers.

When both MPLS and RSVP are enabled on a router, MPLS becomes a client of RSVP. The primary purpose of the Junos OS RSVP software is to support dynamic signaling within label-switched paths (LSPs). RSVP reserves resources, such as for IP unicast and multicast flows, and requests quality-of-service (QoS) parameters for applications. The protocol is extended in MPLS traffic engineering to enable RSVP to set up LSPs that can be used for traffic engineering in MPLS networks.

When MPLS and RSVP are combined, labels are associated with RSVP flows. Once an LSP is established, the traffic through the path is defined by the label applied at the ingress node of the LSP. The mapping of label to traffic is accomplished using different criteria. The set of packets that are assigned the same label value by a specific node belong to the same forwarding equivalence class (FEC), and effectively define the RSVP flow. When traffic is mapped onto an LSP in this way, the LSP is called an LSP tunnel.

LSP tunnels are a way to establish unidirectional label-switched paths. RSVP-TE builds on the RSVP core protocol by defining new objects and modifying existing objects used in the PATH and RESV objects for LSP establishment. The new objects—LABEL-REQUEST object (LRO), RECORD-ROUTE object (RRO), LABEL object, and EXPLICIT-ROUTE object (ERO)—are optional with respect to the RSVP protocol, except for the LRO and LABEL objects, which are both mandatory for establishing LSP tunnels.

In general, RSVP-TE establishes a label-switched path that ensures frame delivery from ingress to egress router. However, with the new traffic engineering capabilities, the following functions are supported in an MPLS domain:

- Possibility to establish a label-switched path using either a full or partial explicit route (RFC 3209).
- Constraint-based LSP establishment over links that fulfill requirements, such as bandwidth and link properties.
- Endpoint control, which is associated with establishing and managing LSP tunnels at the ingress and egress routers.
- Link management, which manages link resources to do resource-aware routing of traffic engineering LSPs and to program MPLS labels.
- MPLS fast reroute (FRR), which manages the LSPs that need protection and assigns backup tunnel information to these LSPs.

Current MPLS RSVP-TE Limitations

Although the RSVP extensions for traffic engineering enable better network utilization and meet requirements of classes of traffic, today's MPLS RSVP-TE protocol suite has several issues inherent to its distributed nature. This causes a number of issues during contention for bisection capacity, especially within an LSP priority class where a subset of LSPs share common setup and hold priority values. The limitations of RSVP-TE include:

- Lack of visibility of individual per-LSP, per-device bandwidth demands—The ingress routers in an MPLS RSVP-TE network establish LSPs without having a global view of the bandwidth demand on the network. Information about network resource utilization is only available as total reserved capacity by traffic class on a per interface basis. Individual LSP state is available locally on each label edge router (LER) for its own LSPs only. As a result, a number of issues related to demand pattern arise, particularly within a common setup and hold priority.
- Asynchronous and independent nature of RSVP signaling—In RSVP-TE, the constraints for path establishment are controlled by an administrator. As such, bandwidth reserved for an LSP tunnel is set by the administrator and does not automatically imply any limit on the traffic sent over the tunnel. Therefore, bandwidth available on a traffic engineering link is the bandwidth configured for the link, excluding the sum of all reservations made on the link. Thus, the unsignaled demands on an LSP tunnel lead to service degradation of the LSP requiring excess bandwidth, as well as the other LSPs that comply with the bandwidth requirements of the traffic engineering link.
- LSPs established based on dynamic or explicit path options in the order of preference—The ingress routers in an MPLS RSVP-TE network establish LSPs for demands based on the order of arrival. Because the ingress routers do not have a global view of the bandwidth demand on the network, using the order of preference to establish LSPs can cause traffic to be dropped or LSPs not being established at all when there is an excess of bandwidth demand.

As an example, [Figure 115 on page 1352](#) is configured with MPLS RSVP-TE, in which A and G are the label edge routers (LERs). These ingress routers establish LSPs independently based on the order of demands and have no knowledge or control over each other's LSPs. Routers B, C, and D are intermediate or transit routers that connect to the egress routers E and F.

Figure 115: Example MPLS Traffic Engineering

The ingress routers establish LSPs based on the order in which the demands arrive. If Router G receives two demands of capacity 5 each for G-F, then G signals two LSPs – LSP1 and LSP2 – through G-B-D-F. In the same way, when Router A receives the third demand of capacity 10 for A-E, then it signals an LSP, LSP3, through A-B-C-E. However, if the demand on the A-E LSP increases from 10 to 15, Router A cannot signal LSP3 using the same (A-B-C-E) path, because the B-C link has a lower capacity.

Router A should have signaled the increased demand on LSP3 using the A-B-D-C-E path. Since LSP1 and LSP2 have utilized the B-D link based on the order of demands received, LSP3 is not signaled.

Thus, although adequate max-flow bandwidth is available for all the LSPs, LSP3 is subject to potentially prolonged service degradation. This is due to Router A's lack of global demand visibility and the lack of systemic coordination in demand placement by the ingress routers A and G.

Use of an External Path Computing Entity

As a solution to the current limitations found in the MPLS RSVP-TE path computation, an external path computing entity with a global view of per-LSP, per-device demand in the network independent of available capacity is required.

Currently, only online and real-time constraint-based routing path computation is provided in an MPLS RSVP-TE network. Each router performs constraint-based routing calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status. The MPLS RSVP-TE tunnels are set up using the CLI. An operator configures the TE LSP, which is then signaled by the ingress router.

In addition to the existing traffic engineering capabilities, the MPLS RSVP-TE functionality is extended to include an external path computing entity, called the Path Computation Element (PCE). The PCE computes

the path for the TE LSPs of ingress routers that have been configured for external control. The ingress router that connects to a PCE is called a Path Computation Client (PCC). The PCC is configured with the Path Computation Client Protocol (PCEP) to facilitate external path computing by a PCE.

For more information, see [“Components of External Path Computing” on page 1353](#).

To enable external path computing for a PCC's TE LSPs, include the **lsp-external-controller pccd** statement at the **[edit mpls]** and **[edit mpls lsp lsp-name]** hierarchy levels.

Components of External Path Computing

IN THIS SECTION

- [Path Computation Element | 1353](#)
- [Path Computation Client | 1354](#)
- [Path Computation Element Protocol | 1355](#)

The components that make up an external path computing system are:

Path Computation Element

A Path Computation Element (PCE) can be any entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. However, a PCE can compute the path for only those TE LSPs of a PCC that have been configured for external control.

A PCE can either be stateful or stateless.

- **Stateful PCE**—A stateful PCE maintains strict synchronization between the PCE and network states (in terms of topology and resource information), along with the set of computed paths and reserved resources in use in the network. In other words, a stateful PCE utilizes information from the traffic engineering database as well as information about existing paths (for example, TE LSPs) in the network when processing new requests from the PCC.

A stateful PCE is of two types:

- **Passive stateful PCE**—Maintains synchronization with the PCC and learns the PCC LSP states to better optimize path calculations, but does not have control over them.
- **Active stateful PCE**—Actively modifies the PCC LSPs, in addition to learning about the PCC LSP states.

NOTE: In a redundant configuration with main and backup active stateful PCEs, the backup active stateful PCE cannot modify the attributes of delegated LSPs until it becomes the main PCE at the time of a failover. There is no preempting of PCEs in the case of a switchover. The main PCE is backed by a backup PCE, and when the main PCE goes down, the backup PCE assumes the role of the main PCE and remains the main PCE even after the PCE that was previously the main PCE is operational again.

A stateful PCE provides the following functions:

- Offers offline LSP path computation.
- Triggers LSP re-route when there is a need to re-optimize the network.
- Changes LSP bandwidth when there is an increase in bandwidth demand from an application.
- Modifies other LSP attributes on the router, such as ERO, setup priority, and hold priority.

A PCE has a global view of the bandwidth demand in the network and maintains a traffic-engineered database to perform path computations. It performs statistics collection from all the routers in the MPLS domain using SNMP and NETCONF. This provides a mechanism for offline control of the PCC's TE LSPs. Although an offline LSP path computation system can be embedded in a network controller, the PCE acts like a full-fledged network controller that provides control over the PCC's TE LSPs, in addition to computing paths.

Although a stateful PCE allows for optimal path computation and increased path computation success, it requires reliable state synchronization mechanisms, with potentially significant control plane overhead and the maintenance of a large amount of data in terms of states, as in the case of a full mesh of TE LSPs.

- **Stateless PCE**—A stateless PCE does not remember any computed path, and each set of requests is processed independently of each other (RFC 5440).

Path Computation Client

A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE.

A PCC can connect to a maximum of 10 PCEs at one time. The PCC to PCE connection can be a configured static route or a TCP connection that establishes reachability. The PCC assigns each connected PCE a priority number. It sends a message to all the connected PCEs with information about its current LSPs, in a process called LSP state synchronization. For the TE LSPs that have external control enabled, the PCC delegates those LSPs to the main PCE. The PCC elects, as the main PCE, a PCE with the lowest priority number, or the PCE that it connects to first in the absence of a priority number.

The PCC re-signals an LSP based on the computed path it receives from a PCE. When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

Path Computation Element Protocol

The Path Computation Element Protocol (PCEP) is used for communication between PCC and PCE (as well as between two PCEs) (RFC 5440). PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain TE LSPs. The PCEP interactions include PCC messages, as well as notifications of specific states related to the use of a PCE in the context of MPLS RSVP-TE. When PCEP is used for PCE-to-PCE communication, the requesting PCE assumes the role of a PCC.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between PCC and a stateful PCE.
- Delegation of control over LSP tunnels to a stateful PCE.

Interaction Between a PCE and a PCC Using PCEP

Figure 116 on page 1355 illustrates the relationship between a PCE, PCC, and the role of PCEP in the context of MPLS RSVP-TE.

Figure 116: PCC and RSVP-TE

The PCE to PCC communication is enabled by the TCP-based PCEP. The PCC initiates the PCEP session and stays connected to a PCE for the duration of the PCEP session.

NOTE: Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440. To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce pce-id]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains key-chain]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce pce-id]** hierarchy level.

The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session, thereby securing the PCEP communication between the devices, which might be subject to attacks and can disrupt services on the network.

For more information on securing PCEP sessions using MD5 authentication, see [“TCP-MD5 Authentication for PCEP Sessions” on page 1364](#).

Once the PCEP session is established, the PCC performs the following tasks:

1. LSP state synchronization—The PCC sends information about all the LSPs (local and external) to all connected PCEs. For external LSPs, the PCC sends information about any configuration change, RRO change, state change, and so on, to the PCE.

For PCE-initiated LSPs, there is no LSP configuration present on the PCC. The PCE initiating the LSP sends the LSP parameters to the PCC that has indicated its capability of supporting PCE-initiated LSPs.

NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

2. LSP delegation—After the LSP state information is synchronized, the PCC then delegates the external LSPs to one PCE, which is the main active stateful PCE. Only the main PCE can set parameters for the external LSP. The parameters that the main PCE modifies include bandwidth, path (ERO), and priority (setup and hold). The parameters specified in the local configuration are overridden by the parameters that are set by the main PCE.

NOTE: When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

In the case of PCE-initiated LSPs, the PCC creates the LSP using the parameters received from the PCE. The PCC assigns the PCE-initiated LSP a unique LSP-ID, and automatically delegates the LSP to the PCE. A PCC cannot revoke the delegation for the PCE-initiated LSPs for an active PCEP session.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs – **delegation cleanup timeout** and **lsp cleanup timer** – to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE, by sending a create request for the LSP.

Control over PCE-initiated LSPs reverts to the PCC at the expiration of the **delegation cleanup timeout**. When the **delegation cleanup timeout** expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated LSPs, the PCC delegates these LSPs to the PCE and the **lsp cleanup timer** timer is stopped.

A PCE may return the delegation of the PCE-initiated LSP to the PCC to allow LSP transfer between PCEs. This triggers the **lsp cleanup timer** for the PCE-initiated LSP. The PCC waits for the LSP cleanup timer to expire before removing the non-delegated PCE-initiated LSPs from the failed PCE.

When the **lsp cleanup timer** expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

3. LSP signaling—On receiving one or more LSP parameters from the main active stateful PCE, the PCC re-signals the TE LSP based on the PCE provided path. If the PCC fails to set up the LSP, it notifies the PCE of the setup failure and waits for the main PCE to provide new parameters for that LSP, and then re-signals it.

When the PCE specifies a path that is incomplete or has loose hops where only the path endpoints are specified, the PCC does not perform local constraint-based routing to find out the complete set of hops. Instead, the PCC provides RSVP with the PCE provided path, as it is, for signaling, and the path gets set up using IGP hop-by-hop routing.

Considering the topology used in [Figure 115 on page 1352](#), [Figure 117 on page 1358](#) illustrates the partial client-side PCE implementation in the MPLS RSVP-TE enabled network. The ingress routers A and G are the PCCs that are configured to connect to the external stateful PCE through a TCP connection.

The PCE has a global view of the bandwidth demand in the network and performs external path computations after looking up the traffic engineering database. The active stateful PCE then modifies one

or more LSP attributes and sends an update to the PCC. The PCC uses the parameters it receives from the PCE to re-signal the LSP.

Figure 117: Example PCE for MPLS RSVP-TE

This way, the stateful PCE provides a cooperative operation of distributed functionality used to address specific challenges of a shortest interdomain constrained path computation. It eliminates congestion scenarios in which traffic streams are inefficiently mapped onto available resources, causing overutilization of some subsets of network resources, while other resources remain underutilized.

LSP Behavior with External Computing

IN THIS SECTION

- LSP Types | 1358
- LSP Control Mode | 1359

LSP Types

In a client-side PCE implementation, there are three types of TE LSPs:

- CLI-controlled LSPs—The LSPs that do not have the **lsp-external-controller pccd** statement configured are called CLI-controlled LSPs. Although these LSPs are under local control, the PCC updates the connected PCEs with information about the CLI-controlled LSPs during the initial LSP synchronization process. After the initial LSP synchronization, the PCC informs the PCE of any new and deleted LSPs as well.

- PCE-controlled LSPs—The LSPs that have the **lsp-external-controller pccd** statement configured are called PCE-controlled LSPs. The PCC delegates the PCC-initiated LSPs to the main PCE for external path computation.

The PCC informs the PCE about the configured parameters of a PCE-controlled LSP, such as bandwidth, ERO, and priorities. It also informs the PCE about the actual values used for these parameters to set up the LSP including the RRO, when available.

The PCC sends such LSP status reports to the PCE only when a reconfiguration has occurred or when there is a change in the ERO, RRO, or status of the PCE-controlled LSPs under external control.

There are two types of parameters that come from the CLI configuration of an LSP for a PCE:

- Parameters that are not overridden by a PCE, and that are applied immediately.
- Parameters that are overridden by a PCE. These parameters include bandwidth, path, and priority (setup and hold values). When the control mode switches from external to local, the CLI-configured values for these parameters are applied at the next opportunity to re-signal the LSP. The values are not applied immediately.
- Externally-provisioned LSPs (or PCE-initiated LSPs)—The LSPs that have the **lsp-provisioning** statement configured are called PCE-initiated LSPs. A PCE-initiated LSP is dynamically created by an external PCE; as a result, there is no LSP configuration present on the PCC. The PCC creates the PCE-initiated LSP using the parameters provided by the PCE, and automatically delegates the LSP to the PCE.

NOTE: Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

The CLI-controlled LSPs, PCE-controlled LSPs, and PCE-initiated LSPs can coexist on a PCC.

The CLI-controlled LSPs and PCE-controlled LSPs can coexist on a PCC.

LSP Control Mode

In a client-side PCE implementation, there are two types of control modes for a PCC-controlled LSP:

- External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP.
- Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control.

A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

For more information about CLI-controlled LSPs and PCE-controlled LSPs, see [“LSP Types” on page 1358](#).

Configuration Statements Supported for External Computing

Table 32 on page 1360 lists the MPLS and existing LSP configuration statements that apply to a PCE-controlled LSP.

Table 32: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements can be configured along with the PCE configuration. However, they take effect only when the local configuration is in use. During PCE control, these configuration statements remain inactive.	<ul style="list-style-type: none"> • admin-group • auto-bandwidth • hop-limit • least-fill • most-fill • random 	<ul style="list-style-type: none"> • admin-group • admin-groups • admin-group-extended • hop-limit • no-cspf • smart-optimize-timer
<p>These configuration statements can be configured along with the PCE configuration, but are overridden by the PCE-controlled LSP attributes. However, when the local configuration is in use, the configured values for these configuration statements are applied.</p> <p>NOTE: Changes to the local configuration using the CLI while the LSP is under the control of a stateful PCE do not have any effect on the LSP. These changes come into effect only when the local configuration is applied.</p>	<ul style="list-style-type: none"> • bandwidth • primary • priority 	<ul style="list-style-type: none"> • priority
These configuration statements cannot be configured along with the PCE configuration.	<ul style="list-style-type: none"> • p2mp • template 	<ul style="list-style-type: none"> • p2mp-lsp-next-hop

The rest of the LSP configuration statements are applicable in the same way as for existing LSPs. On configuring any of the above configuration statements for a PCE-controlled LSP, an MPLS log message is generated to indicate when the configured parameters take effect.

PCE-Controlled LSP Protection

The protection paths, including fast reroute and bypass LSPs, are locally computed by the PCC using constraint-based routing. A stateful PCE specifies the primary path (ERO) only. A PCE can also trigger a non-standby secondary path, even if the local configuration does not have a non-standby secondary path for LSP protection.

PCE-Controlled LSP ERO

For PCE-controlled LSPs (PCC-delegated LSPs and PCE-initiated LSPs), only a full-blown Explicit Route Object (ERO) object has to be sent from the PCE to the PCC; otherwise the PCC rejects the PCUpdate or PCCreate message for that PCEP session.

Starting in Junos OS Release 17.2, in addition to **external cspf**, two new path computation types are introduced for the PCE-controlled LSPs: **local cspf** and **no cspf**.

- **local cspf**—A PCC uses the **local cspf** computation type only when the PCE sends in a Juniper Vendor TLV (enterprise number: 0x0a4c) of type 5.
- **no cspf**—Neither the PCE nor the PCC performs a constrained path calculation. The endpoints and constraints are given to the RSVP module for setting up the LSP with the IGP path.

A PCC uses **no cspf** computation type in the following cases:

- When the PCE sends **local cspf** TLV, and when the Junos OS configuration or matching template for this LSP included **no-cspf** in the PCC-delegated LSP.
- When the PCE sends **local cspf** TLV, and when the Junos OS configuration template for this LSP included **no-cspf** in the PCE-initiated LSP.
- When the PCE does not send **local cspf** TLV with an empty ERO or loose ERO (with loose bit set in the ERO object).

With these new computation types, a PCC can accept an ERO object either as a loose ERO, or as an empty ERO. An external path computing entity that is not capable of computing a path can modify parameters such as bandwidth and color, based on the analytics. In such cases, an empty ERO object or loose ERO is used and the path to be taken is decided by the PCC.

PCE-Controlled Point-to-Multipoint RSVP-TE LSPs

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well. For a PCE, the point-to-multipoint LSP is similar to that of RSVP point-to-multipoint LSP, where the point-to-multipoint LSP is treated as collection of point-to-point LSPs grouped under a point-to-multipoint identifier.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce pce-name]** or **[edit protocols pcep pce-group group-id]** hierarchy levels. After the point-to-multipoint report capability is configured on a PCC, the PCC advertises this capability to the PCE. If the PCE advertises the same point-to-multipoint report capability in return, then the PCC reports the complete point-to-multipoint LSP tree to the PCE for LSP state synchronization.

A PCC with the point-to-multipoint TE LSP capability supports reporting of point-to-multipoint TE LSPs for stateful PCEs, point-to-multipoint update, and LSP database supporting point-to-multipoint LSP name as key. However, the following features and functions are not supported for Junos OS Release 15.1F6 and 16.1:

- Static point-to-multipoint LSPs
- PCE-delegated and PCE-initiated point-to-multipoint LSPs

- Auto-bandwidth
- TE++
- PCE request and reply message
- Creation of point-to-multipoint LSPs using templates
- Configuring forward entry on the PCE-initiated point-to-multipoint LSPs
- Configuring forward entry on the router pointing to a provisioned LSP.

PCE-Initiated Point-to-Point LSPs

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

By default, a PCC rejects the request for provisioning PCE-initiated point-to-point LSPs from a PCE. To enable support of PCE-initiated LSPs on the PCC, include the *lsp-provisioning* statement at the **[edit protocols pcep pce pce-id]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

A PCC indicates its capability of supporting PCE-initiated point-to-point LSPs while establishing the Path Computation Element Protocol (PCEP) session with the PCE. A PCE selects a PCC with this capability to initiate an LSP. The PCE provides the PCC with the PCE-initiated LSP parameters. On receiving the PCE-initiated point-to-point LSP parameters, the PCC sets up the LSP, assigns an LSP ID, and automatically delegates the LSP to the PCE.

When the PCE initiating the LSP does not provide the PCE-initiated point-to-point LSP parameters, the PCC uses the default parameters. An optional LSP template may also be configured to specify values for the PCE-initiated point-to-point LSP when the LSP parameters are not provided by the PCE. To configure an LSP template for PCE-initiated point-to-point LSPs on the PCC, include the [label-switched-path-template](#) statement at the **[edit protocols mpls lsp-external-controller lsp-external-controller]** hierarchy level.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs—**delegation cleanup timeout** and **lsp cleanup timer**—to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE.

A PCE may return the delegation of the PCE-initiated point-to-point LSP to the PCC to allow LSP transfer between PCEs. Control over PCE-initiated LSPs reverts to the PCC at the expiration of the delegation cleanup timeout. When the delegation cleanup timeout expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated point-to-point LSPs, the PCC delegates these LSPs to the PCE and the LSP cleanup timer is stopped.

The PCC waits for the LSP cleanup timer to expire before deleting the non-delegated PCE-initiated point-to-point LSPs from the failed PCE. When the LSP cleanup timer expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

PCE-Initiated Bypass LSP

IN THIS SECTION

- [Understanding PCE-Initiated Bypass LSPs | 1363](#)
- [Benefits of PCE-Initiated Bypass LSP | 1364](#)
- [Behavior of PCE-Initiated Bypass LSPs During PCEP Session Failure | 1364](#)

Understanding PCE-Initiated Bypass LSPs

There can be traffic outages at the time of a link or node failure because the backup protection paths in the network do not have sufficient bandwidth to handle traffic. In such networks, although a PCE may be used to compute all the paths, to optimize network performance, the local protection paths also need to be controlled through the PCE.

Junos OS Release 19.2R1 and later releases provide partial support for the Internet draft draft-cbrt-pce-stateful-local-protection-01 (expires December 2018), *PCEP Extensions for RSVP-TE Local-Protection with PCE-Stateful*, where the PCEP functionality is extended to allow a stateful PCE to initiate, provision, and manage bypass LSPs for a protected interface. Multiple bypass LSPs with bandwidth reservation can be initiated by the PCE to protect a link or node. The bandwidth on the bypass LSP is expected to be smaller than the total bandwidth of the primary LSPs that it might protect.

The existing bypass selection mechanism, that prefers manual bypass LSPs (if available) over dynamic bypass LSPs, is extended to prefer PCE-provisioned bypass LSPs (if available) over dynamic bypass LSPs. The PCE-provisioned bypass LSPs have a higher preference over dynamic bypass LSPs, but are less preferred over manual bypass LSPs.

The set of operations that are used to perform on any operational bypass LSPs, such as **clear rsvp session**, can also be performed on the PCE-initiated bypass LSPs. You can use commands, such as **show path-computation-client status extensive** and **show path-computation-client lsp** to view PCE-initiated bypass LSP statistics.

With the support of PCE-initiated bypass LSP, you can:

- Create a RSVP bypass LSP through PCEP from an external controller, where the bypass LSP:
 - can be for link or node protection.
 - must have a non-zero bandwidth.

- must have a specified strict ERO.
- Update the bandwidth and ERO for an existing PCE-created bypass LSP.
- Oversubscribe the bypass LSP bandwidth for admission control of primary LSPs. This must be a per-bypass parameter, and should allow updating the subscription per bypass LSP.

Benefits of PCE-Initiated Bypass LSP

The PCE-initiated bypass LSPs provide the following benefits:

- Better control over traffic after a failure and more deterministic path computation of protection paths.
- Meet complex constraints and diversity requirements, such as maintaining diverse paths for LSPs, as well as their local protection paths.
- Ensure links are not overloaded during failure events.

Behavior of PCE-Initiated Bypass LSPs During PCEP Session Failure

At the time of a PCEP session failure, the PCE-initiated bypass LSPs become orphan until the expiration of the state timeout timer. The PCE-initiated bypass LSPs get cleaned up on the expiration of the state timeout timer. To obtain control of a PCE-initiated bypass LSP (after PCEP session fails), a PCE (either the primary PCE, or any secondary PCE) sends a PCInitiate message before the expiration of the state timeout timer.

PCE-Initiated Point-to-Multipoint LSPs

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

For more information, see [“Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs” on page 1420.](#)

Auto-Bandwidth and PCE-Controlled LSP

Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs. In earlier releases, the auto-bandwidth option did not apply to PCE-controlled LSPs, although LSPs under the control of auto-bandwidth and constraint-based routing could coexist with PCE-controlled LSPs. The statistics collection for auto-bandwidth was taking effect only when the control mode of a PCE-controlled LSP changes from external to local. This was happening in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

TCP-MD5 Authentication for PCEP Sessions

A stateful PCE server automates the creation of traffic engineering paths across the network, increasing network utilization and enabling a customized programmable networking experience with the use of PCEP communication with a PCC. A PCC sends LSP reports to a PCE server, and the PCE updates or provisions LSPs back to the PCC. The data sent over a PCEP session is crucial for a PCE server to perform external

path computing. As a result, an attack on the PCEP communication can disrupt network services. If altered PCEP messages are sent to a PCC, inappropriate LSPs can be set up. Similarly, if altered PCEP messages are sent to a PCE, an incorrect view of the network is learned by the PCE.

Considering the significance of the PCEP communication between a PCE and PCC in executing the PCE functionalities effectively, Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440. This feature protects the communication between a PCE and PCC over a PCEP session, which might be subject to an attack, and can disrupt network services.

To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce pce-id]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains key-chain]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce pce-id]** hierarchy level.

The following configuration is executed on the PCC to establish a secure PCEP session with a PCE:

- Using MD5 authentication key:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key key
```

- Using predefined authentication keychain:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key-chain key-chain
user@PCC# set authentication-algorithm md5
```

For secure PCEP sessions to be established successfully, the MD5 authentication should be configured with the pre-shared authentication key on both the PCE server and the PCC. The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session.

NOTE:

- Junos OS Release 16.1 supports only TCP-MD5 authentication for PCEP sessions, without extending support for TLS and TCP-AO, such as protection against eavesdropping, tampering, and message forgery.
- Initial application of security mechanism to a PCEP session causes the session to reset.
- If MD5 is misconfigured or not configured on one side of the PCEP session, the session does not get established. Verify that the configurations on the PCC and PCE are matching.
- This feature does not provide support for any session authentication mechanism.
- To view the authentication keychain used by the PCEP session, use the **show path-computation-client status** and **show protocols pcep** command outputs.
- Use the **show system statistics tcp | match auth** command to view the number of packets that get dropped by TCP because of authentication errors.
- Operation of the keychain can be verified by using the **show security keychain detail** command output.

Impact of Client-Side PCE Implementation on Network Performance

The maintenance of a stateful database can be non-trivial. In a single centralized PCE environment, a stateful PCE simply needs to remember all the TE LSPs that the PCE has computed, the TE LSPs that were actually set up (if this can be known), and when the TE LSPs were torn down. However, these requirements cause substantial control protocol overhead in terms of state, network usage and processing, and optimizing links globally across the network. Thus, the concerns of a stateful PCE implementation include:

- Any reliable synchronization mechanism results in significant control plane overhead. PCEs might synchronize state by communicating with each other, but when TE LSPs are set up using distributed computation performed among several PCEs, the problems of synchronization and race condition avoidance become larger and more complex.
- Out-of-band traffic engineering database synchronization can be complex with multiple PCEs set up in a distributed PCE computation model, and can be prone to race conditions, scalability concerns, and so on.
- Path calculations incorporating total network state is highly complex, even if the PCE has detailed information on all paths, priorities, and layers.

In spite of the above concerns, the partial client-side implementation of the stateful PCE is extremely effective in large traffic engineering systems. It provides rapid convergence and significant benefits in terms of optimal resource usage, by providing the requirement for global visibility of a TE LSP state and for ordered control of path reservations across devices within the system being controlled.

Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE

IN THIS SECTION

- [Requirements | 1367](#)
- [Overview | 1367](#)
- [Configuration | 1370](#)
- [Verification | 1377](#)

This example shows how to enable external path computing by a Path Computation Element (PCE) for traffic engineered label-switched paths (TE LSPs) on a Path Computation Client (PCC). It also shows how to configure the Path Computation Element Protocol (PCEP) on the PCC to enable PCE to PCC communication.

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series routers, M Series Multiservice Edge Routers, MX Series 5G Universal Routing Platforms, T Series Core Routers, or PTX Series Transport Router, one of which is configured as a PCC.
- A TCP connection to an external stateful PCE from the PCC.
- Junos OS Release 12.3 or later running on the PCC along with the JSDN add-on package.

NOTE: The JSDN add-on package is required to be installed along with the core Junos OS installation package.

Before you begin:

1. Configure the device interfaces.
2. Configure MPLS and RSVP-TE.
3. Configure IS-IS or any other IGP protocol.

Overview

Starting with Junos OS Release 12.3, the MPLS RSVP-TE functionality is extended to provide a partial client-side implementation of the stateful PCE architecture (draft-ietf-pce-stateful-pce) on a PCC.

NOTE: The partial client-side implementation of the stateful PCE architecture is based on version 2 of Internet draft draft-ietf-pce-stateful-pce. Starting with Junos OS Release 16.1, this implementation is upgraded to support version 7, as defined in Internet draft draft-ietf-pce-stateful-pce-07. Releases prior to 16.1 support the older version of the PCE draft, causing interoperability issues between a PCC running a previous release and a stateful PCE server that adheres to Internet draft draft-ietf-pce-stateful-pce-07.

To enable external path computing by a PCE, include the **lsp-external-controller** statement on the PCC at the **[edit mpls]** and **[edit mpls lsp lsp-name]** hierarchy levels.

```
lsp-external-controller pccd;
```

An LSP configured with the **lsp-external-controller** statement is referred to as a PCE-controlled LSP and is under the external control of a PCE by default. An active stateful PCE can override the parameters set from the CLI, such as bandwidth, path (ERO), and priority, for such PCE-controlled LSPs of the PCC.

To enable PCE to PCC communication, configure PCEP on the PCC at the **[edit protocols]** hierarchy level.

```
pcep { ... }
```

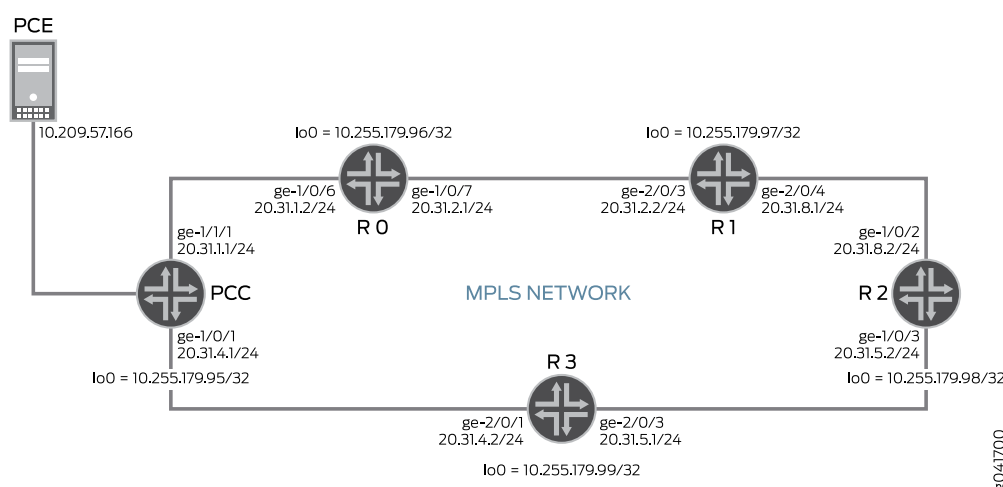

When configuring PCEP on a PCC, be aware of the following considerations:

- The JSDN add-on package is required to be installed along with the core Junos OS installation package.
- Junos OS Release 12.3 supports only stateful PCEs.
- A PCC can connect to a maximum of 10 stateful PCEs. At any given point in time, there can be only one main PCE (the PCE with the lowest priority value, or the PCE that connects to the PCC first in the absence of a PCE priority) to which the PCC delegates LSPs for path computation.
- For Junos OS Release 12.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-controlled LSPs.
- The auto-bandwidth option is turned off for PCE-controlled LSPs, although LSPs under the control of auto-bandwidth and constraint-based routing can coexist with PCE-controlled LSPs.
- PCE-controlled LSPs can be referred to by other CLI configurations, such as `lsp-nexthop` to routes, forwarding adjacencies, CCC connections, and logical tunnels.
- PCE-controlled LSPs do not support GRES.
- PCE-controlled LSPs under logical-systems are not supported.
- PCE-controlled LSPs cannot be point-to-multipoint LSPs.

- Bidirectional LSPs are not supported.
- PCE-controlled LSPs cannot have secondary paths without a primary path.
- PCE-controlled LSPs depend on external path computation, which impacts overall setup time, reroutes, and make-before-break features.
- Setup time and convergence time (reroute, MBB) for existing LSPs is the same as in previous releases, in the absence of PCE-controlled LSPs. However, a small impact is seen in the presence of PCE-controlled LSPs.
- ERO computation time is expected to be significantly higher than local-CSPF.

Topology

Figure 118: Configuring PCEP for MPLS RSVP-TE

In this example, PCC is the ingress router that connects to the external active stateful PCE.

The external LSPs of Router PCC are computed as follows:

1. Router PCC receives the LSP tunnel configuration that was set up using the CLI. Assuming that the received configuration is enabled with external path computing, Router PCC becomes aware that some of the LSP attributes – bandwidth, path, and priority – are under the control of the stateful PCE and delegates the LSP to the PCE.

In this example, the external LSP is called **PCC-to-R2** and it is being set up from Router PCC to Router R2. The CLI-configured ERO for **PCC-to-R2** is PCC-R0-R1-R2. The bandwidth for **PCC-to-R2** is 10m, and both the setup and hold priority values are 4.

2. Router PCC tries to retrieve the PCE-controlled LSP attributes. To do this, Router PCC sends out a PCRpt message to the stateful PCE stating that the LSP has been configured. The PCRpt message communicates the status of the LSP and contains the local configuration parameters of the LSP.

3. The stateful PCE modifies one or more of the delegated LSP attributes and sends the new LSP parameters to Router PCC through the PCUpd message.
4. On receiving the new LSP parameters, Router PCC sets up a new LSP and re-signals it using the PCE-provided path.

In this example, the PCE-provided ERO for **PCC-to-R2** is PCC-R3-R2. The bandwidth for **PCC-to-R2** is 8m, and both the setup and hold priority values are 3.

5. Router PCC sends a PCRpt with the new RRO to the stateful PCE.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PCC:

NOTE: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```

[edit interfaces]
user@PCC# set ge-1/0/1 unit 0 family inet address 20.31.4.1/24
user@PCC# set ge-1/0/1 unit 0 family iso
user@PCC# set ge-1/0/1 unit 0 family mpls
user@PCC# set ge-1/1/1 unit 0 family inet address 20.31.1.1/24
user@PCC# set ge-1/1/1 unit 0 family iso
user@PCC# set ge-1/1/1 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 10.255.179.95/32

```

2. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```

[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable

```

3. Configure the label-switched path (LSP) from Router PCC to Router R2 and enable external control of LSPs by the PCE.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
user@PCC# set mpls label-switched-path PCC-to-R2 to 10.255.179.98/32
user@PCC# set mpls label-switched-path PCC-to-R2 bandwidth 10m
user@PCC# set protocols mpls label-switched-path PCC-to-R2 priority 4 4
user@PCC# set protocols mpls label-switched-path PCC-to-R2 primary to-R2-path
user@PCC# set protocols mpls label-switched-path PCC-to-R2 lsp-external-controller pccd
```

4. Configure the LSP from Router PCC to Router R2, which has local control and is overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path to-R2-path 20.31.1.2/30 strict
user@PCC# set mpls path to-R2-path 20.31.2.2/30 strict
```

5. Enable MPLS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

6. Configure IS-IS on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis interface all
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0
```

7. Define the PCE that Router PCC connects to, and configure the IP address of the PCE.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-ipv4-address 10.209.57.166
```

8. Configure the destination port for Router PCC that connects to a PCE using the TCP-based PCEP.

```
[edit protocols]
user@PCC# set pcep pce pce1 destination-port 4189
```

9. Configure the PCE type.

```
[edit protocols]
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-1/0/1 {
  unit 0 {
    family inet {
      address 20.31.4.1/24;
    }
    family iso;
    family mpls;
  }
}
ge-1/1/1 {
  unit 0 {
    family inet {
      address 20.31.1.1/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.179.95/32;
    }
  }
}
```

```
user@PCC# show protocols
rsvp {
  interface all;
  interface fxp0.0 {
```

```

        disable;
    }
}
mpls {
    lsp-external-controller pccd;
    label-switched-path PCC-to-R2 {
        to 10.255.179.98;
        bandwidth 10m;
        priority 4 4;
        primary to-R2-path;
        lsp-external-controller pccd;
    }
    path to-R2-path {
        20.31.1.2 strict;
        20.31.2.2 strict;
    }
    interface all;
    interface fxp0.0 {
        disable;
    }
}
isis {
    level 1 disable;
    interface all;
    interface fxp0.0 {
        disable;
    }
    interface lo0.0;
}
pcep {
    pce pce1 {
        destination-ipv4-address 10.209.57.166;
        destination-port 4189;
        pce-type active stateful;
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying the PCEP Session Status | 1377](#)
- [Verifying the PCE-Controlled LSP Status When LSP Control Is External | 1378](#)
- [Verifying the PCE-Controlled LSP Status When LSP Control Is Local | 1380](#)

Confirm that the configuration is working properly.

Verifying the PCEP Session Status

Purpose

Verify the PCEP session status between the PCE and Router PCC when the PCE status is up.

Action

From operational mode, run the **show path-computation-client active-pce** command.

user@PCC> show path-computation-client active-pce

```
PCE pce1
General
  IP address          : 10.209.57.166
  Priority             : 0
  PCE status          : PCE_STATE_UP
  Session type        : PCE_TYPE_STATEFULACTIVE
  PCE-mastership      : main

Counters
  PCReqs              Total: 0          last 5min: 0          last hour: 0

  PCC-PCE-NTFS

```

Meaning

The output displays information about the current active stateful PCE that Router PCC is connected to. The **PCE status** output field indicates the current status of the PCEP session between the PCE and Router PCC.

For **pce1**, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established between the PCEP peers.

The statistics of **PCRpts** indicate the number of messages sent by Router PCC to the PCE to report the current status of LSPs. The **PCUpdates** statistics indicate the number of messages received by Router PCC from the PCE. The **PCUpdates** messages include the PCE modified parameters for the PCE-controlled LSPs.

Verifying the PCE-Controlled LSP Status When LSP Control Is External

Purpose

Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP is under external control.

Action

From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

```
user@PCC> show mpls lsp name PCC-to-R2 extensive
```

```

Meaning

In the output, the **LSPTYPE** and **LSP Control Status** output fields show that the LSP is externally controlled. The output also shows a log of the PCEP messages sent between Router PCC and the PCE.

The PCEP session between the PCE and Router PCC is up, and Router PCC receives the following PCE-controlled LSP parameters:

- ERO (path)—20.31.4.2 and 20.31.5.2
- Bandwidth—8Mbps
- Priorities—3 3 (setup and hold values)

Verifying the PCE-Controlled LSP Status When LSP Control Is Local

Purpose

Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP control becomes local.

Action

From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

user@PCC> show mpls lsp name PCC-to-R2 extensive

```
Ingress LSP: 1 sessions

10.255.179.98

Meaning

In the output, the **LSP Control Status** output field shows that the LSP is under local control. Although the PCE-controlled LSP is under local control, Router PCC continues to use the PCE-provided parameters, until the next opportunity to re-signal the LSP.

The output now displays the LSP parameters that were configured using the CLI along with the PCE-provided parameters used to establish the LSP as the actual values in use.

- Bandwidth—10Mbps (ActualBandwidth: 8Mbps)
- Priorities—4 4 (ActualPriorities 3 3)

On the trigger to re-signal the LSP, Router PCC uses the local configuration parameters to establish the PCE-controlled LSP.

The **Computed ERO** is 20.31.1.2, 20.31.2.2, and 20.31.8.2. The PCE-controlled LSP is established using the local configuration parameters.

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

IN THIS SECTION

- [Requirements | 1384](#)
- [Overview | 1384](#)
- [Configuration | 1386](#)
- [Verification | 1391](#)

This example shows how to configure the Path Computation Client (PCC) with the capability of supporting Path Computation Element (PCE)-initiated traffic-engineered point-to-point label-switched paths (LSPs).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- A TCP connection to two external stateful PCEs from the ingress router (PCC).
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE (RSVP-Traffic Engineering).
- Configure OSPF or any other IGP protocol.

Overview

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic

engineering point-to-point LSP dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

When configuring the support of PCE-initiated point-to-point LSPs for a PCC, be aware of the following considerations:

- Junos OS Release 13.3 supports only stateful PCEs.
- For Junos OS Release 13.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-initiated LSPs.
- PCE-initiated LSPs do not support graceful Routing Engine switchover (GRES).
- PCE-initiated LSPs under logical systems are not supported.
- PCE-initiated LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- RSVP-TE for unnumbered links is not supported. PCE-initiated LSPs support only numbered links.
- The PCE initiating a segment routing LSP can use the binding segment ID (SID) labels associated with non-colored segment routing LSPs to provision the PCE-initiated segment routing LSP paths.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to a PCE through a PCEP session. These non-colored segment routing LSPs may have binding SID labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

Topology

Figure 119: Example PCE-Initiated Point-to-Point LSP for MPLS RSVP-TE

In this example, PCC is the ingress router that connects to two external stateful PCEs: PCE1 and PCE2.

When there is a new demand, the active stateful PCE dynamically initiates an LSP to meet the requirement. Since PCC is configured with the capability of supporting the PCE-initiated LSP, path computation on PCC is performed as follows:

1. A PCE sends a PCCreate message to the PCC to initiate and provision an LSP. The PCC sets up the PCE-initiated LSP using the parameters received from the PCE, and automatically delegates the PCE-initiated LSP to the PCE that initiated it.

In this example, PCE1 is the active stateful PCE that initiates and provisions the PCE-initiated LSP on PCC. On receiving the PCE-initiated LSP parameters, PCC sets up the LSP and automatically delegates the PCE-initiated LSP to PCE1.

2. When the PCEP session between PCC and PCE1 is terminated, PCC starts two timers for the PCE1-initiated LSP: delegation cleanup timeout and the LSP cleanup timer. During this time, PCE1 or PCE2 can acquire control of the PCE-initiated LSP.
3. If PCE2 acquires control over the PCE-initiated LSP before the expiration of the LSP cleanup timer, PCC delegates the PCE-initiated LSP to PCE2, and the LSP cleanup timer and the delegation cleanup timeout are stopped.
4. If the delegation cleanup timeout expired, and neither PCE1 nor PCE2 acquired control over the PCE-initiated LSP, PCC takes local control of the non-delegated PCE-initiated LSP until the expiration of the LSP cleanup timer.
5. After the expiration of the LSP cleanup timer, PCC deletes the PCE-initiated LSP provisioned by PCE1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

NOTE: Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```

[edit interfaces]
user@PCC# set ge-0/1/1 unit 0 family inet address 10.0.102.9/24
user@PCC# set ge-0/1/1 unit 0 family iso
user@PCC# set ge-0/1/1 unit 0 family mpls
user@PCC# set ge-0/1/3 unit 0 family inet address 10.0.112.14/24
user@PCC# set ge-0/1/3 unit 0 family iso
user@PCC# set ge-0/1/3 unit 0 family mpls
user@PCC# set lo0 unit 0 family inet address 192.168.12.1/32

```

2. Enable RSVP on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

3. Enable external control of LSPs by the PCEs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd
```

4. Enable MPLS on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure OSPF on all interfaces of the PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
user@PCC# set ospf area 0.0.0.0 interface all
user@PCC# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PCC# set ospf interface lo0.0
```

6. Define the PCE group and enable support of PCE-initiated LSPs for the PCE group.

```
[edit protocols]
user@PCC# set protocols pcep pce-group PCEGROUP pce-type active
user@PCC# set protocols pcep pce-group PCEGROUP pce-type stateful
user@PCC# set protocols pcep pce-group PCEGROUP lsp-provisioning
user@PCC# set protocols pcep pce-group PCEGROUP lsp-cleanup-timer 30
```

7. Define the PCEs that connect to the PCC.

```
[edit protocols]
user@PCC# set pcep pce PCE1 destination-ipv4-address 192.168.69.58
user@PCC# set pcep pce PCE1 destination-port 4189
user@PCC# set pcep pce PCE1 pce-group PCEGROUP
```

```

user@PCC# set pcep pce PCE2 destination-ipv4-address 192.168.70.65
user@PCC# set pcep pce PCE2 destination-port 4189
user@PCC# set pcep pce PCE2 pce-group PCEGROUP

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PCC# show interfaces
ge-0/1/1 {
  unit 0 {
    family inet {
      address 10.0.102.9/24;
    }
    family iso;
    family mpls;
  }
}
ge-0/1/3 {
  unit 0 {
    family inet {
      address 10.0.112.14/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.12.1/32;
    }
  }
}

```

```

user@PCC# show protocols
rsvp {
  interface all;
}
interface fxp0.0 {

```

```

        disable;
    }
}
mpls {
    lsp-external-controller pccd;
    interface all;
    interface fxp0.0 {
        disable;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface all;
        interface fxp0.0 {
            disable;
        }
    }
}
pce-group PCEGROUP {
    pce-type active stateful;
    lsp-provisioning;
    lsp-cleanup-timer 30;
}
pce PCE1 {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    pce-group PCEGROUP;
}
pce PCE2 {
    destination-ipv4-address 192.168.70.65;
    destination-port 4189;
    pce-group PCEGROUP;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

IN THIS SECTION

- [Verifying PCC Status | 1392](#)
- [Verifying PCE1 Status | 1392](#)
- [Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned | 1394](#)

Confirm that the configuration is working properly.

Verifying PCC Status

Purpose

Verify the PCEP session status and LSP summary between the PCC and the connected PCEs.

Action

From operational mode, run the **show path-computation-client status** command.

```
user@PCC# show path-computation-client status
```

Session	Type	Provisioning	Status
PCE1	Stateful Active	On	Up
PCE2	Stateful Active	On	Up

```
LSP Summary
Total number of LSPs      : 1
Static LSPs               : 0
Externally controlled LSPs : 0
Externally provisioned LSPs : 1/16000 (current/limit)
Orphaned LSPs             : 0
```

```
PCE1 (main)
Delegated                  : 1
Externally provisioned    : 1
PCE2
Delegated                  : 0
Externally provisioned    : 0
```

Meaning

The output displays the status of the PCEP session between the active stateful PCEs and the PCC. It also displays information about the different types of LSPs on the PCC, and the number of LSPs provisioned by the connected PCEs and delegated to them.

PCE1 is the main active PCE and has one PCE-initiated LSP that has been automatically delegated to it by the PCC.

Verifying PCE1 Status

Purpose

Verify the status of the main active stateful PCE.

Action

From operational mode, run the **show path-computation-client active-pce detail** command.

user@PCC# **show path-computation-client active-pce**

```

Remote Keepalive timer:    0 [s]  Dead timer:    0 [s]  LSP cleanup timer:
- [s]

Errors
  PCErr-recv
  PCErr-sent
  PCE-PCC-NTFS
  PCC-PCE-NTFS

```

Meaning

The output displays information about the current active stateful PCE to which the PCC is connected. The **PCE status** output field indicates the current status of the PCEP session between a PCE and PCC.

For PCE1, the status of the PCEP session is **PCE_STATE_UP**, which indicates that the PCEP session has been established with the PCC.

Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned

Purpose

Verify the status of the PCE-initiated LSP.

Action

From operational mode, run the **show mpls lsp externally-provisioned detail** command.

```
user@PCC# show mpls lsp externally-provisioned detail
```

```

Ingress LSP: 1 sessions

10.0.101.10
  From: 10.0.102.9, State: Up, ActiveRoute: 0, LSPname: lsp15
  ActivePath: path1 (primary)
  Link protection desired
  LSPTYPE: Externally Provisioned, Penultimate hop popping
  LSP Control Status: Externally controlled
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  *Primary   path1           State: Up
    Priorities: 7 0
    Bandwidth: 8Mbps
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 3)
10.0.102.10 S 10.0.101.9 S
  Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node

```

```
10=SoftPreempt 20=Node-ID):
10.0.102.10 S 10.0.101.9 S
```

Meaning

In the output, the **LSPtype** output field shows that the LSP is externally provisioned.

The PCEP session between PCC and PCE1 is up, and the PCC receives the following PCE-initiated LSP parameters:

- ERO (path)—10.0.102.10 and 10.0.101.9
- Bandwidth—8 Mbps
- Priority—7 0 (setup and hold values)

Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support of PCE-Initiated Point-to-Point LSPs

You can configure a Path Computation Client (PCC) with the capability of supporting dynamically created label switched paths (LSPs) from a centralized external path computing entity. A stateful Path Computaiton Element (PCE) can be used to perform external path computation and generate dynamic LSPs when there is an increase in demand.

A PCC creates the PCE-initiated point-to-point LSP using the PCE-provided LSP parameters, or parameters from a pre-configured LSP template when the PCE does not provision the LSP, and automatically delegates the PCE-initiated point-to-point LSP to the respective PCE. As a result, for PCE-initiated LSPs, there is no need for a locally configured LSP on the PCC.

A CLI-controlled LSP, PCE-controlled LSP, and PCE-initiated LSP can coexist with each other on a PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

To configure PCC to support PCE-initiated point-to-point LSPs, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@PCC# edit protocols pcep
```

2. Specify the number of messages per minute that the PCC can receive at maximum.

```
[edit protocols pcep]
user@PCC# set message-rate-limit messages-per-minute
```

3. Specify the number of externally provisioned label switched paths (LSPs) over all connected PCEs that the PCC can accept at maximum.

```
[edit protocols pcep]
user@PCC# set max-provisioned-lsps max-count
```

4. Specify the unique user defined ID for the connected PCE to configure the PCE parameters.

```
[edit protocols pcep]
user@PCC# edit pce pce-id
```

5. Specify the amount of time (in seconds) that the PCC must wait before returning control of LSPs to the routing protocol process after a PCEP session is disconnected.

```
[edit protocols pcep pce pce-id]
user@PCC# set delegation-cleanup-timeout seconds
```

6. Specify the IPv4 address of the PCE to connect with.

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-ipv4-address ipv4-address
```

7. Specify the TCP port number that the PCE is using

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-port port-number
```

The value can range from 1 through 65535 and the default value is 4189.

8. Specify the amount of time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates.

```
[edit protocols pcep pce pce-id]
```

```
user@PCC# set lsp-cleanup-timer seconds
```

9. Configure the PCC to accept SPs that are externally provisioned by connected PCEs. By default, the PCC rejects PCE-initiated LSPs.

```
[edit protocols pcep pce pce-id]  
user@PCC# set lsp-provisioning
```

10. Specify the number of unknown messages per minute that the PCC can receive at maximum after which the PCEP session is closed.

```
[edit protocols pcep pce pce-id]  
user@PCC# set max-unknown-messages messages-per-minute
```

The value can range from 1 through 16384, and the default value is 0 (disabled or no limit).

11. Specify the number of unknown requests per minute that the PCC can receive at maximum after which the PCEP session is terminated.

```
[edit protocols pcep pce pce-id]  
user@PCC# set max-unknown-requests requests-per-minute
```

The value can range from 0 through 16384, and the default value is 5. A value of 0 disables this statement.

12. Configure the PCE type.

```
[edit protocols pcep pce pce-id]  
user@PCC# set pce-type active stateful
```

13. Specify the amount of time (in seconds) that the PCC must wait for a reply before resending a request.

```
[edit protocols pcep pce pce-id]  
user@PCC# set request-timer seconds
```

The value can range from 0 through 65535 seconds.

14. Verify and commit the configuration.

```
user@PCC# show
user@PCC# commit
```

Sample Output

```
[edit]
user@PCC# edit protocols pcep

[edit protocols pcep]
user@PCC# set message-rate-limit 50

[edit protocols pcep]
user@PCC# set max-provisioned-lsps 16000

[edit protocols pcep]
user@PCC# edit pce PCE

[edit protocols pcep pce PCE]
user@PCC# set delegation-cleanup-timeout 20

[edit protocols pcep pce PCE]
user@PCC# set destination-ipv4-address 192.168.69.58

[edit protocols pcep pce PCE]
user@PCC# set destination-port 4189

[edit protocols pcep pce PCE]
user@PCC# set lsp-cleanup-timer 50

[edit protocols pcep pce PCE]
user@PCC# set lsp-provisioning

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-messages 5

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-requests 5

[edit protocols pcep pce PCE]
user@PCC# set request-timer 50

[edit protocols pcep pce PCE]
user@PCC# up
```

```

[edit protocols pcep]
user@PCC# show
message-rate-limit 50;
max-provisioned-lsps 16000;
pce PCE {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    lsp-provisioning;
    lsp-cleanup-timer 50;
    request-timer 50;
    max-unknown-requests 5;
    max-unknown-messages 5;
    delegation-cleanup-timeout 20;
}

[edit protocols pcep]
user@PCC# commit
commit complete

```

Example: Configuring Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Controlled Point-to-Multipoint LSPs

IN THIS SECTION

- [Requirements | 1399](#)
- [Overview | 1400](#)
- [Configuration | 1401](#)
- [Verification | 1414](#)

This example shows how to configure the Path Computation Client (PCC) with the capability of reporting point-to-multipoint traffic engineered label-switched paths (TE LSPs) to a Path Computation Element (PCE).

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of ACX Series, M Series, MX Series, or T Series routers.
- One virtual machine configured with Virtual Route Reflector (VRR) feature.

- A TCP connection to an external stateful PCE from the VRR.
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

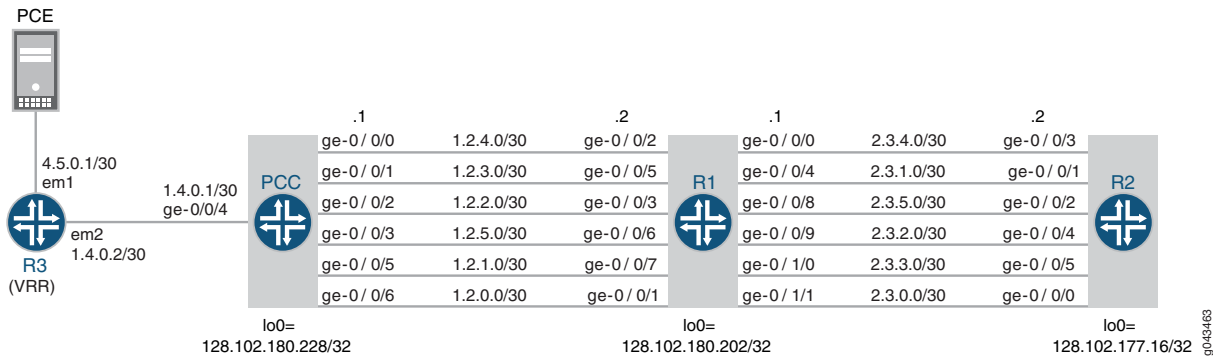

Overview

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce pce-name]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

Topology

Figure 120: Example PCE-Controlled Point-to-Multipoint LSPs

In this example, PCC is the ingress router, Router R1 is the transit router, and Router R2 is the egress router. PCC is connected to a Virtual Route Reflector (VRR) that is connected to a PCE. There are many point-to-multipoint interfaces between PCC, Router R1, and Router R2.

The reporting of point-to-multipoint LSPs is executed as follows:

1. If Router PCC is configured with point-to-point and point-to-multipoint LSPs without the support for point-to-multipoint reporting capability, only the point-to-point LSPs are reported to the connected PCE. By default, a PCC does not support point-to-multipoint LSP reporting capability.
2. When Router PCC is configured with point-to-multipoint LSP reporting capability, PCC first advertises this capability to PCE through a report message.
3. By default, a PCE provides support for point-to-multipoint LSP capability. On receiving the PCC's advertisement for point-to-multipoint LSP capability, the PCE in return advertises its capability to the PCC.
4. On receiving the PCE's advertisement of the point-to-multipoint capability, PCC reports all branches of point-to-multipoint LSPs to the PCE using the update message.
5. Once all the LSPs are reported to the PCE, LSP state is synchronized between the PCE and PCC.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

PCC

```
set interfaces ge-0/0/0 unit 0 family inet address 1.2.4.1/30
set interfaces ge-0/0/0 unit 0 family mpls

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

1. Configure the interfaces of Router PCC. To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

```

[edit interfaces]
user@PCC# set ge-0/0/0 unit 0 family inet address 1.2.4.1/30
user@PCC# set ge-0/0/0 unit 0 family mpls
user@PCC# set ge-0/0/1 unit 0 family inet address 1.2.3.1/30
user@PCC# set ge-0/0/1 unit 0 family mpls
user@PCC# set ge-0/0/2 unit 0 family inet address 1.2.2.1/30
user@PCC# set ge-0/0/2 unit 0 family mpls
user@PCC# set ge-0/0/3 unit 0 family inet address 1.2.5.1/30
user@PCC# set ge-0/0/3 unit 0 family mpls
user@PCC# set ge-0/0/4 unit 0 family inet address 1.4.0.1/30
user@PCC# set ge-0/0/4 unit 0 family mpls
user@PCC# set ge-0/0/5 unit 0 family inet address 1.2.1.1/30
user@PCC# set ge-0/0/5 unit 0 family mpls
user@PCC# set ge-0/0/6 unit 0 family inet address 1.2.0.1/30

```

```
user@PCC# set ge-0/0/6 unit 0 family mpls
```

2. Configure the autonomous system number for Router PCC.

```
[edit routing-options]
user@PCC# set autonomous-system 100
```

3. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure a dynamic LSP and disable automatic path computation for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp_template_no_cspf template
user@PCC# set mpls label-switched-path lsp_template_no_cspf no-cspf
```

6. Configure point-to-multipoint LSPs and define external path computing entity for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp1-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc lsp-external-controller pccd
```

7. Enable external path computing for the MPLS LSPs and assign a template for externally provisioned LSPs.

```
[edit protocols]
```

```

user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pcc_delegated_no_cspf_*
label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pce_initiated_no_ero_no_cspf_*
label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp pce_initiated_loose_ero_no_cspf_*
label-switched-path-template lsp_template_no_cspf

```

8. Configure the LSPs that have local control and are overridden by the PCE-provided LSP parameters.

```

[edit protocols]
user@PCC# set mpls path loose-path 1.2.3.2 loose
user@PCC# set mpls path strict-path 1.2.3.2 strict
user@PCC# set mpls path strict-path 2.3.3.2 strict
user@PCC# set mpls path path-B
user@PCC# set mpls path path-C

```

9. Configure MPLS administrative group policies for constrained-path LSP computation.

```

[edit protocols]
user@PCC# set mpls admin-groups violet 1
user@PCC# set mpls admin-groups indigo 2
user@PCC# set mpls admin-groups blue 3
user@PCC# set mpls admin-groups green 4
user@PCC# set mpls admin-groups yellow 5
user@PCC# set mpls admin-groups orange 6

```

10. Assign the configured administrative group policies to Router PCC interfaces.

```

[edit protocols]
user@PCC# set mpls interface ge-0/0/6.0 admin-group violet
user@PCC# set mpls interface ge-0/0/5.0 admin-group indigo
user@PCC# set mpls interface ge-0/0/2.0 admin-group blue
user@PCC# set mpls interface ge-0/0/1.0 admin-group green
user@PCC# set mpls interface ge-0/0/0.0 admin-group yellow
user@PCC# set mpls interface ge-0/0/3.0 admin-group orange

```

11. Configure a traffic engineering database (TED) import policy.

```

[edit protocols]
user@PCC# set mpls traffic-engineering database import policy TE

```

12. Configure a BGP internal group.

```
[edit protocols]
user@PCC# set bgp group northstar type internal
user@PCC# set bgp group northstar local-address 128.102.180.228
user@PCC# set bgp group northstar neighbor 128.102.180.215
```

13. Configure traffic engineering for BGP and assign the export policy.

```
[edit protocols]
user@PCC# set bgp group northstar family traffic-engineering unicast
user@PCC# set bgp group northstar export TE
```

14. Configure OSPF area 0 on all the point-to-multipoint interfaces of Router PCC.

```
[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface lo0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/3.0
```

15. Configure OSPF area 0 on the point-to-point interface of Router PCC.

```
[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/4.0 interface-type p2p
```

16. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PCC# set ospf traffic-engineering
```

17. Define the PCE that Router PCC connects to, and configure the the PCE parameters.

```
[edit protocols]
user@PCC# set pcep pce pce1 local-address 10.102.180.228
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.246
```

```

user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 lsp-cleanup-timer 0
user@PCC# set pcep pce pce1 delegation-cleanup-timeout 60

```

18. Configure Router PCC to enable point-to-multipoint LSP capability for external path computing.

```

[edit protocols]
set pcep pce pce1 p2mp-lsp-report-capability

```

19. Configure the traffic engineering policy.

```

[edit policy-options]
user@PCC# set policy-statement TE term 1 from family traffic-engineering
user@PCC# set policy-statement TE term 1 then accept

```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PCC# show interfaces

Verification

IN THIS SECTION

- [Verifying LSP Configuration on the PCC | 1415](#)
- [Verifying PCE Configuration on the PCC | 1418](#)

Confirm that the configuration is working properly.

Verifying LSP Configuration on the PCC

Purpose

Verify the LSP type and running state of the point-to-multipoint LSP.

Action

From operational mode, run the **show mpls lsp extensive** command.

```
user@PCC> show mpls lsp extensive
```

```
Ingress LSP: 2 sessions

Meaning

The output displays the active PCE that Router PCC is connected to, and the pce1 PCE parameters and state.

Understanding Path Computation Element Protocol for MPLS RSVP-TE with Support for PCE-Initiated Point-to-Multipoint LSPs

IN THIS SECTION

- [Benefits of PCE-Initiated Point-to-Multipoint LSPs | 1420](#)
- [Signaling of PCE-Initiated Point-to-Multipoint LSPs | 1420](#)
- [Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure | 1421](#)
- [Configuring PCE-Initiated Point-to-Multipoint LSP Capability | 1421](#)
- [Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs | 1421](#)
- [Mapping PCE-initiated Point-To-Multipoint LSPs to MVPN | 1422](#)

With the introduction of point-to-multipoint PCE-initiated LSPs, a PCE can initiate and provision a point-to-multipoint LSP dynamically without the need for local LSP configuration on the PCC. This enables the PCE to control the timing and sequence of the point-to-multipoint path computations within and across Path Computation Element Protocol (PCEP) sessions, thereby creating a dynamic network that is centrally controlled and deployed.

Benefits of PCE-Initiated Point-to-Multipoint LSPs

Meets the requirements of point-to-multipoint traffic engineering LSP placement in response to application demands through dynamic creation and tear down of point-to-multipoint LSPs, thereby creating a dynamic network that is centrally controlled and deployed.

Signaling of PCE-Initiated Point-to-Multipoint LSPs

The signaling of PCE-initiated point-to-multipoint LSPs is as follows:

- **When a new branch is added (Grafting)**—Only the new branch sub-LSP is signaled and does not result in re-signaling of the entire point-to-multipoint tree.

If any topology changes occurred before provisioning of the new sub-LSP, then the Path Computation Server (PCS) re-computes the entire point-to-multipoint tree and updates the point-to-multipoint LSP using a PC update message.

- **When a branch is deleted (Pruning)**—The deleted branch sub-LSP is torn down and does not result in re-signaling of the entire point-to-multipoint tree.
- **When a branch sub-LSP parameter is changed**—Change in sub-LSP parameters, such as Explicit Route Object (ERO), bandwidth, or priority, can happen either because of optimization, or on user request. If

there is a re-signaling request for a sub-LSP, the entire point-to-multipoint tree is re-signaled, and then the switchover to the new instance happens once the new instances of all the branches are up.

- **When a branch sub-LSP path fails**—An error is reported to the PCS for the failed branch sub-LSP. On receiving the new ERO from the PCS, the entire point-to-multipoint tree is re-signaled along with the failed branch sub-LSP, and the switchover to the new instance happens in a make-before-break (MBB) fashion.

Behavior of PCE-Initiated Point-to-Multipoint LSPs After PCEP Session Failure

When a PCEP session fails, the PCE-initiated point-to-multipoint LSPs are orphaned until the expiration of the **state timeout** timer. After the **state timeout** timer expires, the PCE-initiated LSPs are cleaned up.

To obtain control of a PCE-initiated point-to-multipoint LSP after a PCEP session failure, the primary or secondary PCE sends a **PCInitiate** message before the **state timeout** timer expires.

Configuring PCE-Initiated Point-to-Multipoint LSP Capability

By default, the creation and provisioning of point-to-multipoint LSPs by a PCE is not supported on a PCC. To enable this capability, include the **p2mp-lsp-init-capability** and **p2mp-lsp-update-capability** statements at the **[edit protocols pcep pce pce-name]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

The **p2mp-lsp-init-capability** statement provides the capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. The **p2mp-lsp-update-capability** statement provides the capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE.

Supported and Unsupported Features for PCE-Initiated Point-to-Multipoint LSPs

The following features are supported with PCE-initiated point-to-multipoint LSPs:

- Partial compliance with the Internet draft draft-ietf-pce-stateful-pce-p2mp (expires October 2018), *Path Computation Element (PCE) Protocol Extensions for Stateful PCE usage for Point-to-Multipoint Traffic Engineering Label Switched Paths*.

The following features are not supported with PCE-initiated point-to-multipoint LSPs:

- Delegation of point-to-multipoint locally controlled LSP.
- LSP control delegation.
- Interior gateway protocol (IGP) extension for PCE discovery within an IGP routing domain.
- Request/response messaging.
- Direct movement of branch sub-LSP from one point-to-multipoint tree to another.

The same can be achieved by deleting a branch sub-LSP from the first point-to-multipoint tree and re-adding it to another after the **PCReport** message indicates LSP removal from the device.

- IPv6 is not supported.
- SERO based signalling is not supported.

- Empty-ERO feature is not supported.
- Link protection is not supported.

Mapping PCE-initiated Point-To-Multipoint LSPs to MVPN

You can associate a single or range of MVPN multicast flows (S,G) to a dynamically created PCE-initiated point-to-multipoint label-switched path (LSP). You can specify only selective types of flows for this feature to work. This includes:

- Route distinguisher (RD) which is mapped to the MVPN routing-instance.
- (S,G) which is the source of a multicast packet and destination multicast group address. This is used to filter incoming traffic for mapping it to the tunnel.
- Point-to-multipoint LSP that is used to send traffic that matches the above-mentioned flow specification.

For more details, see Internet draft draft-ietf-pce-pcep-flowspec-05 (expires February 16, 2020) *PCEP Extension for Flow Specification*.

The current implementation of this feature does not implement the following sections of the draft:

- Section 3.1.2—Advertising PCE capabilities in IGP
- Section 3.2—PCReq and PCRep message
- Section 7—Most of the flow specifications, except route distinguisher and IPv4 multicast flow specifications, are not supported.

To enable the mapping of PCE-initiated point-to-multipoint LSPs to MVPN:

- Include the **pce_traffic_steering** statement at the **[edit protocols pcep pce pce-id]** hierarchy level to indicate the support for flow specification capability (also called traffic steering) by the PCC.
- Include the **external-controller** statement at the **[edit routing-instances routing-instance-name provider-tunnel]** hierarchy level.

The presence of **external-controller** in the provider-tunnel configuration for MVPN indicates that the point-to-multipoint LSP and (S,G) for this MVPN instance can be provided by the external controller. This enables the external controller to dynamically configure (S,G) and point-to-multipoint LSP for MVPN.

Take the following into consideration for mapping of PCE-initiated point-to-multipoint LSPs to MVPN:

- If you do not enable the **external-controller pccd** statement for a particular MVPN instance, then the PCCD process does not configure (S,G) dynamically.
- If you disable the **external-controller pccd** configuration from the CLI, then the dynamically learned multicast flows (S,G) for that particular MVPN instance is deleted and reported to the external controller.
- When (S,G) is already configured from the CLI, the PCC cannot configure (S,G) dynamically as local configuration has a higher priority.

- If any particular (S,G) is learned from the external controller dynamically and then you configure the same (S,G) for the same MVPN instance, then the dynamically learned (S,G) is deleted and reported to the external controller through the PCC.
- If the routing protocol process reboots, then the PCCD process reconfigures all the (S,G) again.
- If the PCCD process reboots, then MVPN reports all PCCD configured (S,G) to the external controller.
- If user enables **external-controller pccd** for a particular MVPN instance, then MVPN requests the PCCD process to configure (S,G), if any present.
- If there are major configuration changes to a particular MVPN instance, then MVPN requests the PCCD process to reconfigure all (S,G) for that particular MVPN instance.
- All flow specifications associated with any PCE-initiated point-to-multipoint LSP must have the same RD. During PC initiation if all flow specifications do not have the same RD, then the PC initiate message is dropped with an error.
- You can associate a point-to-multipoint LSP only with selective type of flow specifications, otherwise the PC initiate message is dropped with an error.
- During PC update if all flow specifications do not have same the RD either due to a new flow specification addition, or due to existing flow specification update, then the PCC drops the update message.
- During PC update if all flow specifications do not meet the selective condition either due to new flow specification addition, or due to existing flow specifications update, then the PCC drops the update message.
- Behavior for mapping of PCE-initiated point-to-multipoint LSP with MVPN routing-instance and mapping of static (locally configured) point-to-multipoint LSP with MVPN instance is the same at user level.
- A flow specification ID can be associated with only one point-to-multipoint LSP. To associate the same RD and (S,G) to multiple point-to-multipoint LSPs, you can add multiple flow specifications with different IDs and same RD & (S,G).
- For PCEP-mapped dynamic (S,G), the threshold value is always the default value of 0.
- There is no limit on the number of flow specifications mapped to a single PCE-initiated point-to-multipoint LSP.
- The current implementation of this feature does not support:
 - Reporting of forwarding states that are associated with the point-to-multipoint LSP.
 - Inclusive provider tunnel dynamic configuration
 - Mapping for MVPN ingress replication tunnel
 - Programmable routing protocol process (prpd)
 - Reporting of CLI configured point-to-multipoint LSP which is mapped to MVPN multicast flows (S,G).

How to Configure Segment Routing for the Path Computation Element Protocol

SUMMARY

You can enable segment routing or Source Packet Routing in Networking (SPRING) traffic-engineering (SR-TE) with the Path Computation Element Protocol (PCEP) for traffic steering. With this support, the advantages of segment routing are extended to the label-switched paths (LSPs) that are externally controlled by a Path Computation Element (PCE).

- [Segment Routing for Traffic Engineering | 1425](#)
- [Junos OS Implementation of Segment Routing for PCEP | 1425](#)
- [Segment Routing for PCEP Limitations and Unsupported Features | 1431](#)

Benefits of Segment Routing for PCEP

- Setting up of LSPs through an external controller provides a global view of per-LSP and per-device bandwidth demand on the network, enabling online and real-time constraint-based path computation.

The advantages of segment routing are extended to the LSPs initiated by an external controller, also known as a Path Computation Element (PCE), augmenting the benefits of external path computing in an MPLS network.

- A Path Computation Client (PCC, an ingress MX Series router) with delegation capability can take back control of the delegated segment routing LSPs from the PCE when the PCEP session goes down; the LSPs would otherwise be deleted from the PCC. You can thus ensure LSP data protection by averting a situation where packets are silently discarded or dropped (also known as a traffic black-hole condition).

Segment Routing for Traffic Engineering

Segment routing can operate over an IPv4 or IPv6 data plane, and supports equal-cost multipath (ECMP). With the IGP extensions built into it, segment routing integrates with the rich multiservice capabilities of MPLS, including Layer 3 VPN, Virtual Private Wire Service (VPWS), Virtual Private LAN Service (VPLS), and Ethernet VPN (EVPN).

Some of the high-level components of the segment routing-traffic engineering (SR-TE) solution include:

- Use of an IGP for advertising link characteristics. This functionality is similar to RSVP-TE.
- Use of Constrained Shortest Path First (CSPF) on the ingress device or the PCE.
- Use of an IGP for advertising labels for links.

In SR-TE functionality:

1. The ingress device constructs an LSP by stacking the labels of the links that it wants to traverse.
2. The per-link IGP advertisement is combined with label stacking to create source routed LSPs on the ingress device, so the transit devices are not aware of the end-to-end LSPs.
3. LSPs are created between edge nodes without placing any per-LSP memory requirements on the transit devices. (Creation of such LSPs is enabled as there is no per-LSP signaling in SR-TE.)
4. Per-neighbor labels are stacked, which results in the management of a large number of labels, leading to control plane scaling.

Junos OS Implementation of Segment Routing for PCEP

IN THIS SECTION

- [PCE-Initiated Segment Routing LSPs | 1425](#)
- [PCE-Delegated Segment Routing LSPs | 1427](#)

Junos OS implements segment routing for PCEP for two types of LSPs—PCE-initiated LSPs and PCE-delegated LSPs.

PCE-Initiated Segment Routing LSPs

The PCE-initiated segment routing LSPs are those LSPs that the PCE creates for the adjacency and node segmentsadjacency and node segments.

The PCE performs the following functions:

1. Computes the path of the segment routing LSP.
2. Provisions the LSP on the Path Computation Client (PCC) using PCEP segment routing extensions.
3. Parses the PCEP segment routing extensions.
4. Creates a tunnel route on the PCC that has its own preference value and is made available in the inet.3 routing table to resolve IP traffic and services like any other tunnel route.

The PCC performs the following functions:

1. Selects the outgoing interface based on the first network access identifier (NAI) in the source Explicit Route Object (S-ERO).

Junos OS supports S-EROs that contain the first hop as a strict hop; Junos OS doesn't support selection of the outgoing interface on the PCC based on a loose-hop node segment ID (SID). However, the remaining hops can be loose. No specific processing is done for the S-EROs that are beyond the first hop, other than to simply use the label for next-hop creation.

2. Rejects the S-ERO if:

- The S-ERO does not have labels in it.
- The S-ERO carries more than six hops.

Creates an equal-cost multipath (ECMP) route when there are multiple LSPs to the same destination with the same metric.

3. Waits for the PCE to process any event that leads to a change in the segment routing LSP after it is provisioned--for example, if the label is changed or withdrawn, or if one of the interfaces traversed by the LSP goes down.

When the PCEP session goes down, the PCE-initiated segment routing LSP:

1. Remains up for 300 seconds.
2. The LSP is deleted from the PCC after 300 seconds.

For more details, see Internet drafts [draft-ietf-pce-lsp-setup-type-03.txt](#) (expires December 25, 2015), *Conveying path setup type in PCEP messages*, and [draft-ietf-pce-segment-routing-06.txt](#) (expires February 10, 2016), *PCEP Extensions for Segment Routing*.

PCE-Delegated Segment Routing LSPs

The PCE-delegated segment routing LSPs are those LSPs that the PCC configures locally and then delegates to a PCE controller.

NOTE:

Junos OS Release 20.1R1 supports:

- PCE delegation capability only for non-colored segment routing LSPs with IPv4 destinations.
- Delegation and reporting of only the first segment of a segment list to an external controller. Multiple segments are not supported for PCE delegation.

The PCC can delegate a segment routing LSP to an external controller (the PCE) in the following ways:

- **Initial delegation**—The local LSPs are yet to be configured on the PCC, and the delegation of the LSP happens at the time the LSP is configured.
- **Delegation of existing LSP**—The local LSPs are configured on the PCC, and the delegation of the LSP happens after the source-routing path is configured. That is, the delegation capability is enabled on existing segment routing LSPs.

After delegating a segment routing LSP, the PCE controls the delegated LSPs and can modify the LSP attributes for path computation. The LSP control reverts back to the PCC when the PCEP session between the PCC and the PCE goes down. The PCE-delegated LSPs have an advantage over PCE-initiated LSPs in case the PCEP session goes down. For PCE-initiated LSPs, when the PCEP session is down, the LSPs are deleted from the PCC. However, for PCE-delegated LSPs, when the PCEP session goes down, the PCC takes back control of the delegated LSPs from the PCE. As a result, with PCE-delegated LSPs, we avert a situation where packets are silently discarded (also known as a traffic black-hole condition) when the session goes down.

The following types of segment routing LSPs support the PCE-delegation capability:

- **Static LSPs**—Statically configured source-routing paths that have the entire label stack statically configured.
- **Auto-translated LSPs**—Statically configured source-routing-paths that are automatically translated.
- **Computed LSPs**—Statically configured source-routing-paths that are computed with distributed Constrained Shortest Path First (CSPF).
- **Dynamic LSPs**—Dynamically created tunnels triggered through the Dynamic Tunnel Module that have last-hop ERO resolution.

Depending on the source of the segment routing LSP, you can configure the delegation capability on the PCC. To enable delegation of segment routing LSPs, include the **`lsp-external-controller pccd`** statement at the appropriate level under the **`[edit protocols source-packet-routing]`** hierarchy.

Table 33 on page 1428 shows a mapping of the LSP source to the corresponding configuration hierarchy level at which the delegation capability is enabled.

NOTE: You must include the **`lsp-external-controller pccd`** statement at the **`[edit protocols source-packet-routing]`** and **`[edit protocols mpls]`** hierarchy levels before configuring the delegation capability on the PCC.

Table 33: Mapping of Segment Routing LSP Source with Configuration Hierarchy

Source of Segment Routing LSP	Configuration Hierarchy
<ul style="list-style-type: none"> • Auto-translated LSPs • Static LSPs 	Primary segment list at <code>[edit protocols source-packet-routing source-routing-path lsp-name primary path-name]</code>
Computed LSPs (distributed CSPF)	Primary segment list of the source-routing path at: <ul style="list-style-type: none"> • <code>[edit protocols source-packet-routing source-routing-path lsp-name primary path-name compute profile-name]</code> • <code>[edit protocols source-packet-routing source-routing-path lsp-name primary path-name]</code>
Dynamic LSPs	Primary segment list of the source-routing path template at: <ul style="list-style-type: none"> • <code>[edit protocols source-packet-routing source-routing-path-template template-name primary primary-segment-list-name]</code> • <code>[edit protocols source-packet-routing source-routing-path-template template-name]</code>

You can view the control status of the SR-TE LSPs from the **`show spring-traffic-engineering`** command output.

Table 34 on page 1429 displays the PCEP interaction when the **`lsp-external-controller`** statement is configured for a source-routing path.

Table 34: PCEP Interaction LSP Delegation

lsp-external-controller Configuration Hierarchy	source-routing-path Delegation State	PCEP Interaction Between PCC and PCE
Primary segment list of source-routing path	Initial delegation	<ol style="list-style-type: none"> 1. A PCReport is sent to the PCE for delegation. PCReport contains only constraints and path details (such as ERO). 2. PCE calculates the path for LSP and reports path to be in the down state. 3. No route is programmed by the local LSP until the controller computes the ERO and notifies the result to the PCC through PCUpdate. <p>The same behavior is seen when the routing protocol process (rpd) restarts or a Routing Engine switchover happens.</p>

Table 34: PCEP Interaction LSP Delegation (*continued*)

lsp-external-controller Configuration Hierarchy	source-routing-path Delegation State	PCEP Interaction Between PCC and PCE
Primary segment list of source-routing path	Delegation of existing path	<ol style="list-style-type: none"> 1. A PCReport is sent to the PCE for delegation. PCReport contains only constraints and path details (such as ERO). 2. A corresponding primary segment is delegated to the PCE. 3. PCE calculates the path for the LSP. 4. The primary segment continues to contribute to the route as determined by the local configuration or computation until a PCUpdate is received from the PCE. <ul style="list-style-type: none"> • If Seamless BFD (S-BFD) is not configured for the primary segment, then there is no further update to the route and the LSP state is also not monitored and reported to the PCE. The LSP state at this point is reported as up or down depending on whether path computation had succeeded at that point. • If S-BFD is configured for the primary segment, then the state of the primary segment is tracked and reported to the PCE. If BFD detects the primary segment to be down, the corresponding primary path is removed from the route. The same route that was previously calculated is reprogrammed if that path is up now. 5. If a PCUpdate message is received from the PCE, SR-TE uses the received parameter to set up the path for which the PCReport message was sent. The programmed path then includes only the segment list received from the PCE and all the other segment lists that were previously programmed are removed. This reprogramming of the route happens in a make-before-break fashion.
Primary segment of source-routing path	Delegation is not configured or has been deleted	The segment list from the PCE (if available) is no longer used and the computation result from the local configuration is used. When the local result for the segment list is available, the corresponding segment list is used to program the route in a make-before-break fashion.

Table 34: PCEP Interaction LSP Delegation (*continued*)

lsp-external-controller Configuration Hierarchy	source-routing-path Delegation State	PCEP Interaction Between PCC and PCE
Segment list of source-routing path	Delegation is enabled after LSP is configured	Delegation functionality is triggered for the primary segment list under the source-routing path.
Segment list of source-routing path	Delegation is not configured or has been deleted	Delegation functionality is removed from the primary segment list under the source-routing path.
Primary segment list of source-routing path template	Delegation is enabled after LSP is configured	<ul style="list-style-type: none"> Under the source-routing path template—Delegation functionality is triggered for the entire source-routing path. Template configurations can be applied only to the Dynamic Tunnel Module. Under the primary path in the source-routing path template—Delegation functionality is triggered for that particular primary path according to the configuration.
Primary segment list of source-routing path template	Delegation is not configured or has been deleted	Delegation functionality is removed from all the source-routing paths and primary paths that match the template configuration.

Segment Routing for PCEP Limitations and Unsupported Features

The support of segment routing for PCEP does not add to the performance burden on the system; however, it has the following limitations:

- An SR-TE LSP is not locally protected on the PCC. When the LSP is more than six hops, no service is provided on the LSP other than to carry plain IP traffic.
- Graceful Routing Engine switchover (GRES) and unified in-service software upgrade (unified ISSU) are not supported.
- Nonstop active routing (NSR) is not supported.
- IPv6 is not supported.
- PCE-delegated LSPs does not support the following:
 - Colored SR-TE LSPs
 - IPv6 LSPs
 - Secondary segment list of the source-routing path. Only one path of the segment list can be delegated.
 - Multisegment standard. Only the first segment of the segment list is delegated and reported to the controller.

WHAT'S NEXT

For more information on configuring Segment Routing for the Path Computation Element Protocol, see [Example: Configure Segment Routing for the Path Computation Element Protocol](#).

Static Segment Routing Label Switched Path

IN THIS SECTION

- [Understanding Static Segment Routing LSP in MPLS Networks | 1432](#)
- [Example: Configuring Static Segment Routing Label Switched Path | 1457](#)

The segment routing architecture enables the ingress devices in a core network to steer traffic through explicit paths. You can configure these paths using segment lists to define the paths that the incoming traffic should take. The incoming traffic may be labeled or IP traffic, causing the forwarding operation at the ingress device to be either a label swap, or a destination-based lookup.

Source packet routing or segment routing is a control-plane architecture that enables an ingress router to steer a packet through a specific set of nodes and links in the network without relying on the intermediate nodes in the network to determine the actual path it should take.

Introduction to Segment Routing LSPs

Segment routing leverages the source routing paradigm. A device steers a packet through an ordered list of instructions, called segments. A segment can represent any instruction, topological or service-based. A segment can have a local semantic to a segment routing node or to a global node within a segment routing domain. Segment routing enforces a flow through any topological path and service chain while maintaining per-flow state only at the ingress device to the segment routing domain. Segment routing can be directly applied to the MPLS architecture with no change on the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. Upon completion of a segment, the related label is popped from the stack.

Segment routing LSPs can either be dynamic or static in nature.

Dynamic segment routing LSPs—When a segment routing LSP is created either by an external controller and downloaded to an ingress device through Path Computation Element Protocol (PCEP) extensions, or from a BGP segment routing policy through BGP segment routing extensions, the LSP is dynamically provisioned. The segment list of the dynamic segment routing LSP is contained in the PCEP Explicit Route Object (ERO), or the BGP segment routing policy of the LSP.

Static segment routing LSPs—When a segment routing LSP is created on the ingress device through local configuration, the LSP is statically provisioned.

A static segment routing LSP can further be classified as colored and non-colored LSPs based on the configuration of the **color** statement at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level.

For example:

```
[edit protocols]
  source-packet-routing {
    source-routing-path lsp_name {
      to destination_address;
      color color_value;
      binding-sid binding-label;
      primary segment_list_1_name weight weight;
      ...
      primary segment_list_n_name weight weight;
      secondary segment_list_n_name;
      sr-preference sr_preference_value;
    }
  }
```

Here, each primary and secondary statement refers to a segment list.

```
[edit protocols]
  source-packet-routing {
    segment-list segment_list_name {
      hop_1_name label sid_label;
      ...
      hop_n_name label sid_label;
    }
  }
```

Benefits of using Segment Routing LSPs

- Static segment routing does not rely on per LSP forwarding state on transit routers. Hence, removing the need of provisioning and maintaining per LSP forwarding state in the core.
- Provide higher scalability to MPLS networks.

Colored Static Segment Routing LSP

IN THIS SECTION

- [Understanding Colored Static Segment Routing LSPs | 1435](#)
- [Segment List of Colored Segment Routing LSPs | 1435](#)

A static segment routing LSP configured with the **color** statement is called a colored LSP.

Understanding Colored Static Segment Routing LSPs

Similar to a BGP segment routing policy, the ingress route of the colored LSP is installed in the **inetcolor.0** or **inet6color.0** routing tables, with **destination-ip-address, color** as key for mapping IP traffic.

A static colored segment routing LSP may have a binding SID, for which a route is installed in the **mpls.0** routing table. This binding SID label is used to map labeled traffic to the segment routing LSP. The gateways of the route are derived from the segment list configurations under the primary and secondary paths.

Segment List of Colored Segment Routing LSPs

The colored static segment routing LSPs already provide support for first hop label mode of resolving an LSP. However, first hop IP mode is not supported for colored segment routing LSPs. Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops. If this requirement is not met, the commit is blocked.

Non-Colored Static Segment Routing LSP

IN THIS SECTION

- [Understanding Non-Colored Segment Routing LSPs | 1435](#)
- [Segment List of Non-Colored Segment Routing LSPs | 1436](#)

A static segment routing LSP that is configured without the **color** statement is a non-colored LSP. Similar to PCEP segment routing tunnels, the ingress route is installed in the **inet.3** or **inet6.3** routing tables.

Junos OS supports non-colored static segment routing LSPs on ingress routers. You can provision non-colored static segment routing LSP by configuring one source routed path and one or more segment lists. These segment lists can be used by multiple non-colored segment routing LSPs.

Understanding Non-Colored Segment Routing LSPs

The non-colored segment routing LSP has a unique name and a destination IP address. An ingress route to the destination is installed in the **inet.3** routing table with a default preference of 8 and a metric of 1. This route allows non-colored services to be mapped to the segment routing LSP pertaining to the destination. In case the non-colored segment routing LSP does not require an ingress route then the ingress route can be disabled. A non-colored segment routing LSP uses binding SID label to achieve segment routing LSP stitching. This label that can be used to model the segment routing LSP as a segment that may be further used to construct other segment routing LSPs in a hierarchical manner. The transit of the binding SID label, by default, has a preference of 8 and a metric of 1.

Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol

(PCEP) session. These non-colored segment routing LSPs may have binding service identifier (SID) labels associated with them. With this feature, the PCE can use this binding SID label in the label stack to provision PCE-initiated segment routing LSP paths.

A non-colored segment routing LSP can have a maximum of 8 primary paths. If there are multiple operational primary paths then the packet forwarding engine (PFE) distributes traffic over the paths based on the load balancing factors like the weight configured on the path. This is equal cost multi path (ECMP) if none of the paths have a weight configured on them or weighted ECMP if at least one of the paths has a non-zero weight configured on the paths. In both the cases, when one or some of the paths fail, the PFE rebalances the traffic over the remaining paths that automatically leads to achieving path protection. A non-colored segment routing LSP can have a secondary path for dedicated path protection. Upon failure of a primary path, the PFE rebalances the traffic to the remaining functional primary paths. Otherwise, the PFE switches the traffic to the backup path, hence achieving path protection. A non-colored segment routing LSP may specify a metric at `[edit protocols source-packet-routing source-routing-path lsp-name]` for its ingress and binding-SID routes. Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route.

Multiple non-colored segment routing LSPs have the same destination address that contribute to the next hop of the ingress route. Each path, either primary or secondary, of each segment routing LSP is considered as a gateway candidate, if the path is functional and the segment routing LSP has the best preference of all these segment routing LSPs. However, the maximum number of gateways that the next-hop can hold cannot exceed the RPD multi-path limit, which is 128 by default. Extra paths are pruned, firstly secondary paths and then primary paths. A given segment list may be referred multiple times as primary or secondary paths by these segment routing LSPs. In this case, there are multiple gateways, each having a unique segment routing LSP tunnel ID. These gateways are distinct, although they have identical outgoing label stack and interface. A non-colored segment routing LSP and a colored segment routing LSP may also have the same destination address. However, they correspond to different destination addresses for ingress routes, as the colored segment routing LSP's destination address is constructed with both its destination address and color.

NOTE: In the case where a static non-colored segment routing LSP and a PCEP-created segment routing LSP co-exist and have the same to address that contributes to the same ingress route, if they also have the same preference. Otherwise, the segment routing LSP with the best preference is installed for the route.

Segment List of Non-Colored Segment Routing LSPs

A segment list consists of a list of hops. These hops are based on the SID label or an IP address. The number of SID labels in the segment list should not exceed the maximum segment list limit. You can configure the maximum segment list limit at the `[edit protocols source-packet-routing]` hierarchy level.

Prior to Junos OS Release 19.1R1, for a non-colored static segment routing LSP to be usable, the first hop of the segment list had to be an IP address of an outgoing interface and the second to *n*th hops could be

SID labels. Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.

For the first-hop label mode to take effect, you must include the **inherit-label-nexthops** statement globally or individually for a segment list, and the first hop of the segment list must include both IP address and label. If the first hop includes only IP address, the **inherit-label-nexthops** statement does not have any effect.

You can configure **inherit-label-nexthops** at any one of the following hierarchies. The **inherit-label-nexthops** statement takes effect only if the segment list first hop includes both IP address and label.

- **Segment list level**—At the `[edit protocols source-packet-routing segment-list segment-list-name]` hierarchy level.
- **Globally**—At the `[edit protocols source-packet-routing]` hierarchy level.

When the **inherit-label-nexthops** statement is configured globally, it takes precedence over the segment-list level configuration, and the **inherit-label-nexthops** configuration is applied to all the segment lists. When the **inherit-label-nexthops** statement is not configured globally, only segment lists with both labels and IP address present in the first hop, and configured with **inherit-label-nexthops** statement are resolved using SID labels.

For dynamic non-colored static LSPs, that is the PCEP-driven segment routing LSPs, the **inherit-label-nexthops** statement must be enabled globally, as the segment-level configuration is not applied.

[Table 22 on page 711](#) describes the mode of segment routing LSP resolution based on the first hop specification.

Table 35: Non-Colored Static LSP Resolution Based on First Hop Specification

First Hop Specification	Mode of LSP Resolution
IP address only For example: <pre> segment-list path-1 { hop-1 ip-address 172.0.12.2; hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	The segment list is resolved using the IP address.

Table 35: Non-Colored Static LSP Resolution Based on First Hop Specification (*continued*)

First Hop Specification	Mode of LSP Resolution
<p>SID only</p> <p>For example:</p> <pre>segment-list path-2 { hop-1 label 1000011; hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	<p>The segment list is resolved using SID labels.</p>
<p>IP address and SID (without the inherit-label-nexthops configuration)</p> <p>For example:</p> <pre>segment-list path-3 { hop1 { label 801006; ip-address 172.24.1.2; } hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	<p>By default, the segment list is resolved using IP address.</p>
<p>IP address and SID (with the inherit-label-nexthops configuration)</p> <p>For example:</p> <pre>segment-list path-3 { inherit-label-nexthops; hop1 { label 801006; ip-address 172.24.1.2; } hop-2 label 1000012; hop-3 label 1000013; hop-4 label 1000014; }</pre>	<p>The segment list is resolved using SID labels.</p>

You can use the **show route *ip-address* protocol spring-te active-path table inet.3** command to view the non-colored segment routing traffic-engineered LSPs having multiple segment lists installed in the inet.3 routing table.

For example:

```
user@host> show route 7.7.7.7 protocol spring-te active-path table inet.3
```

```
inet.3: 42 destinations, 59 routes (41 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

7.7.7.7/32      *[SPRING-TE/8] 00:01:25, metric 1, metric2 0
                > to 11.1.1.2 via et-0/0/0.1, Push 801007
                  to 21.1.1.2 via et-0/0/2.1, Push 801007
                  to 11.102.1.2 via et-0/0/0.2, Push 801007, Push 801002(top)

                  to 21.202.1.2 via et-0/0/2.2, Push 801007, Push 801005(top)

                  to 11.103.1.2 via et-0/0/0.3, Push 801007, Push 801003(top)

                  to 21.203.1.2 via et-0/0/2.3, Push 801007, Push 801006(top)

                  to 11.104.1.2 via et-0/0/0.4, Push 801007, Push 801003, Push
801002(top)
                  to 21.204.1.2 via et-0/0/2.4, Push 801007, Push 801006, Push
801005(top)
```

NOTE:

The first hop type of segment lists of a static segment routing LSP can cause a commit to fail, if:

- Different segment lists of a tunnel have different first hop resolution types. This is applicable to both colored and non-colored static segment routing LSPs. However, this does not apply for PCEP-driven LSPs; a system log message is generated for the mismatch in the first hop resolution type at the time of computing the path.

For example:

```
segment-list path-1 {
  hop-1 ip-address 172.0.12.2;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
segment-list path-2 {
  hop-1 label 1000011;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
source-routing-path lsp1 {
  to 172.10.10.1;
  primary {
    path-1;
    path-2;
  }
}
```

The commit of tunnel *lsp1* fails, as path-1 is of IP addressmode and path-2 is of label mode.

- The binding SID is enabled for the static non-colored LSP whose segment list type is SID label.

For example:

```
segment-list path-3 {
  hop-1 label 1000011;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
source-routing-path lsp1 {
```

```

to 172.10.10.1;
binding-sid 333;
primary {
    path-3;
}
}

```

Configuring binding SID over label segment list is supported only for colored static LSPs and not for no-colored static LSPs.

Static Segment Routing LSP Provisioning

Segment provisioning is performed on per-router basis. For a given segment on a router, a unique service identifier (SID) label is allocated from a desired label pool which may be from the dynamic label pool for an adjacency SID label or from the segment routing global block (SRGB) for a prefix SID or node SID. The adjacency SID label can be dynamically allocated, which is the default behavior, or be allocated from a local static label pool (SRLB). A route for the SID label is then installed in the mpls.0 table.

Junos OS allows static segment routing LSPs by configuring the **segment** statement at the **[edit protocols mpls static-label-switched-path static-label-switched-path]** hierarchy level. A static segment LSP is identified by a unique SID label that falls under Junos OS static label pool. You can configure the Junos OS static label pool by configuring the **static-label-range static-label-range** statement at the **[edit protocols mpls label-range]** hierarchy level.

Static Segment Routing LSP Limitations

- Junos OS currently has a limitation that the next hop cannot be built to push more than the maximum segment list depth labels. So, a segment list with more than the maximum SID labels (excluding the SID label of the first hop which is used to resolve forwarding next-hop) is not usable for colored or non-colored segment routing LSPs. Also, the actual number allowed for a given segment routing LSP may be even lower than the maximum limit, if an MPLS service is on the segment routing LSP or the segment routing LSP is on a link or a node protection path. In all cases, the total number of service labels, SID labels, and link or node protection labels must not exceed the maximum segment list depth. You can configure the maximum segment list limit at **[edit protocols source-packet-routing]** hierarchy level. Multiple non-colored segment routing LSPs with less than or equal to the maximum SID labels can be stitched together to construct a longer segment routing LSP. This is called segment routing LSP stitching. It can be achieved using binding-SID label.
- The segment routing LSP stitching is actually performed at path level. If a non-colored segment routing LSP has multiple paths that is multiple segment lists, each path can be independently stitched to another non-colored segment routing LSP at a stitching point. A non-colored segment routing LSP which is dedicated to stitching may disable ingress route installation by configuring **no-ingress** statement at **[edit protocols source-packet-routing source-routing-path lsp-name]** hierarchy level.

- A maximum of 8 primary paths and 1 secondary path are supported per non-colored static segment routing LSP. If there is a violation in configuration, commit check fails with an error.
- If any segment-list is configured with more labels than the maximum segment list depth, the configuration commit check fails with an error.

Dynamic Creation of Segment Routing LSPs

IN THIS SECTION

- [Configuring Dynamic Segment Routing LSP Template | 1443](#)
- [Resolving Dynamic Segment Routing LSPs | 1444](#)
- [Considerations for Configuring Dynamic Creation of Segment Routing LSPs | 1448](#)
- [Services Supported over Dynamic Segment Routing LSPs | 1448](#)
- [Behavior With Multiple Tunnel Sources in Segment Routing | 1449](#)
- [Dynamic Segment Routing LSPs Limitations | 1449](#)

In segment routing networks that have each provider edge (PE) device connected to every other PE device, a large amount of configuration is required for setting up the segment routing label-switched paths (LSPs), although only a few segment routing traffic-engineered (SR-TE) paths may be used. You can enable BGP-triggered dynamic creation of these LSPs to reduce the amount of configuration in such deployments.

Configuring Dynamic Segment Routing LSP Template

To configure the template for enabling dynamic creation of segment routing LSPs, you must include the [spring-te](#) statement at the `[edit routing-options dynamic-tunnels]` hierarchy.

- The following is a sample configuration for color dynamic segment routing LSP template:

```
[edit routing-options]
dynamic-tunnels {
  <dynamic-tunnel-name> {
    spring-te {
      source-routing-path-template {
        <template-name1> color [c1 c2];
        <template-name2> color [c3];
        <template-name3> color-any;
      }
      destination-networks {
        <dest1>;
        <dest2>;
      }
    }
  }
}
```

```

    }
  }
}

```

- The following is a sample configuration for non-color dynamic segment routing LSP template:

```

dynamic-tunnels {
  <dynamic-tunnel-name> {
    spring-te {
      source-routing-path-template {
        <template-name1>;
      }
      destination-networks {
        <dest1>;
        <dest2>;
      }
    }
  }
}

```

Resolving Dynamic Segment Routing LSPs

IN THIS SECTION

- [Resolving Colored Dynamic Segment Routing LSP | 1444](#)
- [Resolving Uncolored Dynamic Segment Routing LSPs | 1445](#)
- [Dynamic Segment Routing LSP Sample Configuration | 1445](#)

Resolving Colored Dynamic Segment Routing LSP

When the BGP prefixes are assigned with color community, they initially get resolved over the catch-all-route-for-that-particular-color policy, and in turn, the SR-TE template on which the BGP prefix should be resolved onto is identified. The destinations SID is then derived from the BGP payload prefix next-hop attribute. For example, if the next hop of the BGP payload prefix is an IP address that belongs to Device A, then the node-SID of Device A is taken and a corresponding label is prepared and pushed to the bottom of the stack. The BGP payload prefix is resolved in a color-only mode, where the node-SID of Device A is at the bottom of the final label stack, and the SR-TE path labels are on top.

The final LSP template name is a combination of prefix, color, and tunnel name; for example, **<prefix>:<color>:dt-srte-<tunnel-name>**. The color in the LSP name is displayed in hexadecimal format, and the format of the tunnel name is similar to that of RSVP-triggered tunnel LSP names.

To successfully resolve a colored destination network, the color should have a valid template mapping, either to a specific color, or through the **color-any** template. Without a valid mapping, the tunnel is not created and the BGP route requesting for resolution remains unresolved.

Resolving Uncolored Dynamic Segment Routing LSPs

The catch-all routes for non-colored LSPs are added to the inet.3 routing table. The non-colored tunnel destination must be configured in a different **spring-te** configuration with only one template name in the mapping list. This template name is used for all the tunnel routes matching any of the destination networks configured under the same **spring-te** configuration. These tunnels are similar to RSVP tunnels in functionality.

The final LSP template name is a combination of prefix and tunnel name; for example, **<prefix>:dt-srte-<tunnel-name>**.

Dynamic Segment Routing LSP Sample Configuration

IN THIS SECTION

- [Colored Dynamic Segment Routing LSPs | 1445](#)
- [Non-Colored Dynamic Segment Routing LSPs | 1446](#)
- [Unresolved Dynamic Segment Routing LSP | 1447](#)

The dynamic segment routing LSP template always carries a partial path. The last hop node SID is derived automatically at the tunnel creation time depending on the protocol next-hop address (PNH) node SID. The same template can be used by multiple tunnels to different destinations. In such cases, the partial path remains the same, and only the last hop changes depending on the PNH. Dynamic segment routing LSP templates are not common to a single tunnel, as a result a full path cannot be carried on it. You can use a segment list if a full path is to be used.

Colored Dynamic Segment Routing LSPs

Sample configuration for colored dynamic segment routing LSPs:

```
protocols source-packet-routing {
  source-routing-path-template sr_lsp1 {
    primary sr_sl1
    primary sr_sl2 weight 2
    sr-preference 180;
  }
}
dynamic-tunnels tunnel1 {
  spring-te {
    source-routing-path-template {
```

```

        sr_lsp1 color [ 123 124 125 ];
        sr_lsp2 color-any
    }
    destination-networks {
        22.33.44.0/24;
    }
}
}
}

```

For the above-mentioned sample configuration, the route entries are as follows:

inetcolor.0 tunnel route: 22.33.44.0-0/24 --> RT_NH_TUNNEL

inetcolor6.0 tunnel route: ffff::22.33.44.0-0/120 --> RT_NH_TUNNEL

BGP prefix to tunnel mapping:

R1(prefix) -> 22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

R1(prefix) -> ffff::22.33.44.55-101(PNH) LSP tunnel name = 22.33.44.55:65:dt-srte-tunnel1

R1(prefix) -> ffff::22.33.44.55-124(PNH) LSP tunnel name = 22.33.44.55:7c:dt-srte-tunnel1

inetcolor.0 tunnel route:

22.33.44.55-101/64 --> <next-hop>

22.33.44.55-124/64 --> <next-hop>

inetcolor6.0 tunnel route:

ffff::22.33.44.55-101/160 --> <next-hop>

ffff::22.33.44.55-124/160 --> <next-hop>

Non-Colored Dynamic Segment Routing LSPs

Sample configuration for non-colored dynamic segment routing LSPs:

```

protocols source-packet-routing {
    source-routing-path-template sr_lsp1 {
        primary sr_sl1
        primary sr_sl2 weight 2
        sr-preference 180;
    }
}
dynamic-tunnels {
    tunnel1 {
        spring-te {
            source-routing-path-template {

```

inet.3 tunnel route: 22.33.44.0/24 --> RT_NH_TUNNEL

BGP prefix to tunnel mapping:

R1(prefix) -> ffff::22.33.44.55(PNH) LSP template name = LSP1 --- 22.33.44.55:dt-srte-tunnel2

inet6.3 tunnel route: ffff::22.33.44.55/128 --> <next-hop>

Sample configuration for unresolved dynamic segment routing LSPs:

```
protocols source-packet-routing {
  source-routing-path-template sr_lsp1 {
    primary sr_sl1
    primary sr_sl2 weight 2
    sr-preference 180;
  }
}
dynamic-tunnels tunnel1 {
  spring-te {
```

```

source-routing-path-template {
    sr_lsp1 color [120 121 122 123];
}
destination-networks {
    22.33.44.0/24;
    1.1.1.0/24;
}
}
}

```

For the above-mentioned sample configuration, the route entries are as follows:

inetcolor.0 tunnel route: 22.33.44.0 - 0/24 --> RT_NH_TUNNEL 1.1.1.0 - 0 /24 --> RT_NH_TUNNEL

inetcolor6.0 tunnel route: ffff::22.33.44.0 - 0/120 --> RT_NH_TUNNEL ffff::1.1.1.0 - 0 /24 --> RT_NH_TUNNEL

BGP prefix to tunnel mapping: R1(prefix) -> 22.33.44.55-124(PNH) Tunnel will not be created. (Template not found for the color).

Considerations for Configuring Dynamic Creation of Segment Routing LSPs

When configuring the dynamic creation of segment routing LSPs, take the following into consideration:

- A template can be assigned with a color object. When the dynamic tunnel **spring-te** configuration includes a template with a color object, you must configure all other templates with color objects as well. All destinations are assumed to be colored within that configuration.
- A template can have a list of colors defined on it, or can be configured with the **color-any** option. Both these options can coexist in the same **spring-te** configuration. In such cases, templates assigned with specific colors have a higher preference.
- In a **spring-te** configuration, only one template can be defined with the **color-any** option.
- The color-to-template mapping is done on a one-to-one basis. One color cannot map to multiple templates.
- The template name should be configured in the **spring-te** statement under the **[edit protocols]** hierarchy, and should have the **primary** option enabled.
- Colored and non-colored destinations cannot co-exist in the same **spring-te** configuration.
- You cannot configure same destination networks, with or without color, under different **spring-te** configuration statements.
- In non-colored **spring-te** configuration, only one template can be configured without color object.

Services Supported over Dynamic Segment Routing LSPs

The following services are supported over colored dynamic segment routing LSPs:

- Layer 3 VPN

- BGP EVPN
- Export policy services

The following services are supported over non-colored dynamic segment routing LSPs:

- Layer 3 VPN
- Layer 2 VPN
- Multipath configurations

Behavior With Multiple Tunnel Sources in Segment Routing

When two sources download routes to the same destination from segment routing (for example static and dynamic sourced tunnels), then the segment routing preference is used for choosing the active route entry. A higher value has greater preference. In case the preference remains the same, then the tunnel source is used to determine the route entry.

Dynamic Segment Routing LSPs Limitations

The dynamic SR-TE LSPs do not support the following features and functionalities:

- IPv6 segment routing tunnels.
- Static tunnels.
- 6PE is not supported.
- Distributed CSPF.
- sBFD and LDP tunnelling is not supported for dynamic SR-TE LSPs and in a template.
- Install and B-SID routes in a template.

Color-Based Mapping of VPN Services

IN THIS SECTION

- [VPN Service Coloring | 1450](#)
- [Specifying VPN Service Mapping Mode | 1453](#)
- [Color-IP Protocol Next Hop Resolution | 1454](#)
- [Fallback to IP Protocol Next Hop Resolution | 1455](#)
- [Supported and Unsupported Features for Color-Based Mapping of VPN Services | 1455](#)

You can specify color as a protocol next hop constraint (in addition to the IPv4 or IPv6 address) for resolving transport tunnels over static colored and BGP segment routing traffic-engineered (SRTE) LSPs. This is called the color-IP protocol next hop resolution, where you are required to configure a resolution-map

and apply to the VPN services. With this feature, you can enable color-based traffic steering of Layer 2 and Layer 3 VPN services.

Junos OS supports colored SRTE LSPs associated with a single color. The color-based mapping of VPN services feature is supported on static colored LSPs and BGP SRTE LSPs.

VPN Service Coloring

IN THIS SECTION

- [Egress Color Assignment | 1450](#)
- [Ingress Color Assignment | 1452](#)

In general, a VPN service may be assigned a color on the egress router where the VPN NLRI is advertised, or on an ingress router where the VPN NLRI is received and processed.

You can assign a color to the VPN services at different levels:

- Per routing instance.
- Per BGP group.
- Per BGP neighbor.
- Per prefix.

Once you assign a color, the color is attached to a VPN service in the form of BGP color extended community.

You can assign multiple colors to a VPN service, referred to as multi-color VPN services. In such cases, the last color attached is considered as the color of the VPN service, and all other colors are ignored.

Multiple colors are assigned by egress and/or ingress devices through multiple policies in the following order:

- BGP export policy on the egress device.
- BGP import policy on the ingress device.
- VRF import policy on the ingress device.

The two modes of VPN service coloring are:

Egress Color Assignment

In this mode, the egress device (that is, the advertiser of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it in the VPN service's

routing-instance **vrf-export**, group export, or group neighbor export at the **[edit protocols bgp]** hierarchy level. The VPN NLRI is advertised by BGP with the specified color extended community.

For example:

```
[edit routing-options]
community red-comm {
  members color:0:50;
}
```

```
[edit policy-options]
policy-statement pol-color {
  term t1 {
    from {
      [any match conditions];
    }
    then {
      community add red-comm;
      accept;
    }
  }
}
```

```
[edit routing-instances]
vpn-X {
  ...
  vrf-export pol-color ...;
}
```

Or

NOTE: When you apply the routing policy as an export policy of a BGP group or BGP neighbor, you must include the **vpn-apply-export** statement at the BGP, BGP group, or BGP neighbor level in order for the policy to take an effect on the VPN NLRI.

```
[edit protocols bgp]
group PEs {
  ...
  neighbor PE-A {
    export pol-color ...;
```

```

        vpn-apply-export;
    }
}

```

The routing policies are applied to Layer 3 VPN prefix NLRIs, Layer 2 VPN NLRIs, and EVPN NLRIs. The color extended community is inherited by all the VPN routes, imported, and installed in the target VRFs on one or multiple ingress devices.

Ingress Color Assignment

In this mode, the ingress device (that is, the receiver of the VPN NLRI) is responsible for coloring the VPN service. To enable this mode, you can define a routing policy, and apply it to the VPN service's routing-instance **vrf-import**, group import, or group neighbor import at the **[edit protocols bgp]** hierarchy level. All the VPN routes matching the routing policy is attached with the specified color extended community.

For example:

```

[edit routing-options]
community red-comm {
    members color:0:50;
}

```

```

[edit policy-options]
policy-statement pol-color {
    term t1 {
        from {
            [any match conditions];
        }
        then {
            community add red-comm;
            accept;
        }
    }
}

```

```

[edit routing-instances]
vpn-Y {
    ...
    vrf-import pol-color ...;
}

```

Or

```
[edit protocols bgp]
group PEs {
  ...
  neighbor PE-B {
    import pol-color ...;
  }
}
```

Specifying VPN Service Mapping Mode

To specify flexible VPN service mapping modes, you must define a policy using the **resolution-map** statement, and refer the policy in a VPN service's routing-instance **vrf-import**, group import, or group neighbor import at the **[edit protocols bgp]** hierarchy level. All the VPN routes matching the routing policy are attached with the specified resolution-map.

For example:

```
[edit policy-options]
resolution-map map-A {
  <mode-1>;
  <mode-2>;
  ...
}
policy-statement pol-resolution {
  term t1 {
    from {
      [any match conditions];
    }
    then {
      resolution-map map-A;
      accept;
    }
  }
}
```

You can apply import policy to the VPN service's routing-instance.

```
[edit routing-instances]
vpn-Y {
  ...
  vrf-import pol-resolution ...;
}
```

You can also apply the import policy to a BGP group or BGP neighbor.

```
[edit protocols bgp]
group PEs {
  ...
  neighbor PE-B {
    import pol-resolution ...;
  }
}
```

NOTE: Each VPN service mapping mode should have a unique name defined in the resolution-map. Only a single entry of IP-color is supported in the resolution-map, where the VPN route(s) are resolved using a colored-IP protocol next hop in the form of **ip-address:color**.

Color-IP Protocol Next Hop Resolution

The protocol next hop resolution process is enhanced to support colored-IP protocol next hop resolution. For a colored VPN service, the protocol next hop resolution process takes a color and a resolution-map, builds a colored-IP protocol next hop in the form of *IP-address:color*, and resolves the protocol next hop in the inet6color.0 routing table.

You must configure a policy to support multipath resolution of colored Layer 2 VPN, Layer 3 VPN, or EVPN services over colored LSPs. The policy must then be applied with the relevant RIB table as the resolver import policy.

For example:

```
[edit policy-options]
policy-statement mpath {
  then multipath-resolve;
}
```

```
[edit routing-options]
resolution {
  rib bgp.l3vpn.0 {
    inetcolor-import mpath;
  }
}
resolution {
  rib bgp.l3vpn-inet6.0 {
    inet6color-import mpath;
  }
}
```

```

resolution {
    rib bgp.l2vpn.0 {
        inetcolor-import mpath;
    }
}
resolution {
    rib mpls.0 {
        inetcolor-import mpath;
    }
}
resolution {
    rib bgp.evpn.0 {
        inetcolor-import mpath;
    }
}

```

Fallback to IP Protocol Next Hop Resolution

If a colored VPN service does not have a resolution-map applied to it, the VPN service ignores its color and falls back to the IP protocol next hop resolution. Conversely, if a non-colored VPN service has a resolution-map applied to it, the resolution-map is ignored, and the VPN service uses the IP protocol next hop resolution.

The fallback is a simple process from colored SRTE LSPs to LDP LSPs, by using a RIB group for LDP to install routes in inet{6}color.0 routing tables. A longest prefix match for a colored-IP protocol next hop ensures that if a colored SRTE LSP route does not exist, an LDP route with a matching IP address should be returned.

Supported and Unsupported Features for Color-Based Mapping of VPN Services

The following features and functionality are supported with color-based mapping of VPN services:

- BGP Layer 3 VPN
- BGP Layer 2 VPN (Kompella Layer 2 VPN)
- BGP EVPN
- Resolution-map with a single IP-color option.
- Colored IPv4 and IPv6 protocol next hop resolution.
- Routing information base (also known as routing table) group based fallback to LDP LSP in inetcolor.0 routing table.
- Colored SRTE LSP.
- Virtual platforms.

- 64-bit Junos OS.
- Logical systems.

The following features and functionality are not supported with color-based mapping of VPN services:

- Colored MPLS LSPs, such as RSVP, LDP, BGP-LU, static.
- Layer 2 circuit
- FEC-129 BGP auto-discovered and LDP-signaled Layer 2 VPN.
- VPLS
- MVPN
- IPv4 and IPv6 using resolution-map.
- BGP labeled unicast.

Tunnel Templates for PCE-Initiated Segment Routing LSPs

You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.

When a PCE-Initiated segment routing LSP is being created, the LSP is checked against policy statements (if any) and if there is a match, the policy applies the configured template for that LSP. The template configuration is inherited only if it is not provided by the LSP source (PCEP); for example, metric.

To configure a template:

1. Include the [source-routing-path-template](#) statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure the additional BFD and LDP tunneling parameters here.
2. Include the *source-routing-path-template-map* statement at the **[edit protocols source-packet-routing]** hierarchy level to list the policy statements against which the PCE-initiated LSP should be checked.
3. Define a policy to list the LSPs on which the template should be applied.

The **from** statement can include either the LSP name or LSP regular expression using the **lsp** and **lsp-regex** match conditions. These options are mutually exclusive, so you can specify only one option at a given point in time.

The **then** statement must include the **sr-te-template** option with an accept action. This applies the template to the PCE-initiated LSP.

Take the following into consideration when configuring a template for PCE-initiated LSPs:

- Template configuration is not applicable to statically configured segment routing LSPs, or any other client's segment routing LSP.
- PCEP-provided configuration has precedence over template configuration.

- PCEP LSP does not inherit template segment-list configuration.

Example: Configuring Static Segment Routing Label Switched Path

IN THIS SECTION

- [Requirements | 1457](#)
- [Overview | 1457](#)
- [Configuration | 1458](#)
- [Verification | 1471](#)

This example shows how to configure static segment routing label switched paths (LSPs) in MPLS networks. This configuration helps to bring higher scalability to MPLS networks.

Requirements

This example uses the following hardware and software components:

- Seven MX Series 5G Universal Routing Platforms
- Junos OS Release 18.1 or later running on all the routers

Before you begin, be sure you configure the device interfaces.

Overview

Junos OS a set of explicit segment routing paths are configured on the ingress router of a non-colored static segment routing tunnel by configuring the **segment-list** statement at the **[edit protocols source-packet-routing]** hierarchy level. You can configure segment routing tunnel by configuring the **source-routing-path** statement at **[edit protocols source-packet-routing]** hierarchy level. The segment routing tunnel has a destination address and one or more primary paths and optionally secondary paths that refer to the segment list. Each segment list consists of a sequence of hops. For non-colored static segment routing tunnel, the first hop of the segment list specifies an immediate next hop IP address and the second to Nth hop specifies the segment identifies (SID) labels corresponding to the link or node which the path traverses. The route to the destination of the segment routing tunnel is installed in inet.3 table.

Topology

In this example, configure layer 3 VPN on the provider edge routers PE1 and PE5. Configure the MPLS protocol on all the routers. The segment routing tunnel is configured from router PE1 to router PE5 with a primary path configured on router PE1 and router PE5 . Router PE1 is also configured with secondary path for path protection. The transit routers PE2 to PE4 are configured with adjacency SID labels with label pop and an outgoing interface.

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Configuring Device PE1

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.1/24
set ge-0/0/0 unit 0 family mpls maximum-labels 5

set ge-0/0/1 unit 0 family inet address 10.10.13.1/24
set ge-0/0/1 unit 0 family mpls maximum-labels 5

set ge-0/0/5 unit 0 family inet address 10.10.17.1/24
```

2. Configure autonomous system number and options to control packet forwarding routing options.

```
[edit routing-options]
set autonomous-system 65000
set forwarding-table export load-balance-policy
set forwarding-table chained-composite-next-hop ingress l3vpn
```

3. Configure the interfaces with the MPLS protocol and configure the MPLS label range.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure the type of peer group, local address, protocol family for NLRI in updates, and IP address of a neighbor for the peer group.

```
[edit protocols bgp]
set group pe type internal
set group pe local-address 192.168.147.211
set group pe family inet-vpn unicast
set group pe neighbor 192.168.146.181
```

5. Configure the protocol area interfaces.

```
[edit protocols ospf]
set area 0.0.0.0 interface ge-0/0/0.0
set area 0.0.0.0 interface lo0.0
set area 0.0.0.0 interface ge-0/0/1.0
```

6. Configure the IPv4 address and labels of primary and secondary paths for source routing-traffic engineering (TE) policies of protocol source packet routing (SPRING).

```
[edit protocols source-packet-routing segment-list]
set sl-15-primary hop-1 ip-address 10.10.13.3
set sl-15-primary hop-2 label 1000134
set sl-15-primary hop-3 label 1000145
set sl-15-backup hop-1 ip-address 10.10.12.2
set sl-15-backup hop-2 label 1000123
set sl-15-backup hop-3 label 1000134
set sl-15-backup hop-4 label 1000145
```

7. Configure destination IPv4 address, binding SID label, primary, and secondary source routing path for protocol SPRING.

```
[edit protocols source-packet-routing source-routing-path]
set lsp-15 to 192.168.146.181
set lsp-15 binding-sid 1000999
set lsp-15 primary sl-15-primary
set lsp-15 secondary sl-15-backup
```

8. Configure policy options.

```
[edit policy-options policy-statement]
set VPN-A-export term a from protocol ospf
set VPN-A-export term a from protocol direct
set VPN-A-export term a then community add VPN-A
set VPN-A-export term a then accept
set VPN-A-export term b then reject
set VPN-A-import term a from protocol bgp
set VPN-A-import term a from community VPN-A
set VPN-A-import term a then accept
set VPN-A-import term b then reject
set bgp-to-ospf from protocol bgp
set bgp-to-ospf from route-filter 10.10.0.0/16 orlonger
set bgp-to-ospf then accept
set load-balance-policy then load-balance per-packet
```

9. Configure BGP community information.

```
[edit policy-options]
```

```
set community VPN-A members target:65000:1
```

10. Configure routing instance VRF1 with instance type, interface, router distinguisher, VRF import, export and table label. Configure export policy and interface of area for protocol OSPF.

```
[edit routing-instances VRF1]
set instance-type vrf
set interface ge-0/0/5.0
set route-distinguisher 192.168.147.211:1
set vrf-import VPN-A-import
set vrf-export VPN-A-export
set vrf-table-label
set protocols ospf export bgp-to-ospf
set protocols ospf area 0.0.0.0 interface ge-0/0/5.0
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces

                interface ge-0/0/5.0;
            }
        }
    }
}

```

Configuring Device PE2

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure the interfaces.

```
[edit interfaces]
set ge-0/0/0 unit 0 family inet address 10.10.12.2/24
set ge-0/0/0 unit 0 family mpls

set ge-0/0/1 unit 0 family inet address 10.10.23.2/24
set ge-0/0/1 unit 0 family mpls
```

2. Configure the static LSP for protocol MPLS.

```
[edit protocols mpls static-label-switched-path]
set adj-23 segment 1000123
set adj-23 segment next-hop 10.10.23.3
set adj-23 segment pop
set adj-21 segment 1000221
set adj-21 segment next-hop 10.10.12.1
set adj-21 segment pop
```

3. Configure interfaces and static label range for protocol MPLS.

```
[edit protocols mpls]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
set label-range static-label-range 1000000 1000999
```

4. Configure interfaces for protocol OSPF.

```
[edit protocols ospf area 0.0.0.0]
set interface ge-0/0/0.0
set interface ge-0/0/1.0
```

Results

From configuration mode on router PE2, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

user@PE2# **show interfaces**

```
ge-0/0/0 {
  unit 0 {
    family inet {
      address 55.1.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 55.1.23.2/24;
    }
    family mpls;
  }
}
```

user@PE2# **show protocols**

```
mpls {
  static-label-switched-path adj-23 {
    segment {
      1000123;
      next-hop 55.1.23.3;
      pop;
    }
  }
  static-label-switched-path adj-21 {
    segment {
      1000221;
      next-hop 55.1.12.1;
      pop;
    }
  }
  interface ge-0/0/0.0;
  interface ge-0/0/1.0;
  label-range {
    static-label-range 1000000 1000999;
  }
}
ospf {
  area 0.0.0.0 {
    interface ge-0/0/0.0;
    interface ge-0/0/1.0;
```

```
}
}
```

Verification

IN THIS SECTION

- Verifying Route Entry of Routing Table inet.3 of Router PE1 | 1471
- Verifying Route Table Entries of Routing Table mpls.0 of Router PE1 | 1472
- Verifying SPRING Traffic Engineered LSP of Router PE1 | 1472
- Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1 | 1473
- Verifying the Routing Table Entries of Routing Table mpls.0 of Router PE2 | 1474
- Verifying the Status of Static MPLS LSP Segments of Router PE2 | 1475

Confirm that the configuration is working properly.

Verifying Route Entry of Routing Table inet.3 of Router PE1

Purpose

Verify the route entry of routing table inet.3 of router PE1.

Action

From operational mode, enter the **show route table inet.3** command.

```
user@PE1> show route table inet.3
```

```
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.146.181/32    *[SPRING-TE/8] 03:09:26, metric 1
                    > to 10.10.13.3 via ge-0/0/1.0, Push 1000145, Push 1000134(top)

                    to 10.10.12.2 via ge-0/0/0.0, Push 1000145, Push 1000134,
                    Push 1000123(top)
```

Meaning

The output displays the ingress routes of segment routing tunnels.

Verifying Route Table Entries of Routing Table mpls.0 of Router PE1

Purpose

Verify the route entries of routing table mpls.0

Action

From operational mode, enter the **show route table mpls.0** command.

user@PE1> **show route table mpls.0**

```
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0          *[MPLS/0] 03:25:52, metric 1
            Receive
1          *[MPLS/0] 03:25:52, metric 1
            Receive
2          *[MPLS/0] 03:25:52, metric 1
            Receive
13         *[MPLS/0] 03:25:52, metric 1
            Receive
16         *[VPN/0] 03:25:52
            > via lsi.0 (VRF1), Pop
1000999    *[SPRING-TE/8] 03:04:03, metric 1
            > to 10.10.13.3 via ge-0/0/1.0, Swap 1000145, Push 1000134(top)

            to 10.10.12.2 via ge-0/0/0.0, Swap 1000145, Push 1000134,
            Push 1000123(top)
```

Meaning

The output displays the SID labels of segment routing tunnels.

Verifying SPRING Traffic Engineered LSP of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress routers.

Action

From operational mode, enter the **show spring-traffic-engineering overview** command.

user@PE1> **show spring-traffic-engineering overview**

```

Overview of SPRING-TE:
  Route preference: 8
  Number of LSPs: 1 (Up: 1, Down: 0)
  External controllers:
    < Not configured >

```

Meaning

The output displays the overview of SPRING traffic engineered LSPs on the ingress router.

Verifying SPRING Traffic Engineered LSPs on the Ingress Router of Router PE1

Purpose

Verify SPRING traffic engineered LSPs on the ingress router.

Action

From operational mode, enter the **show spring-traffic-engineering lsp detail** command.

```
user@PE1# show spring-traffic-engineering lsp detail
```

```

Name: lsp-15

            > to 10.10.23.3 via ge-0/0/1.0, Pop
1000123(S=0) *[MPLS/6] 03:22:29, metric 1
            > to 10.10.23.3 via ge-0/0/1.0, Pop
1000221    *[MPLS/6] 03:22:29, metric 1
            > to 10.10.12.1 via ge-0/0/0.0, Pop

```

```
1000221(S=0)          *[MPLS/6] 03:22:29, metric 1
                      > to 10.10.12.1 via ge-0/0/0.0, Pop
```

Verifying the Status of Static MPLS LSP Segments of Router PE2

Purpose

Verify the status of MPLS LSP segments of router PE2.

Action

From operational mode, enter the **show mpls static-lsp** command.

```
user@PE2> show mpls static-lsp
```

```
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

Segment LSPs:
LSPname                SID-label    State
adj-21                 1000221      Up
adj-23                 1000123      Up
Total 2, displayed 2, Up 2, Down 0
```

Meaning

The output displays the status of static MPLS LSP segments of router PE2.

Release History Table

Release	Description
19.4R1	You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.
19.1R1	Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops.
19.1R1	Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.

Enabling Distributed CSPF for Segment Routing LSPs

IN THIS SECTION

- [Distributed CSPF Computation Constraints | 1477](#)
- [Distributed CSPF Computation Algorithm | 1477](#)
- [Distributed CSPF Computation Database | 1478](#)
- [Configuring Distributed CSPF Computation Constraints | 1478](#)
- [Distributed CSPF Computation | 1480](#)
- [Interaction Between Distributed CSPF Computation and SRTE Features | 1480](#)
- [Distributed CSPF Computation Sample Configurations | 1481](#)

Prior to Junos OS Release 19.2R1S1, for traffic engineering of segment routing paths, you could either explicitly configure static paths, or use computed paths from an external controller. With the distributed Constrained Shortest Path First (CSPF) for segment routing LSP feature, you can compute a segment routing LSP locally on the ingress device according to the constraints you have configured. With this feature, the LSPs are optimized based on the configured constraints and metric type (traffic-engineering or IGP). The LSPs are computed to utilize the available ECMP paths to the destination with segment routing label stack compression enabled or disabled.

Distributed CSPF Computation Constraints

Segment routing LSP paths are computed when all the configured constraints are met.

The distributed CSPF computation feature supports the following subset of constraints specified in the Internet draft, draft-ietf-spring-segment-routing-policy-03.txt, *Segment Routing Policy for Traffic Engineering*:

- Inclusion and exclusion of administrative groups.
- Inclusion of loose or strict hop IP addresses.

NOTE: You can specify only router IDs in the loose or strict hop constraints. Labels and other IP addresses cannot be specified as loose or strict hop constraints in Junos OS Release 19.2R1-S1.

- Maximum number of segment IDs (SIDs) in the segment list.
- Maximum number of segment lists per candidate segment routing path.

The distributed CSPF computation feature for segment routing LSPs does not support the following types of constraints and deployment scenarios:

- IPv6 addresses.
- Inter domain segment routing traffic engineering (SRTE) LSPs.
- Unnumbered interfaces.
- Multiple protocols routing protocols such as, OSPF, ISIS, and BGP-LS, enabled at the same time.
- Computation with prefixes or anycast addresses as destinations.
- Including and excluding interface IP addresses as constraints.

Distributed CSPF Computation Algorithm

IN THIS SECTION

- [Label Stack Compression Enabled | 1478](#)
- [Label Stack Compression Disabled | 1478](#)

The distributed CSPF computation feature for segment routing LSPs uses the label stack compression algorithm with CSPF.

Label Stack Compression Enabled

A compressed label stack represents a set of paths from a source to a destination. It generally consists of node SIDs and adjacency SIDs. When label stack compression is enabled, the result of the computation is a set of paths that maximize ECMP to the destination, with minimum number of SIDs in the stack, while conforming to constraints.

Label Stack Compression Disabled

The multipath CSPF computation with label stack compression disabled finds up to N segment lists to destination, where:

- The cost of all segment lists is equal to and the same as the shortest traffic-engineering metric to reach the destination.
- Each segment list is comprised of adjacency SIDs.
- The value of N is the maximum number of segment lists allowed for the candidate path by configuration.
- No two segment lists are identical.
- Each segment list satisfies all the configured constraints.

Distributed CSPF Computation Database

The database used for SRTE computation has all links, nodes, prefixes and their characteristics irrespective of whether traffic-engineering is enabled in those advertising nodes. In other words, it is the union of the traffic-engineering database (TED) and the IGP link state database of all domains that the computing node has learnt from.

Configuring Distributed CSPF Computation Constraints

You can use a compute profile to logically group the computation constraints. These compute profiles are referenced by the segment routing paths for computing the primary and secondary segment routing LSPs.

To configure a compute profile, include the **compute-profile** statement at the **[edit protocols source-packet-routing]** hierarchy level.

The configuration for the supported computation constraints include:

• Administrative groups

You can configure **admin-groups** under the **[edit protocols mpls]** hierarchy level. Junos OS applies the administrative group configuration to the segment routing traffic-engineering (SRTE) interfaces.

To configure the computation constraints you can specify three categories for a set of administrative groups. The computation constraint configuration can be common to all candidate segment routing paths, or it can be under individual candidate paths.

- **include-any**—Specifies that any link with at least one of the configured administrative groups in the list is acceptable for the path to traverse.

- **include-all**—Specifies that any link with all of the configured administrative groups in the list is acceptable for the path to traverse.
- **exclude**—Specifies that any link which does not have any of the configured administrative groups in the list is acceptable for the path to traverse.

- **Explicit path**

You can specify a series of router IDs in the compute profile as a constraint for computing the SRTE candidate paths. Each hop has to be an IPv4 address and can be of type strict or loose. If the type of a hop is not configured, strict is used. You must include the **compute** option under the [segment-list](#) statement when specifying the explicit path constraint.

- **Maximum number of segment lists (ECMP paths)**

You can associate a candidate path with a number of dynamic segment-lists. The paths are ECMP paths, where each segment-list translates into a next hop gateway with active weight. These paths are a result of path computation with or without compression.

You can configure this attribute using the **maximum-computed-segment-lists** *maximum-computed-segment-lists* option under the [compute-profile](#) configuration statement. This configuration determines the maximum number of such segment lists computed for a given primary and secondary LSP.

- **Maximum segment list depth**

The maximum segment list depth computation parameter ensures that amongst the ECMP paths that satisfy all other constraints such as administrative group, only the paths that have segment lists less than or equal to the maximum segment list depth are used. When you configure this parameter as a constraint under the compute-profile, it overrides the **maximum-segment-list-depth** configuration under the **[edit protocols source-packet-routing]** hierarchy level, if present.

You can configure this attribute using the **maximum-segment-list-depth** *maximum-segment-list-depth* option under the [compute-profile](#) configuration statement.

- **Protected or unprotected adjacency SIDs**

You can configure protected or unprotected adjacency SID as a constraint under the [compute-profile](#) to avoid links with the specified SID type.

- **Metric type**

You can specify the type of metric on the link to be used for computation. By default, SR-TE LSPs use traffic-engineering metrics of the links for computation. The traffic-engineering metric for links is advertised by traffic-engineering extensions of IGP protocols. However, you may also choose to use the IGP-metric for computation by using the metric-type configuration in the compute profile.

You can configure this attribute using the **metric-type (igp | te)** option under the [compute-profile](#) configuration statement.

Distributed CSPF Computation

The SRTE candidate paths are computed locally such that they satisfy the configured constraints. When label stack compression is disabled, the multi-path CSPF computation result is a set of adjacency SID stacks. When label stack compression is enabled, the result is a set of compressed label stacks (composed of adjacent SIDs and node SIDs).

When secondary paths are computed, the links, nodes and SRLGs taken by the primary paths are not avoided for computation. For more information on primary and secondary paths, see [“Configuring Primary and Secondary LSPs” on page 569](#).

For any LSPs with unsuccessful computation result, the computation is retried as traffic-engineering database (TED) changes.

Interaction Between Distributed CSPF Computation and SRTE Features

IN THIS SECTION

- [Weights Associated With Paths of an SRTE Policy | 1480](#)
- [BFD Liveness Detection | 1480](#)
- [inherit-label-nexthops | 1480](#)
- [Auto-Translate Feature | 1480](#)

Weights Associated With Paths of an SRTE Policy

You can configure weights against computed and static SRTE paths, which contribute to the next hops of the route. However, a single path that has computation enabled can result in multiple segment lists. These computed segment lists are treated as ECMP amongst themselves. You can assign hierarchical ECMP weights to these segments, considering the weights assigned to each of the configured primaries.

BFD Liveness Detection

You can configure BFD liveness detection for the computed primary or secondary paths. Every computed primary or secondary path can result in multiple segment lists, as a result, the BFD parameters configured against the segment lists are applied to all the computed segment lists. If all the active primary paths go down, the pre-programmed secondary path (if provided) becomes active.

inherit-label-nexthops

You are not required to explicitly enable the **inherit-label-nexthops** configuration under the **[edit protocols source-packet-routing segment-list segment-list-name]** hierarchy for the computed primary or secondary paths, as it is a default behavior.

Auto-Translate Feature

You can configure the auto-translate feature on the segment lists, and the primary or secondary paths with the auto-translate feature reference these segment lists. On the other hand, the primary or secondary

on which compute feature is enabled cannot reference any segment list. As a result, you cannot enable both the compute feature and the auto-translate feature for a given primary or secondary path. However, you could have an LSP configured with a primary path with compute type and another with auto-translate type.

Distributed CSPF Computation Sample Configurations

IN THIS SECTION

- [Example 1 | 1481](#)
- [Example 2 | 1482](#)
- [Example 3 | 1482](#)

Example 1

In Example 1,

- The non-computed primary path references a configured segment-list. In this example, the configured segment list *static_sl1* is referenced, and it also serves as the name for this primary path.
- A computed primary should have a name configured, and this name should not reference any configured segment list. In this example, *compute_segment1* is not a configured segment list.
- The *compute_profile_red* compute-profile is applied to the primary path with the name *compute_segment1*.
- The *compute_profile_red* compute-profile includes a segment list of type **compute**, which is used to specify the explicit path constraint for the computation.

```
[edit protocols source-packet-routing]
segment-list static_sl1{
  hop1 label 80000
}
segment-list exp_path1 {
  hop1 ip-address 10.1.1.1 loose
  hop2 ip-address 2.2.2.2
  compute
}
compute-profile compute_profile_red {
  include-any red
  segment-list exp_path1
  maximum-segment-list-depth 5
}
```

The weights for computed path next-hops and static next-hops are 2 and 3, respectively. Assuming the next-hops for computed paths are *comp_nh1*, *comp_nh2*, and *comp_nh3*, and the next-hop for static path is *static_nh*, the weights are applied as follows:

Next-Hop	Weight
comp_nh1	2
comp_nh2	2
comp_nh3	2
static_nh	9

Example 2

In Example 2, both the primary and secondary paths can be of compute type and can have their own compute-profiles.

```
[edit protocols source-packet-routing]
compute-profile compute_profile_green{
  include-any green
  maximum-segment-list-depth 5
}
compute-profile compute_profile_red{
  include-any red
  maximum-segment-list-depth 8
}
```

Example 3

In Example 3, when compute is mentioned under a primary or secondary path, it results in local computation of a path to the destination without any constraints or other parameters for the computation.

```
[edit protocols source-packet-routing]
source-routing-path srte_colored_policy1 {
  to 5.5.5.5
  color 5
  binding-sid 10001
  primary {
    compute_segment1 {
      compute
    }
  }
}
```

Example: Configuring CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs

SUMMARY

CoS-based forwarding (CBF) and policy-based routing (PBR, also known as filter-based forwarding) can be enabled for non-colored segment routing-traffic engineered (SR-TE) LSPs to steer selective traffic over an explicit SR-TE path, providing you the benefit of servicing traffic based on class-of-service or a policy.

IN THIS SECTION

- [CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs Overview | 1483](#)
- [Configure CoS-Based Forwarding and Policy-Based Routing for SR-TE LSPs | 1484](#)

CoS-Based Forwarding and Policy-Based Routing For SR-TE LSPs Overview

IN THIS SECTION

- [Benefits of CoS-Based Forwarding \(CBF\) and Policy-Based Routing \(PBR\) For SR-TE LSPs | 1483](#)
- [Segment Routing Path Sources Supporting CBF and PBR | 1483](#)
- [Considerations for Configuring CBF and PBR for SR-TE LSPs | 1484](#)

Benefits of CoS-Based Forwarding (CBF) and Policy-Based Routing (PBR) For SR-TE LSPs

With CBF and PBR you can:

- Use combinations of segment routing-traffic engineering (SR-TE) paths to steer service traffic in the core.
- Choose the supporting services to resolve over the selected SR-TE paths.

Segment Routing Path Sources Supporting CBF and PBR

The following segment routing path sources support CoS-based forwarding and policy-based routing:

- **Static SR-TE paths**—Statically configured source-routing paths that have the entire label stack statically configured.
- **PCEP**—Dynamically provisioning source-routing paths created on a controller, and downloaded to an ingress router in an ERO either through PCEP segment routing extensions, or in a BGP segment routing policy through BGP segment routing extensions.

- **Dynamic LSPs**—Dynamically created tunnels triggered through the Dynamic Tunnel Module that have last-hop ERO resolution.
- **Auto-translated paths**—Statically configured source-routing paths that are automatically translated.

Considerations for Configuring CBF and PBR for SR-TE LSPs

Remember:

- CBF and PBR is enabled only on non-colored SR-TE LSPs that are either statically or dynamically configured.
- Both CBF and PBR configurations for SR-TE LSPs can co-exist on a device; the order of configuration decides the type in which the routes are forwarded.
- For PBR, if the first-hop of the SR-TE LSP is a label, then you must include the **resolution preserve-nexthop-hierarchy** statement at the **[edit routing-options]** hierarchy level.
- The class-based forwarding of routes for CBF is visible only in the forwarding table and not on the routes.
- The policy-based forwarding of routes for PBR is done on the routes and is seen in the **show route** command output.

Configure CoS-Based Forwarding and Policy-Based Routing for SR-TE LSPs

SUMMARY

CoS-based forwarding (CBF) and policy-based routing (PBR, also known as filter-based forwarding FBF) can be used to steer selective traffic using an explicit segment routing-traffic engineered (SR-TE) label-switched path (LSP). Only non-colored segment routing LSPs that have the next hop configured as first hop label or IP address support CBF and PBR .

Before You Begin

- You must be running Junos OS Release 20.1 and later releases to enable CBF and PBR for non-colored SR-TE LSPs.
- Configure the device interfaces and ensure the devices are connected to the network.
- Define segment lists and configure SR-TE LSPs and their associated parameters.

To configure an SR-TE LSP, do the following:

1. Define the segment list with label parameters.

```
[edit protocol]
```

```

user@host# set source-packet-routing segment-list segment-list-name hop-name ip-address ip-address
user@host# set source-packet-routing segment-list segment-list-name hop-name label number

```

For example:

```

[edit protocol]
user@host# set source-packet-routing segment-list sr1 hop1 ip-address 11.1.1.2
user@host# set source-packet-routing segment-list sr1 hop2 label 801002
user@host# set source-packet-routing segment-list sr1 hop3 label 801003
user@host# set source-packet-routing segment-list sr1 hop4 label 801007
user@host# set source-packet-routing segment-list sr1 hop1 ip-address 11.1.1.2
user@host# set source-packet-routing segment-list sr1 hop2 label 801002
user@host# set source-packet-routing segment-list sr1 hop3 label 801003
user@host# set source-packet-routing segment-list sr1 hop4 label 801007
user@host# set source-packet-routing segment-list sr2 hop1 ip-address 11.11.1.2
user@host# set source-packet-routing segment-list sr2 hop2 label 801002
user@host# set source-packet-routing segment-list sr2 hop3 label 801003
user@host# set source-packet-routing segment-list sr2 hop4 label 801007
user@host# set source-packet-routing segment-list sr3 hop1 ip-address 11.12.1.2
user@host# set source-packet-routing segment-list sr3 hop2 label 801002
user@host# set source-packet-routing segment-list sr3 hop3 label 801003
user@host# set source-packet-routing segment-list sr3 hop4 label 801007
user@host# set source-packet-routing segment-list sr4 hop1 ip-address 11.13.1.2
user@host# set source-packet-routing segment-list sr4 hop2 label 801002
user@host# set source-packet-routing segment-list sr4 hop3 label 801003
user@host# set source-packet-routing segment-list sr4 hop4 label 801007

```

2. Configure the source-routing path for the SR-TE LSPs and specify the preference value and primary segment for the path.

```

[edit protocols]
user@host# set source-packet-routing source-routing-path source-routing-path-name to destination-ip-address
user@host# set source-packet-routing source-routing-path source-routing-path-name preference preference
user@host# set source-packet-routing source-routing-path source-routing-path-name primary primary-segment

```

For example:

```

[edit protocols]
user@host# set source-packet-routing source-routing-path srtel1 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtel1 preference 1
user@host# set source-packet-routing source-routing-path srtel1 primary sr1
user@host# set source-packet-routing source-routing-path srtel2 to 7.7.7.7

```

```

user@host# set source-packet-routing source-routing-path srtelsp2 preference 1
user@host# set source-packet-routing source-routing-path srtelsp2 primary sr2
user@host# set source-packet-routing source-routing-path srtelsp3 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtelsp3 preference 1
user@host# set source-packet-routing source-routing-path srtelsp3 primary sr3
user@host# set source-packet-routing source-routing-path srtelsp4 to 7.7.7.7
user@host# set source-packet-routing source-routing-path srtelsp4 preference 1
user@host# set source-packet-routing source-routing-path srtelsp4 primary sr4

```

You can now configure CBF and PBR for the configured SR-TE LSPs.

To configure CBF, do the following

1. Define Differentiated Services Code Point (DSCP) classifiers to handle incoming IPv4 packets, forwarding classes, and option values.

```

[edit class-of-service]
user@host# set classifiers dscpclassifier-name forwarding-class forwarding-class-name loss-priority level
code-points [ aliases ] [ 6 bit-patterns ]

```

For example:

```

[edit class-of-service]
user@host# set classifiers dscp mydscp forwarding-class af11 loss-priority low code-points 001010
user@host# set classifiers dscp mydscp forwarding-class af11 loss-priority medium-high code-points 001100
user@host# set classifiers dscp mydscp forwarding-class af11 loss-priority high code-points 001110
user@host# set classifiers dscp mydscp forwarding-class af21 loss-priority low code-points 010010
user@host# set classifiers dscp mydscp forwarding-class af21 loss-priority medium-high code-points 010100
user@host# set classifiers dscp mydscp forwarding-class af21 loss-priority high code-points 010110
user@host# set classifiers dscp mydscp forwarding-class af31 loss-priority low code-points 011010
user@host# set classifiers dscp mydscp forwarding-class af31 loss-priority medium-high code-points 011100
user@host# set classifiers dscp mydscp forwarding-class af31 loss-priority high code-points 011110
user@host# set classifiers dscp mydscp forwarding-class af41 loss-priority low code-points 100010
user@host# set classifiers dscp mydscp forwarding-class af41 loss-priority medium-high code-points 100100
user@host# set classifiers dscp mydscp forwarding-class af41 loss-priority high code-points 100110

```

2. Define forwarding classes (FCs) for grouping packets for transmission, and assign packets to output queues.

```

[edit class-of-service]
user@host# set forwarding-classes queue queue-numner class-name

```

For example:

```
[edit class-of-service]
user@host# set forwarding-classes queue 0 af11
user@host# set forwarding-classes queue 1 af21
user@host# set forwarding-classes queue 2 af31
user@host# set forwarding-classes queue 3 af41
```

3. Assign the configured classifiers to the device interfaces.

```
[edit class-of-service]
user@host# set interfaces interface-name unit unit classifiers dscp classifier-name
```

For example:

```
[edit class-of-service]
user@host# set interfaces ge-0/0/8 unit 1 classifiers dscp mydscp
user@host# set interfaces ge-0/0/8 unit 2 classifiers dscp mydscp
```

4. Define CoS-based forwarding policy options with LSP next-hop as the SR-TE LSP.

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map map-name forwarding-classes class-name lsp-next-hop
source-routing-path-name
```

For example:

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af11 lsp-next-hop srtelsp1
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af21 lsp-next-hop srtelsp2
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af41 lsp-next-hop srtelsp3
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class af31 lsp-next-hop srtelsp4
```

5. Discard traffic that does not meet any forwarding class in the next-hop map.

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map map-name forwarding-class-default discard
```

For example:

```
[edit class-of-service]
user@host# set forwarding-policy next-hop-map my_cbf forwarding-class-default discard
```

6. Configure a policy statement that specifies that routes matching the route filter are subject to the CoS next-hop mapping specified by map-name.

```
[edit policy-options]
user@host# set policy-statement policy-name from route-filter destination-prefix match-type <actions>
user@host# set policy-statement policy-name then cos-next-hop-map map-name
```

For example:

```
[edit policy-options]
user@host# set policy-statement cbf from route-filter 4.0.0.1/16 orlonger
user@host# set policy-statement cbf then cos-next-hop-map my_cbf
```

7. Apply the policy to routes being exported from the routing table into the forwarding table. This enables CBF for SR-TE LSPs.

```
[edit routing-options]
user@host# set forwarding-table export policy-name
```

For example:

```
[edit routing-options]
user@host# set forwarding-table export cbf
```

8. Commit the configuration.

```
user@host# commit
```

Verify CBF Configuration

You can verify the CBF configuration using the **show route forwarding-table destination *ip-address* vpn *vpn-name* extensive** command.

```
user@host> show route forwarding-table destination 4.0.0.1 vpn vpn1 extensive
```

```
Routing table: vpn1.inet [Index 8]
Internet:

Destination:  4.0.0.1/32
Route type:   user
Route reference: 0                      Route interface-index: 0
```

```

Route type: idx:xx
Next-hop type: discard          Index: 34      Reference: 2

```

For CBF, the class-based forwarding of routes is visible only in the forwarding table, unlike PBR, where the filtered routes are visible in the **show route** command output.

To configure PBR, do the following

1. Configure a policy statement which specifies that routes matching the protocol and route filter are subject to the LSP next-hop, or are load balanced as equal-cost multipath (ECMP) in the forwarding table.

```

[edit policy-options]
user@host# set policy-statement policy-name from protocol protocol-name

```

```

user@host# set policy-statement policy-name from route-filter destination-prefix match-type <actions>
user@host# set policy-statement policy-name then install-nexthop lsp lsp-name
user@host# set policy-statement policy-name then load-balance per-packet

```

For example:

```

[edit policy-options]
user@host# set policy-statement pbr term 1 from protocol bgp
user@host# set policy-statement pbr term 1 from route-filter 4.0.0.1/32 exact
user@host# set policy-statement pbr term 1 then install-nexthop lsp srtelsp1
user@host# set policy-statement pbr term 1 then load-balance per-packet
user@host# set policy-statement pbr term 1 then reject

```

2. Configure the device to perform custom route resolution on protocol next hops of routes.

NOTE: The **resolution preserve-nexthop-hierarchy** statement is mandatory for PBR to work when the first-hop of the SR-TE LSP is a label.

```

[edit routing-options]
user@host# set resolution preserve-nexthop-hierarchy

```

3. Apply the policy to routes being exported from the routing table into the forwarding table. This enables PBR for SR-TE LSPs.

```

[edit routing-options]
user@host# set forwarding-table export policy-name

```

For example:

```

[edit routing-options]
user@host# set forwarding-table export pbr

```

4. Commit the configuration.

```

user@host# commit

```

Verify PBR Configuration

You can verify the PBR configuration using the **show route destination-prefix** command.

user@host> **show route 4.0.0.1**

```
vpn1.inet.0: 10003 destinations, 10003 routes (10003 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

4.0.0.1/32          *[BGP/170] 00:24:12, localpref 100, from 7.7.7.7
                   AS path: 10 I, validation-state: unverified
                     to 11.1.1.2 via ge-0/0/1.1, Push 50983, Push 801007, Push
801003, Push 801002(top)
                     > to 11.11.1.2 via ge-0/0/1.2, Push 50983, Push 801007, Push
801003, Push 801002(top)
                     to 11.12.1.2 via ge-0/0/1.3, Push 50983, Push 801007, Push
801003, Push 801002(top)
                     to 11.13.1.2 via ge-0/0/1.4, Push 50983, Push 801007, Push
801003, Push 801002(top)
```

user@host> **show route 4.0.0.1 expanded-nh extensive**

```
vpn1.inet.0: 10003 destinations, 10003 routes (10003 active, 0 holddown, 0 hidden)
4.0.0.1/32 (1 entry, 1 announced)
Installed-nexthop:
Indr (0xc7aaa54) 7.7.7.7 Push 50983 Session-ID: 0x16f
  Krt_inh (0xc745a84) Index:1048579 PNH: 7.7.7.7
    Chain (0xc7aa798) Index:823 Push 50983
      Router (0xc417034) 11.1.1.2 Push 801007, Push 801003, Push 801002(top) via
ge-0/0/1.1
```

The output displays all next-hops for the destination prefix, 4.0.0.1. The **expanded-nh extensive** options displays the filtered next-hops under the **Krt_inh** output field.

user@host> **show route 4.0.0.2**

```
vpn1.inet.0: 10003 destinations, 10003 routes (10003 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

4.0.0.2/32          *[BGP/170] 00:30:14, localpref 100, from 7.7.7.7
                   AS path: 10 I, validation-state: unverified
                     to 11.1.1.2 via ge-0/0/1.1, Push 569, Push 801007, Push
801003, Push 801002(top)
                     > to 11.11.1.2 via ge-0/0/1.2, Push 569, Push 801007, Push
```

```

801003, Push 801002(top)
           to 11.12.1.2 via ge-0/0/1.3, Push 569, Push 801007, Push
801003, Push 801002(top)
           to 11.17.1.2 via ge-0/0/1.8, Push 569, Push 801007, Push
801003, Push 801002(top)

```

user@host> **show route 7.7.7.7 protocol spring-te**

```

inet.0: 10082 destinations, 10119 routes (10082 active, 0 holddown, 0 hidden)

inet.3: 25 destinations, 77 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

7.7.7.7/32      *[SPRING-TE/1] 00:00:32, metric 1, metric2 4
>   to 11.1.1.2 via ge-0/0/1.1, Push 801007, Push 801003, Push
801002(top)
           to 11.11.1.2 via ge-0/0/1.2, Push 801007, Push 801003, Push
801002(top)
           to 11.12.1.2 via ge-0/0/1.3, Push 801007, Push 801003, Push
801002(top)
           to 11.17.1.2 via ge-0/0/1.8, Push 801007, Push 801003, Push
801002(top)

```

For PBR the **show route** command output does the policy-based filtering of routes.

Release History Table

Release	Description
19.4R1	You can associate a single or range of MVPN multicast flows (S,G) to a dynamically created PCE-initiated point-to-multipoint label-switched path (LSP).
19.4R1	You can configure a tunnel template for PCE-initiated segment routing LSPs to pass down two additional parameters for these LSPs - Bidirectional forwarding detection (BFD) and LDP tunneling.
19.1R1	Starting in Junos OS Release 19.1R1, a commit check feature is introduced to ensure that all the segment lists contributing to the colored routes have the minimum label present for all hops.
19.1R1	Starting in Junos OS Release 19.1R1, this requirement does not apply, as the first hop of the non-colored static LSPs now provides support for SID labels, in addition to IP addresses. With the first hop label support, MPLS fast reroute (FRR) and weighted equal-cost multipath is enabled for resolving the static non-colored segment routing LSPs, similar to colored static LSPs.
18.2R1	Starting in Junos OS Release 18.2R1, statically configured non-colored segment routing LSPs on the ingress device are reported to the Path Computation Element (PCE) through a Path Computation Element Protocol (PCEP) session.
17.2R1	Starting in Junos OS Release 17.2, in addition to external cspf , two new path computation types are introduced for the PCE-controlled LSPs: local cspf and no cspf .
16.1	Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440.
16.1	Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440.
14.2R4	Starting in Junos OS Release 14.2R4, support of auto-bandwidth is provided for PCE-controlled LSPs.

Verify MPLS Interfaces

Purpose

If the MPLS protocol is not configured correctly on the routers in your network, the interfaces are not able to perform MPLS switching.

NOTE: For a labeled route to be resolved over an interface, **family mpls** must be configured at the **[edit interfaces]** hierarchy level for the route to be successfully resolved. When the interface is not configured with **family mpls**, labelled routes do not get resolved.

Action

To verify MPLS interfaces, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls interface
```

Sample Output 1

The following sample output is for all routers in the network shown in *MPLS Network Topology*.

```
user@R1> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>

user@R2> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
```

```
so-0/0/3.0      Up      <none>
```

```
user@R3> show mpls interface
```

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>
so-0/0/3.0	Up	<none>

```
user@R4> show mpls interface
```

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>
so-0/0/3.0	Up	<none>

```
user@R5> show mpls interface
```

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>

```
user@R6> show mpls interface
```

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/2.0	Up	<none>
so-0/0/3.0	Up	<none>

Sample Output 2

```
user@R6> show mpls interface
```

Interface	State	Administrative groups
so-0/0/0.0	Up	<none>
so-0/0/1.0	Up	<none>
so-0/0/3.0	Up	<none>

so-0/0/2.0 is missing

Sample Output 3

```
user@host> show mpls interface
MPLS not configured
```

Meaning

Sample Output 1 shows that all MPLS interfaces on all routers in the network are enabled (**Up**) and can perform MPLS switching. If you fail to configure the correct interface at the **[edit protocols mpls]** hierarchy level or include the **family mpls** statement at the **[edit interfaces type-fpc/pic/port unit number]** hierarchy level, the interface cannot perform MPLS switching, and does not appear in the output for the **show mpls interface** command.

Administrative groups are not configured on any of the interfaces shown in the example network in *MPLS Network Topology*. However, if they were, the output would indicate which affinity class bits are enabled on the router.

Sample Output 2 shows that interface **so-0/0/2.0** is missing and therefore might be incorrectly configured. For example, the interface might not be included at the **[edit protocols mpls]** hierarchy level, or the **family mpls** statement might not be included at the **[edit interfaces type-fpc/pic/port unit number]** hierarchy level. If the interface is configured correctly, RSVP might not have signaled over this interface yet. For more information on determining which interface is incorrectly configured, see *Verify Protocol Families*.

Sample Output 3 shows that the MPLS protocol is not configured at the **[edit protocols mpls]** hierarchy level.

Verify the MPLS Configuration

Purpose

After you have checked the transit and ingress routers, use the **traceroute** command to verify the BGP next hop, and used the **ping** command to verify the active path, you can check for problems with the MPLS configuration at the **[edit protocols mpls]** and **[edit interfaces]** hierarchy levels.

NOTE: For a labeled route to be resolved over an interface, **family mpls** must be configured at the **[edit interfaces]** hierarchy level for the route to be successfully resolved. When the interface is not configured with **family mpls**, labelled routes do not get resolved.

Action

To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```

user@host> show configuration protocols mpls
user@host> show configuration interfaces

```

Sample Output 1

```

user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured

```

Sample Output 2

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {

}
}

```

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the **[edit protocols mpls]** hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

Checking the MPLS Layer

Purpose

After you have configured the label-switched path (LSP), issued the **show mpls lsp** command, and determined that there is an error, you might find that the error is not in the physical, data link, Internet Protocol (IP), interior gateway protocol (IGP), or Resource Reservation Protocol (RSVP) layers. Continue investigating the problem at the MPLS layer of the network.

[Figure 122 on page 1502](#) illustrates the MPLS layer of the layered MPLS model.

Figure 122: Checking the MPLS Layer

g015547

With the MPLS layer, you check whether the LSP is up and functioning correctly. If the network is not functioning at this layer, the LSP does not work as configured.

Figure 123 on page 1502 illustrates the MPLS network used in this topic.

Figure 123: MPLS Network Broken at the MPLS Layer

The network shown in [Figure 123 on page 1502](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the reverse LSP is down without a path from **R6** to **R1**.

The cross shown in [Figure 123 on page 1502](#) indicates where the LSP is broken. Some possible reasons the LSP is broken might include an incorrectly configured MPLS protocol, or interfaces that are incorrectly configured for MPLS.

In the network shown in [Figure 123 on page 1502](#), a configuration error on egress router **R6** prevents the LSP from traversing the network as expected.

To check the MPLS layer, follow these steps:

1. [Verify the LSP | 1503](#)
2. [Verify the LSP Route on the Transit Router | 1507](#)
3. [Verify the LSP Route on the Ingress Router | 1509](#)
4. [Verify MPLS Labels with the traceroute Command | 1511](#)
5. [Verify MPLS Labels with the ping Command | 1512](#)
6. [Take Appropriate Action | 1514](#)
7. [Verify the LSP Again | 1515](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

Sample Output 1

```

```

Meaning

Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-toR1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only one LSP is configured in the example network in [“MPLS Network Broken at the MPLS Layer” on page 1502](#). However, in a large network with many LSPs configured, the results would be quite different between the two commands.

Verify the LSP Route on the Transit Router

Purpose

If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

Action

To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

Sample Output 1

```
user@R3> show route table mpls.0
```

```

mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
1          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
2          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive

```

Sample Output 2

user@R3> show route table mpls.0

```

mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
1          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
2          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
100864     *[RSVP/7] 00:07:23, metric 1
            > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0) *[RSVP/7] 00:07:23, metric 1
            > via so-0/0/2.0, label-switched-path R6-to-R1
100880     *[RSVP/7] 00:07:01, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0) *[RSVP/7] 00:07:01, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6

```

Meaning

Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see *Checklist for Verifying LSP Use*.

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries represent two routes. There are two entries per route

because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

Verify the LSP Route on the Ingress Router

Purpose

Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

Action

To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

Sample Output 1

```
user@R1> show route 10.0.0.6
```

```
inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.6/32      *[IS-IS/18] 6d 01:41:37, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0
```

```
user@R6> show route 10.0.0.1
```

```
inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32      *[IS-IS/18] 5d 01:01:38, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0
```

Sample Output 2

user@R1> show route 10.0.0.6

```
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.6/32      *[IS-IS/18] 6d 02:13:42, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0
```

```
inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.6/32      *[RSVP/7] 00:08:07, metric 20
                  > via so-0/0/2.0, label-switched-path R1-to-R6
```

user@R6> show route 10.0.0.1

```
inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.1/32      *[IS-IS/18] 5d 01:34:03, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0
```

```
inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.0.0.1/32      *[RSVP/7] 00:10:39, metric 20
                  > via so-0/0/3.0, label-switched-path R6-to-R1
```

Meaning

Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router.

BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in [“MPLS Network Broken at the MPLS Layer”](#) on page 1502.

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

Verify MPLS Labels with the traceroute Command

Purpose

Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the **traceroute** command as a debugging tool to determine whether the LSP is being used to forward traffic.

Action

To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

Sample Output 2

```
user@R1> traceroute 100.100.6.1
to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
```

```

MPLS Label=100912 CoS=0 TTL=1 S=1
2 10.1.36.2 (10.1.36.2) 0.577 ms !N 0.597 ms !N 0.546 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
1 10.1.36.1 (10.1.36.1) 0.802 ms 0.716 ms 0.688 ms
MPLS Label=100896 CoS=0 TTL=1 S=1
2 10.1.13.1 (10.1.13.1) 0.570 ms !N 0.568 ms !N 0.546 ms !N

```

Meaning

Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in [“MPLS Network Broken at the MPLS Layer” on page 1502](#)) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

Verify MPLS Labels with the ping Command

Purpose

When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

Action

To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

Sample Output 1

```

user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.

```

Sample Output 2

```

user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.15.2 (10.1.15.2)  0.708 ms  0.613 ms  0.576 ms
 2  10.0.0.6 (10.0.0.6)  0.763 ms  0.708 ms  0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

Meaning

Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the **[edit protocols mpls]** hierarchy level on egress router **R6**.

Solution

To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

Sample Output

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
```

```

user@R6# activate interface so-0/0/3

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete

```

Meaning

The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the **[edit protocols mpls]** hierarchy level. The LSP can now come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

Action

To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```

user@host> show mpls lsp extensive

```

Sample Output

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1,  State: Up ,  ActiveRoute: 1 ,  LSPname: R1-to-R6

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify That Node-Link Protection Is Up

Purpose

After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in [“Node-Link Protection” on page 277](#), two bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

Action

To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

```
show mpls lsp
show mpls lsp extensive
show rsvp interface
show rsvp interface extensive
show rsvp session detail
```

Sample Output

```
user@R1> show mpls lsp
```

Ingress LSP: 1 sessions

To	From	State	Rt	ActivePath	P	LSPname
192.168.5.1	192.168.1.1	Up	0	via-r2	*	lsp2-r1-to-r5

```

Meaning

Sample output from **R1** for the **show mpls lsp** command shows a brief description of the state of configured and active LSPs for which **R1** is the ingress, transit, and egress router. All LSPs are up. **R1** is the ingress router for **lsp2-r1-to-r5**, and the egress router for return LSP **r5-to-r1**. Two LSPs transit **R1**, **lsp1-r6-to-r0** and the return LSP **r0-to-t6**. For more detailed information about the LSP, include the **extensive** option when you issue the **show mpls lsp** command.

Sample Output

```

user@R1> show mpls lsp extensive

Meaning

Sample output from **R1** for the **show mpls lsp extensive** command shows detailed information about all LSPs for which **R1** is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass LSP **Bypass->10.0.12.14->10.0.24.2**.

Sample Output

```

user@R1> show rsvp interface
RSVP interface: 4 active

```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample output from **R1** for the **show rsvp interface** command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**. Interface **fe-0/1/0.0** is the connecting interface between **R1** and **R2**, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the **show rsvp interface extensive** command.

Sample Output

```

user@R1> show rsvp interface extensive
RSVP interface: 3 active
fe-0/1/0.0 Index 67, State Ena/Up

```

```

[...Output truncated...]

```

Meaning

Sample output from **R1** for the **show rsvp interface extensive** command shows more detailed information about the activity on all RSVP interfaces (3). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14** is a link protection bypass path (**Type: LP**), protecting the link between **R1** and **R2 fe-0/1/0.0**. The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding **R2** in case of node failure.

Sample Output

```

user@R1> show rsvp session detail
Ingress RSVP: 2 sessions

192.168.4.1

Meaning

Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5**) originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

Conclusion

Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment. Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

Related Information

For additional information about MPLS fast reroute and MPLS protection methods, see the following:

Verify That Link Protection Is Up

Purpose

When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in *Many-to-One or Link Protection*, a bypass path should be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

Action

To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface
```

Sample Output

```
user@R1> show mpls lsp extensive | no-more
Ingress LSP: 1 sessions

Meaning

The sample output from ingress router **R1** shows that **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have link protection up, and both LSPs are using the bypass path, **10.0.12.14**. However, the **show mpls lsp** command does not list the bypass path. For information about the bypass path, use the **show rsvp session** command.

```

Meaning

The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the **show mpls lsp** command. However, because link protection is an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass > interface-address**, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1 (lsp2-r1-to-r5)** is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0**. Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

Sample Output

```
user@R1> show rsvp interface
RSVP interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	35Mbps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

Verify One-to-One Backup

Purpose

You can verify that one-to-one backup is established by examining the ingress router and the other routers in the network.

Action

To verify one-to-one backup, enter the following Junos OS CLI operational mode commands:

```
user@host> show mpls lsp ingress extensive
user@host> show rsvp session
```

Sample Output

The following sample output is from the ingress router **R1** :

```
user@R1> show mpls lsp ingress extensive
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5

```

Meaning

The sample output from **R1** shows that the **FastReroute desired** object was included in the Path messages for the LSP, allowing **R1** to select the active path for the LSP and establish a detour path to avoid **R2**.

In line 8, **Fast-reroute Detour Up** shows that the detour is operational. Lines 6 and 7 indicate that transit routers **R2** and **R4** have established their detour paths.

R2, 10.0.12.14, includes (**flag=9**), indicating that node protection is available for the downstream node and link. **R4, 10.0.24.2**, includes (**flag=1**), indicating that link protection is available for the next downstream link. In this case, **R4** can protect only the downstream link because the node is the egress router **R5**, which cannot be protected. For more information about flags, see the *Junos User Guide*.

The output for the **show mpls lsp extensive** command does not show the actual path of the detour. To see the actual links used by the detour paths, you must use the **show rsvp session ingress detail** command.

Sample Output

The following sample output is from the ingress router **R1** in the network shown in *One-to-One Backup Detours*.

```

```

Meaning

The sample output from **R1** shows the RSVP session of the main LSP. The detour path is established, **Detour is Up**. The physical path of the detour is displayed in **Detour Explct route**. The detour path uses **R7** and **R9** as transit routers to reach **R5**, the egress router.

Sample Output

The following sample output is from the first transit router R2 in the network shown in *One-to-One Backup Detours*:

```
user@R2> show rsvp session transit detail
Transit RSVP: 1 sessions

192.168.5.1
  From: 192.168.1.1, LSPstate: Up, ActiveRoute: 1

  Detour Label out: 100736
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R2** shows the detour is established (**Detour is Up**) and avoids **R4**, and the link connecting **R4** and **R5** (**10.0.45.2**). The detour path is through **R7** (**10.0.27.2**) and **R9** (**10.0.79.2**) to **R5**

(10.0.59.1), which is different from the explicit route for the detour from **R1**. **R1** has the detour passing through the 10.0.17.14 link on **R7**, while **R1** is using the 10.0.27.2 link. Both detours merge at **R9** through the 10.0.79.2 link to **R5** (10.0.59.1).

Sample Output

The following sample output is from the second transit router **R4** in the network shown in *One-to-One Backup Detours*:

```
user@R4> show rsvp session transit detail
Transit RSVP: 1 sessions

192.168.5.1

    Detour Label out: 100352
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R4** shows the detour is established (**Detour is Up**) and avoids the link connecting **R4** and **R5** (10.0.45.2). The detour path is through **R9** (10.0.49.2) to **R5** (10.0.59.1). Some of the information

is similar to that found in the output for **R1** and **R2**. However, the explicit route for the detour is different, going through the link connecting **R4** and **R9** (so-0/0/3 or 10.0.49.2).

Sample Output

The following sample output is from **R7**, which is used in the detour path in the network shown in *One-to-One Backup Detours*:

```
user@R7> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

192.168.5.1

      PATH sentto: 10.0.79.2 (so-0/0/1.0) 0 pkts
      RESV rcvfrom: 10.0.79.2 (so-0/0/1.0) 0 pkts
      Explct route: 10.0.79.2 10.0.59.1
      Record route: 10.0.17.13 <self> 10.0.79.2 10.0.59.1
      Label in: 100752, Label out: 100368
Total 1 displayed, Up 1, Down 0
```

Meaning

The sample output from **R7** shows the same information as for a regular transit router used in the primary path of the LSP: the ingress address (**192.168.1.1**), the egress address (**192.168.5.1**), and the name of the LSP (**r1-to-r5**). Two detour paths are displayed; the first to avoid **R4** (**192.168.4.1**) and the second to avoid **R2** (**192.168.2.1**). Because **R7** is used as a transit router by **R2** and **R4**, **R7** can merge the detour paths together as indicated by the identical **Label out** value (**100368**) for both detour paths. Whether **R7** receives traffic from **R4** with a label value of **100736** or from **R2** with a label value of **100752**, **R7** forwards the packet to **R5** with a label value of **100368**.

Sample Output

The following sample output is from **R9**, which is a router used in the detour path in the network shown in *One-to-One Backup Detours*:

```
user@R9> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

192.168.5.1
  From: 192.168.1.1, LSPstate: Up, ActiveRoute: 1

Explit route: 10.0.59.1
Record route: 10.0.12.13 10.0.27.1 10.0.79.1 <self> 10.0.59.1
Label in: 100368, Label out: 3
Total 1 displayed, Up 1, Down 0

```

Meaning

The sample output from **R9** shows that **R9** is the penultimate router for the detour path, the explicit route includes only the egress link address (**10.0.59.1**), and the **Label out** value (**3**) indicates that **R9** has performed penultimate-hop label popping. Also, the detour branch from **10.0.27.1** does not include path information because **R7** has merged the detour paths from **R2** and **R4**. Notice that the **Label out** value in the detour branch from **10.0.17.13** is **100368**, the same value as the **Label out** value on **R7**.

Sample Output

The following sample output is from the egress router **R5** in the network shown in *One-to-One Backup Detours*:

```

user@R5> show rsvp session egress detail
Egress RSVP: 1 sessions, 1 detours

Total 1 displayed, Up 1, Down 0

```

Meaning

The sample output from **R5** shows the main LSP in the **Record route** field and the detours through the network.

Verify That the Primary Path Is Operational

Purpose

Primary paths must always be used in the network if they are available, therefore an LSP always moves back to the primary path after a failure, unless the configuration is adjusted. For more information on adjusting the configuration to prevent a failed primary path from reestablishing, see [“Preventing Use of a Path That Previously Failed” on page 283](#).

Action

To verify that the primary path is operational, enter the following Junos OS command-line interface (CLI) operational mode commands:

```

user@host> show mpls lsp extensive ingress
user@host> show rsvp interface

```

Sample Output 1

```

user@R1> show mpls lsp extensive ingress
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
    ActivePath: via-r2 (primary)
    LoadBalance: Random
    Encoding type: Packet, Switching type: Packet, GPID: IPv4
*Primary via-r2                State: Up
    Priorities: 6 6
    Bandwidth: 35Mbps
    SmartOptimizeTimer: 180
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 11)
10.0.12.14 S 10.0.24.2 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt):

    No computed ERO.
    Created: Sat Apr 29 14:40:43 2006
Total 1 displayed, Up 1, Down 0

```

Sample Output 2

```

user@R1> show rsvp interface
RSVP interface: 3 active

```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps

```
so-0/0/3.0  Up           1    100%   155.52Mbps   155.52Mbps   0bps       0bps
```

Meaning

Sample output 1 shows that the LSP is operational and is using the primary path (**via-r2**) with **R2 (10.0.12.14)** and **R4 (10.0.24.2)** as transit routers. The priority values are the same for setup and hold, **6 6**. Priority 0 is the highest (best) priority and 7 is the lowest (worst) priority. The Junos OS default for setup and hold priority is 7:0. Unless some LSPs are more important than others, preserving the default is a good practice. Configuring a setup priority that is better than the hold priority is not allowed, resulting in a failed commit in order to avoid preemption loops.

Verify That the Secondary Path Is Established

Purpose

When the secondary path is configured with the **standby** statement, the secondary path should be *up* but *not active*; it will become active if the primary path fails. A secondary path configured without the **standby** statement will not come up unless the primary path fails. To test that the secondary path is correctly configured and would come up if the primary path were to fail, you must deactivate a link or node critical to the primary path, then issue the **show mpls lsp *lsp-path-name* extensive** command.

Action

To verify that the secondary path is established, enter the following Junos OS CLI operational mode command:

Sample Output

```
user@R1> show mpls lsp extensive
```

Sample Output

The following sample output shows a correctly configured secondary path before and after it comes up. In the example, interface **fe-0/1/0** on **R2** is deactivated, which brings down the primary path **via-r2**. The ingress router **R1** switches traffic to the secondary path **via-r7**.

```

user@R1> show mpls lsp extensive

```

Meaning

The sample output from egress router **R1** shows a correctly configured standby secondary path in a down state because the primary path is still up. Upon deactivation of an interface (**interface fe-0/1/0** on **R2**) critical to the primary path, the primary path **via-r2** goes down and the standby secondary path **via-r7** comes up, allowing **R1** to switch traffic to the standby secondary path.

Verifying the Physical Layer

Purpose

After you have configured the LSP, issued the **show mpls lsp extensive** command, and determined that there is an error, you can start investigating the problem at the physical layer of the network.

Figure 124 on page 1544 illustrates the physical layer of the layered MPLS model.

Figure 124: Verifying the Physical Layer

0015543

With this layer, you must ensure that the routers are connected, and that the interfaces are up and configured correctly on the ingress, egress, and transit routers.

If the network is not functioning at this layer, the label-switched path (LSP) does not work as configured.

Figure 125 on page 1545 illustrates the MPLS network and the problem described in this topic.

Figure 125: MPLS Network Broken at the Physical Layer

The network shown in [Figure 125 on page 1545](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, traffic does not use the configured LSP. Instead traffic uses the alternate route from **R1** through **R2** to **R6**, and in the reverse direction, from **R6** through **R5** to **R1**.

When you become aware of a situation where an alternate route is used rather than the configured LSP, verify that the physical layer is functioning correctly. You might find that routers are not connected, or that interfaces are not up and configured correctly on the ingress, egress, or transit routers.

The cross shown in [Figure 125 on page 1545](#) indicates where the LSP is broken because of a configuration error on ingress router **R1**.

To check the physical layer, follow these steps:

1. [Verify the LSP | 1545](#)
2. [Verify Router Connection | 1547](#)
3. [Verify Interfaces | 1548](#)
4. [Take Appropriate Action | 1549](#)
5. [Verify the LSP Again | 1550](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However, for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls**

lsp extensive) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@ingress-router> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows that the LSP is using an alternate path rather than the configured path. The configured path for the LSP is **R1** through **R3** to **R6**, and for the reverse LSP, **R6** through **R3** to **R1**. The alternate path used by the LSP is **R1** through **R2** to **R6**, and for the reverse LSP, **R6** through **R5** to **R1**.

Verify Router Connection

Purpose

Confirm that the appropriate ingress, transit, and egress routers are functioning by examining whether the packets have been received and transmitted with 0% packet loss.

Action

To determine that the routers are connected, enter the following command from the ingress and transit routers:

```
user@host> ping host
```

Sample Output

```

user@R1> ping 10.0.0.3 count 3
PING 10.0.0.3 (10.0.0.3): 56 data bytes
64 bytes from 10.0.0.3: icmp_seq=0 ttl=254 time=0.859 ms
64 bytes from 10.0.0.3: icmp_seq=1 ttl=254 time=0.746 ms
64 bytes from 10.0.0.3: icmp_seq=2 ttl=254 time=0.776 ms

--- 10.0.0.3 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.746/0.794/0.859/0.048 ms

user@R3> ping 10.0.0.6 count 3
PING 10.0.0.6 (10.0.0.6): 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=0 ttl=255 time=0.968 ms
64 bytes from 10.0.0.6: icmp_seq=1 ttl=255 time=3.221 ms
64 bytes from 10.0.0.6: icmp_seq=2 ttl=255 time=0.749 ms

--- 10.0.0.6 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.749/1.646/3.221/1.117 ms

```

Meaning

The sample output shows that ingress router **R1** is receiving packets from transit router **R3**, and that the transit router is receiving packets from the egress router. Therefore, the routers in the LSP are connected.

Verify Interfaces

Purpose

Confirm that the interfaces are configured correctly with the **family mpls** statement.

Action

To determine that the relevant interfaces are up and configured correctly, enter the following commands from the ingress, transit, and egress routers:

```

user@host> show interfaces terse
user@host> show configuration interfaces type-fpc/pic/port

```

Sample Output

```

user@R1> show interfaces so* terse
Interface          Admin Link Proto Local          Remote
so-0/0/0           up   up
so-0/0/0.0         up   up   inet  10.1.12.1/30
                               iso
                               mpls
so-0/0/1           up   up
so-0/0/1.0         up   up   inet  10.1.15.1/30
                               iso
                               mpls
so-0/0/2           up   up
so-0/0/2.0         up   up   inet  10.1.13.1/30
                               iso  <<< family mpls is missing
so-0/0/3           up   down

```

```

user@R1> show configuration interfaces so-0/0/2
unit 0 {
    family inet {
        address 10.1.13.1/30;
    }
    family iso; <<< family mpls is missing
}

```

Meaning

The sample output shows that interface **so-0/0/2.0** on the ingress router does not have the **family mpls** statement configured at the **[edit interfaces type-fpc/pic/port]** hierarchy level, indicating that the interface is incorrectly configured to support the LSP. The LSP is configured correctly at the **[edit protocols mpls]** hierarchy level.

The output from the transit and egress routers (not shown) shows that the interfaces on those routers are configured correctly.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the **family mpls** statement, which was missing, is included in the configuration of ingress router **R1**.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces type-fpc/pic/port]
user@R1# set family mpls
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2 unit 0]
user@R1# set family mpls

[edit interfaces so-0/0/2 unit 0]
user@R1# show
family inet {
    address 10.1.13.1/30;
}
family iso;
family mpls;

[edit interfaces so-0/0/2 unit 0]
user@R1# commit
commit complete
```

Meaning

The sample output from ingress router **R1** shows that the **family mpls** statement is configured correctly for interface **so-0/0/2.0**, and that the LSP is now functioning as originally configured.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the physical layer has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
```

Meaning

Sample Output 1 from ingress router **R1** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 2 from ingress router **R1** shows that the LSP is forced to take the intended path because MPLS is deactivated on **R1** interfaces **so-0/0/0.0** and **so-0/0/1.0**. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Checking the Data Link Layer

Purpose

After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical layer. Continue investigating the problem at the data link layer of the network.

[Figure 126 on page 1553](#) illustrates the data link layer of the layered MPLS model.

g015544

With this layer, you must check the encapsulation mode, for example, Point-to-Point Protocol (PPP) or Cisco High-Level Data Link Control (HDLC); PPP options, for example, header encapsulation; frame check sequence (FCS) size; and whether keepalive frames are enabled or disabled. Also, check the ingress, egress, and transit routers.

Figure 127 on page 1553 illustrates the MPLS network used in this topic.

Figure 127: MPLS Network Broken at the Data Link Layer

The network shown in [Figure 127 on page 1553](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

When you verify that the data link layer is not functioning correctly, you might find a mismatch with PPP or Cisco HDLC encapsulation, PPP options, or keepalive frames.

The cross shown in [Figure 127 on page 1553](#) indicates where the LSP is broken because of a configuration error on ingress router **R1** that prevents the LSP from traversing the network as expected.

To check the data link layer, follow these steps:

1. [Verify the LSP | 1554](#)
2. [Verify Interfaces | 1555](#)
3. [Take Appropriate Action | 1560](#)
4. [Verify the LSP Again | 1561](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name name** or **show mpls lsp name name extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows the LSPs within which it participates. The ingress LSP is down, without a path from **R1** to **R6**. Because a reverse LSP is configured in the network shown in [“MPLS Network Broken at the Data Link Layer” on page 1553](#), we would expect an egress LSP session to be up. However, **R1** does not have any egress LSPs, indicating that the LSP from **R6** to **R1** is not functioning.

Verify Interfaces

Purpose

From your network topology, determine the adjacent interfaces through which the LSP is meant to traverse, and examine the output for the encapsulation type, PPP options, FCS size, and whether keepalive frames are enabled or disabled

NOTE: Before you proceed with this step, check the physical layer to ensure that the problem is not in the physical layer.

Action

To verify the functioning of adjacent interfaces, enter the following commands from the relevant routers:

```
user@host> show interfaces type-fpc/pic/port extensive
user@host> show interfaces type-fpc/pic/port
```

Sample Output 1

```
user@R6> show interfaces so-0/0/3 extensive

  Flags: None
  Addresses, Flags: Is-Preferred Is-Primary
    Destination: 10.1.36.0/30, Local: 10.1.36.1, Broadcast: 10.1.36.3
Protocol iso, MTU: 4470
  Flags: None
Protocol mpls, MTU: 4458
  Flags: None

```

Meaning

Sample Output 1 from egress router **R6** shows that there are no SONET alarms or defects (**none**), the states are all **OK**, and the path trace shows the distant end (**R3 so-0.0.0**), indicating that the physical link is up. However, the logical link is down, and the link-level type is Cisco HDLC.

Sample Output 2 from transit router **R3** shows that the link-level type is PPP, indicating that the encapsulation types are mismatched, resulting in the LSP going down.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In the example below, the encapsulation types are mismatched.

Solution

To correct the error in this example, enter the following commands:

```

[edit interfaces so-0/0/3]
user@R1# show
user@R1# delete encapsulation
user@R1# show
user@R1# commit

```

Sample Output

```

[edit interfaces so-0/0/3]
user@R6# show
encapsulation cisco-hdlc;
unit 0 {
  family inet {
    address 10.1.36.2/30;
  }
  family iso;
}

```

```

        family mpls;
    }

[edit interfaces so-0/0/3]
user@R6# delete encapsulation

[edit interfaces so-0/0/3]
user@R6# show
unit 0 {
    family inet {
        address 10.1.36.2/30;
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/3]
user@R6# commit
commit complete

```

Meaning

The sample output from egress router **R6** shows that the Cisco HDLC was incorrectly configured on interface **so-0/0/3** which prevented the LSP from using the intended path. The problem was corrected when the **encapsulation** statement was deleted and the configuration committed.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the data link layer has been resolved.

Action

From the ingress, egress, and transit routers, verify that the LSP is up and traversing the network as expected:

```

user@host> show mpls lsp extensive

```

Sample Output 1

```

user@R1> show mpls lsp extensive

Meaning

Sample Outputs 1 and 2 from ingress router **R1** and egress router **R6**, respectively, show that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Sample Output 3 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**.

Sample Output 4 shows the interfaces that were deactivated on the ingress, egress, and transit routers, forcing the LSP to take the intended path. If these interfaces were not deactivated, even though the configuration is now correct, the LSP would still traverse the network through the alternate path.

Verifying the IP and IGP Layers

Problem

Description: After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical or data link layers. Continue investigating the problem at the IP and IGP layers of the network.

[Figure 128 on page 1567](#) illustrates the IP and IGP layers of the layered MPLS model.

Figure 128: IP and IGP Layers

Data Link Layer	show interfaces extensive "JUNOS Interfaces Operations Guide"
Physical Layer	show interfaces show interfaces terse ping <i>host</i>

g015545

Solution

At the IP and IGP layers, you must check the following:

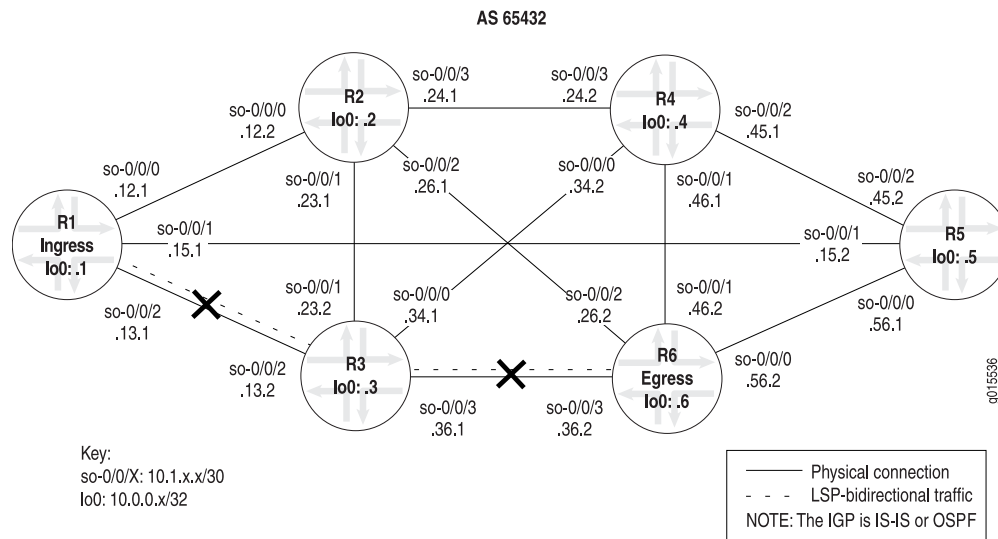

- Interfaces have correct IP addressing, and the IGP neighbors or adjacencies are established.
- Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) protocols are configured and running correctly.
 - If the OSPF protocol is configured, check the IP layer first, then the OSPF configuration, making sure that the protocol, interfaces, and traffic engineering are configured correctly.
 - If the IS-IS protocol is configured, it doesn't matter whether you check IS-IS or IP first because both protocols are independent of each other. Verify that IS-IS adjacencies are up, and that the interfaces and IS-IS protocol are configured correctly.

NOTE: The IS-IS protocol has traffic engineering enabled by default.

If the network is not functioning at the IP or IGP layers, the LSP does not work as configured.

Figure 129 on page 1568 illustrates the MPLS network used in this topic.

Figure 129: MPLS Network Broken at the IP and IGP Layers

The network shown in [Figure 129 on page 1568](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6**, through **R3**, to **R1**, creating bidirectional traffic. The crosses in [Figure 129 on page 1568](#) indicate where the LSP is not working because of the following problems at the IP and IGP layer:

- An IP address is configured incorrectly on the ingress router (**R1**).
- The OSPF protocol is configured with a router ID (RID) but without the loopback (**lo0**) interface, and traffic engineering is missing from the transit router (**R3**).
- Levels in the IS-IS network are mismatched.

Verifying the IP Layer

Purpose

You can check the IP layer before or after you check the interior gateway protocol (IGP) layer, depending on whether you have OSPF or IS-IS configured as the IGP. If your MPLS network is configured with OSPF as the IGP, you must first verify the IP layer, checking that the interfaces have correct IP addressing and that the OSPF neighbors are established before you check the OSPF layer.

If you have IS-IS configured as the IGP in your MPLS network, you can verify either the IP layer or the IS-IS protocol layer first. The order in which you check the IP or IS-IS layer does not affect the results.

Figure 130: MPLS Network Broken at the IP Layer

The cross in [Figure 130 on page 1569](#) indicates where the LSP is broken because of the incorrect configuration of an IP address on ingress router **R1**.

1. [Verify the LSP | 1569](#)
2. [Verify IP Addressing | 1570](#)
3. [Verify Neighbors or Adjacencies at the IP Layer | 1572](#)
4. [Take Appropriate Action | 1577](#)
5. [Verify the LSP Again | 1578](#)

Verify the LSP

Purpose

After configuring the LSP, you must verify that the LSP is up. LSPs can be ingress, transit, or egress. Use the **show mpls lsp** command for quick verification of the LSP state, with the **extensive** option (**show mpls lsp extensive**) as a follow-up if the LSP is down. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name name** or **show mpls lsp name name extensive**).

Action

To verify that the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Dn, ActiveRoute: 0, LSPname: R1-to-R6

Egress LSP: 0 sessions
Total 0 displayed , Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed , Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows that an MPLS label allocation failure occurred and the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.6** on **R6**.

Verify IP Addressing

Purpose

When you investigate the IP layer, you verify that interfaces have correct IP addressing, and that OSPF neighbors or IS-IS adjacencies are established. In this example, an IP address is configured incorrectly on the ingress router (**R1**).

Action

To verify IP addressing, enter the following command from the ingress, transit, and egress routers:

```
user@host> show interfaces terse
```

Sample Output

```
user@R1> show interfaces terse
```

```

Meaning

The sample output shows that the IP addresses for interface **so-0/0/2.0** on **R1** and interface **so-0/0/2.0** on **R3** are identical. Interface IP addresses within a network must be unique for the interface to be identified correctly.

Verify Neighbors or Adjacencies at the IP Layer

Purpose

If the IP addressing is configured incorrectly then the OSPF neighbors or IS-IS adjacencies both need to be checked to determine if one or both of them are established.

Action

To verify neighbors (OSPF) or adjacencies (IS-IS), enter the following commands from the ingress, transit, and egress routers:

```

user@host> show ospf neighbor extensive
user@host> show isis adjacency extensive

```

Sample Output 1

```

user@R1> show ospf neighbor extensive

Meaning

Sample Output 1 from the ingress, transit, and egress routers shows that **R1** and **R3** are not established OSPF neighbors. Considering that the two interfaces **so-0/0/2.0** (**R1** and **R3**) are configured with identical IP addresses, you would expect this. The OSPF protocol routes IP packets based solely on the destination IP address contained in the IP packet header. Therefore, identical IP addresses in the autonomous system (AS) result in neighbors not establishing.

Sample Output 2 from the ingress, transit, and egress routers shows that **R1** and **R3** have established an IS-IS adjacency despite the identical IP addresses configured on interfaces **so-0/0/2.0** on **R1** and **R3**. The

IS-IS protocol behaves differently from the OSPF protocol because it does not rely on IP to establish an adjacency. However, if the LSP is not up, it is still useful to check the IP subnet addressing in case there is a mistake in that layer. Correcting the addressing error might bring the LSP back up.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, the IP address of an interface on transit router **R2** is incorrectly configured.

Solution

To correct the error in this example, enter the following commands:

```
[edit interfaces so-0/0/2]
user@R1# show
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30
user@R1# show
user@R1# commit
```

Sample Output

```
[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.2/30; <<< Incorrect IP address
    }
    family iso;
    family mpls;
}

[edit interfaces so-0/0/2]
user@R1# rename unit 0 family inet address 10.1.13.2/30 to address 10.1.13.1/30

[edit interfaces so-0/0/2]
user@R1# show
unit 0 {
    family inet {
        address 10.1.13.1/30; <<< Correct IP address.
    }
    family iso;
    family mpls;
```

```

}

[edit interfaces so-0/0/2]
user@R1# commit
commit complete

```

Meaning

The sample output shows that interface **so-0/0/2** on ingress router **R1** is now configured with the correct IP address. This correction results in unique subnet IP addresses for all interfaces in the MPLS network in [“MPLS Network Broken at the IP and IGP Layers” on page 1568](#), and the possibility that the LSP might come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the OSPF protocol has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up. The output shows that the egress LSP session **R6-to-R1** received and sent a recovery label.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the IS-IS protocol has been resolved.

Action

To verify that the LSP is up and traversing the network as expected, enter the following command from the ingress, egress, and transit routers:

```
user@host> show mpls lsp extensive
```

Sample Output

```
user@R1> show mpls lsp extensive
```

```
Ingress LSP: 1 sessions
```

Meaning

The sample output from ingress router **R1** and egress router **R6** shows that the LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**. In addition, the sample output from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6**, and the other from **R6** to **R1**.

Checking the RSVP Layer

Purpose

After you have configured the label-switched path (LSP), issued the **show mpls lsp extensive** command, and determined that there is an error, you might find that the error is not in the physical, data link, or Internet Protocol (IP) and interior gateway protocol (IGP) layers. Continue investigating the problem at the RSVP layer of the network.

Figure 131 on page 1586 illustrates the RSVP layer of the layered MPLS model.

Figure 131: Checking the RSVP Layer

g015546

With this layer, you check that dynamic RSVP signaling is occurring as expected, neighbors are connected, and interfaces are configured correctly for RSVP. Check the ingress, egress, and transit routers.

If the network is not functioning at this layer, the LSP does not work as configured.

Figure 132 on page 1587 illustrates the MPLS network used in this topic.

Figure 132: MPLS Network Broken at the RSVP Layer

The network shown in [Figure 132 on page 1587](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the LSP is down without a path in either direction, from **R1** to **R6** or from **R6** to **R1**.

The crosses shown in [Figure 132 on page 1587](#) indicate where the LSP is broken. Some possible reasons the LSP is broken might include that dynamic RSVP signaling is not occurring as expected, neighbors are not connected, or interfaces are incorrectly configured for RSVP.

In the network in [Figure 132 on page 1587](#), a configuration error on transit router **R3** prevents the LSP from traversing the network as expected.

To check the RSVP layer, follow these steps:

1. [Verify the LSP | 1587](#)
2. [Verify RSVP Sessions | 1589](#)
3. [Verify RSVP Neighbors | 1592](#)
4. [Verify RSVP Interfaces | 1593](#)
5. [Verify the RSVP Protocol Configuration | 1595](#)
6. [Take Appropriate Action | 1596](#)
7. [Verify the LSP Again | 1598](#)

Verify the LSP

Purpose

Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

Action

To determine whether the LSP is up, enter the following command from the ingress router:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Total 1 displayed, Up 0,  Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output shows that the LSP is down in both directions, from **R1** to **R6**, and from **R6** to **R1**. The output from **R1** shows that **R1** is using a no-cspf LSP since it tried to originate the call without being able to reach the destination. The output from **R6** shows that the Constrained Shortest Path First (CSPF) algorithm failed, resulting in no route to destination **10.0.0.1**.

Verify RSVP Sessions

Purpose

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, the LSP does not work as configured.

Action

To verify currently active RSVP sessions, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp session
```

Sample Output 1

```

user@R1> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Total 1 displayed, Up 1 , Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

Sample Output 1 from all routers shows that no RSVP sessions were successfully created, even though the LSP **R6-to-R1** is configured.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the output from the ingress, transit, and egress routers when the RSVP configuration is correct, and the LSP is traversing

the network as configured. **R1** and **R6** both show an ingress and egress RSVP session, with the LSP **R1-to-R6**, and the reverse LSP **R6-to-R1**. Transit router **R3** shows two transit RSVP sessions.

Verify RSVP Neighbors

Purpose

Display a list of RSVP neighbors that were learned dynamically when exchanging RSVP packets. Once a neighbor is learned, it is never removed from the list of RSVP neighbors unless the RSVP configuration is removed from the router.

Action

To verify RSVP neighbors, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp neighbor
```

Sample Output 1

```
user@R1> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.2         10  1/0      9:22          9    64/64    32

user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.13.1         0  1/0     28:20          9   190/190   41
10.1.36.2        16:50 1/1     15:37          9   105/78   38

user@R6> show rsvp neighbor
RSVP neighbor: 1 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx MsgRcvd
10.1.36.1        17:30 1/1     16:15          9   104/78   39
```

Sample Output 2

```
user@R3> show rsvp neighbor
RSVP neighbor: 2 learned
```

Address	Idle	Up/Dn	LastChange	HelloInt	HelloTx/Rx	MsgRcvd
10.1.13.1	5	1/0	9:14	9	63/63	33
10.1.36.2	5	1/0	9:05	9	62/62	32

```
user@R6> show rsvp neighbor
```

```
Rsvp neighbor: 1 learned
```

Address	Idle	Up/Dn	LastChange	HelloInt	HelloTx/Rx	MsgRcvd
10.1.36.1	5	1/0	8:54	9	61/61	32

Meaning

Sample Output 1 shows that **R1** and **R6** have one RSVP neighbor each, **R3**. However, the values in the **Up/Dn** field are different. **R1** has a value of **1/0** and **R6** has a value of **1/1**, indicating that **R1** is an active neighbor with **R3**, but **R6** is not. When the up count is one more than the down count, the neighbor is active; if the values are equal, the neighbor is down. The values for **R6** are equal, **1/1**, indicating that the neighbor **R3** is down.

Transit router **R3** knows about two neighbors, **R1** and **R6**. The **Up/Dn** field indicates that **R1** is an active neighbor and **R6** is down. At this point it is not possible to determine if the problem resides with **R3** or **R6**, because both neighbors are not active.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the correct neighbor relationship between transit router **R3** and egress router **R6**. The **Up/Dn** field shows the up count to be one more than the down count, **1/0**, indicating that the neighbors are active.

Verify RSVP Interfaces

Purpose

Display the status of each interface on which RSVP is enabled to determine where the configuration error occurred.

Action

To verify the status of RSVP interfaces, enter the following command from the ingress, transit, and egress routers:

```
user@host> show rsvp interface
```

Sample Output 1

```
user@R1> show rsvp interface
```

```
RSVP interface: 3 active
```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps

```
user@R6> show rsvp interface
```

```
Rsvp interface: 4 active
```

Interface	State	Active resv	Subscription	Static BW	Available BW	Reserved BW	Highwater mark
so-0/0/0.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/1.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/2.0	Up	0	100%	155.52Mbps	155.52Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

Meaning

Sample Output 1 shows that even though each router has interfaces that are up and have RSVP active, there are no reservations (**Active resv**) on any of the routers. In this example, we would expect at least one reservation on the ingress and egress routers, and two reservations on the transit router.

In addition, interface **so-0/0/3** on transit router **R3** is not included in the configuration. The inclusion of this interface is critical to the success of the LSP.

In contrast to Sample Output 1 and to illustrate correct output, Sample Output 2 shows the relevant interfaces with active reservations.

Verify the RSVP Protocol Configuration

Purpose

After you have checked RSVP sessions, interfaces, neighbors, and determined that there might be a configuration error, verify the RSVP protocol configuration.

Action

To verify the RSVP configuration, enter the following command from the ingress, transit, and egress routers:

```
user@host> show configuration protocols rsvp
```

Sample Output

```
user@R1> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {
    disable;
}

user@R6> show configuration protocols rsvp
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;
interface fxp0.0 {
    disable;
}
```

Meaning

The sample output shows that **R3** has interface **so-0/0/3.0** missing from the RSVP protocol configuration. This interface is critical for the correct functioning of the LSP.

Take Appropriate Action

Problem

Description: Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is missing from the configuration of router R3.

Solution

To correct the error in this example, follow these steps:

1. Include the missing interface in the configuration of transit router R3:

```
user@R3> edit
user@R3# edit protocols rsvp
[edit protocols rsvp]
user@R3# show
user@R3# set interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols rsvp]
user@R3# show
user@R3# commit
```

Sample Output

```
user@R3> edit
Entering configuration mode

[edit]
user@R3# edit protocols rsvp

[edit protocols rsvp]
user@R3# show
interface so-0/0/0.0;
interface so-0/0/1.0;
interface so-0/0/2.0; <<< Missing interface so-0/0/3.0
interface fxp0.0 {

```

Meaning

The sample output shows that the missing interface **so-0/0/3.0** on transit router **R3** is now correctly included at the **[edit protocols rsvp]** hierarchy level. This results in the possibility that the LSP might come up.

Verify the LSP Again

Purpose

After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the MPLS layer has been resolved.

Action

To verify the LSP again, enter the following command on the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

Sample Output 1

```

user@R1> show mpls lsp extensive

```

Meaning

Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

Determining LSP Statistics

Purpose

Display detailed information about RSVP objects to assist the diagnosis of an LSP problem.

Action

To verify RSVP objects, enter the following Junos OS CLI operational mode command:

```
user@host> show rsvp session detail
```

Sample Output

```
user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output shows that there is one ingress and one egress RSVP session. The ingress session has a source address of **10.0.0.1 (R1)**, and the session is up, with one active route. The LSP name is **R1-to-R6** and it is the primary path for the LSP.

The recovery label (**100064**) is sent by a graceful restart router to its neighbor to recover a forwarding state. It is probably the old label that the router advertised before it went down.

This session is using the fixed filter (**FF**) reservation style (**Resv style**). Since this is an ingress router, there is no inbound label. The outbound label (provided by the next downstream router) is **100064**.

The **Time Left** field provides the number of seconds remaining in the RSVP session, and the **Tspec** object provides information about the controlled load rate (**rate**) and maximum burst size (**peak**), an infinite value (**Infbps**) for the guaranteed delivery option, and the indication that packets smaller than 20 bytes are treated as 20 bytes, while packets larger than 1500 bytes are treated as 1500 bytes.

The port number is the IPv4 tunnel ID, while the sender/receiver port number is the LSP ID. The IPv4 tunnel ID is unique for the life of the LSP, while the sender/receiver LSP ID can change, for example, with an SE style reservation.

The **PATH rcvfrom** field includes the source of the path message. Since this is the ingress router, the local client originated the path message.

The **PATH sentto** field includes the path message destination (**10.1.13.2**) and outgoing interface (**so-0/0/2.0**). The **RESV rcvfrom** field includes both the source of the Resv message received (**10.1.13.2**) and the incoming interface (**so-0/0/2.0**).

The RSVP explicit route and the route record values are identical: **10.1.13.2** and **10.1.36.2**. In most cases, the explicit route and the record route values are identical. Differences indicate that some path rerouting has occurred, typically during Fast-Reroute.

The **Total** fields indicate the total number of ingress, egress, and transit RSVP sessions, with the total being equal to the sum of the up and down sessions. In this example, there is one ingress session, one egress session, and no transit RSVP sessions.

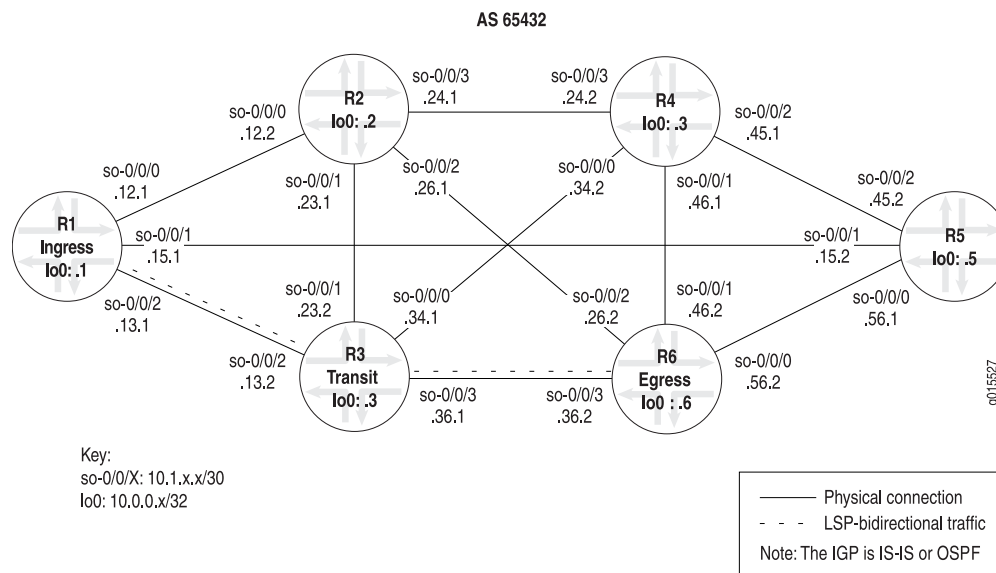

Verifying LSP Use in Your Network

Purpose

When you verify the valid use of an LSP on the ingress and transit routers in your network, you can determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network.

Figure 133 on page 1604 describes the example network used in this topic.

Figure 133: MPLS Topology for Verifying LSP Use

The MPLS network in Figure 133 on page 1604 illustrates a router-only network with SONET interfaces that consist of the following components:

- A full-mesh interior Border Gateway Protocol (IBGP) topology, using AS 65432
- MPLS and Resource Reservation Protocol (RSVP) enabled on all routers
- A **send-statics** policy on routers R1 and R6 that allows a new route to be advertised into the network
- An LSP between routers R1 and R6

The network shown in [Figure 133 on page 1604](#) is a Border Gateway Protocol (BGP) full-mesh network. Since route reflectors and confederations are not used to propagate BGP learned routes, each router must have a BGP session with every other router running BGP.

To verify LSP use in your network, follow these steps:

1. [Verifying an LSP on the Ingress Router | 1605](#)
2. [Verifying an LSP on a Transit Router | 1606](#)

Verifying an LSP on the Ingress Router

Purpose

You can verify the availability of an LSP when it is up by examining the **inet.3** routing table on the ingress router. The **inet.3** routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses.

Action

To verify an LSP on an ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show route table inet.3
```

Sample Output

```
user@R1> show route table inet.3
```

```
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32          *[RSVP/7] 4w0d 22:40:57, metric 20
                    > via so-0/0/2.0, label-switched-path R1-to-R6
```

Meaning

The sample output shows the **inet.3** routing table. By default, only BGP and MPLS virtual private networks (VPNs) can use the **inet.3** route table to resolve next-hop information. One destination is listed in the route table, **10.0.0.6**. This destination (**10.0.0.6**) is signaled by RSVP, and is the current active path, as indicated by the asterisk (*). The protocol preference for this route is **7**, and the metric associated with it is **20**. The label-switched path is **R1-to-R6**, through interface **so-0/0/2.0**, which is the physical next-hop transit interface.

Typically, the penultimate router in the LSP either pops the packet's label or changes the label to a value of 0. If the penultimate router pops the top label and an IPv4 packet is underneath, the egress router routes the IPv4 packet, consulting the IP routing table **inet.0** to determine how to forward the packet. If another type of label (such as one created by Label Distribution Protocol (LDP) tunneling or VPNs, but not IPv4) is underneath the top label, the egress router does not examine the **inet.0** routing table. Instead, it examines the **mpls.0** routing table for forwarding decisions.

If the penultimate router changes the packet's label to a value of 0, the egress router strips off the 0 label, indicating that an IPv4 packet follows. The packet is examined by the **inet.0** routing table for forwarding decisions.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or whether this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the **inet.0** and **inet.3** routing tables, seeking the next hop with the lowest preference; for example, RSVP preference 7 is preferred over OSPF preference 10. The RSVP signaled LSP is used to reach the BGP next hop. This is the default when the BGP next hop equals the LSP egress address. Once the BGP next hop is resolved through an LSP, the BGP traffic uses the LSP to forward BGP transit traffic.

Verifying an LSP on a Transit Router

Purpose

You can verify the availability of an LSP when it is up by examining the **mpls.0** routing table on a transit router. MPLS maintains the **mpls.0** routing table, which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Action

To verify an LSP on a transit router, enter the following Junos OS CLI operational mode command:

```
user@host> show route table mpls.0
```

Sample Output

```
user@R3> show route table mpls.0
```

```
mpls.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                * [MPLS/0] 7w3d 22:20:56, metric 1
                  Receive
1                * [MPLS/0] 7w3d 22:20:56, metric 1
```

```

                Receive
2              * [MPLS/0] 7w3d 22:20:56, metric 1
                Receive
100064        * [RSVP/7] 2w1d 04:17:36, metric 1
              > via so-0/0/3.0, label-switched-path R1-to-R6
100064 (S=0)  * [RSVP/7] 2w1d 04:17:36, metric 1
              > via so-0/0/3.0, label-switched-path R1-to-R6

```

Meaning

The sample output from transit router **R3** shows route entries in the form of MPLS label entries, indicating that there is only one active route, even though there are five active entries.

The first three MPLS labels are reserved MPLS labels defined in RFC 3032. Packets received with these label values are sent to the Routing Engine for processing. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label and Label 2 is the IPv6 explicit null label.

The two entries with the **100064** label are for the same LSP, **R1-to-R6**. There are two entries because the stack values in the MPLS header may be different. The second entry, **100064 (S=0)**, indicates that the stack depth is not 1 and additional label values are included in the packet. In contrast, the first entry of **100064** has an inferred S=1 which indicates a stack depth of 1 and makes it the last label in the packet. The dual entry indicates that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

The incoming label is the MPLS header of the MPLS packet, and is assigned by RSVP to the upstream neighbor. Juniper Networks routers dynamically assign labels for RSVP traffic-engineered LSPs in the range from 100,000 through 1,048,575.

The router assigns labels starting at label 100,000, in increments of 16. The sequence of label assignments is 100,000, 100,016, 100,032, 100,048, and so on. At the end of the assigned labels, the label numbers start over at 100001, incrementing in units of 16. Juniper Networks reserves labels for various purposes. [Table 36 on page 1607](#) lists the various label range allocations for incoming labels.

Table 36: MPLS Label Range Allocations

Incoming Label	Status
0 through 15	Reserved by IETF
16 through 1023	Reserved for static LSP assignment
1024 through 9999	Reserved for internal use (for example, CCC labels)
10,000 through 99,999	Reserved for static LSP assignment

Table 36: MPLS Label Range Allocations (*continued*)

Incoming Label	Status
100,000 through 1,048,575	Reserved for dynamic label assignment

Verify That Load Balancing Is Working

Purpose

After configuring load balancing, check that traffic is load-balanced equally across paths. In this section, the command output reflects the load-balancing configuration of the example network shown in [“Load-Balancing Network Topology” on page 166](#). The **clear** commands are used to reset LSP and interface counters to zero so that the values reflect the operation of the load-balancing configuration.

Action

To verify load balancing across interfaces and LSPs, use the following command on the ingress router:

```
user@host# show configuration
```

To verify load balancing across interfaces and LSPs, use the following commands on a transit router:

```
user@host# show route
user@host# show route forwarding-table
user@host# show mpls lsp statistics
user@host# monitor interface traffic
user@host# clear mpls lsp statistics
user@host# clear interface statistics
```

Sample Output

The following sample output is for the configuration on ingress router **R1**:

```
user@R1> show configuration | no-more
[...Output truncated...]
routing-options {
  [...Output truncated...]
  forwarding-table {
    export lbpp;
  }
}
```

```
[...Output truncated...]
policy-options {
    policy-statement lbpp {
        then {
            load-balance per-packet;
        }
    }
}
```

Meaning

The sample output for the **show configuration** command on ingress router **R1** shows that load balancing is correctly configured with the **lbpp** policy statement. Also, the **lbpp** policy is exported into the forwarding table at the **[edit routing-options]** hierarchy level.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route 192.168.0.1 terse

inet.0: 25 destinations, 27 routes (25 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
A Destination      P Prf  Metric 1   Metric 2   Next hop      AS path
* 192.168.0.1/32   O 10      3           so-0/0/1.0
                   >so-0/0/2.0

[...Output truncated...]
```

Meaning

The sample output for the **show route** command issued on transit router **R2** shows the two equal-cost paths (**so-0/0/1** and **so-0/0/2**) through the network to the loopback address to **R0 (192.168.0.1)**. Even though the right angle bracket (>) usually indicates the active route, in this instance it does not, as shown in the following four sample outputs.

Sample Output

The following sample output is from transit router R2:

```
user@R2> monitor interface traffic

R2                               Seconds: 65                Time: 11:41:14
```

Interface	Link	Input packets	(pps)	Output packets	(pps)
so-0/0/0	Up	0	(0)	0	(0)
so-0/0/1	Up	126	(0)	164659	(2128)
so-0/0/2	Up	85219	(1004)	164598	(2128)
so-0/0/3	Up	0	(0)	0	(0)
fe-0/1/0	Up	328954	(4265)	85475	(1094)
fe-0/1/1	Up	0	(0)	0	(0)
fe-0/1/2	Up	0	(0)	0	(0)
fe-0/1/3	Up	0	(0)	0	(0)

[...Output truncated...]

Meaning

The sample output for the **monitor interface traffic** command issued on transit router **R2** shows that output traffic is evenly distributed across the two interfaces **so-0/0/1** and **so-0/0/2**.

Sample Output

The following sample output is from transit router R2:

```

user@R2> show mpls lsp statistics
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output for the **show mpls lsp statistics** command issued on transit router **R2** shows that output traffic is evenly distributed across the four LSPs configured on ingress router **R6**.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route forwarding-table destination 10.0.90.14
Routing table: inet
Internet:
Destination          Type RtRef Next hop          Type Index NhRef Netif
10.0.90.12/30        user      0                ulst 262144  6
                    ucst 345  5 so-0/0/1.0
                    ucst 339  2 so-0/0/2.0
```

Meaning

The sample output for the **show route forwarding-table destination** command issued on transit router R2 shows **ulst** in the **Type** field, which indicates that load balancing is working. The two unicast (**ucst**) entries in the **Type** field are the two next hops for the LSPs.

Sample Output

The following sample output is from transit router R2:

```
user@R2> show route forwarding-table | find mpls
Routing table: mpls
MPLS:
Destination          Type RtRef Next hop          Type Index NhRef Netif
default              perm      0                dscd   38    1
0                    user      0                recv   37    3
1                    user      0                recv   37    3
2                    user      0                recv   37    3
100112                user      0                Swap 100032      so-0/0/1.0
100128                user      0                Swap 100048      so-0/0/1.0
100144                user      0 10.0.12.13          Swap 100096      fe-0/1/0.0
100160                user      0                Swap 100112      so-0/0/2.0
100176                user      0                Swap 100128      so-0/0/2.0
```

Meaning

The sample output for the **show route forwarding-table | find mpls** command issued on transit router R2 shows the MPLS routing table that contains the labels received and used by this router to forward packets to the next-hop router. This routing table is used mostly on transit routers to route packets to the next router along an LSP. The first three labels in the **Destination** column (Label 0, Label 1, and Label 2) are automatically entered by MPLS when the protocol is enabled. These labels are reserved MPLS labels

defined in RFC 3032. Label 0 is the IPv4 explicit null label. Label 1 is the MPLS equivalent of the IP Router Alert label, and Label 2 is the IPv6 explicit null label.

The remaining five labels in the **Destination** column are nonreserved labels that the router uses to forward traffic, and the last column **Netif**, shows the interfaces used to send the labeled traffic. For nonreserved labels, the second **Type** column shows the operation performed on matching packets. In this example, all non-reserved packets are swapped for outgoing packet labels. For example, packets with the label **100112** have their label swapped for **100032** before they are pushed out of interface **so-0/0/1.0**.

Verify the Operation of Uneven Bandwidth Load Balancing

Purpose

When a router is performing unequal-cost load balancing between LSPs paths, the **show route detail** command displays a balance field associated with each next hop being used.

Action

To verify that an RSVP LSP is unevenly load-balanced, use the following Junos OS CLI operational mode commands:

```
user@host> show route protocol rsvp detail
user@host> show mpls lsp statistics
```

Sample Output

```
user@R1> show route protocol rsvp detail

inet.0: 25 destinations, 25 routes (25 active, 0 holddown, 0 hidden)

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output from ingress router **R1** shows that traffic is distributed according to the LSP bandwidth configuration, as indicated by the **Balance: xx%** field. For example, **lsp1** has 10 Mbps of bandwidth configured, as reflected in the **Balance: 10%** field.

Use the traceroute Command to Verify MPLS Labels

Purpose

You can use the **traceroute** command to verify that packets are being sent over the LSP.

Action

To verify MPLS labels, enter the following Junos OS CLI operational mode command, where **host-name** is the IP address or the name of the remote host:

```
user@host> traceroute host-name
```

Sample Output 1

```

user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.861 ms  0.718 ms  0.679 ms
    MPLS Label=100048 CoS=0 TTL=1 S=1
 2  10.1.24.2 (10.1.24.2)  0.822 ms  0.731 ms  0.708 ms
    MPLS Label=100016 CoS=0 TTL=1 S=1
 3  10.1.46.2 (10.1.46.2)  0.571 ms !N  0.547 ms !N  0.532 ms !N

```

Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.605 ms  0.548 ms  0.503 ms
 2  10.0.0.6 (10.0.0.6)  0.761 ms  0.676 ms  0.675 ms
```

Meaning

Sample Output 1 shows that MPLS labels are used to forward packets through the network. Included in the output is a label value (**MPLS Label=100048**), the time-to-live value (**TTL=1**), and the stack bit value (**S=1**).

The **MPLS Label** field is used to identify the packet to a particular LSP. It is a 20-bit field, with a maximum value of $(2^{20}-1)$, or approximately 1,000,000.

The TTL value contains a limit on the number of hops that this MPLS packet can travel through the network (1). It is decremented at each hop, and if the TTL value drops below one, the packet is discarded.

The bottom of the stack bit value (**S=1**) indicates that is the last label in the stack and that this MPLS packet has one label associated with it. The MPLS implementation in the Junos OS supports a stacking depth of 3 on the M-series routers and up to 5 on the T-series platforms. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

MPLS labels appear in Sample Output 1 because the **traceroute** command is issued to a BGP destination where the BGP next hop for that route is the LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 shows that MPLS labels do not appear in the output for the **traceroute** command. If the BGP next hop does not equal the LSP egress address or the destination is an IGP route, the BGP traffic does not use the LSP. Instead of using the LSP, the BGP traffic is using the IGP (IS-IS, in this case) to reach the egress address (**R6**).

Troubleshooting GMPLS and GRE Tunnel

Problem

Description: The logical control channel for GMPLS must be a point-to-point link and must have some form of IP reachability. On broadcast interfaces or when there are multiple hops between control channel peers, use a GRE tunnel for the control channel. For more detailed information on GMPLS and GRE tunnels see the *Junos MPLS Applications Configuration Guide* and the *Junos User Guide*.

A tunnel PIC is *not* required to configure a GRE tunnel for the GMPLS control channel. Instead, use the software-based **gre** interface, rather than the hardware-based **gr-fpc/pic/port** interface.

CAUTION: Due to restrictions to the software-based **gre** interface, the GMPLS control channel is the only supported use of the software-based **gre** interface. Any other use is expressly unsupported and might cause an application failure.

The following example shows a basic **gre** interface configuration. In this case, the tunnel source is the loopback address of the local router and the destination address is the loopback destination of the remote router. Traffic that has a next hop of the tunnel destination will use the tunnel. The tunnel is not automatically used by all the traffic passing through the interface. Only traffic with the tunnel destination as the next hop uses the tunnel.

Sample Output

```
user@R1> show configuration interfaces
[...Output truncated...]
gre {
    unit 0 {
        tunnel {
            source 10.0.12.13;
            destination 10.0.12.14;
        }
        family inet {
            address 10.35.1.6/30;
        }
        family mpls;
    }
}
```

Sample Output

The following sample output for the **show interfaces** command shows the encapsulation type and header, the maximum speed, packets through the logical interface, the destination, and logical address.

```
user@R1> show interfaces gre
Physical interface: gre, Enabled, Physical link is Up
Interface index: 10, SNMP ifIndex: 8
Type: GRE, Link-level type: GRE, MTU: Unlimited, Speed: Unlimited
Device flags : Present Running
Interface flags: Point-To-Point SNMP-Traps
Input packets : 0
Output packets: 0
```

```

Logical interface gre.0 (Index 70) (SNMP ifIndex 47)
  Flags: Point-To-Point SNMP-Traps 0x4000
    IP-Header 10.0.12.14:10.0.12.13:47:df:64:0000000000000000
    Encapsulation: GRE-NULL
    Input packets : 171734
    Output packets: 194560
    Protocol inet, MTU: 1476
      Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.35.1.4/30, Local: 10.35.1.6, Broadcast: 10.35.1.7
    Protocol mpls, MTU: 1464
      Flags: None

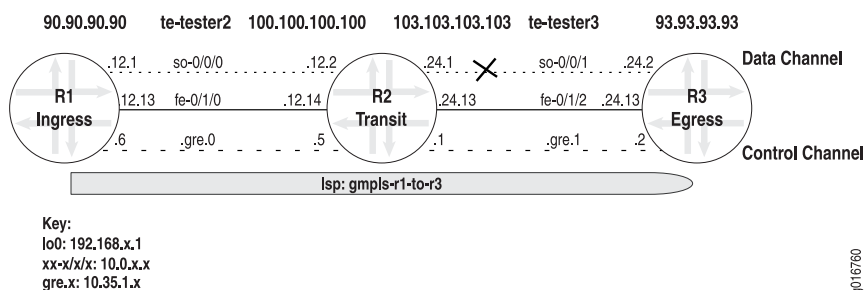

```

The following are various requirements when you configure a GMPLS LSP using a GRE tunnel:

- The data channel must start and end on the same type of interface.
- The control channel can be a GRE tunnel that starts and ends on the same or different interface type.
- The GRE tunnel must be configured indirectly with the **peer-interface *peer-name*** statement at the **[edit protocols ospf]** hierarchy level.
- The GRE interface must be disabled at the **[edit protocols ospf]** and **[edit protocols rsvp]** hierarchy levels.
- Data and control channels must be defined correctly in the LMP configuration .
- It is optional to disable Constrained Shortest Path First (CSPF) with the **no-cspf** statement.

This case focuses on the incorrect configuration of the endpoints of the GRE tunnel. However, you can use a similar process and commands to diagnose other GRE tunnel problems. [Figure 134 on page 1617](#) illustrates a network topology with MPLS tunneled through a GRE interface.

Figure 134: GMPLS Network Topology

The MPLS network topology in [Figure 134 on page 1617](#) shows Juniper Networks routers configured with a GRE tunnel that consists of the following components:

- A strict GMPLS LSP path from the ingress router to the egress router.
- On the ingress router, CSPF disabled with the **no-cspf** statement at the [edit protocol mpls label-switched-path *lsp-name*] hierarchy level.
- Traffic-engineering links and control channels within the **peer** statement at the [edit protocols link-management] hierarchy level on all routers.
- OSPF and OSPF traffic engineering configured on all routers.
- A reference to the **peer-interface** in both OSPF and RSVP on all routers.
- A switching-type problem between **R2** and **R3**.

Symptom

The LSP in the network shown in [Figure 134 on page 1617](#) is down, as indicated by the output from the **show mpls lsp** and **show rsvp session** commands, which display very similar information. The **show mpls lsp** command shows all LSPs configured on the router, as well as all transit and egress LSPs. The **show rsvp session** command displays summary information about RSVP sessions. You can use either command to verify the state of the LSP. In this case, LSP **gmpls-r1-to-r3** is down (**Dn**).

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From          State Rt ActivePath      P      LSPname

To          From          State  Rt Style Labelin Labelout LSPname
192.168.4.1 192.168.1.1 Dn   0 0 -   -   - gmpls-r1-to-r3
Bidir
Total 1 displayed, Up 0, Down 1

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

```
Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

Cause

The cause of the problem with the GMPLS LSP is the configuration of different interface types at both ends of the GMPLS data channel.

Troubleshooting Commands

The Junos OS includes commands that are useful when troubleshooting a problem. This topic provides a brief description of each command, followed by sample output, and a discussion of the output in relation to the problem.

You can use the following commands when troubleshooting a GMPLS problem:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show link-management peer
user@host> show link-management te-link
user@host> show configuration protocols mpls
user@host> monitor start filename
user@host> show log filename
```

Sample Output

Use the show mpls lsp extensive command on transit router R1 to display detailed information about all LSPs transiting, terminating, and configured on the router.

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

192.168.4.1
  From: 192.168.1.1, State: Dn, ActiveRoute: 0, LSPname: gmpls-r1-to-r3
  Bidirectional

Total 1 displayed, Up 0, Down 1

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output for the **show mpls lsp extensive** command shows an error message (**MPLS label allocation failure**) in the log section of the output. This LSP event indicates that the MPLS protocol or the **family mpls** statement were not configured properly. When the LSP event is preceded by an IP address, the address is typically the router that has the MPLS configuration error. In this case, it appears that the router with the **lo0** address of **192.168.4.1 (R3)** has an MPLS configuration error.

Sample Output

Use the **show rsvp session detail** command to display detailed information about RSVP sessions.

```

user@R1> show rsvp session detail
Ingress RSVP: 1 sessions

192.168.4.1

    Explt route: 100.100.100.100 93.93.93.93

```

Total 1 displayed, Up 0, Down 1

Egress RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning

The sample output for the **show RSVP session detail** command shows that LSP **gmpls-r1-to-r3** is down (**LSPstate: Dn**). The route record is incomplete, indicating a problem with the explicit route **100.100.100.100/32**. The address **100.100.100.100** is the data channel on **R2** so-0/0/0, and the address **93.93.93.93** is the data channel on **R3**.

Sample Output

Use the `show link-management peer` command to display MPLS peer link information.

```
user@R1> show link-management peer
```

Peer name: tester2, System identifier: 48428

State: Up, Control address: 10.35.1.5

```
Control-channel      State

```

TE links:

te-tester3

```

user@R3> show link-management peer
Peer name: tester3, System identifier: 48429
State: Up, Control address: 10.35.1.1
Control-channel          State
gre.0                    Active
TE links:
te-tester3

```

Meaning

The sample output from all routers in the example network in [Figure 134 on page 1617](#) for the **show link-management peer** command shows that all control channels are up and active. A detailed analysis of the output shows the following information:

- Name of the peer, **tester2** or **tester3**, which is the same on neighboring routers for ease of troubleshooting.
- Internal identifier for the peer, **48428** for **tester2** and **48429** for **tester3**. The internal identifier is a range of values from 0 through 64,000.
- The state of the peer, which can be up or down. In this case, all peers are up.
- The address to which a control channel is established, for example, **10.35.1.5**.
- The state of the control channel, which can be up, down, or active.
- The traffic-engineered links that are managed by their peer, indicating that control channel **gre.0** is managed by **tester3**.

Sample Output

Use the **show link-management te-link** command to display the resources used to set up Multiprotocol Label Switching (MPLS) traffic-engineered forwarding paths.

```

user@R1> show link-management te-link
TE link name:  tester2, State: Up

```

Meaning

The sample output for the **show link-management te-link** command issued on the three routers in the network in [Figure 134 on page 1617](#) shows the resources allocated to the traffic-engineered links **te-tester2** and **te-tester3**. The resources are the SONET interfaces **so-0/0/0** and **so-0/0/1**. On **R1** and **R2**, the SONET interfaces are used for the LSP **gmpls-r1-to-r3**, as indicated by **Yes** in the **Used** field. However, the SONET interface **so-0/0/1** on **R3** is down (**Dn**) and is not used for the LSP (**Used No**). Further investigation is required to discover why the SONET interface on **R3** is down.

Sample Outut

Use the `show log filename` command to display the contents of the specified log file. In this case, the log file `rsvp.log` is configured at the `[edit protocols rsvp traceoptions]` hierarchy level. When the log file is configured, you must issue the `monitor start filename` command to begin logging messages to the file.

```
user@R1> show configuration protocols rsvp
traceoptions {
    file rsvp.log size 3m world-readable;
    flag state detail;
    flag error detail;
    flag packets detail;
}

user@R1> monitor start rsvp.log
```

NOTE: The **find Error** option entered after the pipe (|) searches the output for an instance of the term *Error*.

Sample Output

```
user@R3>
show log rsvp.log | find Error

```

Meaning

The sample output from the egress router **R3** for the **show log rsvp.log** command is a snippet taken from the log file. The snippet shows a Link Management Protocol (LMP) resource request for the LSP **gmpls-r1-to-r3**. The request has problems with the encoding type (SDH/SONET), indicating a possible error with the SONET interface connecting **R2** and **R3**. Further investigation of the configuration of the LMP on **R2** and **R3** is required.

Sample Output

Use the show configuration *statement-path* command to display a specific configuration hierarchy; in this instance, link-management.

```

user@R2> show configuration protocols link-management
te-link te-tester2 {
    local-address 100.100.100.100;
    remote-address 90.90.90.90;
    remote-id 22292;
    interface so-0/0/0 {
        local-address 100.100.100.100;
        remote-address 90.90.90.90;
        remote-id 21253;
    }
}
te-link te-tester3 {
    local-address 103.103.103.103;
    remote-address 93.93.93.93;
    remote-id 21254;
    interface so-0/0/1 {
        local-address 103.103.103.103;
        remote-address 93.93.93.93;
        remote-id 21252;
    }
}
peer tester2 {
    address 10.35.1.6;
}

```

```

        control-channel gre.0;
        te-link te-tester2;
    }
    peer tester3 {
        address 10.35.1.2;
        control-channel gre.1;
        te-link te-tester3;
    }

user@R3> show configuration protocols link-management
te-link te-tester3 {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
}
    interface at-0/3/1 {
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}

```

Meaning

The sample output from transit router **R2** and ingress router **R3** for the **show configuration protocols link-management** command shows that the interface type on the two routers is different. The resource allocated to **te-tester3** on transit router **R2** is a SONET interface, while the resource allocated to **te-tester3** on egress router **R3** is an ATM interface. The interface type on each end of the data or control channels must be of the same type. In this case, both ends should be SONET or ATM.

Solution

Solution

The solution to the problem of different interface or encapsulation types at either end of the GMPLS LSP is to make sure that the interface type is the same at both ends. In this case, the ATM interface was deleted from the link-management configuration on **R3**, and a SONET interface was configured instead.

The following commands illustrate the correct configuration and commands to verify that the GMPLS LSP is up and using the data channel:

```

user@R3> show configuration protocols link-management
user@R3> show mpls lsp
user@R3> show link-management te-link

```

Sample Output

```

user@R3> show configuration protocols link-management
te-link te-tester3 {
    local-address 93.93.93.93;
    remote-address 103.103.103.103;
    remote-id 21254;
    interface so-0/0/1 { # SONET interface replaces the incorrect ATM interface
        local-address 93.93.93.93;
        remote-address 103.103.103.103;
        remote-id 21252;
    }
}
peer tester3 {
    address 10.35.1.1;
    control-channel gre.0;
    te-link te-tester3;
}

user@R3> show mpls lsp
Ingress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
Egress LSP: 1 sessions

```

To	From	State	Rt	Style	Labelin	Labelout	LSPname

```

Bidir
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@R3> show link-management te-link
TE link name: te-tester3, State: Up
Local identifier: 7003, Remote identifier: 21254, Local address: 93.93.93.93,
Remote address: 103.103.103.103,
Encoding: SDH/SONET, Switching: PSC-1, Minimum bandwidth: 155.52Mbps, Maximum
bandwidth: 155.52Mbps, Total bandwidth: 155.52Mbps,
Available bandwidth: 0bps

```

Name	State	Local ID	ID	Remote ID	Bandwidth Used	LSP-name
so-0/0/1	Up	21252	21252	155.52Mbps	Yes	gmpls-r1-to-r3

Meaning

The sample output for the **show protocols link-management**, **show mpls lsp**, and **show link-management te-link** commands from ingress router **R3** show that the problem is solved. LMP is correctly configured, and the LSP **gmpls-r1-to-r3** is up and using the data channel **so-0/0/1**.

Conclusion

In conclusion, both ends of a GMPLS data channel must be the same encapsulation or interface type. This case illustrates the correct configuration of the data channel. The principles are the same for the control channel.

Router Configurations

Output that shows the configurations of the ingress router in the network. The **no-more** option entered after the pipe (|) prevents the output from being paginated if the output is longer than the length of the terminal screen.

Sample Output

The following sample output is for ingress router R1:

```
user@R1> show configuration | no-more
[...Output truncated...]
interfaces {
  so-0/0/0 {
    unit 0 {
      family inet {
        address 10.0.12.1/32 {

```

Determining LSP Status

Display detailed information about Resource Reservation Protocol (RSVP) objects and the label-switched path (LSP) history to pinpoint a problem with the LSP.

[Figure 135 on page 1639](#) illustrates the network topology used in this topic.

Figure 135: MPLS Network Topology

To determine the LSP state, follow these steps:

1. [Check the Status of the LSP | 1639](#)
2. [Display Extensive Status About the LSP | 1640](#)

Check the Status of the LSP

Purpose

Display the status of the label-switched path (LSP).

Action

To determine the LSP status, on the ingress router, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show mpls lsp
```

Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From      State Rt ActivePath      P      LSPName
10.0.0.6    10.0.0.1    Up    1      *    R1-to-R6
Total 1 displayed, Up 1, Down 0
```

```

Egress LSP: 1 sessions
To          From          State Rt  Style  Labelin Labelout LSPname
10.0.0.1    10.0.0.6    Up   0 1 FF   3    - R6-to-R1
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information. Ingress information is for the sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1 (10.0.0.1)** to **R6 (10.0.0.6)**. This route is currently up, and is an active route installed in the routing table (**Rt**). The LSP **R1-to-R6** is the primary path (**P**) as opposed to the secondary path, and is indicated by an asterisk (*). The route to **R6** does not contain a named path (**ActivePath**).

There is one egress LSP from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see *Checklist for Working with the Layered MPLS Troubleshooting Model*.

Display Extensive Status About the LSP

Purpose

Display extensive information about LSPs, including all past state history and the reasons why an LSP might have failed.

Action

To display extensive information about LSPs, on the ingress router, enter the following Junos OS CLI operational mode command:

```
user@host> show mpls lsp extensive
```

Sample Output

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Meaning

The sample output is from the ingress router (**R1**), and shows ingress, egress, and transit LSP information in detail, including all past state history and the reasons why an LSP failed. Ingress information is for sessions that originate from this router, egress information is for sessions that terminate on this router, and transit information is for sessions that transit through this router.

There is one ingress route from **R1 (10.0.0.1)** to **R6 (10.0.0.6)**. This route is currently up (**State**), with one route actively using the LSP, **R1-to-R6**. The LSP active path is the primary path. Even if the LSP does not contain a **primary** or **secondary** keyword, the router still treats the LSP as a primary LSP, indicating that if the LSP fails, the router will attempt to signal inactive LSPs at 30-second intervals, by default.

Load balancing is **Random**, which is the default, indicating that when selecting the physical path for an LSP, the router randomly selects among equal-cost paths that have an equal hop count. Other options that you can configure are **Least-fill** and **Most-fill**. **Least-fill** places the LSP over the least utilized link of the equal-cost paths with equal hop count. **Most-fill** places the LSP over the most utilized link of the equal-cost paths sharing an equal hop count. Utilization is based on the percentage of available bandwidth.

The **Encoding type** field shows Generalized MPLS (GMPLS) signaling parameters (**Packet**), indicating IPv4. The **Switching type** is **Packet**, and the Generalized Payload Identifier (**GPID**) is IPv4.

The primary path is the active path, as indicated by an asterisk (*). The state of the LSP is **Up**.

The Explicit Route Object (**ERO**) includes the Constrained Shortest Path First (CSPF) cost (**20**) for the physical path that the LSP follows. The presence of the CSPF metric indicates that this is a CSPF LSP. The absence of the CSPF metric indicates a no-CSPF LSP.

The field **10.1.13.2 S** indicates the actual ERO. The RSVP signaling messages went to **10.1.13.2** strictly (as a next hop) and finished at **10.1.36.2** strictly. All ERO addresses are strict hops when the LSP is a CSPF LSP. Loose hops can only display in a no-CSPF LSP.

The received Record Route Object (**RRO**) has the following protection flags:

- **0x01**—Local protection available. The link downstream of this node is protected by a local repair mechanism. This flag can only be set if the Local protection flag was set in the **SESSION_ATTRIBUTE** object of the corresponding path message.
- **0x02**—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).
- **0x04**—Bandwidth protection. The downstream router has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.

- **0x08**—Node protection. The downstream router has a backup path providing protection against link and node failure on the corresponding path section. If the downstream router can set up only a link-protection backup path, the “Local protection available” bit is set but the “Node protection” bit is cleared.
- **0x10**—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engineered LSP. This indicates to the ingress label edge router (LER) of this LSP that it should be rerouted.

For more information on protection flags, see the *Junos Routing Protocols and Policies Command Reference*.

The field **10.1.13.2.10.1.36.2** is the actual received record route (**RRO**). Note that the addresses in the **RRO** field match those in the **ERO** field. This is the normal case for CSPF LSPs. If the RRO and ERO addresses do not match for a CSPF LSP, the LSP has to reroute or detour.

The lines numbered 91 through 42 contain the 49 most recent entries to the history log. Each line is time stamped. The most recent entries have the largest log history number and are at the top of the log, indicating that line 91 is the most recent history log entry. When you read the log, start with the oldest entry (**42**) to the most recent (**91**).

The history log was started on July 10, and displays the following sequence of activities: an LSP was selected as active, was found to be down, MPLS label allocation failed several times, was deleted several times, was preempted because of an ResvTear, was deselected as active, and was cleared. In the end, the router computed a CSPF ERO, signaled the call, the LSP came up with the listed RRO (line 90), and was listed as active.

For more information on error messages, see the *Junos MPLS Network Operations Guide Log Reference*.

The total number of ingress LSPs displayed is **1**, with **1** up and **0** down. The number in the **Up** field plus the number in the **Down** field should equal the total.

There is one egress LSP session from **R6** to **R1**. The **State** is up, with no routes installed in the routing table. RSVP reservation style (**Style**) consists of two parts. The first is the number of active reservations (**1**). The second is the reservation style, which is **FF** (fixed filter). The reservation style can be **FF**, **SE** (shared explicit), or **WF** (wildcard filter). There are three incoming labels (**Labelin**) and no labels going out (**Labelout**) for this LSP.

There are no transit LSPs.

For more information on checking the LSP state, see *Checklist for Working with the Layered MPLS Troubleshooting Model*.

Checking That RSVP Path Messages Are Sent and Received

Purpose

The presence or absence of various RSVP messages can help determine if there is a problem with Multiprotocol Label Switching (MPLS) in your network. For example, if path messages occur in the output without Resv messages, it might indicate that label-switched paths (LSPs) are not being created.

Action

To check that RSVP Path messages are sent and received, enter the following Junos OS command-line interface (CLI) operational mode command:

```
user@host> show rsvp statistics
```

Sample Output

```
user@R1> show rsvp statistics
```

PacketType	Total		Last 5 seconds	
	Sent	Received	Sent	Received
Path	114523	80185	1	0
PathErr	5	10	0	0
PathTear	12	6	0	0
Resv FF	80515	111476	0	0
Resv WF	0	0	0	0
Resv SE	0	0	0	0
ResvErr	0	0	0	0
ResvTear	0	5	0	0
ResvConf	0	0	0	0
Ack	0	0	0	0
SRefresh	0	0	0	0
Hello	915851	915881	0	0
EndtoEnd RSVP	0	0	0	0

Errors	Total	Last 5 seconds
Rcv pkt bad length	0	0
Rcv pkt unknown type	0	0
Rcv pkt bad version	0	0
Rcv pkt auth fail	0	0
Rcv pkt bad checksum	0	0
Rcv pkt bad format	0	0
Memory allocation fail	0	0
No path information	0	0
Resv style conflict	0	0
Port conflict	0	0
Resv no interface	0	0
PathErr to client	15	0
ResvErr to client	0	0
Path timeout	0	0

Resv timeout	0	0
Message out-of-order	0	0
Unknown ack msg	0	0
Recv nack	0	0
Recv duplicated msg-id	0	0
No TE-link to recv Hop	0	0

Meaning

The sample output shows RSVP messages sent and received. The total number of RSVP Path messages is 11,4532 sent and 80,185 received. Within the last 5 seconds, no messages have been sent or received.

A total of 5 **PathErr** messages were sent and 10 received. When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. In this case, **R1** sent at least 10 path messages with an error, as indicated by the 10 PathErr messages that **R1** has received. The downstream router sent **R1** five path messages with an error, as indicated by the five PathErr messages that **R1** has sent. PathErr messages transmit in the opposite direction to path messages.

A total of 12 **PathTear** messages were sent and 6 received, none in the last 5 seconds. In contrast to PathErr messages, PathTear messages travel in the same direction as path messages. Since path messages are both sent and received, PathTear messages are also sent and received. However, if only path messages are sent, then only the PathTear messages that are sent appear in the output.

A total of 80,515 reservation (**Resv**) messages with the fixed filter (**FF**) reservation style were sent and 111,476 received, none in the last 5 seconds. An **FF** reservation style indicates that within each session, each receiver establishes its own reservation with each upstream sender, and that all selected senders are listed. No messages for the wildcard filter (**WF**) or shared explicit (**SE**) reservation styles are sent or received. For more information on RSVP reservation styles, see the *Junos MPLS Applications Configuration Guide*.

Other RSVP message types are not sent or received. For information on the ResvErr, ResvTear, and Resvconf message types, see the *Junos MPLS Applications Configuration Guide*.

Ack and summary refresh (SRefresh) messages do not appear in the output. Ack and summary refresh messages are defined in RFC 2961 and are part of the RSVP extensions. Ack messages are used to reduce the amount of RSVP control traffic in the network.

A total of 915,851 hello messages were sent and 915,881 received, with none transmitted or received in the last 5 seconds. The RSVP hello interval is 9 seconds. If more than one hello message is sent or received in the last 5 seconds, it implies that more than one interface supports RSVP.

EndtoEnd RSVP messages are legacy RSVP messages that are not used for RSVP traffic engineering. These counters increment only when RSVP forwards legacy RSVP messages issued by a virtual private network (VPN) customer for transit across the backbone to the other site(s) in the VPN. They are called end-to-end

messages because they are intended for the opposite side of the network and only have meaning at the two ends of the provider network.

The **Errors** section of the output shows statistics about RSVP packets with errors. A total of 15 **PathErr to client** packets were sent to the Routing Engine. The total combines the sent and received **PathErr** packets.

abstract-hop

Syntax

```
abstract-hop abstract-hop-name {
    constituent-list constituent-list-name (include-any-list | include-all-list | exclude-all-list | exclude-any-list);
    operators (AND | OR);
}
```

Hierarchy Level

```
[edit logical systems logical-systems-name protocols mpls]
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 17.1 for all platforms.

Description

Define router clusters or groups, similar to the sequence of real-hop constraints (strict or loose), as a sequence of abstract hops for setting up a label-switched path (LSP).

An abstract hop is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and Shared Risk Link Groups (SRLGs), along with the ordering property of real hops. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes. A path can use a combination of real and abstract hops as constraints.

Options

abstract-hop-name—Name of the abstract hop that is a logical combination of the existing traffic engineering constraints, such as administrative groups, extended administrative groups, and SRLGs, along with the ordering property of real hops.

constituent-list constituent-list-name—Name of the predefined constituent list to be included in defining the abstract hop. A constituent list enables you to define a set of constituent attributes that is identified with a user-defined name.

include-any-list—Satisfy any one of the attributes specified in the constituent list.

include-all-list—Satisfy all of the attributes specified in the constituent list.

exclude-all-list—Satisfy none of the attributes specified in the constituent list.

exclude-any-list—Fail to satisfy any one of the attributes specified in the constituent list.

operators—Specify the operation between constituent lists when more than one constituent list is included in the abstract hop definition.

AND—Satisfy all the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

OR—Satisfy at least one of the constituent lists referenced in the abstract hop definition for the attached node to be a member of the abstract hop.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

During reroute, do not double-count bandwidth on links shared by the old and new paths. Including this statement causes RSVP to use shared explicit (SE) reservation styles and assists in smooth transition during rerouting.

Default

The configured object is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

adjust-threshold

Syntax

```
adjust-threshold percent;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],  
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Specify in percentage how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in bandwidth utilization.

To specify the changes in the automatic bandwidth adjustment for a LSP in absolute value, use the [adjust-threshold-absolute](#) statement instead.

Options

percent—Bandwidth demand for the current bandwidth adjustment interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the percentage specified by this statement, the LSP's bandwidth is adjusted to the current bandwidth demand.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring the Automatic Bandwidth Adjustment Threshold](#) | 520

adjust-threshold-absolute

Syntax

```
adjust-threshold-absolute bps;
```

Hierarchy Level

```
[edit logical-systems name protocols mpls label-switched-path name auto-bandwidth ],
[edit logical-systems name routing-instances name protocols mpls label-switched-path name auto-bandwidth ],
[edit protocols mpls label-switched-path name auto-bandwidth ],
[edit routing-instances name protocols mpls label-switched-path name auto-bandwidth ]
```

Release Information

Statement introduced before Junos OS Release 17.4R1 on all platforms.

Description

Specify in bits per second how sensitive the automatic bandwidth adjustment for a label-switched path (LSP) is to changes in the average LSP utilization.

The **adjust-threshold-absolute** statement works in conjunction with the **adjust-threshold** statement, which specifies the change in automatic bandwidth adjustment for an LSP as a percentage.

By triggering automatic bandwidth LSP resignaling based on absolute change in bandwidth instead of percentage bandwidth change, LSP resignaling can be optimized for both big and small LSPs at the same time.

Options

bps—Change in average LSP utilization to trigger automatic bandwidth adjustment in bits per second.

Default: 0 bps

Required Privilege Level

routing

RELATED DOCUMENTATION

[Configuring the Automatic Bandwidth Adjustment Threshold](#) | 520

adjust-threshold-activate-bandwidth

Syntax

```
adjust-threshold-activate-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],  
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 14.1.

Description

Specify an absolute value to prevent automatic adjustment of signaled bandwidth and aggressive re-signaling of a label-switched path (LSP) when the actual bandwidth over the LSP is below the configured threshold, although the adjust-threshold percentage condition is satisfied.

Options

bps—Amount of bandwidth that is compared with the maximum of all traffic samples during an adjustment interval. If the maximum average bandwidth is less than this configured value, automatic bandwidth adjustment or re-signaling does not happen, even if the adjust-threshold percentage condition is satisfied.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

  path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced in Junos OS Release 11.1.

Description

Specifies the group name and group identifier for an administrative group. The group identifier must be within the range of values specified by the **admin-groups-extended-range** statement. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

apply-groups—Apply the specified administrative groups for the LSP or for the primary and secondary paths.

apply-groups-except—Exclude the specified administrative groups from the LSP or from the primary and secondary paths.

exclude—Define the administrative groups to exclude from an LSP or from the primary and secondary paths.

include-all—Require the LSP to traverse links that include all of the defined administrative groups.

include-any—Define the administrative groups to include for an LSP for the primary and secondary paths.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 11.1.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Enables you to configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in IGPs (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. By default, Juniper Networks routers interpret this 32-bit value as a bit mask with each bit representing a group. This normally limits each network to a total of 32 distinct administrative groups (value range 0 through 31).

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by CSPF for path computation.

Options

maximum *maximum-number*—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

minimum *minimum-number*—The range of configurable values is between 32 and 4,294,967,295. The range maximum must be greater than the range minimum.

[edit protocols mpls label-switched-path lsp-name egress-protection context-identifier context-id]
```

Release Information

Statement introduced in Junos OS Release 13.3.

Description

Configure the method for the interior gateway protocol (IGP) to advertise egress protection availability.

Egress protection availability is advertised in the IGP. Label protocols along with CSPF use this information to do egress protection.

Options

stub-alias—Context identifier has an alias.

In the alias method, the LSP end-point address has an explicit backup egress node where the backup node can be learned or configured on the penultimate hop node (PHN) of a protected LSP. With this model, the PHN of a protected LSP sets up the bypass LSP tunnel to back up the egress node by avoiding the primary egress node. This model requires a Junos OS upgrade in core nodes, but is flexible enough to support all traffic engineering constraints.

stub-proxy—Context-identifier has a stub proxy node.

A stub node is one that only appears at the end of an AS path, which means it does not provide transit service. In this mode, known as the virtual or proxy mode, the LSP end-point address is represented as a node with bidirectional links, with the LSP's primary egress node and backup egress node. With this representation, the penultimate hop of the LSP primary egress point can behave like a PLR in setting up a bypass tunnel to back up the egress by avoiding the primary egress node. This model has the advantage that you do not need to upgrade Junos OS on core nodes and thereby helps operators to deploy this technology.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

always-mark-connection-protection-tlv

Syntax

```
always-mark-connection-protection-tlv;
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols mpls interface interface-name],  
[edit protocols mpls interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 10.2.

Description

(MX Series routers only) Enable you to switch an LSP away from a network node using a bypass LSP. This feature could be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.

This statement marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, you then need to configure the **switch-away-lsps** statement.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

associate-backup-pe-groups;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],  
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 9.0.

Description

Enable an LSP to monitor the status of its destination PE router. You can configure multiple backup PE router groups using the same router's address. Backup PE router groups provide ingress PE router redundancy when point-to-multipoint LSPs are configured for multicast distribution. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. This statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to the destination address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for QFX Series switches.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Allow an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel.

NOTE: In calculating the value for **Max AvgBW** (relative to the ingress LSP), the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.

Options

adjust-threshold-absolute *adjust-threshold-absolute-value*—Configure an absolute value based threshold along with the percentage based threshold that helps avoid the bandwidth getting triggered for LSPs of both small and large bandwidth reservations.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for QFX10000 Series switches in release 15.1X53-D40.

Description

Enable the automatic policing of all the MPLS LSPs on the router or logical system.

Options

class all—Apply the same policer action to all the class types (**ct0**, **ct1**, **ct2**, and **ct3**).

class ctnumber—Specific class type (**ct0**, **ct1**, **ct2**, or **ct3**) to which to apply a policer action.

Policer actions—You can specify the following policer actions:

Default: no action

- **drop**—Drop all packets.
- **loss-priority-high**—Set the packet loss priority (PLP) to high.
- **loss-priority-low**—Set the PLP to low.

Required Privilege Level

routing—To view this statement in the configuration.

[edit protocols mpls label-switched-path lsp-name fast-reroute],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

When configuring an LSP, specify the traffic rate associated with the LSP.

When configuring fast reroute, allocate bandwidth for the reroute path. By default, no bandwidth is reserved for the rerouted path. The fast reroute bandwidth does not need to be identical to that allocated for the LSP itself.

When configuring a multiclass LSP, use the **ctnumber bandwidth** statements to specify the bandwidth to be allocated for each class type.

Options

bps—Bandwidth, in bits per second. You can specify this as an integer value. You can also use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

NOTE: On the ACX Series, *bps* is the only supported option.

ctnumber bps—Bandwidth for the specified class type, in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion [also called a thousand million]).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify that the label-switched path be a passive LSP associated with a bidirectional LSP when it is signaled at the ingress router. This passive LSP enables the MPLS application to utilize the reverse LSP. You cannot configure this statement at the same time as the **corouted-bidirectional** statement.

Default

This statement is disabled by default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

credibility

Syntax

```
credibility {  
    direct;  
    isis-level-1;  
    isis-level-2;  
    ospf;  
    static;  
    unknown;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls traffic-engineering database export],  
[edit protocols mpls traffic-engineering database export]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.1R1 on QFX Series and QFX10000 switches.

Description

Configure preference values for entries from BGP-TE to the traffic engineering database. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value.

The credibility order for the BGP-TE protocols is as follows:

- **Unknown**—80
- **OSPF**—81
- **ISIS Level 1**—82
- **ISIS Level 2**—83
- **Static**—84
- **Direct**—85

Options

direct— Entries sourced from directly connected links.

isis-level-1—Entries sourced from IS-IS Level 1.

isis-level-2—Entries sourced from IS-IS Level 2.

ospf—Entries sourced from OSPF.

static—Entries sourced from static configuration.

unknown—Entries sourced from unknown entities.

Range: 0 through 512

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

delay (responder)

Syntax

```
delay {
  min-query-interval milliseconds;
}
```

Hierarchy Level

```
[edit protocols mpls oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name primary path-name oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name secondary path-name oam performance-monitoring responder]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure delay measurement options.

Options

min-query-interval *milliseconds*—(Optional) Specify the minimum query interval that the responder supports. If the minimum query interval of the responder is greater than the query interval configured at querier, the effective message query rate will be the minimum query interval configured for the responder.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

dual-transport

Syntax

```
dual-transport {  
    inet-lsr-id inet-lsr-id;  
    inet6-lsr-id inet6-lsr-id;  
}
```

Hierarchy Level

[edit protocols ldp]

Release Information

Statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description

Configure to allow Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. **inet-lsr-id** and **inet6-lsr-id** are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Options

inet-lsr-id *inet-lsr-id*— Configure the LSR ID to establish an LDP session over IPv4 TCP transport.

inet6-lsr-id *inet6-lsr-id*— Configure the LSR ID to establish an LDP session over IPv6 TCP transport.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

dynamic (Source Packet Routing)

Syntax

```
dynamic {  
  protected {  
    mandatory;  
  }  
  unprotected {  
    mandatory;  
  }  
}
```

Hierarchy Level

[edit protocols source-packet-routing [segment-list](#)]

Release Information

Statement introduced in Junos OS Release 19.2R1 on all platforms.

Description

Enable dynamic computation of segment routing label-switched paths (LSPs) based on tunnel destination and translation service to fetch the corresponding segment identifiers (SIDs).

NOTE:

When the dynamic statement is enabled, all the next hops must have an IP address assigned as a minimum configuration. In the case of segment-lists, if a next hop has both IP address and label configured, then the configured label is retained.

NOTE:

- Because translation service use IGP instance of traffic-engineered database (TED), you must include the **igp-topology** statement at the **[edit protocols isis traffic-engineering]** hierarchy level for successful translation.
- The **auto-translation** and **dynamic** statements are mutually exclusive, and only either of them can be configured under a segment-list.

Options

protected—(Optional) Ensures a protected adjacency SID is used for the links of the LSP.

unprotected—(Optional) Ensures an unprotected adjacency SID is used for the links of the LSP.

mandatory—(Optional) Enabled translation to fail if the specified type of adjacency SID cannot be found for a link. This option does not have effect on node SIDs.

Required Privilege Level

[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Configure a dynamic tunnel between two PE routers.

NOTE: ACX Series routers do not support the **gre** statement.

Configure dynamic IPv4-over-IPv6 tunnels and define their attributes to forward IPv4 traffic over an IPv6-only network. IPv4 traffic is tunneled from customer premises equipment to IPv4-over-IPv6 gateways. You must also configure **extended-nexthop** option at **[edit protocols bgp family inet unicast]** hierarchy level to allow BGP to route IPv4 address families over an IPv6 session.

Options

gre—Enable dynamic generic routing encapsulation type tunnel mode for IPv4

Values:

- **next-hop-based-tunnel**—Enable next hop base dynamic-tunnel for steering IPv4 traffic with IPv6 next hop address.

source-address—Specify the source address of the tunnel.

tunnel-name—Name of the dynamic tunnel.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

entropy-label

Syntax

```
entropy-label {  
    ingress-policy ingress-policy-name;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Assists the transit router in load-balancing MPLS traffic across ECMP paths or Link Aggregation groups by introducing the entropy label to the MPLS label stack. The entropy label allows routers to load balance MPLS traffic by using a hash-input without the need to perform deep packet inspection. Deep packet inspection requires more of the router's processing power and is not a capability shared by all routers.

Options

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols bgp family inet labeled-unicast],
[edit protocols bgp group group-name family inet labeled-unicast],
[edit protocols bgp group group-name neighbor address labeled-unicast]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Insert the entropy label into the BGP labeled unicast LSP packets, which assists the transit router in load-balancing BGP traffic across equal-cost multipaths or link aggregation groups. The ingress label edge router inspects the flow information of a packet and maps it to an entropy label, which is inserted into the BGP label stack. LSRs in the core use this entropy label as the key to hash the packet and direct it to the correct path.

Options

import *policy-name*— (Optional) Specify a policy that lists the routes that allow the use of entropy labels.

no-next-hop-validation—(Optional) Do not validate the next-hop field in the entropy label capability attribute against the route next hop.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name link-protection bypass destination],  
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass destination]
```

Release Information

Statement introduced in Junos OS Release 11.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Exclude Shared Risk Link Group (SRLG) links for the secondary path for critical links where it is imperative to keep the secondary and primary label-switched paths completely disjoint from any common SRLG.

When specified, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. When not specified and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

Required Privilege Level

routing—To view this statement in the configuration.

  [edit class-of-service code-point-aliases],
  [edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules],
  [edit class-of-service rewrite-rules]
```

Release Information

Statement introduced in Junos OS Release 10.1 for EX Series switches.

Description

Define the experimental bits (EXP) code point mapping that is applied to MPLS packets. You can define an **exp** classifier only on EX3200 switches, EX4200 and EX8200 standalone switches, and EX8200 Virtual Chassis. You can bind an **exp** rewrite rule on EX8200 standalone switches and EX8200 Virtual Chassis.

EX Series switches support only one EXP code mapping on the switch (either default or custom). It is applied globally and implicitly to all the MPLS-enabled interfaces on the switch. You cannot bind it or disable it on individual interfaces.

Options

classifier-name—Name of the classifier.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

expand-loose-hop

Syntax

```
expand-loose-hop;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced in Junos OS Release 7.6.

Point-to-multipoint LSP support introduced in Junos OS Release 11.2.

Description

Allow an LSP to traverse multiple OSPF areas within a service provider's network.

Allows a point-to-multipoint LSP to span multiple domains in a network. Effectively, this allows you to configure one or more sub-LSPs (branches) in separate network domains. Examples of such domains include OSPF areas and autonomous systems (ASs). A sub-LSP of an inter-domain point-to-multipoint LSP can be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source). Only OSPF areas are supported for inter-domain point-to-multipoint LSPs. IS-IS levels are not supported.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

explicit-null (Protocols MPLS)

Syntax

```
explicit-null;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Advertise label 0 to the egress router of an LSP.

Default

If you do not include the **explicit-null** statement in the MPLS configuration, label 3 (implicit null) is advertised.

NOTE: Junos OS does not support explicit null routes with next hops to virtual tunnel (vt-) interfaces.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

failure-action (Protocols MPLS)

Syntax

```
failure-action {  
    make-before-break teardown-timeout seconds;  
    teardown;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls oam bfd-liveness-detection],  
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name oam bfd-liveness-detection],  
[edit protocols mpls label-switched-path lsp-name oam bfd-liveness-detection],  
[edit protocols mpls oam bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Configure route and next-hop properties in the event of a Bidirectional Forwarding Detection (BFD) protocol session failure event on an RSVP label-switched path (LSP). The failure event could be an existing BFD session that has gone down or a BFD session that never came up. RSVP adds back the route or next hop when the relevant BFD session comes back up.

Options

make-before-break—When a BFD session fails for an RSVP LSP, an attempt is made to signal a new LSP path before tearing down the old LSP path.

teardown—When a BFD session fails for an RSVP LSP, the associated LSP path is taken down and resigaled immediately.

teardown-timeout *seconds*—When you configure the **make-before-break** option, you can specify a time in seconds for the **teardown-timeout** option. At the end of the time specified, the associated RSVP LSP is automatically torn down and resigaled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

family

Syntax

```
family {  
    inet;  
    inet6;  
}
```

Hierarchy Level

```

        source-msb;
        source-lsb;
        destination-msb;
        destination-lsb;
      }
    }
  }
}
```

Hierarchy Level

[edit forwarding-options hash-key]

Release Information

Statement introduced before Junos OS Release 7.4.

no-label-1-exp option introduced in Junos OS Release 8.0.

label-3 and **no-labels** options introduced in Junos OS Release 8.1.

ether-pseudowire statement introduced in Junos OS Release 9.1 (M320 and T Series routers only); support extended to M120 and MX Series routers in Junos OS Release 9.4.

all-labels and **payload ip disable** options introduced in Junos OS Release 12.1X48R2. (PTX Series Packet Transport Routers only).

zero-control-word option introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

Description

For aggregated Ethernet and SONET/SDH interfaces only, configure load balancing based on MPLS labels and payload. Only the IPv4 protocol is supported.

Options

family mpls—(Aggregated Ethernet interfaces, aggregated SONET/SDH interfaces, and multiple equal-cost MPLS next hops only) Incorporate MPLS label and payload information into the hash key for per-flow load balancing. Only the IPv4 protocol is supported.

- **all-labels**—(PTX Series Packet Transport Routers only) Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This is the default setting.
- **label-1**—(M120, M320, MX Series, and T Series routers only) Include the first MPLS label into the hash key. This is used for a one-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels.
- **label-2**—(M120, M320, MX Series, and T Series routers only) Include the second MPLS label into the hash key. This is used for a two-label packet for per-flow load balancing IPv4 VPLS traffic based on IP information and MPLS labels. To use the second MPLS label in the hash key, include both the **label-1** and **label-2** statements at the **[edit forwarding-options hash-key family mpls]** hierarchy level. By default, the router provides hashing on the first and second labels. If both labels are specified, the entire first label and the first 16 bits of the second label are hashed.
- **label-3**—(M120, M320, MX Series, and T Series routers only) Include the third MPLS label into the hash key. To use the third MPLS label, include the **label-1**, **label-2**, and **label-3** statements at the **[edit forwarding-options hash-key family mpls]** hierarchy level.
- **no-labels**—Include no MPLS labels into the hash key.
- **no-label-1-exp**—(M120, M320, MX Series, and T Series routers only) The EXP bit of the first label is not used in the hash calculation to avoid reordering complications.
- **payload**—Incorporate bits from the IP payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
 - **disable**—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
 - **ether-pseudowire**—(M120, M320, MX Series, and T Series routers only) Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.
 - **zero-control-word**—(M Series, MX Series, and PTX Series) Precedes Ethernet packet to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.
 - **ip**—Include the IP address of the IPv4 or IPv6 payload into the hash key for per-flow load balancing Layer 2 information based on MPLS labels. For the PTX Series Packet Transport Routers, this is the default setting with both Layer 3 and Layer 4 IP information included in the hash key.
 - **disable**—(PTX Series Packet Transport Routers only) Exclude IP payload from the hash key.
 - **layer-3-only**—Include only Layer 3 IP information from the IP payload data into the hash key for per-flow load balancing Layer 2 information based on MPLS labels.
 - **port-data**—(M120, M320, MX Series, and T Series routers only) Include the source and destination port field information into the hash key. By default, the most significant byte and least significant byte of the source and destination port fields are hashed. To select specific bytes to be hashed,

include one or more of the **source-msb**, **source-lsb**, **destination-msb**, and **destination-lsb** options at the **[edit forwarding-options hash-key family mpls payload ip port-data]** hierarchy level. To prevent all four bytes from being hashed, include the **layer-3-only** statement at the **[edit forwarding-options hash-key family mpls payload ip]** hierarchy level.

- **destination-lsb**—Include the least-significant byte of the destination port.
- **destination-msb**—Include the most-significant byte of the destination port.
- **source-lsb**—Include the least-significant byte of the source port.
- **source-msb**—Include the most-significant byte of the source port.

Required Privilege Level

[edit routing-instances routing-instance-name routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Specify a backup path in case the primary path becomes unusable.

You specify one or more objects with common characteristics within a group. All objects are treated as /32 host addresses. The objects can be a LAN interface, a router ID, or a point-to-point link. Sequence is insignificant.

Changing the fate-sharing database does not affect existing established LSPs until the next CSPF reoptimization. The fate-sharing database does affect fast-reroute detour path computations.

Options

cost *value*—Cost assigned to the group.

Range: 1 through 65,535

Default: 1

from *address*—Address of the router or address of the LAN/NBMA interface. For example, an Ethernet network with four hosts in the same fate-sharing group would require you to list all four of the separate **from** addresses in the group.

group *group-name*—Each fate-sharing group must have a name, which can have a maximum of 32 characters, including letters, numbers, periods (.), and hyphens (-). You can define up to 512 groups.

to *address*—(Optional) Address of egress router. For point-to-point link objects, you must specify both a **from** and a **to** address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

gre (Routing Options)

Syntax

```
gre;  
next-hop-based-tunnel;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options dynamic-tunnels tunnel-name],  
[edit routing-options dynamic-tunnels tunnel-name]
```

Release Information

Statement introduced in Junos OS Release 10.1.

next-hop-based-tunnel option introduced in Junos OS Release 16.2.

Description

Enable generic routing encapsulation (GRE) type for IPv4 to automatically establish label-switched paths (LSPs) for any new provider edge (PE) router added to a full mesh of LSPs.

Options

next-hop-based-tunnel—Create a tunnel composite next hop for every dynamic GRE tunnel configured.

The tunnel composite next hop includes the dynamic tunnel's encapsulation data and a VPN label (when chained composite next hop is not enabled). When this option is not configured, the default interface-based tunnel mode is enabled. By configuring this option, a device can scale up to 32,000 IP tunnels, which is otherwise restricted to the system limit on the number of interfaces supported.

At a given point in time, either the next-hop-based dynamic tunnel or the default interface-based dynamic GRE tunnel can exist on a device. A switchover from one tunnel mode to another deletes the existing tunnels and creates new tunnels in the new tunnel mode. As a result, a tunnel mode switchover can impact network performance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

Range: 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)

Default: 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

import (MPLS Traffic Engineering Database)

Syntax

```
import {
  bgp-ls-identifier domain-identifier;
  identifier identifier;
  policy policy-name;
  igp-topology{
    bgp-link-state;
  }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls traffic-engineering database],
[edit protocols mpls traffic-engineering database]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Configure the traffic engineering database import parameters.

Options

bgp-ls-identifier *domain-identifier*—BGP-TE domain identifier.

identifier *identifier*—BGP-TE identifier.

Range: 2 through 18446744073709551615

policy *policy-name*—Name of the import policy.

igp-topology—Download IGP topology information into the traffic engineering database (TED). In Junos OS, the IGP installs topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. The IGP routes are installed by the traffic engineering database on behalf of the corresponding IGP into a user-visible routing table called `Isdist.0`, subject to route policies.

bgp-link-state—Export IGP topology information into BGP-Link State (BGP-LS) from the `Isdist.0` routing table. The `Isdist.0` routing table stores the network topology information from the traffic engineering database. The BGP-LS reads IGP entries from `Isdist.0` and advertises the information to BGP peers.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

    mode (strict | loose);  
    fail-filter filter-name;  
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
```

Release Information

Statement introduced in Junos OS Release 17.1 for MX Series Routers with MICs.

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (strict | loose)—(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

Default: If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*—(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 18.4R1 on MX Series routers with MPC and MIC interfaces.

Description

Define Layer 3 and Layer 4 match items to match IPv4 packets for IP-based filtering of MPLS traffic.

Options

destination-address *ip-address*—Match MPLS traffic with the specified IPv4 destination address.

destination-prefix-list *destination-prefix-list-name*—Match MPLS traffic with the specified IPv4 destination prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level.

protocol *protocol*—Specify one or a range of inner IPv4 protocols for IP-based filtering of MPLS traffic.

source-address *ip-address*—Match MPLS traffic with the specified IPv4 source address.

source-prefix-list *source-prefix-list-name*—Match MPLS traffic with the specified IPv4 source prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

ipv6 (Family MPLS)

Syntax

```

ipv6 {
  destination-address destination-ip-address {
    except;
  }
  destination-prefix-list prefix-list-name {
    except;
  }
  protocol protocol {
    (source-port | source-port-except);
    (destination-port | destination-port-except);
  }
  source-address ip-address {
    except;
  }
  source-prefix-list source-prefix-list-name {
    except;
  }
}

```

Hierarchy Level

```
[edit firewall family mpls filter name term name from ip-version],
```

Release Information

Statement introduced in Junos OS Release 18.4R1 on MX Series routers with MPC and MIC interfaces.

Description

Define Layer 3 and Layer 4 match items to match IPv6 packets for IP-based filtering of MPLS traffic.

Options

destination-address *ip-address*—Match MPLS traffic with the specified IPv6 destination address.

destination-prefix-list *destination-prefix-list-name*—Match MPLS traffic with the specified list of IPv6 destination prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level. You must configure separate prefix-lists for IPv4 and IPv6 addresses.

protocol *protocol*—Specify one or a range of inner IPv6 next header for IP-based filtering of MPLS traffic.

source-address *ip-address*—Match MPLS traffic with the specified IPv6 source address.

source-prefix-list *source-prefix-list-name*—Match MPLS traffic with the specified IPv6 source prefixes. The prefix-list is defined under the **[edit policy-options prefix-list *prefix-list-name*]** hierarchy level. You must configure separate prefix-lists for IPv4 and IPv6 addresses.

Required Privilege Level

firewall

ip-version (Family MPLS)

Syntax

```
ip-version {
  ipv4;
  ipv6;
}
```

Hierarchy Level

```
[edit firewall family mpls filter name term name from]
```

Release Information

Statement introduced in Junos OS Release 18.4R1 on MX Series routers with MPC and MIC interfaces.

Description

Specify inner IP version to enable IP-based filtering of MPLS family filter.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

Required Privilege Level

firewall—To view this statement in the configuration.

[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
[edit protocols source-packet-routing source-routing-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Support at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level introduced in Junos OS Release 19.1R1.

Description

Associate one or more prefixes with an LSP. When the LSP is up, all the prefixes are installed as entries into the inet.3 or inet6.3 routing table.

The support of the **install** statement at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** is applicable for both colored and non-colored segment routing LSPs.

For static colored LSPs, when the install prefix is configured, a route similar to the tunnel ingress route is installed in the **inetcolor.0** or **inet6color.0** routing table.

On the other hand, for static non-colored LSPs, when the install prefix is configured, a route similar to the tunnel **to** route is installed in **inet.3** or **inet6.3** routing table.

You can use the [show route table](#) command to view the **install** routes for both colored and non-colored segment routing traffic-engineered LSPs.

NOTE:

Take the following into consideration when configuring the **install *destination-prefix*** statement at the **[edit protocols source-packet-routing source-routing-path *lsp-name*]** hierarchy level:

- The install prefixes should be unique in a tunnel, and should not be the same as the tunnel **to** address. A commit check is done to ensure that the prefixes are unique.
- If two install prefixes are same across two different tunnels, then the gateways of the both tunnels are considered only if the segment lists are of the same resolution type. If the first hop resolution types vary, the route is not installed. In such cases, a system log message is generated to record the error.

For example:

```
[edit protocols source-packet-routing]
segment-list path-1 {
  hop-1 ip-address 172.0.12.2;
  hop-2 label 1000012;
  hop-3 label 1000013;
  hop-4 label 1000014;
}
source-routing-path lsp1 {
  to 10.10.10.1;
  install 20.20.20.2;
  install 30.30.30.3;
  primary {
    path-1;
  }
}
```

The **inet.3** routing table has two additional routes (to 20.20.20.2 and 30.30.30.3) with next hops derived from the same segment list path-1 with same attributes as the **to** address route.

Options

active—(Optional) Install the route into the inet.0 or inet6.0 routing table. This allows you to issue a **ping** or **traceroute** command on this address.

NOTE: The **install *destination-prefix* active** statement is not supported on static LSPs. When the **install *destination-prefix* active** statement is configured for a static LSP, the MPLS routes do not get installed into the inet.0 routing table.

destination-prefix—IPv4 or IPv6 address to associate with the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-system logical-system-name protocols ldp oam],  
[edit protocols ldp entropy-label],  
[edit protocols ldp oam]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Statement introduced at the **[edit protocols ldp entropy-label]** hierarchy level in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Configure an LDP ingress policy for either the entropy label or Operation, Administration, and Management (OAM).

For OAM, configure the ingress policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

Options

ingress-policy-names—Specify the names of the ingress policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ip-tunnel-rpf-check

Syntax

```
ip-tunnel-rpf-check {
    mode (strict | loose);
    fail-filter filter-name;
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
```

Release Information

Statement introduced in Junos OS Release 17.1 for MX Series Routers with MICs.

Description

Configure the system to enable anti-spoofing protection for next-hop-based dynamic tunnels, where reverse path forwarding checks are placed to ensure that the tunnel traffic is received from a legitimate source through designated IP tunnel, where the source is reachable on the same tunnel on which the packet was received.

When a packet comes from a nondesignated source, the reverse path forwarding check fails in the strict mode, and passes in the loose mode. When a packet comes from a nonexistent source, the reverse path forwarding check fails.

By default, the reverse path forwarding check is in strict mode, where the packets are not forwarded if the source of the packet is from a nondesignated tunnel.

Options

mode (strict | loose)—(Optional) Specify the mode of the reverse path forwarding check to enable anti-spoofing protection for next-hop-based dynamic tunnels.

In the strict mode (default), the reverse path forwarding check fails when the packet is received from a nondesignated tunnel source. The check passes only for packets from designated tunnels.

In the loose mode, the reverse path forwarding check passes even if the packet is received from a nondesignated tunnel source.

When the packet is from a nonexistent tunnel source, the reverse path forwarding check fails in both the strict and loose modes.

Default: If you omit the mode statement, the default behavior is strict mode.

fail-filter *filter-name*—(Optional) Attach a filter to the Layer 3 VPN to log packets that failed the reverse path forwarding check.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ipv6-tunneling

Syntax

```
ipv6-tunneling;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches.

Description

Allow IPv6 routes to be resolved over an MPLS network by converting LDP and RSVP routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

cross-credibility-cspf option introduced in Junos OS Release 14.2.

self-ping-duration and **no-self-ping** options introduced in Junos OS Release 16.1.

Description

Configure an LSP to use in dynamic MPLS. When configuring an LSP, you must specify the address of the egress router in the **to** statement. All remaining statements are optional.

Options

lsp-name—Name that identifies the LSP. The name can be up to 64 characters and can contain letters, digits, periods, and hyphens. To include other characters, enclose the name in quotation marks. The name must be unique within the ingress router.

cross-credibility-cspf—Enable path computation across credibility levels. The constraint path computation is run across multi-protocol links and nodes, instead of a credibility-by-credibility basis.

link-protection—Enable protection for LSP from link faults only.

no-self-ping—Disable self-ping for the LSP.

NOTE: Starting in Junos OS 17.4, you can override the behavior of self-ping running by default using ***no-self-ping*** statement.

self-ping-duration seconds—Specify the duration (in seconds) for which to run the self-ping mechanism unless the ping succeeds sooner.

LSP self-ping for an LSP starts at the ingress label edge router (LER), once a Resv message for that LSP has been received. The configured self-ping time indicates the duration for which the self-ping mechanism runs once the LSP instance is signaled to be **UP**.

By default, self-ping is enabled. The LSP types like CCC, P2MP, VLAN-based , and non-default instances do not support self-ping .

The self-ping mechanism runs until the self-ping probe is received back (at which point the traffic is immediately switched to it) , or until the configured self-ping duration for the LSP is over (at which point traffic is switched over).

When LSP self-ping-duration is enabled, the LSP behavior reverts back to a timer-based mechanism similar to the ***optimize-switchover-delay***, where a specific amount of time is provided for all the downstream nodes to install the forwarding path before switchover. When LSP self-ping-duration is not enabled, the default behavior is to wait for an infinite amount of time for the self-ping to succeed before switching the traffic.

Range: 1 through 65535 seconds

NOTE: Starting in Junos OS 17.4R1, the default time-out duration for which the self-ping runs on an LSP instance is reduced from 65535 (runs until success) to 1800 seconds. You can also configure the self ping duration value between 1 to 65535 (runs until success) seconds.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Statement introduced in Junos OS Release 18.2. under the heirarchy level [edit routing-instances *instance-name* provider-tunnel]

Description

Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs.

Options

default-template—Specify that the default LSP template be used for the dynamically generated LSPs.

lsp-template-name—Specify the name of an LSP to be used as a template for the dynamically generated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[container-label-switched-path](#) | 1701

ldp-tunneling

Syntax

```
ldp-tunneling;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],  
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable the LSP to be used for LDP tunneling.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

link-protection (Dynamic LSPs)

Syntax

```
link-protection;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],  
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable link protection on the specified LSP, which helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails. For point-to-multipoint LSPs, including this statement extends link protection to all of the paths used by the LSP.

To fully enable link protection, you must also include the **link-protection** statement at the **[edit protocols rsvp interface *interface-name*]** or **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]** hierarchy level.

Default

Link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[link-protection \(RSVP\) | 1983](#)

link-protection (Static LSPs)

Syntax

```
link-protection bypass-name name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name ingress],  
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name ingress],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced in Junos OS Release 10.1.

Description

Enable link protection on the specified static LSP. Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

Default

Link protection is disabled.

Options

bypass-name *name*—Bypass LSP name.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

load-balance-label-capability

Syntax

```
load-balance-label-capability;
```

Hierarchy Level

```
[edit forwarding-options]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Description

Enables the router to push and pop the load balancing label and causes LDP and RSVP to advertise the entropy label TLV to neighboring routers.

The **load-balance-label-capability** and **no-load-balance-label-capability** statements at the **[edit forwarding-options]** hierarchy level are mutually exclusive, and at a given point in time, configuring one statement overrides the other.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

RELATED DOCUMENTATION

log-updown (Protocols MPLS)

Syntax

```
log-updown {  
  no-trap {  
    mpls-lsp-traps;  
    rfc3812-traps;  
  }  
  (syslog | no-syslog);  
  trap;  
  trap-path-down;  
  trap-path-up;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

The **mpls-lsp-traps** and **rfc-3812-traps** options added in Junos OS Release 9.0.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Log a message or send an SNMP trap whenever an LSP makes a transition from up to down, or vice versa, and whenever an LSP switches from one active path to another. Only the ingress router performs these operations.

NOTE: System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the **no-syslog** option under the **log-updown** statement.

Default

There is no default behavior for this statement. If you do not specify the options, the configuration cannot be committed.

Options

no-syslog—Do not log a message to the system log file.

no-trap—Do not send an SNMP trap.

syslog—Log a message to the system log file.

trap—Send an SNMP trap.

trap-path-down—Send an SNMP trap when an LSP path goes down.

trap-path-up—Send an SNMP trap when an LSP path comes up.

The **no-trap** statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

longest-match

Syntax

```
longest-match {  
  policy value |(expression) | [values ];  
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 16.1 for the M Series, MX Series, and PTX Series.

Description

Enable longest match to allow LDP to learn the routes aggregated or summarized across OSPF areas or IS-IS levels in inter-domain.

Options

policy *value* |(expression) | [*values*]— Specify policy to provide per prefix granularity.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

loss (responder)

Syntax

```
loss {
  min-query-interval milliseconds;
}
```

Hierarchy Level

```
[edit protocols mpls oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name primary path-name oam performance-monitoring responder],
[edit protocols mpls label-switched-path lsp-name secondary path-name oam performance-monitoring responder]
```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure loss measurement options.

Options

min-query-interval *milliseconds*—(Optional) Specify the minimum query interval that the responder supports. If the minimum query interval of the responder is greater than the query interval configured at the querier, the effective message query rate is the minimum query interval configured for the responder.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

lsp-attributes

Syntax

```
lsp-attributes {
  encoding-type (ethernet | packet | pdh | sonet-sdh);
  gpid (ethernet | hdlc | ipv4 | pos-scrambling-crc-16 | pos-no-scrambling-crc-16 | pos-scrambling-crc-32 |
    pos-no-scrambling-crc-32 | ppp);
  signal-bandwidth type;
  switching-type (fiber | lambda | psc-1 | tdm);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

pos-scrambling-crc-16, **pos-no-scrambling-crc-16**, **pos-scrambling-crc-32**, and **pos-no-scrambling-crc-32** options added in Junos OS Release 8.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Define the parameters signaled during LSP setup. These usually determine the nature of the resource (label) allocated for the LSP.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

lsping-channel-type

Syntax

```
lsping-channle-type {
  ipv4;
  on-demand-cv;
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name oam mpls-tp-mode]
[edit protocols mpls oam mpls-tp-mode]
```

Release Information

Statement introduced in Junos OS Release 16.1.

Description

Specify the control-channel types for MPLS-TP mode. By default, LSPING (0x0008) is used, and the GACH-TLV is used along with this channel type.

As per RFC 7026, GACH-TLV is deprecated for ipv4 and on-demand-cv channel types.

Options

ipv4—Channel type 0x0021. This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

on-demand-cv—Channel type 0x0025. This is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

minimum-bandwidth

Syntax

```
minimum-bandwidth bps;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],  
[edit protocols mpls label-switched-path lsp-name auto-bandwidth]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Set the minimum bandwidth in bps for an LSP with automatic bandwidth allocation enabled.

NOTE: For a label-switched path (LSP) that has both **bandwidth** and **minimum-bandwidth** for autobandwidth configured under the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level, the LSP bandwidth is adjusted differently.

The LSP is initiated with the bandwidth value configured under the **bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. At the expiry of the **adjust-interval** timer, the LSP bandwidth gets adjusted based on the traffic flow.

If the bandwidth to be signaled is less than the value configured under the **minimum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the minimum bandwidth.

If the bandwidth to be signaled is greater than the value configured under the **maximum-bandwidth** statement at the **[edit protocols mpls label-switched-path lsp-name autobandwidth]** hierarchy level, then the LSP is signaled only using the maximum bandwidth.

Options

bps—Minimum bandwidth for the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth](#) | 519

monitor-bandwidth

Syntax

[edit protocols l2circuit]

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Description

Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router or switch to the local customer edge (CE) router or switch. All the Layer 2 circuits using a particular remote PE router or switch designated for remote CE routers or switches are listed under the **neighbor** statement (neighbor designates the PE router or switch). Each neighbor is identified by its IP address and is usually the end-point destination for the LSP tunnel (transporting the Layer 2 circuit).

Options

address—IP address of a neighboring router or switch.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-bfd-triggered-local-repair

Syntax

```
no-bfd-triggered-local-repair;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],  
[edit routing-options]
```

Release Information

Statement introduced in Junos OS Release 12.2.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Disable Bidirectional Forwarding Detection (BFD) sessions to trigger fast reroute (FRR) using MPLS-FRR and loop-free alternates (LFAs). When this statement is configured, no BFD-triggered local repair is supported. However, logical interface down-based local repair is in force.

When using this statement to disable local repair, you also must restart routing to ensure proper behavior. To restart routing, include the **graceful-restart** command for the interior gateway protocol (IGP) used in your configuration. For example, if your IGP is OSPF, include the **graceful-restart** statement at the [edit protocols ospf] hierarchy level.

Default

BFD-triggered local repair is the default behavior. The loss of a neighbor results in BFD local repair for all next hops that derive themselves from the base next hop with which the BFD session is established.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable constrained-path LSP computation.

An explicit-path LSP is completely configured through operator action. Once configured, it is initiated only along the explicitly specified path.

A constrained-path LSP relies on an ingress router to compute the complete path. The ingress router takes into account the following information during the computation:

- Interior gateway protocol (IGP) topology database
- Link utilization information from extensions in the IGP link-state database
- Administrative group information from extensions in the IGP link-state database
- LSP requirements, including bandwidth, hop count, and administrative group

Constrained-path LSPs can generally avoid link failures and congested links. They also permit recomputation (therefore, a new path) during topology changes or unsuccessful setup.

Default

Constrained-path LSP computation enabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 on the QFX Series.

Statement introduced in Junos OS Evolved Release 19.3R1 on PTX10003.

Statement introduced in Junos OS Evolved Release 20.1R1 on PTX10008.

Description

Disable normal time-to-live (TTL) decrementing, which decrements the TTL field in the IP header by 1. This statement decrements the IP TTL by 1 before encapsulating the IP packet within an MPLS packet. When the penultimate router pops off the top label, it does not use the standard write-back procedure of writing the MPLS TTL into the IP TTL field. Therefore, the IP packet is decremented by 1. The ultimate router then decrements the packet by one more for a total cloud appearance of 2, thus hiding the network topology.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit routing-instances routing-instance-name routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.1 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

You configure the graceful restart routing option globally to enable the feature, but not to enable graceful restart for all routing protocols in a routing instance. To enable graceful restart globally, include the graceful-restart statement under the **[edit routing options]** hierarchy level. This enables graceful restart globally for all routing protocols. You can, optionally, modify the global settings at the individual protocol level.

NOTE:

- For VPNs, the **graceful-restart** statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.
- For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.
- LDP sessions flap when **graceful-restart** configurations change.

Default

Graceful restart is disabled by default.

Options

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-load-balance-label-capability

Syntax

```
no-load-balance-label-capability;
```

Hierarchy Level

```
[edit forwarding-options]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Description

Disables advertisement of entropy label capability in LDP and RSVP.

When you configure the **no-load-balance-label-capability** statement, it also disables the flow-aware transport of pseudowires (FAT) flow label for FEC 128.

The **load-balance-label-capability** and **no-load-balance-label-capability** statements at the **[edit forwarding-options]** hierarchy level are mutually exclusive, and at a given point in time, configuring one statement overrides the other.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

no-mcast-replication

Syntax

```
no-mcast-replication;
```

Hierarchy Level

```
[edit chassis fpc slot-number pic pic-number],  
[edit chassis lcc number fpc slot-number pic pic-number]
```

Release Information

Statement introduced in Junos OS Release 11.3.

Description

For point-to-multipoint LSPs configured on T Series routers, protect the Packet Forwarding Engine (PFE) from bandwidth saturation. When a PFE does not need to replicate traffic, the PFE's bandwidth is less likely to become saturated. When you include the **no-mcast-replication** statement, the PFE is forced to be a leaf node in the binary tree. Leaf nodes, unlike branch nodes, do not replicate traffic in the process of forwarding traffic. Because leaf nodes have no children, they do not need to replicate traffic, and thus are less likely to become saturated with traffic.

Default

If you omit the **no-mcast-replication** statement, the PFE can become a branch node or a leaf node. When the PFE becomes a branch node, the PFE must replicate traffic.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

RELATED DOCUMENTATION

no-propagate-ttl

Syntax

```
no-propagate-ttl;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 on the QFX Series.

Statement introduced in Junos OS Evolved Release 20.1R1 on PTX10008.

Description

Disable normal time-to-live (TTL) decrementing. You configure this statement once per router, and it affects all RSVP-signaled or LDP-signaled LSPs. When this router acts as an ingress router for an LSP, it pushes an MPLS header with a TTL value of 255, regardless of the IP packet TTL. When the router acts as the penultimate router, it pops the MPLS header without writing the MPLS TTL into the IP packet.

When you add the **no-propagate-ttl** statement to the configuration or delete it from the configuration, the effect takes place immediately. There is no need to clear existing RSVP LSPs or LDP sessions.

Default

Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

node-protection bypass-name name next-next-label label;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name ingress],  
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name ingress],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced in JUNOS Release 10.1.

Description

Enable node protection on the specified static bypass LSP. Node protection ensures that traffic from an LSP traversing a neighboring router can continue to reach its destination even if the neighboring router fails.

Default

Node protection is disabled.

Options

bypass-name *name*—Bypass LSP name.

next-next-label *label*—Bypass LSP name.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

normalization

Syntax

```
normalization {
    failover-normalization;
    no-incremental-normalize;
    normalization-retry-duration seconds;
    normalization-retry-limits number;
    normalize-interval seconds;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.2R1 for QFX Series switches.

Description

Perform normalailzation.

Options

failover-normalization—Enable the ingress router to pro-actively normalize or re-distribute traffic when a link or node failure happens on a member LSP. A member LSP can go down between two scheduled normalization events because of a link-failure or pre-emption.

Default: Disabled

no-incremental-normalize—Disables automatic switchover by the ingress router to a new instance of the container LSP until the desired demand is satisfied, although the given number of LSPs can be successfully signaled such that the new aggregate bandwidth value exceeds the old aggregate bandwidth value.

Default: False (disabled)

normalization-retry-duration *seconds*—Specifies the duration before which the ingress router performs a normalization reattempt when the previous normalization has not been successful. Normalization is done until a sufficient number of LSPs come up with an aggregate bandwidth that is more than the current aggregate or desired bandwidth.

Default: 30 seconds

normalization-retry-limits *number*—Specifies the maximum number of times the ingress router performs normalization reattempts until a sufficient number of LSPs come up successfully with new bandwidth values.

Default: 1

normalize-interval *seconds*—Specifies the duration between two normalization events.

Range: 21600 seconds through 6 hours

Default: 21600 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

lsp-ping-interval option introduced in Junos OS Release 9.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

performance-monitoring configuration statement introduced in Junos OS Release 15.1.

Description

Enable Operation, Administration, and Maintenance (OAM) for RSVP-signaled LSPs.

Options

lsp-ping-interval *seconds*—Specify the duration of the LSP ping interval in seconds. To issue a ping on an RSVP-signaled LSP, use the **ping mpls rsvp** command.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-adaptive-teardown

Syntax

```
optimize-adaptive-teardown {  
  p2p:  
    delay value (3..65535 seconds)  
}
```

Hierarchy Level

[edit protocols mpls]

Release Information

Statement introduced in Junos OS Release 15.1R1.

Description

Make use of a new feedback mechanism from TAG library which relies on RPD infrastructure to decide when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover. When this statement is configured, the **optimize-hold-dead-delay** statement, which delays the teardown of the old LSP instance after MBB switchover, is ignored.

Options

p2p—Only point-to-point LSPs configured in the system will be affected.

delay—Delays the tearing down of old optimized LSP paths based on the configured value.

Range: from 3 through 65535 seconds

Default: 600 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

optimize-aggressive

Syntax

```
optimize-aggressive;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

If enabled, the LSP reoptimization is based solely on the IGP metric. The reoptimization process ignores the available bandwidth ratio calculations, the least-fill 10 percent congestion improvement rule, and the hop-counts rule. This statement makes reoptimization more aggressive than the default.

Default

Aggressive optimization is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-hold-dead-delay

Syntax

```
optimize-hold-dead-delay seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switch-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switch-path lsp-name]
```

Description

Allows you to specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths. This delay timer starts when the timer specified by the **optimize-switchover-delay** statement has elapsed, which is typically 30 seconds, and at the start of the next retry sequence (in other words, the delay is not an absolute countdown of the seconds configured here).

You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The specified delay helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths.

Options

seconds—Configure the time in seconds to wait before tearing down the old paths that were in use prior to the last LSP optimization.

Default: 60 to 90 seconds

Range: 0 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 11.1R1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Delays the switch over of LSPs to newly optimized paths. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The specified delay helps to ensure that the new optimized paths have been established before traffic is switched over from the old paths.

Options

seconds—Configure the time in seconds to wait before switching LSPs to newly optimized paths.

Default: 1 second

Range: 1 through 900 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

Description

Enable periodic reoptimization of an LSP that is already set up. If topology changes occur, an existing path might become suboptimal, and a subsequent recomputation might be able to determine a better path. This feature is useful only on LSPs for which constrained-path computation is enabled; that is, for which the **no-cspf** statement is not configured. Also, you only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers).

To avoid extensive resource consumption that might result because of frequent path recomputations, or to avoid destabilizing the network as a result of constantly changing LSPs, we recommend that you either leave the timer value sufficiently large or disable the timer value.

Default

The optimize timer is disabled.

Options

seconds—Length of the optimize timer, in seconds.

Range: 0 through 65,535 seconds

Default: 0 seconds (the optimize timer is disabled)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for the QFX Series Virtual Chassis and Virtual Chassis Fabric.

abstract-hop-name option introduced in Junos OS Release 17.1 for all platforms.

Description

Create a named path and optionally specify the sequence of explicit routers that form the path.

You must include this statement when configuring explicit LSPs.

Options

abstract-hop-name—Name of the predefined abstract hop. The abstract hop can be used in combination with real IP next hops. An abstract hop is traversed by traversing the member nodes. This traversal can be done by either links that satisfy the logical combination of defined constituent attributes, or by any kind of link. This choice is controlled by the use of abstract hop qualifiers – abstract, loose, loose-link, and strict.

abstract—Indicate that the next hop configured in the **path** statement is an abstract hop..

loose-link—Indicate that the next hop in the **path** statement is a loose-link abstract hop. This means that the LSP cannot traverse other routers before reaching this router. In other words, the abstract hop of type loose-link is processed only if any of the viable routers is reached in constraint through a link of associated abstract hop membership.

loose—Indicate that the next hop in the **path** statement is a loose abstract hop. The path can traverse any real nodes that do not have abstract hop membership, before reaching a node with abstract hop membership, which is a feasible starting point for processing the next abstract hop.

strict—Indicate that the next hop in the **path** statement is a strict abstract hop. After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership, before reaching a node with abstract hop membership, which is a feasible starting point for processing the next abstract hop.

address—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.

hostname—See **address**.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.

loose—(Optional) Indicate that the next address in the **path** statement is a loose link. This means that the LSP can traverse through other routers before reaching this router.

Default: **strict**

path-name—Name that identifies the sequence of nodes that form an LSP. The name can contain up to 32 characters and can include letters, digits, periods, and hyphens. To include other characters or use a longer name, enclose the name in quotation marks. The name must be unique within the ingress router.

strict—(Optional) Indicate that the LSP must go to the next address specified in the **path** statement without traversing other nodes. This is the default.

Release Information

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Configure path protection on your MPLS network.

Options

destination —Name of a label switched path (LSP). In addition to specifying the name of the configured LSP, you can include some other designation such as **primary-path**.

address —(Optional) IP address of each transit switch (or the IP address of the loopback interface on the switch) in the LSP. If you want to control exactly which switches are selected for the LSP, specify the address or hostname of each transit switch. Specify the addresses in order, starting with the first provider (transit) switch, and continuing sequentially along the path until reaching the egress provider edge switch.

Default: If you do not specify the addresses or hostnames of any switches, the LSP is calculated by the switch.

hostname —(Optional) See **address** .

Default: If you do not specify the addresses or hostnames of any switches, the LSP is calculated by the switch.

loose—(Optional) Indicates that the next address in the **path** statement is a loose link. This means that the LSP can traverse through other switches before reaching this switch.

Default: **strict**

strict—(Optional) Indicates that the LSP must go to the next address specified in the **path** statement without traversing other switches. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 12.1x48 for PTX Series Packet Transport Routers.

Statement introduced in Junos OS Release 12.3 for M Series, T Series, and MX Series routers.

Description

Allocate a unique label for each prefix. The **per-prefix-label** statement helps minimize packet loss in most deployments.

Although allocating a label for each prefix is not generally ideal for scaling, it is assumed that a small number of labels are used for BGP labeled-unicast. When labeled BGP is used to set up transport label-switched paths (LSPs), the common case is that each prefix has a unique next hop. Thus, the use of per-prefix labels does not have an adverse scaling impact. On the contrary, the use of per-prefix labels reduces churn in the network when multipath load balancing is enabled for IPv4 labeled-unicast, and a subset of the paths are withdrawn for some reason.

The advantage of per-prefix labeling is that the advertised upstream label is more stable during network changes. That is, if the downstream label changes, the advertised upstream label remains the same under most scenarios. This way, the upstream router is isolated from the downstream network change, and the overall network is more stable. The greater stability of the advertised upstream label helps to reduce traffic loss during many different network change scenarios.

Default

By default, label allocation is per next-hop router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit tenants name routing-instances name routing-options rib]
```

Release Information

Statement introduced in Junos OS Release 19.1R1 for all platforms.

Description

Create policy-based multipath route using a combination of segment routing traffic-engineered (SR-TE) LDP or RSVP routes and SR-TE IP routes. You can resolve BGP service routes over the multipath route, and apply export policies to steer traffic differently for different prefixes. The policy-based multipath feature is supported for both IP and IPv6 protocols.

Options

policy—Import policy to create policy-based multipath.

NOTE: This statement is supported only at the **[edit routing-option policy-multipath]** hierarchy level.

Any action commands configured in the policy, such as apply, is evaluated using the active route. For non-active routes, the policy is applied to check if the routes can participate in the multipath route or not. Multipath routes inherit all attributes of the active route. These attributes can be modified using the multipath policy configuration.

The remaining statements are explained separately. See [CLI Explorer](#).

Description

Define a routing policy, including subroutine policies.

A *term* is a named structure in which match conditions and actions are defined. Routing policies are made up of one or more terms. Each routing policy term is identified by a term name. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in double quotation marks.

Each term contains a set of match conditions and a set of actions:

- Match conditions are criteria that a route must match before the actions can be applied. If a route matches all criteria, one or more actions are applied to the route.
- Actions specify whether to accept or reject the route, control how a series of policies are evaluated, and manipulate the characteristics associated with a route.

Generally, a router compares a route against the match conditions of each term in a routing policy, starting with the first and moving through the terms in the order in which they are defined, until a match is made and an explicitly configured or default action of **accept** or **reject** is taken. If none of the terms in the policy match the route, the router compares the route against the next policy, and so on, until either an action is taken or the default policy is evaluated.

If none of the match conditions of each term evaluates to true, the final action is executed. The final action is defined in an unnamed term. Additionally, you can define a default action (either **accept** or **reject**) that overrides any action intrinsic to the protocol.

The order of match conditions in a term is not relevant, because a route must match all match conditions in a term for an action to be taken.

To list the routing policies under the **[edit policy-options]** hierarchy level by **policy-statement** *policy-name* in alphabetical order, enter the **show policy-options** configuration command.

The statements are explained separately.

Options

actions—(Optional) One or more actions to take if the conditions match. The actions are described in *Configuring Flow Control Actions*.

family *family-name*—(Optional) Specify an address family protocol. Specify **inet** for IPv4. Specify **inet6** for 128-bit IPv6, and to enable interpretation of IPv6 router filter addresses. For IS-IS traffic, specify **iso**. For IPv4 multicast VPN traffic, specify **inet-mvpn**. For IPv6 multicast VPN traffic, specify **inet6-mvpn**. For multicast-distribution-tree (MDT) IPv4 traffic, specify **inet-mdt**. For BGP route target VPN traffic, specify **route-target**. For traffic engineering, specify **traffic-engineering**.

NOTE: When **family** is not specified, the routing device or routing instance uses the address family or families carried by BGP. If multiprotocol BGP (MP-BGP) is enabled, the policy defaults to the protocol family or families carried in the network layer reachability information (NLRI) as configured in the *family* statement for BGP. If MP-BGP is not enabled, the policy uses the default BGP address family unicast IPv4.

from—(Optional) Match a route based on its source address.

as-path-unique-count *count* (*equal* | *orhigher* | *orlower*)—(Optional) Specify a number from 0 through 1024 to filter routes based on the number of unique autonomous systems (ASs) in the AS path. Specify the match condition for the unique AS path count.

aggregate-bandwidth—(Optional) Enable BGP to advertise aggregate outbound link bandwidth for load balancing.

dynamic-tunnel-attributes *dynamic-tunnel-attributes*—(Optional) Choose a set of defined dynamic tunnel attributes for forwarding traffic over V4oV6 tunnels.

match-conditions—(Optional in **from** statement; required in **to** statement) One or more conditions to use to make a match. The qualifiers are described in *Routing Policy Match Conditions*.

multipath-resolve *multipath-resolve*—(Optional) Enable the use of all paths for resolution over the specified prefix.

limit-bandwidth *limit-bandwidth*—(Optional) Specify the limit for advertised aggregate outbound link bandwidth for load balancing.

Range: 0 through 4,294,967,295 bytes

no-entropy-label-capability—(Optional) Disable the entropy label capability advertisement at egress or transit routes specified in the policy.

priority (*high* | *medium* | *low*)—(Optional) Configure the priority for an IS-IS route to change the default order in which the routes are installed in the routing table, in the event of a network topology change.

policy subroutine-policy-name—Use another policy as a match condition within this policy. The name identifying the subroutine policy can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" "). Policy names cannot take the form `__.*-internal__`, as this form is reserved. For information about how to configure subroutines, see *Understanding Policy Subroutines in Routing Policy Match Conditions*.

policy-name—Name that identifies the policy. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" ").

prefix-list prefix-list-name—Name of a list of IPv4 or IPv6 prefixes.

prefix-list-filter prefix-list-name—Name of a prefix list to evaluate using qualifiers; **match-type** is the type of match, and **actions** is the action to take if the prefixes match.

protocol protocol-name—Name of the protocol used to control traffic engineering database import at the originating point.

Starting in Junos OS Release 19.1R1, you can specify options to match label IS-IS and label OSPF routes using the **l-isis** and **l-ospf** options, respectively. The **isis** options matches all IS-IS routes, excluding labelled IS-IS routes. The **ospf** option matches all OSPF routes, including OSPFv2, OSPFv3 and labelled OSPF routes.

resolution-map—(Optional) Set resolution map modes. A given resolution-map can be shared across multiple policy-statements.

route-filter destination-prefix match-type <actions>—(Optional) List of routes on which to perform an immediate match; **destination-prefix** is the IPv4 or IPv6 route prefix to match, **match-type** is the type of match (see *Configuring Route Lists*), and **actions** is the action to take if the **destination-prefix** matches.

source-address-filter source-prefix match-type <actions>—(Optional) Unicast source addresses in multiprotocol BGP (MBGP) and Multicast Source Discovery Protocol (MSDP) environments on which to perform an immediate match. **source-prefix** is the IPv4 or IPv6 route prefix to match, **match-type** is the type of match (see *Configuring Route Lists*), and **actions** is the action to take if the **source-prefix** matches.

tag value—(Optional) A numeric value that identifies a route. You can tag certain routes to prioritize them over other routes. In the event of a network topology change, Junos OS updates these routes in the routing table before updating other routes with lower priority. You can also tag some routes to identify and reject them based on your requirement.

term term-name—Name that identifies the term. The term name must be unique in the policy. It can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" "). A policy statement can include multiple terms. We recommend that you name all terms. However, you do have the option to include an unnamed term which must be the final term in the policy. To configure an unnamed term, omit the **term** statement when defining match conditions and actions.

to—(Optional) Match a route based on its destination address or the protocols into which the route is being advertised.

then—(Optional) Actions to take on matching routes. The actions are described in *Configuring Flow Control Actions* and *Configuring Actions That Manipulate Route Characteristics*.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Understanding Source Packet Routing in Networking (SPRING)

pop

Syntax

```
pop;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Remove the label from the top of the label stack. If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name],
[edit protocols mpls static-label-switched-path lsp-name ingress]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Preference for the route.

You can optionally configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for LSPs is lower (more preferred) than all learned routes except direct interface routes.

Options

preference—Preference to assign to the route. A route with a lower preference value is preferred.

Range: 1 through 255

Default: 5 for static MPLS LSPs, 7 for RSVP MPLS LSPs, 9 for LDP MPLS LSPs

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the setup priority and reservation priority for an LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. Sessions with lower hold priorities are preempted.

Options

reservation-priority—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 0 (Once the session is set up, no other session can preempt it.)

setup-priority—Setup priority.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 7 (The session cannot preempt any existing sessions.)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify whether an LSP should actively record the path by sending the record route object (RRO) of an LSP. The RRO is used to record the path that the LSP traverses. It includes the IP address, router ID, and node ID of the routers in the path. Recording LSP path can be useful for diagnostics and loop detection.

Default

Recording LSP path is enabled by default when you have node or link protection configured on the device.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name routing-options multicast],  
[edit routing-options multicast]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description

Enable you to control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to Protocol Independent Multicast (PIM) islands situated downstream from the egress routers of the point-to-multipoint LSPs.

Options

policy—Name of the RPF check routing policy.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations. The more time you configure, the more time a source node (ingress of an RSVP LSP) can have to learn about the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes.

Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the database and the network.

Options

seconds—Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations.

Range: 0 through 240 seconds

Default: 25 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

sampling (Protocols MPLS)

Syntax

```
sampling {
  cut-off-threshold percentile;
  use-average-aggregate;
  use-percentile percentile;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.2R1 for the QFX Series switches.

Description

Configure traffic sampling. By default, sampling mode is set to **Max Aggregate** which means the system will compare each new sample with the previous sample. If the new sample is higher than the old sample, then the newer sample is considered **Sampled Aggregate bandwidth**

Max Aggregate Example

If normalization happens every 20min (T0, T20, T40..) then if at time T0 the traffic rate is 185Gbps, and subsequently drops to 7.5Gbps at time T3, the max-aggregate sample for the current normalization window T0-T20 will be 185Gbps. When the current normalization window expires at time T20, we use the previous sampled max-aggregate of 185Gbps to calculate the split/merge activities of the next (or now current) normalization window between T20 – T40. If traffic remains at 7.5Gbps for this second normalization period, then at time T40 the max-aggregate sample of 7.5Gbps would then be used for split/merge activities. Even though traffic volumes dropped at time T3, LSP split/merge activities would not occur until time T40 which might be unexpected. This default behavior can be modified with use-average-aggregate or use-percentile to achieve alternative normalization behavior if desired.

Options

cut-off-threshold *percentile*—Specify the percentile value to be used as a cut-off threshold in removing outlier bandwidth samples. All the aggregate bandwidth samples determined as outliers are used for computing aggregate bandwidth used at the time of normalization.

Default: 0 percentile (the ingress considers all aggregate bandwidth samples for normalization.)

Range: 0 through 100

use-average-aggregate—Specify the ingress router to take average of the aggregate samples for normalization.

This option is mutually exclusive with the **use-percentile** configuration option.

use-percentile *percentile*—Specify the ingress router to compute and use the **pth** percentile from all the bandwidth samples, and use that for normalization.

This option is mutually exclusive with the **use-average-aggregate** configuration option.

Range: 0 through 100

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit routing-instances name protocols mpls static-label-switched-path]
```

Release Information

Statement introduced in Junos OS Release OS 18.1R1 for MX Series, PTX Series, and QFX Series.

Description

Static segment for segment routing. A static segment is identified by a unique name. This segment type is assigned a segment identifier (SID) which falls under a default range of 100000 through 1048575. The segment has label operation such as pop-and-forward for adjacency segment and swap-and-forward for prefix or node segment. For both types of label operation, the segment is assigned a next hop that specifies the remote IP address if the outgoing interface is a multi-access interface, or the name of the outgoing interface if the interface is a point-to-point interface. Static segment configuration is used to statically configure or provision the adjacency SIDs, node SIDs, and prefix SIDs on transit routers.

Options

pop—Pop the SID label

swap—Swap the SID label to this label

description—Text description of label-switched path

next-hop—IPv4 address or interface of next-hop router

sid-label—Segment identifier (SID) label

The remaining statements are explained separately. See [CLI Explorer](#).

Release Information

Statement introduced in Junos OS Release 17.4R1 for MX Series and PTX Series with FPC-PTX-P1-A.

ip-address statement introduced in Junos OS Release 18.1R1 on MX Series routers.

inherit-label-nexthops, **node-type**, and **auto-translate** statements introduced in Junos OS Release 19.1R1 on MX Series routers.

dynamic statement introduced in Junos OS Release 19.2R1 on all platforms.

compute, **loose**, and **strict** statements introduced in Junos OS Release 19.1R1-S1 on MX Series routers.

Description

Specify an name to identify the segment routing list (used in traffic engineering policy) and the explicit path for source routing label switched path (LSPs) to traverse through traffic engineering segments. The segment list is essentially a stack of segment identifiers.

Starting in Junos OS release 19.1R1 for MX and PTX Series routers, you can enable a translation service to translate next-hop IP addresses into the corresponding segment identifier (SID) labels. The translation service keeps track of the node reached at each hop.

When configured, the **segment-list** of a segment routing traffic engineering (SR-TE) LSP accepts IP addresses for all the hops along the path. These IP addresses can be either the loopback address of a node, or the

IP address of a link, as identified by the **node-type**. When **auto-translation** is enabled, next hop IP addresses are automatically translated to corresponding SIDs using the translation service. A retry rate can be set for the retry timer at the **source-packet-routing** hierarchy level.

NOTE: The segment list enables BGP and static segment routing LSP to steer traffic based on segment routing policies. When a segment list is used by the protocol BGP, the BGP protocol validates these segment identifiers and selects valid segments for traffic engineering.

Options

<hop-name>—Indicates the next hop in the segment routing traffic engineering policy (SR-TE).

- **ip-address**—Specify the IP address of the hop. For a segment-list to be used by a non-colored segment routing LSP, the first hop must specify an IP address.
- **label**—Specify the SID label of the hop in a segment routing traffic engineering segment list. In static segment routing LSPs, the source routing path uses the segment list only if the second to Nth hop specifies segment identifiers (SID) labels.

NOTE: The range is from 0 to 1,048,576 and is applies to BGP and static segment routing LSPs.

- **label-type**—Use with the option below to indicate that the specified address is the IP address of the node, for example, its loopback address, as opposed to that of a link.
- **node**—Hops that have been specified as **node** are translated to a prefix SID, which can be either a node SID or an anycast SID depending on the type of hop IP address. IP addresses not identified as **node** are consider to be a link.

NOTE: If the first hop is a **node**, for LSP resolution to work correctly, **inherit-label-nexthops** must be enabled at either **source-packet-routing** hierarchy level, or at the relevant **segment-list** hierarchy level.

- **loose | strict**—IP hops specified using router IDs in the sequence can be strict or loose hops. A strict hop must be directly connected to the previous node in the sequence. A loose hop is not necessarily directly connected to the previous node.

NOTE: You can specify only router IDs as loose or strict hop constraints. Labels and other IP addresses are not supported as loose or strict hop constraints in Junos OS Release 19.2R1-S1.

auto-translate— This option must be enabled before a given segment list can use IP addresses instead of SIDs for any hop other than the first hop. In addition, all hops in the segment list must have IP addresses. If any hops on the list have both an IP address and a label configured, the label will be retained. Link addresses are only translated into labels if the preceding node advertises an adjacency SID for the address (otherwise translation fails).

NOTE: In Junos OS Release 19.1R1, for auto-translate to work for OSPF, RSVP for segment routing must be enabled on all participating interfaces.

- **protected**—(Optional) Enable this option to ensure the adjacency SID is eligible to have a backup path, and that a B-flag is set in adjacency SID advertisements. Note that unless **mandatory** is also selected, the choice succeeds regardless.
- **mandatory**—(Optional) Enable this option to have translation fail if any *unprotected* links are found in the hop-list.
- **unprotected**—(Optional) Enable this option to ensure that no backup path is calculated for a specific adjacency SID, and that a B-flag is not set in adjacency SID advertisements. Note that unless **mandatory** is also selected, the choice succeeds regardless.
- **mandatory**—(Optional) Enable this option to have translation fail if any *protected* links are found in the hop-list.

compute—(Optional) Enable use of explicit paths specified in segment list for path computation.

inherit-label-nexthops—Inherit label next hops for first hop in this segment list that have both IP address and label configured in the first hop.

You can configure the **inherit-label-nexthops** statement globally or individually for each segment list.

The **inherit-label-nexthops** statement takes effect only when the segment list first hop has both IP address and SID label present.

If the **inherit-label-nexthops** is not configured at the **[edit protocols source-packet-routing segment-list]** hierarchy, and the first hop in the segment list has both IP address and label specified, the default behavior is to use the IP address.

The remaining statements are explained separately. Search for a statement in [CLI Explorer](#) or click a linked statement in the Syntax section for details.

smart-optimize-timer

Syntax

```
smart-optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable the smart optimization timer. When you enable the smart optimization timer on a router, the Junos OS operates on the assumption that the original LSP path is preferable to any alternate or secondary path. When you enable the smart optimization timer and an LSP fails and its traffic is switched to an alternate path, the smart optimization timer starts and waits 3 minutes (this time is configurable). After 3 minutes have passed, the LSP is switched back to the original path. If the original path fails again and the LSP is switched to an alternate path again, the router waits 1 hour before attempting to switch the LSP back to its original path.

If you want to disable the smart optimizer, you can set it to zero. The **smart-optimize-timer** value in seconds indicates the time before which the LSP is switched back to its primary path in case the primary path becomes available. Otherwise, the time to wait is controlled by the **optimize-timer**, which is usually set to a high value. Some ISPs have the **optimize-timer** set to once a day. Sometimes after the smart optimizer causes the LSP to be placed back on its primary path, the primary path goes down again within 60 minutes. When this happens, the **smart-optimize-timer** is disabled automatically, and the **optimize-timer** (regular path optimization) goes into effect. This is to protect against a flapping link being used.

Default

The smart optimization timer is enabled by default.

Options

seconds—(Optional) Specify the number of seconds to wait before switching an LSP back to its original path. If you do not specify the number of seconds, the default value is used.

Range: 0 through 65,535 seconds

Default: 180 seconds

```

Release Information

Statement introduced in Junos OS Release 17.4R1 for MX Series and PTX Series with FPC-PTX-P1-A. The **metric**, **no-ingress**, and **secondary** statements are introduced in Junos OS Release 18.1R1 for MX Series.

lsp-external-controller statement introduced in Junos OS Release 20.1R1.

Description

Configure a source routing label switched path (LSP) for steering traffic at an ingress router. Specify a binding segment identifier from the static label range. Configure other parameters such as color, weight, preference, and segment routing preference for traffic engineering.

Starting with Junos OS Release 18.1R1, compute static non-colored segment routing label switched paths (LSPs) for protocol SPRING-TE in an MPLS network. Configure parameters such as destination address, binding SIDs, primary segment, secondary segment, metric, and preference. These segment routing LSPs do not have a color associated with them. If an ingress route is not required for a non-colored segment routing LSP then the ingress route installation in inet.3 table can be disabled.

Options

name—Specify a name to identify a source routing path.

binding-sid—(Optional) Specify the binding label to enable transit functionality for this tunnel. For a non-colored static segment routing LSP, the binding SID label of protocol SPRING-TE have a default preference value of 8 and a metric of 1.

Range: 16 through 1,048,576

color—(Colored segment routing LSPs only) Specify a color identifier for the tunnel end point. For non-colored segment routing LSPs, you do not have to configure the color parameter.

lsp-external-controller—Enable external path computing capability for the device. See [lsp-external-controller](#) for more information.

metric—Specify metric for routes downloaded for the non-colored static segment routing tunnel.

You can configure the label range at `[edit protocols mpls label-range static label-range]` hierarchy level.

Default: 1000000 through 1048575

Range:

NOTE:

1 through 16777215 (for BGP)

no-ingress—Disable ingress route that is not required for the non-colored static segment routing tunnel

primary— Specify a primary segment list for the configured source routing path.

The non-colored static segment routing LSP can have a maximum of 8 primary paths. incase of multiple operational primary paths, the PFE distributes the traffic over the paths based on the weight configured on the paths. If none of the paths have weights configured then the weights default to 1 making it an ECMP path. the paths become weighted ECMP if at least one of the paths have a non-zero weight. In both cases , when one or some of the paths fail, the PFE automatically re-balances the traffic over the remaining paths resulting in path protection.

weight weight_value— Specify a percentage of the bandwidth with respect to the sum of weights of all paths for the primary segment list. If forwarding interfaces are also configured with weighted ECMP, then Junos OS applies hierarchical weighted ECMP. If the weight percentage is not configured, then only IGP weights are applied on the forwarding interfaces.

secondary—Specify a secondary segment list for the configured non-colored static segment routing LSP.

sr-preference— Configure a preference for segment routing routes for traffic engineering. BGP chooses a higher preference over a lower preference value.

Range: 0 through 4,294,967,295

to—Specify the IP address of the tunnel end-point

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.2R1.

bfd-liveness-detection and **ldp-tunneling** options introduced in Junos OS Release 19.4R1.

lsp-external-controller statement introduced in Junos OS Release 20.1R1.

Description

Configure a source-routing-path-template for dynamic creation of segment routing label-switched paths (LSPs).

Options

name—Name of the source routing path.

bfd-liveness-detection—Configure Bidirectional forwarding detection (BFD) options for PCE-initiated segment routing LSP template. See *bfd-liveness-detection* for more information.

ldp-tunneling—Allow LDP to use this LSP for tunneling. This configuration can be applied to PCE-initiated segment routing LSPs only.

lsp-external-controller—Enable external path computing capability for the device. See [lsp-external-controller](#) for more information.

metric—Metric for routes downloaded for this tunnel.

Range: 1 through 16777215

no-ingress—Disable ingress functionality for this tunnel.

primary name—Configure a named identifier for the segment-list that describes the primary segment routing path along which the packet is to be routed. This segment list must have the **dynamic** statement enabled for dynamic creation of segment routing LSPs.

weight weight—(Optional) Specify the balance factor for this segment list in SR-TE tunnel.

If the forwarding interfaces have weights assigned by IGP, then hierarchical weighted ECMP is applied. When weight is not specified, only the IGP weights are applied on the forwarding interfaces.

secondary name—Configure a named identifier for the segment-list that describes the secondary segment routing path along which the packet is to be routed. This segment list must have the **dynamic** statement enabled for dynamic creation of segment routing LSPs.

sr-preference—Segment routing preference for the segment routing traffic engineered (SR-TE) routes. A greater value indicates higher preference.

The preference value of the routes programmed for the segment routing LSP is inherited from the **preference value** statement at the **[edit protocols source-packet-routing]** hierarchy level. When this value is not configured, the default preference value of 8 is used.

Range: 0 through 4294967295

Required Privilege Level

routing

splitting-merging

Syntax

```
splitting-merging {
  maximum-member-lsps number;
  maximum-signaling-bandwidth bps;
  merging-bandwidth bps;
  minimum-member-lsps number;
  minimum-signaling-bandwidth bps;
  normalization;
  sampling;
  splitting-bandwidth bps;
  splitting-merging-threshold percent;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced for QFX Series switches in Junos OS Release 15.1X53-D30.

Description

Perform splitting and merging.

Options

maximum-member-lsps *number*—Number of label-switched paths (LSPs) that a container LSP can have as member LSPs at maximum.

Default: 1

maximum-signaling-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at maximum after normalization. When **maximum-signaling-bandwidth** is not configured, the value is derived from the **splitting-bandwidth**.

When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the **splitting-bandwidth**.

Default: 1 bps

merging-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that is used for merging during normalization.

Default: 1 bps

minimum-member-lsps *number*—Number of LSPd that a container LSP can have as member LSPs at minimum.

Default: 64

minimum-signaling-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at minimum after normalization. When **minimum-signaling-bandwidth** is not configured, the value is derived from the **merging-bandwidth**.

When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the **merging-bandwidth**.

Default: 1 bps

splitting-bandwidth *bandwidth*—Amount of bandwidth in bits per second (bps) that can be used for splitting during normalization.

Default: 1 bps

splitting-merging-threshold *percent*—Percentage changes in aggregate bandwidth relevant for splitting and merging.

Default: 0%

The remaining statements are explained separately. See [CLI Explorer](#).

spring-te (Dynamic Tunnels)

Syntax

```
spring-te {
  destination-networks name;
  source-routing-path-template name {
    (color [ color ... ] | color-any);
  }
}
```

Hierarchy Level

```
[edit routing-options dynamic-tunnels],
```

Release Information

Statement introduced in Junos OS Release 19.2R1 on all platforms.

Description

Enable next hop-base dynamic tunnel mode.

Options

source-routing-path-template *template-name*—Configure template color mapping for segment routing traffic-engineered (SPRING-TE) dynamic LSP parameters.

color—Specify set of color list to be mapped to corresponding SPRING-TE template.

- When enabled, all templates should have color objects defined.
- All destinations are assumed to be colored as well.
- A color can be mapped to only one template at a given point in time.
- Both the **color** and **color-any** statements can coexist. When the two statements are enabled together, preference is given to a specific color template than color-any.
- A colored and non-colored destination cannot co-exist in the same SR-TE configuration.

color-any—Enables mapping of any color to corresponding SPRING-TE template. Only one color-any template can be configured for one SR-TE LSP.

Required Privilege Level

srgb-label-range

Syntax

```
srgb-label-range <range-start> <range-end>
```

Hierarchy Level

```
[edit protocols mpls label-range],  
[edit protocols ospf source-packet-routing srgb]
```

Release Information

Statement introduced in Junos OS Release 19.1 for MX Series routers.

Description

SRGB configured under **mpls label-range** is termed as global SRGB. The MPLS label range is based on the start range and the end range. The value of the start range indicates the start of the label range, and the value of the end range along with the value of the start range indicate the end of the label range.

Options

<range-start> <range-end>—Start range and end range of the global SRGB label block.

statistics (Protocols MPLS)

Syntax

```
statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
  traffic-class-statistics;
  transit-statistics-polling;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

traffic-class-statistics option introduced in Junos OS Release 14.2.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Enable MPLS statistics collection and reporting.

Options

file *filename*—(Optional) Name of the file to receive the output. We recommend that you place MPLS tracing output in the file `mpls-stat` in the `/var/log` directory.

files *number*—(Optional) Maximum number of trace files. When a trace file named *file* reaches its maximum size, it is renamed *file.0*, then *file.1*, and so on, until the maximum number of files is reached. Then, the oldest file is overwritten.

Range: 2 or more

Default: 2 files

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option.

interval *seconds*—Interval at which to periodically collect statistics.

Range: 1 through 65,535

Default: 300 seconds

no-world-readable—(Optional) Prevent users from reading the log file.

size *size*—(Optional) Maximum size of each file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a file named *file* reaches this size, it is renamed *file.0*. When the *file* again reaches its maximum size, *file.0* is renamed *file.1* and *file* is renamed *file.0*. This renaming scheme continues until the maximum number of files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of files with the **files** option.

world-readable—(Optional) Enable users to read the log file.

Syntax: Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

traffic-class-statistics—(Optional) Create counters that maintain data traffic statistics per traffic class at the ingress of all types of LSPs and egress of ultimate hop popping (UHP) point-to-point LSPs. These counters are not created by default and are required to be configured to perform traffic-class-scoped loss measurement.

transit-statistics-polling—(Optional) Enable the polling and display of MPLS statistics for LSPs transiting the router. By default, RSVP does not periodically poll for transit LSP statistics. You cannot configure this statement and the **no-transit-statistics** statement at the same time.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

swap

Syntax

```
swap out-label;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name transit incoming-label],  
[edit protocols mpls static-label-switched-path lsp-name transit incoming-label]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Remove the label at the top of the label stack and replace it with the specified label. Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. This statement is used to configure static LSPs at transit routers.

Options

out-label—Manually assigned outgoing label value.

Range: 0 through 1,048,575

Default: If you do not define the **out-label** option, the original label value remains unchanged.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

switch-away-lsps

Syntax

```
switch-away-lsps;
```

Hierarchy Level

```
[edit logical-systems logical-systems-name protocols mpls interface interface-name],  
[edit protocols mpls interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 10.2.

Description

(MX Series routers only) Enable you to switch an LSP away from a network node using a bypass LSP. This feature could be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic. Configure this statement only after you have configured and committed the **always-mark-connection-protection-tlv** statement.

The **always-mark-connection-protection-tlv** statement marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. When you configure the **switch-away-lsps** statement, traffic is switched to the bypass LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

sync-active-path-bandwidth

Syntax

```
sync-active-path-bandwidth;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name auto-bandwidth],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name],
[edit protocols mpls label-switched-path lsp-name auto-bandwidth],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Release Information

Statement introduced in Junos OS Release 13.2.

Description

When you have a primary and a secondary path configuration, specify that a path needs to be signaled with the active-path bandwidth when the auto-bandwidth adjustment happens and that the secondary path synchronizes the bandwidth reservations to that of the primary path.

When a primary path fails, bandwidth reservations are made by the secondary path on the links that it uses. If you include the **sync-active-path-bandwidth** statement, the secondary path releases the bandwidth it has reserved and adjusts its bandwidth after the primary path begins carrying traffic.

For example, suppose the active path is a secondary path with a reserved bandwidth of 10 GB as a result of the automatic bandwidth adjustment. Then suppose there is a switchover from the secondary path to the primary path. After some time the primary path reserves 5 GB as a result of a new automatic adjustment. Without the **sync-active-path-bandwidth** statement, the secondary path does not release the 10 GB after a switchover occurs. That bandwidth is wasted. If the **sync-active-path-bandwidth** is included in the configuration, the secondary path adjusts its bandwidth to 5 GB along with the primary path.

Default

When you have a primary and a secondary path configuration, and the primary path fails, bandwidth reservations are made by the secondary path on the links that it uses. When the primary path comes back and the traffic switches over, the secondary path does not release its bandwidth reservations.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols mpls diffserv-te]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the traffic engineering class matrix for a multiclass LSP or a DiffServ-aware traffic engineering LSP.

Default

The default traffic engineering class matrix is:

```
te-class-matrix {
  te0 traffic-class ct0 priority 7;
  te1 traffic-class ct1 priority 7;
  te2 traffic-class ct2 priority 7;
  te3 traffic-class ct3 priority 7;
  te4 traffic-class ct0 priority 0;
  te5 traffic-class ct1 priority 0;
  te6 traffic-class ct2 priority 0;
  te7 traffic-class ct3 priority 0;
}
```

If you define any of the traffic engineering classes, all the default values are dropped.

Options

ctnumber—Specify the number of the class type. It can be one of four values: **ct0**, **ct1**, **ct2**, or **ct3**.

priority *priority*—Specify the priority of the class type. It can be one of eight values from 0 through 7.

tenumber—Specify the number of the traffic engineering class. It can be one of eight values: **te0**, **te1**, **te2**, **te3**, **te4**, **te5**, **te6**, or **te7**. You must configure the traffic engineering classes in order, starting with **te0**.

traffic-class—Specify the traffic class for the traffic engineering class.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traceoptions (Protocols MPLS)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

ted-export option introduced in Junos OS Release 14.2.

ted-import option introduced in Junos OS Release 14.2.

lsp-history option added in Junos OS Release 15.1.

Description

Configure MPLS tracing options at the protocol level or for a label-switched path.

To specify more than one tracing operation, include multiple **flag** statements.

Default

The default MPLS protocol-level tracing options are inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MPLS Tracing Flags

- **all**—Trace all operations
- **autobw-state**—Automatic bandwidth events.
- **connection**—All circuit cross-connect (CCC) activity
- **connection-detail**—Detailed CCC activity
- **cspf**—CSPF computations
- **cspf-link**—Links visited during CSPF computations
- **cspf-node**—Nodes visited during CSPF computations
- **error**—MPLS error packets
- **graceful-restart**—Trace MPLS graceful restart events
- **lsp-history**—Trace LSP history events
- **lsping**—Trace lsping packets and return codes
- **nsr-synchronization**—Trace NSR synchronization events
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail
- **state**—All LSP state transitions
- **static**—Trace static label-switched path
- **ted-export**—Trace leaking of entries from **lsdist.0** table into the traffic engineering database
- **ted-import**—Trace leaking traffic engineering database entries into the **lsdist.0** table
- **timer**—Timer usage

no-world-readable—(Optional) Allow only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 15.1.

Description

Configure traffic class specific options.

Specify the traffic classes for which loss measurement has to be performed. This parameter takes one of the *tc-all|tc-0|tc-1|tc-2|tc-3|tc-4|tc-5|tc-6|tc-7|tc-none* traffic-class values. For each traffic class, you can configure the respective parameters.

To enable traffic-class parameters, configure the **traffic-class-statistics** configuration statement under the **[edit protocol mpls statistic]** hierarchy level.

Options

average-sample-size *sample size*—(Optional) Specify the number of samples used for calculating the average of various metrics.

Default: 5

Range: 1 through 30

padding-size *size*—(Optional) Specify the delay-measurement message length, which is used to calculate the delay experienced by messages of different sizes.

Default: 0

Range: 1 through 1500

query-interval *milliseconds*—Specify the minimum transmit interval, which signifies how often the loss measurement message is generated from the querier.

Default: 10 seconds

Range: 1000 through 4294967295 milliseconds

rtt-delay-threshold *rtt threshold value*—Specify the round-trip delay threshold value.

Range: 1 through 4294967295 microseconds

twcd-delay-threshold *twcd threshold value*—Specify the two-way channel delay threshold value.

Range: 1 through 4294967295 microseconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traffic-engineering (Protocols MPLS)

Syntax

```
traffic-engineering (bgp | bgp-igp | bgp-igp-both-ribs | mpls-forwarding);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit protocols mpls]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Select whether MPLS performs traffic engineering on BGP destinations only or on both BGP and IGP destinations. Affects only LSPs originating from this routing device, not transit or egress LSPs.

Default

bgp

Options

bgp—On BGP destinations only. Ingress routes are installed in the inet.3 routing table.

bgp-igp—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 routing table. If IGP shortcuts are enabled, the shortcut routes are automatically installed in the inet.0 routing table.

bgp-igp-both-ribs—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 and inet.3 routing tables. This option is used to support VPNs.

mpls-forwarding—On both BGP and IGP destinations. Use ingress routes for forwarding only, not for routing.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

traffic-engineering

Syntax

```
traffic-engineering {
  disable;
}
```

Hierarchy Level

```
[edit protocols ospf | isis]
```

Release Information

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Description

Enable the traffic engineering features of the specified routing protocol.

Default

Traffic engineering is disabled.

Starting in Junos OS release 15.1, traffic engineering is enabled by default whenever the IS-IS protocol is enabled. You can disable it by including the **disable** statement at the **[edit protocols isis traffic-engineering]** hierarchy level. For the EX3300, EX4200, EX4500, EX4550, EX8200 and XRE200, you can disable traffic engineering starting in Junos OS release 15.1R7.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced on QFX5100 switches in Junos OS Release 15.1

Statement introduced on QFX10000 switches in Junos OS Release 17.1.

Description

Enable traffic engineering address family. This generates a multiprotocol address family indicator (AFI) and a subsequent address family identifier (SAFI) to be negotiated with the BGP peers.

The BGP network layer reachability information (NLRI) information is exchanged between the peers only when the traffic engineering AFI and SAFI are shared between them. If the peers do not agree on the use of the AFI and SAFI, the connection between the peers is terminated.

Options

unicast—Include BGP-TE NLRI.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ultimate-hop-popping

Syntax

```
ultimate-hop-popping;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit logical-systems logical-system-name protocols mpls label-switched-path label-switched-path-name],
[edit protocols mpls],
[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

Description

Enable ultimate-hop popping on LSPs. Configure this statement on the device at the LSP ingress. In ultimate-hop popping, the MPLS label is popped from the IP packet at the PE router. The IP address is checked in a second address lookup (also at the PE router), and then the packet is forwarded to its destination.

Be aware of the following platform requirements and restrictions:

- UHP LSPs using VT interfaces—Supported on all M Series, MX Series, T Series, and TX Matrix routers.
- UHP LSPs using LSI interfaces—Supported on MX 3D Series routers only.
- UHP LSP requirements for the egress PE device—For M Series and T Series routers, a VT interface is needed.
- UHP LSPs and Layer 3 VPNs—UHP LSPs are supported for Layer 3 VPNs configured on MX 3D Series routers only.
- UHP LSPs and VPLS—UHP LSPs are supported for VPLS configured on MX 3D Series routers only. You must configure the *no-tunnel-services* statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

Default

Ultimate-hop popping is disabled by default on LSPs. Penultimate-hop popping is the default behavior. In penultimate-hop popping, the final MPLS label is popped from the IP packet at the last provider router in the network before being forwarded to the PE router. The PE router receives the packet and checks the IP address, and then the packet is forwarded to its destination.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

vrf-table-label

Syntax

```
vrf-table-label {  
    source-class-usage;  
    static;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name],  
[edit routing-instances routing-instance-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for the **source-class-usage** statement added in Junos OS Release 9.3.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Statement introduced in Junos OS Release 15.1F5 and 16.1R2 for PTX5000 routers with third-generation FPCs installed.

Statement introduced in Junos OS Release 15.1F6 and 16.1R2 for PTX3000 routers with third-generation FPCs.

Statement introduced in Junos OS Release 16.1X65 and 17.2R1 for PTX1000 routers.

Statement introduced in cRPD Release 19.4R1.

Support for the **static** statement added in Junos OS Release 17.2.

Description

Map the inner label of a packet to a specific VPN routing and forwarding (VRF) instance. This allows the examination of the encapsulated IP header. The first lookup is done on the VPN label to determine which VRF instance to refer to, and the second lookup is done on the IP header to determine how to forward packets to the correct end hosts.

When you include the **vrf-table-label** statement in the configuration of a VRF routing instance, a label-switched interface (LSI) logical interface label is created and mapped to the VRF routing table. Any routes in the VRF routing table are advertised with the LSI logical interface label allocated for the VRF routing table. When packets destined for the VRF routing instance arrive on a core-facing interface, they are treated as if the enclosed IP packet arrived on the LSI interface and are then forwarded and filtered based on the correct table.

All routes in a VRF routing instance configured with this option are advertised with one label allocated per VRF.

NOTE:

- The **vrf-table-label** statement is supported on PTX5000 and PTX3000 routers only when third-generation FPCs are installed on the router and **enhanced-ip** command is configured on the chassis.
- Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability. The **vrf-table-label** space is increased to at least 16,000, if the platform can support the scale.

Options

The remaining statements are explained separately.

Range: 16 through 1,048,575 for static label value.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

admin-group

Syntax

```
admin-group {
  exclude [ group-names ];
  include-all [ group-names ];
  include-any [ group-names ];
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced in Junos OS Release 9.2.

Description

Enable you to configure administrative groups for bypass label-switched paths (LSPs). You can configure administrative groups either globally for all bypass LSPs traversing an interface or for just a specific bypass LSP.

Options

exclude *group-names*—Specify the administrative groups to exclude for a bypass LSP.

include-all *group-names*—Specify the administrative groups whose links the bypass LSP must traverse.

include-any *group-names*—Specify the administrative groups whose links the bypass LSP can traverse.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

aggregate (Protocols RSVP)

Syntax

```
(aggregate | no-aggregate);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp peer-interface peer-interface-name],  
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the use of RSVP aggregate messages on an interface or peer interface, as described below.

NOTE: Starting in Junos OS Release 15.2, the **aggregate** statement is deprecated at the **[edit protocols rsvp interface *interface-name*]** and **[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name*]** hierarchy levels, as RSVP message aggregation is enabled by default.

- **aggregate**—Use RSVP aggregate messages.
- **no-aggregate**—Do not use RSVP aggregate messages.

Aggregate messages can pack multiple RSVP messages into a single transmission, thereby reducing network overhead and enhancing efficiency. The number of supportable sessions and processing overhead are significantly improved when aggregation is enabled.

Not all routers connected to a subnet need to support aggregation simultaneously. Each RSVP router negotiates its intention to use aggregate messages on a per-neighbor basis. Only when both routers agree are aggregate messages sent.

To have refresh reduction and reliable delivery, you must include the **aggregate** and **reliable** statements.

Default

Aggregation is enabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

authentication-key (Protocols RSVP)

Syntax

```
authentication-key key;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],  
[edit logical-systems logical-system-name protocols rsvp peer-interface peer-interface-name],  
[edit protocols rsvp],  
[edit protocols rsvp interface interface-name],  
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Authentication key (password). Neighboring routers use the password to verify the authenticity of packets sent from this interface or peer interface. To authenticate node hellos or remote messages between the Point of Local Repair (PLR) to the Merge Point (MP), enable **authentication-key** at the **[edit protocols rsvp]** hierarchy level.

RSVP uses HMAC-MD5 authentication, which is defined in RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*.

All routers that are connected to the same IP subnet must use the same authentication scheme and password.

Options

key—Authentication password. It can be 1 through 16 contiguous digits or letters. Separate decimal digits with periods. Separate hexadecimal digits with periods and precede the string with 0x. If you include spaces in the password, enclose the entire password in quotation marks (" ").

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit protocols rsvp interface interface-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

For certain logical interfaces (such as Asynchronous Transfer Mode [ATM], Permanent Virtual Circuit [PVC], or Frame Relay), you cannot determine the correct bandwidth from the hardware. This statement enables you to specify the actual available bandwidth.

This statement also enables you to specify the bandwidth for a bypass label switched path (LSP). If you have configured multiple bypasses, this statement is mandatory and is applied to all of the bypass LSPs.

Default

The hardware raw bandwidth is used.

Options

bps—Bandwidth in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations **k** (for a thousand), **m** (for a million), or **g** (for a billion [also called a thousand million]).

Range: Any positive integer

Default: 0 (no bandwidth is reserved)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring the Bandwidth for Bypass LSPs | 379](#)

[Configuring Bypass LSPs | 378](#)

bypass (Signaled LSP)

Syntax

```
bypass bypass-name {
  bandwidth bps;
  description text;
  hop-limit number;
  no-cspf;
  path address <strict | loose>;
  priority setup-priority reservation-priority;
  subscription subscription-percentage;
  to address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.

description option was added in Junos OS Release 10.4.

subscription *subscription-percentage* option introduced in Junos OS Release 19.2R1 on all platforms.

Description

Enables you to configure specific bandwidth and path constraints for a bypass LSP. It is possible to individually configure multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.

If you specify the **bandwidth**, **hop-limit**, and **path** statements for the bypass LSP, these values take precedence over the values configured at the **[edit protocols rsvp interface *interface-name* link-protection]** hierarchy level. The other attributes (**subscription**, **no-node-protection**, and **optimize-timer**) are inherited from the general constraints.

Options

bypass-name—(Required) Specify a name for the bypass LSP. The name can be up to 64 characters.

description—Provides a textual description of the bypass LSP. Enclose any descriptive text that includes spaces in quotation marks (" "). Any descriptive text you include is displayed in the output of the **show mpls lsp bypass detail** command and has no effect on the operation of the bypass LSP. The description text can be no more than 80 characters in length.

subscription *subscription-percentage*—(Optional) Specify the subscription percentage per manual bypass LSP. The subscription percentage configured under a particular manual bypass LSP overrides the subscription percentage configured commonly for all manual bypass LSPs under an interface.

Range: 0 through 65000

to *address*—(Required) Specify the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

bypass (Static LSP)

Syntax

```
bypass bypass-name {  
    bandwidth bps;  
    description string;  
    next-hop (address | interface-name | address/interface-name);  
    push out-label;  
    to address;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name],  
[edit protocols mpls static-label-switched-path lsp-name]
```

Release Information

Statement introduced before Junos OS Release 10.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure specific bandwidth and path constraints for a bypass ingress LSP. It is possible to configure multiple bypass LSPs individually. If you do not, they all share the same path and bandwidth constraints.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

chained-composite-next-hop

Syntax

```
chained-composite-next-hop {  
    ingress;  
    transit;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table],  
[edit routing-options forwarding-table]
```

NOTE: The **[edit logical-systems]** hierarchy level is not supported on the QFX10000 switches.

Release Information

Statement introduced in Junos OS Release 12.1.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Statement introduced in Junos OS Release 15.1 for QFX10000 Series switches.

Description

Allows you to configure the chained composite next hops for devices handling ingress or transit traffic in the network.

Chained composite next hops help to facilitate the handling of large volumes of transit traffic in the core of large networks by allowing the router to process much larger volumes of routes. A chained composite next hop allows the router to direct sets of routes sharing the same destination to a common forwarding next hop, rather than having each route also include the destination. In the event that a network destination is changed, rather than having to update all of the routes sharing that destination with the new information, just the shared forwarding next hop is updated with the new information. The chained composite next hops continue to point to this forwarding next hop which now contains the new destination.

On platforms containing only MPCs, such as PTX Series Packet Transport Routers, the MX80 router, the MX2020 router, and the QFX10000 switches, chained composite next hops are enabled by default. On MX Series 5G Universal Routing Platforms containing both DPC and MPC FPCs and on T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default and need to be explicitly configured.

To explicitly configure chained composite next hops, include the **enhanced-ip** statement at the **[edit chassis network-services]** hierarchy level. However, take the following into consideration when enabling the **enhanced-ip** mode:

- Non-service DPCs do not work with enhanced network services mode options. Only MPCs, MS-DPCs, and MS-MPCs provide support for the **enhanced-ip** configuration.
- If you configure chained composite next hops on MX Series routers with both MPCs, and DPCs or DPCEs, the network services mode must be changed from **enhanced-ip** to **ethernet** for the DPC or DPCE to come online.

You can verify the FPC status in such cases, using the **show chassis fpc** command output, where the DPCs and DPCEs are marked as **FPC misconfiguration**.

NOTE:

- When chained composite next hops are enabled on a device, the BGP connections are reset.
- On MX Series routers with DPCs or DPCEs, only the *l3vpn* option is supported under the *ingress* configuration statement; all other configuration options and functionality are not supported.
- The **transit** statement and the associated functionality is supported only on PTX Packet Transport Routers and QFX10000 switches.
- On MX Series routers, removing the **chained-composite-next-hop** statement from a PE device configuration causes all IBGP sessions to be torn down and triggers the BGP session to flap as well. A similar change on a router configured as a route reflector does not have any effect, however.

The following is a sample system log message that is generated to record such an event:

```
Nov  6 15:16:21.670 host PE1: rpd[6947]: bgp_peer_mgmt_clear:5995:
NOTIFICATION sent to 10.0.100.2 (External AS 100): code 6 (Cease) subcode
 4 (Administratively Reset), Reason: Management session cleared BGP
neighbor
```

- Starting with Junos OS Release 17.2, you cannot configure **chained-composite-next-hop ingress l3vpn extended-space** on a logical system.

The remaining statements are explained separately. See [CLI Explorer](#).

Default

This statement is disabled by default.

Options

ingress—Enable or disable composite chained next hop for ingress traffic.

transit—(PTX and QFX10000) Enable or disable composite chained next hop for transit traffic. Starting in Junos OS Release 14.1, the **transit l3vpn** statement is enabled by default on PTX Series Packet Transport Routers only.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

class-of-service (Protocols RSVP)

Syntax

```
class-of-service cos-value;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],  
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],  
[edit protocols rsvp interface interface-name link-protection],  
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Class-of-service (CoS) value given to all packets in the bypass LSP. You can specify a single CoS value for all the bypass LSPs traversing an interface. You can also configure CoS values for specific bypass LSPs traversing an interface.

The CoS value might affect the scheduling or queuing algorithm of traffic traveling along an LSP.

Options

cos-value—CoS value. A higher value typically corresponds to a higher level of service.

Range: 0 through 7

Default: If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

devices

Syntax

```
devices device-names;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 8.1.

Description

Specifies one of the virtual tunnel (VT) interfaces to de-encapsulate the egress traffic for ultimate-hop popping on point-to-multipoint LSPs. If no device is specified, the selection process is performed automatically.

Default

The device selection process is performed automatically if no device is configured. Junos OS selects one of the available VT interfaces to de-encapsulate the egress traffic.

Options

device-names—Specify which VT interfaces are used to handle the RSVP traffic.

Range: 0 to 8 devices

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable RSVP or RSVP graceful restart. Explicitly disable link protection on the specified interface.

Default

RSVP is enabled on interfaces and peer interfaces configured with the RSVP **interface** statement. RSVP graceful restart is enabled on the router. Link protection is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Syntax

```
dynamic-bidirectional-transport {  
    template template;  
}
```

Hierarchy Level

```
[edit protocols rsvp peer-interface peer-interface-name]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Enable the dynamic setup of associated bidirectional packet LSP for transporting non-packet Generalized Multiprotocol Label Switching (GMPLS) label-switched path (LSP).

Options

template *template*—Name of the template for the dynamic bidirectional packet LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

fast-reroute (Protocols RSVP)

Syntax

```
fast-reroute optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement added in Junos OS Release 7.5.

Statement introduced in Junos OS Release 14.1 for the QFX Series.

Description

Configure the optimize timer for fast reroute. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

Options

seconds—Specify the number of seconds between fast reroute detour LSP optimizations.

Range: 0 through 65,535 seconds

Default: 0 (disabled)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

graceful-restart (Protocols RSVP)

Syntax

```
graceful-restart {  
  disable;  
  helper-disable;  
  maximum-helper-recovery-time seconds;  
  maximum-helper-restart-time seconds;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],  
[edit protocols rsvp],  
[edit routing-options]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure graceful restart on the router. You must configure the **graceful-restart** statement at the **[edit routing-options]** hierarchy level to enable graceful restart on the router.

Options

disable—Disable graceful restart on the router or for RSVP.

helper-disable—Disable RSVP graceful restart helper mode (this option is only available at the **[edit protocols rsvp]** hierarchy level).

Default: Helper mode is enabled by default.

maximum-helper-recovery-time *seconds*—The maximum length of time the router stores the state of neighboring routers when they undergo a graceful restart. The value applies to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

Default: 180 seconds

Range: 1 through 3600 seconds

maximum-helper-restart-time *seconds*—The maximum length of time the router waits between when it discovers that a neighboring router has gone down and when it declares the neighbor down. This value is applied to all neighboring routers, so it should be based on the time that the slowest RSVP neighbor requires for restart.

Default: 20 seconds

Range: 1 through 1800 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable hello messages from nonsession neighbors to be acknowledged with a hello acknowledgment message. Once hello acknowledgments are enabled, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or the configuration is changed by an administrator.

Default

Hello acknowledgments are disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:

- LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.
- Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.
- Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.

Options

number—Maximum number of hops.

Range: 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)

Default: 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

keep-multiplier

Syntax

```
keep-multiplier number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify a value used by RSVP to calculate timer values for network outages, and declare that a reservation or a neighbor is down. It indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

Starting in Junos OS Release 16.1, for MX Series routers and PTX Series routers, the default RSVP message refresh time, to which this multiplier is applied, has increased from 30 seconds to 20 minutes. The higher message refresh time provides support for RSVP Refresh Reduction Extensions, and improved scaling for MPLS traffic-engineered LSPs, as defined in RFC 2961. The changes are backward compatible so if any nodes in the two-hop neighborhood do not support the higher refresh time, the updated node will automatically fall back to the previous default refresh time to prevent error or tear down messages.

Options

number—Multiplier value.

Range: 1 through 255

Default: 3

NOTE: For MX Series routers and PTX Series routers (running Junos OS release 16.1 or later), this multiplier is applied to a default refresh time of 20 minutes. In earlier Junos OS releases, and for other platforms, the default refresh time remains 30 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 8.5.

Statement introduced in Junos OS Release 18.2. under the heirarchy level [edit routing-instances *instance-name* provider-tunnel]

Description

Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs. This feature can be used for a number of applications, including point-to-multipoint LSPs, flooding VPLS traffic, configuring ingress replication for IP multicast using MBGP MVPNs, and to enable RSVP automatic mesh. There is no default setting for the **label-switched-path-template** statement, so you must configure either the default-template using the **default-template** option, or you must specify the name of your preconfigured LSP template.

Options

default-template—Specify that the default LSP template be used for the dynamically generated LSPs.

lsp-template-name—Specify the name of an LSP to be used as a template for the dynamically generated LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

Description

Enable link protection on the specified interface. Using link protection, you can configure a network to reroute traffic quickly around broken links. To fully enable link protection, you also need to configure the **link-protection** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level. You can configure single or multiple bypasses for protected interface.

Default

Link protection is disabled.

Options

no-node-protection—Disable node-link protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

load-balance (Protocols RSVP)

Syntax

```
load-balance {  
    bandwidth;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Load-balance traffic between RSVP LSPs.

Options

bandwidth—Load-balance traffic between RSVP LSPs based on the bandwidth configured for each LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring Load Balancing Across RSVP LSPs | 801](#)

max-bypasses

Syntax

```
max-bypasses number;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],  
[edit protocols rsvp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Range modified in Junos OS Release 9.3.

Description

Specify the maximum number of dynamic bypass LSPs permitted for protecting this interface. When this option is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled. The limit on bypasses configured applies only to dynamically generated bypass LSPs. By default, this option is disabled and only one dynamic bypass LSP is enabled for each interface. If you configure **max-bypasses**, you must also configure the **bandwidth** statement.

Options

number—Configure the maximum number of bypass LSPs. If you configure a value of 0, no dynamic bypass LSPs are allowed to be established for the interface. Only static bypass LSPs can be configured.

Range: 0 through 99

Default: 1

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Configuring the Maximum Number of Bypass LSPs | 380](#)

no-local-reversion

Syntax

```
local-reversion;  
no-local-reversion;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.4.

Description

Disable RSVP local revertive mode as specified in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, **no-local-reversion** is enabled by default, that is, local reversion is not running, and the statement has been deprecated. To enable local reversion, use the **local-reversion** statement.

RSVP local revertive mode is supported on all Juniper Networks routers running Junos OS. It is the default behavior. If you include this statement, the Juniper Networks router uses global revertive mode instead. You might need to disable RSVP local revertive mode on Juniper Networks routers if your network includes equipment that does not support this mode.

The following information can also be found in RFC 4090. Refer to the RFC for additional information. When an LSP fails, the connection can be repaired locally using a traffic protection mechanism such as fast reroute. To restore the LSP to a full working path, RFC 4090 specifies the following strategies:

- Local revertive mode—Upon detecting that the path is restored, the point of local repair (PLR) resignals each of the LSPs that were formerly routed over the restored path. Every LSP successfully resignaled along the restored path is switched back.
- Global revertive mode—The ingress router of each tunnel is responsible for reoptimizing the LSPs that used the failed path. There are several potential reoptimization triggers: RSVP error messages, inspection of OSPF LSAs or IS-IS LSPs, and timers. This re-optimization process can proceed as soon as the failure is detected. It is not tied to the restoration of the failed path.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

node-hello

Syntax

```
(node-hello | no-node-hello);
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable node-ID based RSVP hellos globally on all of the RSVP interfaces on the router to allow Juniper Networks routers to interoperate with the equipment of other vendors. By default, the Junos OS uses interface-based RSVP hellos; node-ID based RSVP hellos are disabled. If you have not enabled RSVP node IDs on the router, Junos OS does not accept any node-ID hello packets.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, when using enhanced FRR, node-ID based hellos are enabled by default. To disable node-id based hello sessions, use the **no-node-hello** statement.

NOTE: If **link-protection** is enabled, remote node hellos that are initiated by the Point of Local Repair (PLR) to Node Protecting Merge Point (NP-MP) are enabled automatically. Similarly, if **no-enhanced-frr-profile** is enabled (that is, enhanced FRR is off), remote node hellos are automatically disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

no-adjacency-down-notification (Protocols IS-IS)

Syntax

```
no-adjacency-down-notification;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols isis interface interface-name],  
[edit protocols isis interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Description

Disable adjacency down notification for IS-IS to allow for migration from IS-IS to OSPF without disruption of the RSVP neighbors and associated RSVP-signaled label-switched paths (LSPs).

Whenever IS-IS is deactivated, the IS-IS adjacencies are brought down. IS-IS signals to RSVP to bring down any RSVP neighbors associated with the IS-IS adjacencies, and this further causes the associated LSPs signaled by RSVP to go down as well.

A similar process occurs whenever OSPF is deactivated. The OSPF neighbors are brought down. OSPF signals to RSVP to bring down any of the RSVP neighbors associated with the OSPF neighbors, and this further causes the associated LSPs signaled by RSVP to go down as well.

If you need to migrate from IS-IS to OSPF or from OSPF to IS-IS, the internal gateway protocol (IGP) notification to RSVP for an adjacency or neighbor down event needs to be ignored. Using the **no-adjacency-down-notification** or **no-neighbor-down-notification** statements, you can disable IS-IS adjacency down notification or OSPF neighbor down notification, respectively, until the migration is complete. The network administrator is responsible for configuring the statements before the migration, and then removing them from the configuration afterward, so that IGP notification can function normally.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[no-neighbor-down-notification](#) | 1995

no-authentication-check (Protocols RSVP)

Syntax

```
no-authentication-check;
```

Hierarchy Level

```
[edit protocols rsvp],
```

Release Information

Statement introduced in Junos OS Release 18.4R1.

Description

Skip authentication check for received messages.

Required Privilege Level

routing

RELATED DOCUMENTATION

[RSVP Authentication](#) | [771](#)

no-cspf (Protocols RSVP)

Syntax

```
no-cspf;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],  
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],  
[edit protocols rsvp interface interface-name link-protection],  
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced in Junos OS Release 7.5.

Description

Disable CSPF computation on all bypass LSPs or on a specific bypass LSP. You need to disable CSPF for link protection to function properly on interarea paths.

Default

CSPF is enabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Disabling CSPF for Bypass LSPs](#) | 381

no-interface-hello

Syntax

```
no-interface-hello;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 10.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable RSVP interface hellos globally on the router.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, the behavior of this statement has changed. On these platforms, rather than disabling RSVP interface hellos globally, the **no-interface-hello** command triggers a switch back to the previous profile for all label-switched paths (LSPs.)

This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the [hello-interval](#) statement. This configuration disables RSVP interface hellos globally but enables RSVP interface hellos on the specified interface. This configuration might be necessary in a heterogeneous network where some devices support RSVP node-ID hellos and other devices support RSVP interface hellos.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-neighbor-down-notification;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ospf area area-id interface interface-name],  
[edit protocols ospf area area-id interface interface-name]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Description

Disable neighbor down notification for OSPF to allow for migration from OSPF to IS-IS without disruption of the RSVP neighbors and associated RSVP-signaled LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

no-node-id-subobject

Syntax

```
no-node-id-subobject;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable the record route object (RRO) node-ID subobject for compatibility with earlier versions of Junos OS.

NOTE: For Junos OS Release 16.1 running on MX Series or PTX Series routers, the behavior of this statement has changed. On these platforms, rather than disabling the record route object (RRO) node ID sub-object, the **no-node-id-subobject** command triggers a switch back to the previous profile for all label-switched paths (LSPs).

To interoperate with other vendors' equipment, Junos OS supports the RRO node-ID subobject for use in inter-AS link and node protection configurations.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

no-p2mp-sublsp

Syntax

```
no-p2mp-sublsp;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 9.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Reject Resv messages that include the S2L_SUB_LSP object. By default, Resv messages that include the S2L_SUB_LSP object are accepted. However, in a network which includes Juniper Networks devices running both Junos OS Release 9.2 and later and Junos OS Release 9.1 and earlier, it is necessary to configure the **no-p2mp-sublsp** statement on devices running Junos OS Release 9.2 and later to ensure that point-to-multipoint LSPs function properly.

Default

Resv messages that include the S2L_SUB_LSP object are accepted.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

optimize-timer (Protocols RSVP)

Syntax

```
optimize-timer seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],  
[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure an optimize timer for a bypass LSP. The optimize timer initiates a periodic optimization process that reshuffles data LSPs among bypass LSPs to achieve the most efficient use of network resources. The optimization process attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all bypasses, or both.

Options

seconds—Specify the number of seconds between optimizations.

Range: 0 through 65,535 seconds

Default: 0 (disabled)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

path (Protocols RSVP)

Syntax

```
path address <strict | loose>;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure an explicit path (a sequence of strict or loose routes) to control where and how a bypass LSP is established. If multiple bypasses are configured, they all will use the same explicit path.

Default

No path is configured. CSPF automatically calculates the path the bypass LSP takes.

Options

address—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is **loose**. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.

Default: If you do not specify any routers explicitly, no routing limitations are imposed on the bypass LSP.

loose—(Optional) The next address in the **path** statement is loose. The LSP can traverse other routers before reaching this router.

Default: **strict**

strict—(Optional) The LSP must go to the next address specified in the **path** statement without traversing other nodes. This is the default.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

preemption

Syntax

```
preemption {  
  (aggressive | disabled | normal);  
  soft-preemption {  
    cleanup-timer seconds;  
  }  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control RSVP session preemption.

Default

normal

Options

aggressive—Preempt RSVP sessions whenever bandwidth is insufficient to handle all sessions. A session is preempted whenever bandwidth is lowered or a new higher-priority session is established.

disabled—Do not preempt RSVP sessions.

normal—Preempt RSVP sessions to accommodate new higher-priority sessions when bandwidth is insufficient to handle all sessions.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

priority (Protocols RSVP)

Syntax

```
priority setup-priority reservation-priority;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection bypass bypass-name],
[edit protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name link-protection bypass bypass-name],
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the setup priority and reservation priority for a bypass LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. The session with the lower-hold priority is preempted.

Options

reservation-priority—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 0 (Once the session is set up, no other session can preempt it.)

setup-priority—Setup priority.

Range: 0 through 7, where 0 is the highest and 7 is the lowest priority.

Default: 7 (The session cannot preempt any existing sessions.)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Statement introduced in Junos OS Release 10.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Statement introduced in 19.4R1 for cRPD instances.

Description

Configure a static LSP.

Options

lsp-name—Name of the path.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

subscription

Syntax

```
subscription percentage {
  ct0 percentage;
  ct1 percentage;
  ct2 percentage;
  ct3 percentage;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],
[edit logical-systems logical-system-name protocols rsvp interface interface-name link-protection],
[edit protocols rsvp interface interface-name],
[edit protocols rsvp interface interface-name link-protection]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the amount of bandwidth subscribed to a class type (when you have enabled Differentiated Services) or bypass LSP (when you have enabled link protection). **subscription** is the percentage of the link bandwidth that can be used for the RSVP reservation process.

Options

ctnumber percentage—Percentage of the class-type bandwidth allowed for reservations. If you specify a value greater than 100, you are oversubscribing the class type. You can specify bandwidth subscriptions for class types 0 through 3. This option is not available for bypass LSPs.

Range: 0 through 65,000

Default: 100 percent

percentage—Percentage of the class-type or bypass LSP bandwidth allowed for reservations. If you specify a value greater than 100, you are oversubscribing the class type or bypass LSP.

Range: 0 through 65,000

Default: 100 percent

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traceoptions (Protocols RSVP)

Syntax

```
traceoptions {
  enhanced-frr ;
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],
[edit protocols rsvp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable RSVP-level trace options.

Default

The default RSVP-level trace options are those inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

enhanced-frr—(Optional) Enable this option to trace internal events and state changes related to the FRR facility protection enhancements associated with the increased RSVP scaling introduced in Junos OS Release 16.1.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**.

files number—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **all**—All tracing operations
- **error**—All detected error conditions
- **event**—RSVP-related events
- **io-event [detail] [disable]** —Enable tracing of events that occur within the RSVP I/O task; can only be configured for the master routing instance. The trace output is generally independent of routing instance.
- **io-packets [detail] [disable] [receive] [send]** —Enable tracing of messages as they are received from the network or as they are sent out. This flag can be configured independently for each routing instance. Both bundled and individual messages are identified. Use *detail* to show all objects contained in the message. Use *send* and *receive* to limit tracing to outgoing or incoming packets.
- **lmp**—RSVP-LMP interactions
- **packets**—All RSVP packets
- **path**—All path messages
- **pathtear**—PathTear messages
- **resv**—Resv messages
- **resvtear**—ResvTear messages
- **route**—Routing information
- **state**—Session state transitions, including when RSVP-signaled LSPs come up and go down.

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-world-readable—(Optional) Enable only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

[edit routing-instances name protocols mpls static-label-switched-path name],
[edit tenants name routing-instances name protocols mpls static-label-switched-path name]
```

Release Information

Statement introduced in Junos OS Release 10.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

switch option introduced in Junos OS Release 14.1X53-D25.

member-interface option introduced in Junos OS Release 17.4R1 for the MX Series and PTX 5000.

Description

Configure a transit static LSP.

NOTE: When configuring transit static LSPs with label operation as **stitch**, the configured next-hop can only be a valid IP address and not an interface name.

Options

incoming-label—Incoming label value.

Range: 1000000 through 1048575

member-interface—Aggregated Ethernet (AE) member interface name.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

tunnel-services (RSVP)

Syntax

```
tunnel-services {  
    devices device-names;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp],  
[edit protocols rsvp]
```

Release Information

Statement introduced in Junos OS Release 8.1.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable ultimate-hop popping on point-to-multipoint LSPs. The Junos OS selects one of the available virtual tunnel (VT) interfaces to de-encapsulate the egress traffic. By default, the selection process is performed automatically.

Default

Ultimate-hop popping is disabled.

Options

devices *device-names*—Specify which VT interfaces are used to handle the RSVP traffic.

Range: 0 to 8 devices

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

| [Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs](#) | 810

ultimate-hop-popping

Syntax

```
ultimate-hop-popping;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],  
[edit logical-systems logical-system-name protocols mpls label-switched-path label-switched-path-name],  
[edit protocols mpls],  
[edit protocols mpls label-switched-path label-switched-path-name]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Statement introduced in Junos OS Release 13.2 for PTX Series Packet Transport Routers.

Description

Enable ultimate-hop popping on LSPs. Configure this statement on the device at the LSP ingress. In ultimate-hop popping, the MPLS label is popped from the IP packet at the PE router. The IP address is checked in a second address lookup (also at the PE router), and then the packet is forwarded to its destination.

Be aware of the following platform requirements and restrictions:

- UHP LSPs using VT interfaces—Supported on all M Series, MX Series, T Series, and TX Matrix routers.
- UHP LSPs using LSI interfaces—Supported on MX 3D Series routers only.
- UHP LSP requirements for the egress PE device—For M Series and T Series routers, a VT interface is needed.
- UHP LSPs and Layer 3 VPNs—UHP LSPs are supported for Layer 3 VPNs configured on MX 3D Series routers only.
- UHP LSPs and VPLS—UHP LSPs are supported for VPLS configured on MX 3D Series routers only. You must configure the *no-tunnel-services* statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

Default

Ultimate-hop popping is disabled by default on LSPs. Penultimate-hop popping is the default behavior. In penultimate-hop popping, the final MPLS label is popped from the IP packet at the last provider router in the network before being forwarded to the PE router. The PE router receives the packet and checks the IP address, and then the packet is forwarded to its destination.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[explicit-null | 1733](#)

update-threshold

Syntax

```
update-threshold {  
    threshold-percent;  
    threshold-value threshold-value;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols rsvp interface interface-name],  
[edit protocols rsvp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

threshold-value option introduced in Junos OS Release 19.4R1 on all platforms.

Description

Adjust the threshold at which a change in bandwidth triggers an interior gateway protocol (IGP) update.

Options

threshold-percent—Specify the percentage change in reserved bandwidth to trigger IGP update.

Default: 10 percent

Range: 0.001 through 20 percent

threshold-value *threshold-value*—Specify the change in reserved bandwidth to trigger IGP update. (is capped at 20% of link bandwidth).

If the threshold-value is configured to greater than 20% of bandwidth on that link, the threshold-value is capped at 20% of bandwidth.

For instance, if bandwidth on an interface is 1Gbps, and the **threshold-value** is configured greater than 200Mbps, the **threshold-value** is capped at 200Mbps. The *threshold-percent* is displayed as 20.000% and the **threshold-value** as 200Mbps.

NOTE: The two options, *threshold-percent* and **threshold-value**, are mutually exclusive. You can configure only one option at a given point in time to generate an IGP update for lower bandwidth reservations. As a result, when one option is configured, the other option is calculated and displayed on the CLI.

For instance, on a link of 1Gbps, if the *threshold-percent* is configured to 5%, the **threshold-value** is calculated and displayed as 50Mbps. Similarly, if the **threshold-value** is configured to 50m, then the *threshold-percent* is calculated and displayed as 5%.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

Statement introduced for BGP in Junos OS Release 8.0.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Statement introduced for BMP in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced for BMP in Junos OS Release 13.3.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Configure an authentication algorithm type.

NOTE: Keep the following points in mind when you configure the authentication algorithm in an IPsec proposal:

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, an error occurs and the tunnel is not established in this scenario. For example, if one end of the tunnel contains router 1 configured with the authentication algorithm as hmac-sha-256-128 and the other end of the tunnel contains router 2 configured with the authentication algorithm as hmac-md5-96, the VPN tunnel is not established.
- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, and when one end of the tunnel contains two IPsec proposals to check whether a less secure algorithm is selected or not, an error occurs and the tunnel is not established. For example, if you configure two authentication algorithms for an IPsec proposal as hmac-sha-256-128 and hmac-md5-96 on one end of the tunnel, router 1, and if you configure the algorithm for an IPsec proposal as hmac-md5-96 on the other end of the tunnel, router 2, the tunnel is not established and the number of proposals mismatch.
- When you configure two IPsec proposals at both ends of a tunnel, such as the **authentication-algorithm hmac-sha-256-128** and **authentication-algorithm hmac-md5-96** statements at the `[edit services ipsec-vpn ipsec proposal proposal-name]` hierarchy level on one of the tunnel, router 1 (with the algorithms in two successive statements to specify the order), and the **authentication-algorithm hmac-md5-96** and **authentication-algorithm hmac-sha-256-128** statements at the `[edit services ipsec-vpn ipsec proposal proposal-name]` hierarchy level on one of the tunnel, router 2 (with the algorithms in two successive statements to specify the order, which is the reverse order of router 1), the tunnel is established in this combination as expected because the number of proposals is the same on both ends and they contain the same set of algorithms. However, the authentication algorithm selected is hmac-md5-96 and not the stronger algorithm of hmac-sha-256-128. This method of selection of the algorithm occurs because the first matching proposal is selected. Also, for a default proposal, regardless of whether the router supports the Advanced Encryption Standard (AES) encryption algorithm, the 3des-cbc algorithm is chosen and not the aes-cfb algorithm, which is because of the first algorithm in the default proposal being selected. In the sample scenario described here, on router 2, if you reverse the order of the algorithm configuration in the proposal so that it is the same order as the one specified on router 1, hmac-sha-256-128 is selected as the authentication method.
- You must be aware of the order of proposals in an IPsec policy at the time of configuration if you want the matching of proposals to happen in a certain order of preference, such as the strongest algorithm to be considered first when a match is made when both policies from the two peers have a proposal.

Options

algorithm—Specify one of the following types of authentication algorithms:

- **aes-128-cmac-96**—Cipher-based message authentication code (AES128, 96 bits).
- **hmac-sha-1-96**—Hash-based message authentication code (SHA1, 96 bits).
- **md5**—Message digest 5.

Default: **hmac-sha-1-96**

NOTE: The default is not displayed in the output of the **show bgp bmp** command unless a key or key-chain is also configured.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems name routing-instances instance-name protocols ldp session address],  
[edit protocols ldp session address],  
[edit routing-instances instance-name protocols ldp session address]
```

Release Information

Statement introduced in Junos OS Release 8.0.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Apply and enable an authentication keychain to the routing device. Note that the referenced key chain must be defined. When configuring the authentication key update mechanism for LDP, you cannot commit the **0.0.0.0/allow** statement with authentication keys or key chains. The CLI issues a warning and fails to commit such configurations.

NOTE: You must also configure an authentication algorithm using the **authentication-algorithm** statement.

Options

key-chain—Authentication keychain name. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Configure session parameters for LDP sessions established with the remote LFA node that are automatically targeted using the loopback addresses. Configure parameters of automatically targeted sessions for remote LFA only.

Options

maximum-sessions *seconds* —Specify the maximum number of auto-targeted LDP sessions allowed. Include this statement to optimize the use of router memory.

Default: 100

Range: 1 through 1000

teardown-delay *seconds* —Specify the minimum time period for which the auto-targeted session must be alive before tearing down the auto-targeted LDP sessions to the remote LFA node. Include this statement to prevent rapid route-resolution in case of temporary change in IGP topology.

Default: 90 seconds

Range: 1 through 300 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name protocols ldp oam fec address],
[edit protocols ldp oam],
[edit protocols ldp oam fec address]

```

Release Information

Statement introduced in Junos OS Release 7.6.

Support for the **bfd-liveness-detection** statement at the **[edit protocols ldp oam fec address]** hierarchy level and the **ecmp** option added in Junos OS Release 9.0.

Support for the **failure-action** statement with the **remove-nexthop** and **remove-route** options and the **holddown-interval** statement added in Junos OS Release 9.4.

Description

Enable Bidirectional Forwarding Detection (BFD) for all MPLS LSPs or for just a specific LSP.

Options

minimum-interval—Minimum transmit and receive interval.

Range: 50 through 255,000 milliseconds

Default: 50

minimum-receive-interval—Minimum receive interval.

Range: 50 through 255,000 milliseconds

Default: 50

minimum-transmit-interval—Minimum transmit interval.

Range: 50 through 255,000 milliseconds

Default: 50

multiplier—Detection time multiplier.

Range: 50 through 255

Default: 3

The other options are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

deaggregate

Syntax

```
deaggregate | no-deaggregate;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control forwarding equivalence class (FEC) deaggregation on the router. The use of the **deaggregate** statement in LDP is a standard practice that we recommend for LDP deployments.

Default

Deaggregation is disabled on the router.

Options

deaggregate—Deaggregate FECs.

no-deaggregate—Aggregate FECs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

disable (Protocols LDP)

Syntax

```
disable;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp graceful-restart],
[edit logical-systems logical-system-name protocols ldp interface interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp interface
  interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-options graceful-restart],
[edit protocols ldp graceful-restart],
[edit protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name routing-options graceful-restart]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Explicitly disable LDP on an interface, or explicitly disable LDP graceful restart.

Default

LDP is enabled on interfaces configured with the LDP **interface** statement. LDP graceful restart is automatically enabled when graceful restart is enabled under the **[edit routing-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

dod-request-policy

Syntax

```
dod-request-policy dod-request-policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 12.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify the name of the LDP downstream on demand request policy. The **dod-request-policy** statement performs exact match, as a result, LDP sends label request messages only for those FECs matching in the downstream on demand request policy.

Options

dod-request-policy-name—Specify the name of the downstream on demand request policy.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[Example: Configuring LDP Downstream on Demand](#) | 971

downstream-on-demand

Syntax

```
downstream-on-demand;
```

Hierarchy Level

```
[edit logical systems logical-system-name protocols ldp session session-address],  
[edit protocols ldp session session-address]
```

Release Information

Statement introduced in Junos OS Release 12.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Enable LDP downstream on demand on the LDP session. LDP is widely deployed in downstream unsolicited advertisement mode. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between access and aggregation networks to minimize the workload for the access node (AN) control plane and to avoid the storage of tens of thousands of label bindings from upstream aggregation nodes.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[Example: Configuring LDP Downstream on Demand](#) | 971

ecmp

Syntax

```
ecmp;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-liveness-detection],  
[edit logical-systems logical-system-name protocols ldp oam fec address bfd-liveness-detection],  
[edit protocols ldp oam bfd-liveness-detection],  
[edit protocols ldp oam fec address bfd-liveness-detection]
```

Release Information

Statement introduced in Junos OS Release 8.5.

Statement introduced in Junos OS Release 15.1X53-D30 for QFX Series switches.

Description

Allows LDP to establish BFD sessions for all ECMP paths configured for the specified FEC. If you configure the **ecmp** statement, you must also configure the **periodic-traceroute** statement for the specified FEC. If you do not do so, the commit operation fails. You can configure the **periodic-traceroute** statement at the global hierarchy level ([**edit protocols ldp oam**]) while only configuring the **ecmp** statement for a specific FEC ([**edit protocols ldp oam fec *address* bfd-liveness-detection**]).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

egress-policy

Syntax

```
egress-policy [ policy-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the prefixes advertised into LDP.

Default

Only the loopback address is advertised.

Options

policy-names—Name of one or more routing policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

explicit-null (Protocols LDP)

Syntax

```
explicit-null;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Advertise label 0 to the egress router of a label-switched path (LSP).

Default

If you do not include the **explicit-null** statement in the MPLS configuration, label 3 (implicit null) is advertised.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

failure-action (Protocols LDP)

Syntax

```
failure-action {
  remove-nexthop;
  remove-route;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp oam bfd-livenesss-detection],
[edit logical-systems logical-system-name protocols ldp oam fec address bfd-livenesss-detection],
[edit protocols ldp oam bfd-livenesss-detection],
[edit protocols ldp oam fec address bfd-livenesss-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Configure route and next-hop properties in the event of a BFD session failure event on an LDP LSP. The failure event could be an existing BFD session that has gone down or could be a BFD session that never came up. LDP adds back the route or next hop when the relevant BFD session comes back up.

Options

remove-nexthop—Remove a route corresponding to a next hop of the LSP's route at the ingress node when a BFD session failure event is detected.

remove-route—Remove the route corresponding to an LSP from the appropriate routing tables when a BFD session failure event is detected. If the LSP is configured with ECMP and a BFD session corresponding to any path goes down, the route is removed.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

graceful-restart (Protocols LDP)

Syntax

```
graceful-restart {  
  disable;  
  helper-disable;  
  maximum-neighbor-recovery-time value;  
  reconnect-time seconds;  
  recovery-time value;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure LDP graceful restart on the LDP master protocol instance or for a specific routing instance.

NOTE: When you alter the graceful restart configuration at either the **[edit routing-options graceful-restart]** or **[edit protocols ldp graceful-restart]** hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp interface
  interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp targeted-hello],
[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for LDP targeted hellos added in Junos OS Release 9.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Control the LDP timer that regulates how often hello messages are sent. You can control the rate both link hello messages and targeted hello messages are sent depending on the hierarchy level at which you configure the **hello-interval** statement.

Options

seconds—Length of time between transmission of hello packets.

Range: 1 through 65,535 seconds

Default: 5 seconds for link hello messages, 15 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

helper-disable (LDP)

Syntax

```
helper-disable;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp graceful-restart],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp graceful-restart],  
[edit protocols ldp graceful-restart],  
[edit routing-instances routing-instance-name protocols ldp graceful-restart]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Disable helper mode for LDP graceful restart. When helper mode is disabled, a router cannot help a neighboring router that is attempting to restart LDP.

Default

Helper mode is enabled by default on all routing protocols (including LDP) that support graceful restart.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit protocols ldp oam bfd-livenesss-detection],  
[edit protocols ldp oam fec address bfd-livenesss-detection]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Description

Specify how long the BFD session should be up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

Options

holddown-interval—Number of seconds the BFD session should remain up before adding the route or next hop.

Default: 0 seconds

Range: 0 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols ldp interface interface-name],
[edit protocols ldp targeted-hello],
[edit routing-instances routing-instance-name protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp targeted-hello]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for LDP targeted hellos added in Junos OS Release 9.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. You can specify times for both link hello messages and targeted hello messages depending on the hierarchy level at which you configure the **hold-time** statement.

Options

seconds—Hold-time value.

Range: 1 through 65,535 seconds

Default: 15 seconds for link hello messages, 45 seconds for targeted hello messages

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

ignore-lsp-metrics

Syntax

```
ignore-lsp-metrics;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ospf traffic-engineering shortcuts],  
[edit protocols ospf traffic-engineering shortcuts]
```

Release Information

Statement introduced in Junos OS Release 7.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Cause OSPF to ignore the RSVP LSP metric.

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This can cause interoperability problems when you configure LDP tunneling over RSVP LSPs in heterogeneous networks.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 9.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

Options

holddown-interval *seconds*—Time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational.

Default: 10 seconds

Range: 10 through 60 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols ldp oam]
```

Release Information

Statement introduced in Junos OS Release 9.4.

Statement introduced at the **[edit protocols ldp entropy-label]** hierarchy level in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Configure an LDP ingress policy for either the entropy label or Operation, Administration, and Management (OAM).

For OAM, configure the ingress policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

Options

ingress-policy-names—Specify the names of the ingress policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

dual-transport statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

family statement introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

transport-preference option introduced in Junos OS Release 16.1 for the M320 Series, MX Series, and PTX Series.

Description

Enable LDP routing on the router or switch.

You must include the **ldp** statement in the configuration to enable LDP on the router or switch.

Default

LDP is disabled on the router.

Options

transport-preference ipv4 | ipv6— Select the preferred transport for TCP connection when both IPv4 and IPv6 are enabled. If **transport-preference ipv4** is configured, LDP will attempt to establish the TCP connection using IPv4. If **transport-preference ipv6** is configured, LDP will attempt to establish the TCP connection using IPv6.

Default: ipv6

make-before-break (LDP)

Syntax

```
make-before-break {  
    timeout seconds;  
    switchover-delay seconds;  
}
```

Hierarchy Level

```
[edit protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Description

Configures make before break (MBB) for multicast LDP (MLDP) link protection to ensure minimum packet loss when attempting to signal a new label-switched path (LSP) before tearing down the old LSP path.

Options

timeout *seconds*—Specify a value to change a make -before-break timeout for point-to-multipoint LSPs.

Even if an MBB acknowledgment is not received for a point-to-multipoint LSP before the specified timeout period expires, the label-switching router (LSR) performs an MBB switchover from the old LSR to the new upstream LSR.

Range: 1 through 300 seconds

Default: 30 seconds

switchover-delay *seconds*—Specify a value to change switchover delay for a point-to-multipoint LSP from the old LSR to the new upstream LSR. If an MBB acknowledgment is received on a point of local repair (PLR) router, the PLR waits for the specified seconds to switch its upstream LSR from the old LSR to the new LSR.

Range: 1 through 300 seconds

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

mldp-inband-signalling (Protocols Multipoint LDP)

Syntax

```
mldp-inband-signalling {
  policy policy-name;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim],
[edit protocols pim],
```

Release Information

Statement introduced in Junos OS Release 13.2.

Support added in Junos OS Release 18.2R1 for using this command in conjunction with distributed MLD or distributed IGMP.

Description

Multipoint LDP (mLDP) in-band signalling lets you carry multicast traffic across an existing IP/MPLS backbone, while avoiding the use of PIM in the provider core.

On the label-edge router (LER), enable PIM to use mLDP in-band signaling for the upstream neighbors when the LER does not detect a PIM upstream neighbor. On the egress nodes, configure the MPLS LSP root in the PIM configuration, using the **policy** statement.

When used in conjunction with distributed MLD or distributed IGMP, mLDP inband signalling supports interconnecting separate PIM domains via a MPLS-based core. To enable the inter-working, **chassis network-services enhanced-ip** must be enabled and you need to set the **dynamic-profiles profile-name protocols igmp|mld interface interface-name** to **distributed**. Enabling this command, **mldp-inband-signalling**, has PIM act as a multipoint LDP inband edge router.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

mofrr-asm-starg (Multicast-Only Fast Reroute in a PIM Domain)

Syntax

```
mofrr-asm-starg;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-options multicast
stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

Enable **mofrr-asm-starg** to include any-source multicast (ASM) for (*,G) joins in the Multicast-only fast reroute (MoFRR).

NOTE: **mofrr-asm-starg** applies to IP-PIM only. When enabled for group G, *,G will undergo MoFRR as long as there is no S#,G for Group G. In other words, *,G MoFRR will cease and any old states will be torn down when S#,G is created. Note too, that **mofrr-asm-starg** is not supported for mLDP (since mLDP itself does not support *,G).

In a PIM domain with MoFRR enabled, the default for **stream-protection** is S,G routes only.

Context: Multicast-only fast reroute (MoFRR) can be used to reduce traffic loss in a multicast distribution tree in the event of link down. To employ MoFRR, a downstream router is configured with an alternative path back towards the source, over which it receives a backup live stream of the same multicast traffic. That router propagates the same (S,G) join toward both upstream neighbors in order to create duplicate multicast trees. If a failure is detected on the primary tree, the router switches to the backup tree to prevent packet loss.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

When you configure multicast-only fast reroute (MoFRR) in a PIM domain, allow only a disjoint RPF (an RPF on a separate plane) to be selected as the backup RPF path.

In a multipoint LDP MoFRR domain, the same label is shared between parallel links to the same upstream neighbor. This is not the case in a PIM domain, where each link forms a neighbor. The **mofrr-disjoint-upstream-only** statement does not allow a backup RPF path to be selected if the path goes to the same upstream neighbor as that of the primary RPF path. This ensures that MoFRR is triggered only on a topology that has multiple RPF upstream neighbors.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

MoFRR is supported on both equal-cost multipath (ECMP) paths and non-ECMP paths. Unicast loop-free alternate (LFA) routes need to be enabled to support MoFRR on non-ECMP paths. LFA routes are enabled with the link-protection statement in the interior gateway protocol (IGP) configuration. When you enable link protection on an OSPF or IS-IS interface, Junos OS creates a backup LFA path to the primary next hop for all destination routes that traverse the protected interface.

In the context of load balancing, MoFRR prioritizes the disjoint backup in favor of load balancing the available paths.

For Junos OS releases before 15.1R7, for both ECMP and Non-ECMP scenarios, the default MoFRR behavior was *sticky*, that is, if the Active link went down, the Active Path selection would give preference to Backup Path for the transition. The Active Path would not follow the unicast selected gateway

Starting in Junos OS Release 15.1R7 however, the default behavior for non-EMCP scenarios is to be *nonsticky*, that is, the selection of Active Path strictly follows unicast selected gateway. MoFRR no longer chooses a unicast LFA path to become the MoFRR Active path; only a unicast LFA path can be selected to become MoFRR Backup.

Default

By default, the backup path gets promoted to be the primary path when MoFRR is configured in a PIM domain.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

neighbor (Protocols LDP)

Syntax

```
neighbor neighbor-address;
```

Hierarchy Level

```
[edit protocols ldp],
```

Release Information

Statement introduced in Junos OS Release 14.2R1 on all platforms.

Description

Configure an LDP targeted neighbor.

LDP sends a targeted hello message to the configured remote neighbor with a targeted request-send-targeted hello message (T) bit set. If the remote neighbor allows receipt of asymmetric hello messages, or if it is configured with the source address as the targeted neighbor, it responds with a targeted hello message. The receipt of a targeted hello message establishes a targeted adjacency with the remote neighbor as described in RFC 5036. Subsequently, a targeted session is established to the remote neighbor.

Options

neighbor-address—IP address of the remote LDP neighbor.

Required Privilege Level

routing

p2mp (Protocols LDP)

Syntax

```
p2mp {
  no-rsvp-tunneling;
  recursive;
  root-address root-address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],
[edit protocols ldp],
[edit routing-instances routing-instance-name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 11.2.

no-rsvp-tunneling option added in Junos OS Release 16.1R5.

Description

Enable point-to-multipoint MPLS LSPs in an LDP-signaled LSP.

Options

no-rsvp-tunneling—(Optional) Disable LDP point-to-multipoint LSPs from using RSVP-TE LSPs for tunneling, and use LDP paths instead.

NOTE: The **no-rsvp-tunneling** option is introduced in Junos OS Release 16.1R5, 17.3R1, 17.2R2, 16.2R3, and later releases.

Starting in Junos OS Release 12.3R1, Junos OS provides support for Multipoint LDP (M-LDP) for Targeted LDP (T-LDP) sessions with unicast replication, in addition to link sessions. As a result, the default behavior of M-LDP over RSVP tunneling is similar to unicast LDP. However, because T-LDP is chosen over LDP and link sessions to signal point-to-multipoint LSPs, the **no-rsvp-tunneling** option enables LDP natively throughout the network.

recursive—(Optional) Configure point-to-multipoint recursive parameters, including **route**.

root-address *root-address*—(Optional) Specify the root address of the point-to-multipoint LSP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

policy (Multicast-Only Fast Reroute)

Syntax

```
policy policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-options multicast
stream-protection],
[edit logical-systems logical-system-name routing-options multicast stream-protection],
[edit routing-instances routing-instance-name routing-options multicast stream-protection],
[edit routing-options multicast stream-protection]
```

Release Information

Statement introduced in Junos OS Release 14.1.

Statement introduced in Junos OS Release 17.4R1 for QFX Series switches.

Description

When you configure multicast-only fast reroute (MoFRR), apply a routing policy that filters for a restricted set of multicast streams to be affected by your MoFRR configuration. You can apply filters that are based on source or group addresses.

For example:

```
routing-options {
  multicast {
    stream-protection {
      policy mofrr-select;
    }
  }
}
policy-statement mofrr-select {
  term A {
    from {
      source-address-filter 225.1.1.1/32 exact;
    }
    then {
      accept;
    }
  }
  term B {
    from {
```

```

        source-address-filter 226.0.0.0/8 orlonger;
    }
    then {
        accept;
    }
}
term C {
    from {
        source-address-filter 227.1.1.0/24 orlonger;
        source-address-filter 227.4.1.0/24 orlonger;
        source-address-filter 227.16.1.0/24 orlonger;
    }
    then {
        accept;
    }
}
term D {
    from {
        source-address-filter 227.1.1.1/32 exact;
    }
    then {
        reject; #MoFRR disabled
    }
}
term E {
    from {
        route-filter 227.1.1.0/24 orlonger;
    }
    then accept;
}
...
}

```

policy (Protocols Multipoint LDP)

Syntax

```
policy policy-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim mldp-inband-signalling],  
[edit protocols pim mldp-inband-signalling]
```

Release Information

Statement introduced in Junos OS Release 13.2.

Description

Multipoint LDP (M-LDP) in-band signaling enables you to carry multicast traffic across an existing IP/MPLS backbone, while avoiding the use of PIM in the provider core.

On the egress nodes of the point-to-multipoint LSP, specify an M-LDP join translation filter policy where PIM messages are translated into M-LDP FEC bindings. The policy statement is needed when internal BGP (IBGP) is not available in the core site or to override IBGP-based LSP root detection.

The filter policy is configured at the **[edit policy-options]** hierarchy level. The policy generally specifies one or more source-address filters and the point-to-multipoint LDP root IP address using the **p2mp-lsp-root** policy action.

Options

policy-name—Name of a policy configured at the **[edit policy-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

preference (Protocols LDP)

Syntax

```
preference preference;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit protocols ldp interface interface-name],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit protocols ldp interface interface-name],  
[edit routing-instances routing-instance-name protocols ldp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Set the route preference level for LDP routes.

Options

preference—Preferred value.

Range: 0 through 255

Default: 9

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

[edit routing-options source-packet-routing mapping-server-entry]
```

Release Information

Statement introduced in Junos OS Release 18.2R1.

Description

Configure the IP address and index number of the prefix segment for the LDP mapping server.

Options

prefix-segment—IP address of the prefix segment.

index *index*—Prefix segment index.

Range: 0 through 199999

Required Privilege Level

routing

[edit routing-options source-packet-routing mapping-server-entry]
```

Release Information

Statement introduced in Junos OS Release 18.2R1.

attached, **domain-wide-flooding**, and **no-node-segment** options introduced in Junos OS Release 19.1R1.

Description

Configure the prefix segment range for the LDP mapping server.

Options

prefix-segment-range-name—Name of the prefix segment range.

attached—(Optional) Set the flag in IS-IS mapping server advertisement to indicate that the prefixes and SIDs advertised in the SID or Label Binding TLV are directly connected to their originators.

domain-wide-flooding—(Optional) Set an S flag in the IS-IS mapping server advertisement to indicate that the SID or Label Binding TLV is flooded across the entire routing domain.

no-node-segment—(Optional) Clear the node segment flag in the mapping server prefix segment to indicate that the prefix has originated from a single node.

size *size*—Size of prefix segment range.

Range: 1 through 1024

start-index *start-index*—Include start index.

Range: 0 through 199999

start-prefix *start-prefix*—Include start prefix.

Required Privilege Level

- routing—To view this statement in the configuration.
- routing-control—To add this statement to the configuration.

}
```

Hierarchy Level

```
[edit logical-systems name protocols ldp],
[edit logical-systems name routing-instances name protocols ldp],
[edit protocols ldp],
[edit routing-instances name protocols ldp]
```

Release Information

Statement introduced before Junos OS Release 7.4.

authentication-algorithm statement introduced in Junos OS Release 7.6.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

transport-address option introduced in Junos OS Release 19.1R1 for all platforms.

Description

Configure LDP session parameters by specifying the session destination address.

Options

session-address—Session destination address.

authentication-algorithm—Authentication algorithm name.

Values:

- **aes-128-cmac-96**—Cipher-based Message Authentication Code (AES128) (96 bits).
- **hmac-sha-1-96**—Hash-based Message Authentication Code (SHA1) (96 bits).
- **md5**—Message Digest 5.

authentication-key—MD5 authentication key.

authentication-key-chain—Key chain name.

downstream-on-demand—Configure downstream on demand label distribution mode.

mtu-discovery—Enable TCP path MTU discovery.

no-mtu-discovery—Disable TCP path MTU discovery.

transport-address *transport-address*—IP address used for TCP sessions to the LDP neighbors that have targeted-LDP adjacencies.

You cannot configure this statement for LDP sessions that have discovered adjacencies.

The transport-address configuration can be rejected at the time of validation, if there is no interface with the configured IP address.

Required Privilege Level

routing

session-group

Syntax

```
session-group name {
  authentication-algorithm (aes-128-cmac-96 | hmac-sha-1-96 | md5);
  authentication-key authentication-key;
  authentication-key-chain authentication-key-chain;
  downstream-on-demand;
  (mtu-discovery | no-mtu-discovery);
  transport-address transport-address;
}
```

Hierarchy Level

```
[edit logical-systems name protocols ldp],
[edit logical-systems name routing-instances name protocols ldp],
[edit protocols ldp],
[edit routing-instances name protocols ldp]
```

Release Information

Statement introduced in Junos OS Release 16.1.

transport-address option introduced in Junos OS Release 19.1R1 for all platforms.

Description

Specify the prefix address of the aggregated group of LDP neighbors for the remote end of the LDP session.

The **session-group** statement is useful when an LDP neighbor is dynamic; for instance, in the case of remote loop free alternate (LFA), a targeted or indirect LDP neighbor is automatically picked from any of the nodes in the network.

The **session-group** statement can also be used for configuring authentication for a prefix group, as LDP authentication for all sessions or authentication at the interface level is not supported.

The remaining statements are explained separately. See [CLI Explorer](#).

Options

name—Session destination address or prefix length.

authentication-algorithm—Authentication algorithm name.

Values:

- *aes-128-cmac-96*—Cipher-based Message Authentication Code (AES128) (96 bits)
- *hmac-sha-1-96*—Hash-based Message Authentication Code (SHA1) (96 bits)

- *md5*—Message Digest 5

authentication-key—MD5 authentication key.

authentication-key-chain—Authentication key chain name.

downstream-on-demand—Configure downstream on demand label distribution mode.

mtu-discovery | no-mtu-discovery—Enable and disable TCP path MTU discovery, respectively.

transport-address *transport-address*—IP address used for TCP sessions to the LDP neighbors that have targeted-LDP adjacencies, and fall under the same IP subnet.

You cannot configure this statement for LDP sessions that have discovered adjacencies.

The transport-address configuration can be rejected at the time of validation, if there is no interface with the configured IP address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

session-protection

Syntax

```
session-protection {  
    timeout seconds;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols ldp],  
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols ldp],  
[edit protocols ldp],  
[edit routing-instances routing-instance-name protocols ldp]
```

Description

Configure when an LDP session is torn down and resignaled after the router stops receiving hello messages from a neighboring router. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished. The LDP session remains up for the duration specified as long as the routers maintain IP network connectivity.

Options

timeout *seconds*—Time in seconds before the LDP session is torn down and resignaled.

Range: 1 through 65,535 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

match-on address option for the **filter** flag modifier added in Junos OS Release 10.4.

nsr-synchronization and **p2mp-nsr-synchronization** operations for **flag** statement introduced in Junos OS Release 13.3.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Specify LDP protocol-level trace options.

Default

The default LDP protocol-level trace options are inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **ldp-log**. We recommend that you place LDP tracing output in the file **ldp-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **address**—Operation of address and address withdrawal messages
- **binding**—Label-binding operations
- **error**—Error conditions
- **event**—Protocol events
- **initialization**—Operation of initialization messages
- **label**—Operation of label request, label map, label withdrawal, and label release messages
- **notification**—Operation of notification messages
- **nsr-synchronization**— Nonstop active routing synchronization events
- **p2mp-nsr-synchronization**—Point-to-multipoint nonstop active routing synchronization events
- **packets**—Equivalent to setting **address**, **initialization**, **label**, **notification**, and **periodic** flags (see also the **filter** flag modifier)
- **path**—Label-switched path operations
- **periodic**—Operation of hello and keepalive messages
- **route**—Operation of route messages
- **state**—Protocol state transitions

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information.
- **disable**—Disable this trace flag.
- **filter**—Filter to apply to this flag. The **filter** flag modifier can be applied only to the **route**, **path**, and **binding** flags. This flag modifier has the following options:
 - **match-on**—Match on argument specified. The **match-on** option has the following suboptions:
 - **address**—Filter based on the source and destination addresses of packets. Available for the **packets** flag option only.
 - **fec**—Filter based on the FEC associated with the traced object.
 - **policy *policy-name***—Specify the filter policy.
- **receive**—Packets being received.
- **send**—Packets being transmitted.

no-world-readable—(Optional) Prevent all users from reading the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

LDP traffic statistics display the amount of traffic passed through a router for a particular FEC.

Options

file *filename*—Name of the file to receive the output of the LDP statistics operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.

files *number*—(Optional) Maximum number of LDP statistics files. When a statistics file named ***ldp-stat*** reaches its maximum size, it is renamed ***ldp-stat.0***, then ***ldp-stat.1***, and so on, until the maximum number of LDP statistics files is reached. Then the oldest file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you also must include the **size** statement to specify the maximum file size.

interval *seconds*—(Optional) Specify the interval at which the statistics are polled and written to the file.

Default: 300 seconds (5 minutes)

no-penultimate-hop—(Optional) Do not collect traffic statistics on the penultimate hop router.

no-world-readable—(Optional) Prevent all users from reading the log file.

size *size*—(Optional) Maximum size of each statistics file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a statistics file named *ldp-stat* reaches this size, it is renamed *ldp-stat.0*. When *ldp-stat* again reaches this size, *ldp-stat.0* is renamed *ldp-stat.1* and *ldp-stat* is renamed *ldp-stat.0*. This renaming scheme continues until the maximum number of statistics files is reached. Then the oldest statistics file is overwritten.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you also must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable log file access for all users.

[edit protocols ldp interface interface-name],
[edit routing-instances routing-instance-name protocols ldp interface interface-name]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

address option introduced in Junos OS Release 19.1R1 for all platforms.

Description

Enables you to configure the IP address used to specify the TCP session for the LDP session. Routers must first establish a TCP session between one another before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

Default

router-id

Options

address—Use the specified IP address as the transport address for the LDP session.

interface—Use the first IP address on the interface as the transport address for any LDP sessions to neighbors that can be reached over that interface. You cannot specify the **interface** option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the **router-id** option.

router-id—Use router identifier as the transport address. Unless otherwise configured, the router identifier is the loopback address.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers

(**ethernet**, **vlan-ccc**, and **vlan-tcc** options only).

Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Metro Routers. Only the **atm-ccc-cell-relay** and **atm-ccc-vc-mux** options are supported on ACX Series routers.

Statement introduced in Junos OS Release 17.3R1 for QFX10000 Series switches (**ethernet-ccc** and **vlan-ccc** options only).

Description

Configure a logical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.

Starting in Junos OS Release 20.1R1, aggregated ethernet interfaces supports VLAN TCC (Translational cross-connect) encapsulation on MX series platforms. See [“Configuring VLAN TCC Encapsulation” on page 1298](#) for more details. Non-ethernet media types, SONET and ATM interfaces are only supported. It is expected that the user will have the member links of aggregated ethernet with supported hardware for configuring VLAN TCC encapsulation and no commit check is performed externally for the aggregated ethernet (AE) interfaces.

Options

atm-ccc-cell-relay—Use ATM cell-relay encapsulation.

atm-ccc-vc-mux—Use ATM virtual circuit (VC) multiplex encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

atm-cisco-nlpid—Use Cisco ATM network layer protocol identifier (NLPID) encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-mlppp-llc—For ATM2 IQ interfaces only, use Multilink Point-to-Point (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a Link Services or Voice Services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.

atm-nlpid—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-ppp-llc—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over AAL5 LLC encapsulation.

atm-ppp-vc-mux—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over ATM AAL5 multiplex encapsulation.

atm-snap—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM subnetwork attachment point (SNAP) encapsulation.

atm-tcc-snap—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.

atm-tcc-vc-mux—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

atm-vc-mux—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

ether-over-atm-llc—(All IP interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) For interfaces that carry IP traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.

ether-vpls-over-atm-llc—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

ether-vpls-over-fr—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, per RFC 2427, *Multiprotocol Interconnect over Frame Relay*.

NOTE: The SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, and the DS3/E3 MIC do not support Ethernet over Frame Relay encapsulation.

ether-vpls-over-ppp—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Point-to-Point Protocol (PPP) encapsulation to support Bridged Ethernet over PPP-encapsulated TDM interfaces for VPLS applications.

ethernet—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

ethernet-ccc—Use Ethernet CCC encapsulation on Ethernet interfaces.

ethernet-vpls—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

ethernet-vpls-fr—Use in a VPLS setup when a CE device is connected to a PE router over a time-division multiplexing (TDM) link. This encapsulation type enables the PE router to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

frame-relay-ether-type—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ether-type-tcc—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ppp—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only.

frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

gre-fragmentation—For adaptive services interfaces only, use GRE fragmentation encapsulation to enable fragmentation of IPv4 packets in GRE tunnels. This encapsulation clears the do not fragment (DF) bit in the packet header. If the packet's size exceeds the tunnel's maximum transmission unit (MTU) value, the packet is fragmented before encapsulation.

multilink-frame-relay-end-to-end—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

multilink-ppp—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

ppp-over-ether—Use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

ppp-over-ether-over-atm-llc—(MX Series routers with MPCs using the ATM MIC with SFP only) For underlying ATM interfaces, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

vlan-bridge—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible-ethernet-services, and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

vlan-ccc—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-vci-ccc—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-tcc—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

vlan-vpls—Use Ethernet VLAN encapsulation on VPLS circuits.

vxlan—Use VXLAN data plane encapsulation for EVPN.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release History Table

Release	Description
20.1R1	Starting in Junos OS Release 20.1R1, aggregated ethernet interfaces supports VLAN TCC (Translational cross-connect) encapsulation on MX series platforms.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.5.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (**flexible-ethernet-services**, **ethernet-ccc**, and **ethernet-tcc** options only).

Description

For M Series, MX Series, QFX Series, T Series, PTX Series, specify the physical link-layer encapsulation type.

For SRX Series, specify logical link layer encapsulation.

NOTE: Not all encapsulation types are supported on the switches. See the switch CLI.

Default

ppp—Use serial PPP encapsulation.

Physical Interface Options and Logical Interface Options

[Warning: element unresolved in stylesheets: <title> (in <config-options>). This is probably a new element that is not yet supported in the stylesheets.]

Physical Interface Options and Logical Interface Options

For physical interfaces:

NOTE: Frame Relay, ATM, PPP, SONET, and SATSOP options are not supported on EX Series switches.

- **atm-ccc-cell-relay**—Use ATM cell-relay encapsulation.
- **atm-pvc**—Defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. When you configure physical ATM interfaces with ATM PVC encapsulation, an RFC 2684-compliant ATM Adaptation Layer 5 (AAL5) tunnel is set up to route the ATM cells over a Multiprotocol Label Switching (MPLS) path that is typically established between two MPLS-capable routers using the Label Distribution Protocol (LDP).
- **cisco-hdlc**—Use Cisco-compatible High-Level Data Link Control (HDLC) framing. E1, E3, SONET/SDH, T1, and T3 interfaces can use Cisco HDLC encapsulation. Two related versions are supported:
 - CCC version (**cisco-hdlc-ccc**)—The logical interface does not require an encapsulation statement. When you use this encapsulation type, you can configure the **ccc** family only.
 - TCC version (**cisco-hdlc-tcc**)—Similar to CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **cisco-hdlc-ccc**—Use Cisco-compatible HDLC framing on CCC circuits.
- **cisco-hdlc-tcc**—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.
- **ethernet-bridge**—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.
- **ethernet-over-atm**—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.
- **ethernet-tcc**—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.
- **ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.
- **ethernet-vpls-ppp**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.
- **ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.
- **extended-frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC. When you use this encapsulation type, you can configure the **ccc** family only.
- **extended-frame-relay-ether-type-tcc**—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.
- **extended-frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.
- **extended-vlan-bridge**—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.
- **extended-vlan-ccc**—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. Extended VLAN CCC encapsulation supports TPIDs 0x8100, 0x9100, and 0x9901. When you use this encapsulation type, you can configure the **ccc** family only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.
- **extended-vlan-tcc**—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

- **extended-vlan-vpls**—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

- **flexible-ethernet-services**—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and for Gigabit Ethernet interfaces, use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.
- **flexible-frame-relay**—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.
- **frame-relay**—Use Frame Relay encapsulation is defined in RFC 1490, *Multiprotocol Interconnect over Frame Relay*. E1, E3, link services, SONET/SDH, T1, T3, and voice services interfaces can use Frame Relay encapsulation.
- **frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation is same as standard Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to CCC. The logical interface must also have **frame-relay-ccc** encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay. IETF frame relay encapsulation identifies the payload format using NLPID and SNAP formats. Cisco-compatible Frame Relay encapsulation uses the Ethernet type to identify the type of payload.

NOTE: When the encapsulation type is set to Cisco-compatible Frame Relay encapsulation, ensure that the LMI type is set to ANSI or Q933-A.

- **frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. This encapsulation is Cisco-compatible Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to TCC.

- **frame-relay-port-ccc**—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. The connection between the two CE routers can be either user-to-network interface (UNI) or network-to-network interface (NNI); this is completely transparent to the PE routers. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-tcc**—This encapsulation is similar to Frame Relay CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **generic-services**—Use generic services encapsulation for services with a hierarchical scheduler.
- **multilink-frame-relay-uni-nni**—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.
-
- **ppp**—Use serial PPP encapsulation. This encapsulation is defined in RFC 1661, *The Point-to-Point Protocol (PPP) for the Transmission of Multiprotocol Datagrams over Point-to-Point Links*. PPP is the default encapsulation type for physical interfaces. E1, E3, SONET/SDH, T1, and T3 interfaces can use PPP encapsulation.
- **ppp-ccc**—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.
- **ppp-tcc**—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.
- **vlan-ccc**—Use Ethernet VLAN encapsulation on CCC circuits. VLAN CCC encapsulation supports TPID 0x8100 only. When you use this encapsulation type, you can configure the **ccc** family only.
- **vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE:

- Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.
- Starting with Junos OS release 13.3, a commit error occurs when you configure **vlan-vpls** encapsulation on a physical interface and configure **family inet** on one of the logical units. Previously, it was possible to commit this invalid configuration.

For logical interfaces:

- **frame-relay**—Configure a Frame Relay encapsulation when the physical interface has multiple logical units, and the units are either point to point or multipoint.
- **multilink-frame-relay-uni-nni**—Link services interfaces functioning as FRF.16 bundles can use Multilink Frame Relay UNI NNI encapsulation.
- **ppp**—For normal mode (when the device is using only one ISDN B-channel per call). Point-to-Point Protocol is for communication between two computers using a serial interface.
- **ppp-over-ether**—This encapsulation is used for underlying interfaces of pp0 interfaces.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

interface-switch

Syntax

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],
[edit protocols connections]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure Layer 2 switching cross-connects. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

For Layer 2 switching cross-connects to work, you must also configure MPLS.

Options

connection-name—Connection name (up to 128 characters in Junos 12.3 and later).

interface interface-name.unit-number—Interface name. Include the logical portion of the name, which corresponds to the logical unit number.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration

l2circuit-control-passthrough

Syntax

```
l2circuit-control-passthrough;
```

Hierarchy Level

```
[edit forwarding-options]
```

Release Information

Statement introduced in Junos OS Release 19.3R1 for PTX Series routers.

Description

Configure the device to allow LACP, LLDP, OAM LFM, and OAM CFM packets to cross the Layer 2 circuit. If the **l2circuit-control-passthrough** statement is not configured, LACP, LLDP, OAM LFM, and OAM CFM packets are classified as control packets and are not transmitted across the Layer 2 circuit.

NOTE: For MX Series routers, the functionality that the **l2circuit-control-passthrough** command provides is performed automatically.

Default

By default, this statement is not configured.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

p2mp-receive-switch

Syntax

```
p2mp-receive-switch point-to-multipoint-switch-name {  
    output-interface [ interface-name.unit-number ];  
    receive-p2mp-lsp receiving-point-to-multipoint-lsp;  
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols connections],  
[edit protocols connections]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure the CCC switch for a point-to-multipoint LSP on the egress PE router.

Options

point-to-multipoint-switch-name—Point-to-multipoint CCC receive switch name.

output-interface *interface-name.unit-number*—Name of the egress interfaces for the point-to-multipoint LSP traffic. You can configure multiple output interfaces.

receive-p2mp-lsp *receiving-point-to-multipoint-lsp*—Name of the point-to-multipoint LSP that is switched to the output interface.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for the **realm** statement introduced in Junos OS Release 9.2.

Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Disable OSPF, an OSPF interface, or an OSPF virtual link.

By default, control packets sent to the remote end of a virtual link must be forwarded using the default topology. In addition, the transit area path consists only of links that are in the default topology. You can disable a virtual link for a configured topology, but not for a default topology. Include the **disable** statement at the **[edit protocols ospf area *area-id* virtual-link neighbor-id router-id transit-area *area-id* topology *name*]** hierarchy level.

NOTE: If you disable the virtual link by including the **disable** statement at the **[edit protocols ospf area *area-id* virtual-link neighbor-id router-id transit-area *area-id*]** hierarchy level, you disable the virtual link for all topologies, including the default topology. You cannot disable the virtual link only in the default topology.

Default

The configured object is enabled (operational) unless explicitly disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Apply one or more policies to routes being exported from the routing table into BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no routes match the filters, the routing table exports into BGP only the routes that it learned from BGP. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of **metric 500** defined in the next policy.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Apply one or more routing policies to routes being imported into the Junos OS routing table from BGP.

If you specify more than one policy, they are evaluated in the order specified, from left to right, and the first matching filter is applied to the route. If no match is found, BGP places into the routing table only those routes that were learned from BGP routing devices. The policy framework software evaluates the routing policies in a chain sequentially. If an action specified in one of the policies manipulates a route characteristic, the policy framework software carries the new route characteristic forward during the evaluation of the remaining policies. For example, if the action specified in the first policy of a chain sets a route's metric to 500, this route matches the criterion of **metric 500** defined in the next policy.

It is also important to understand that in Junos OS, although an import policy (inbound route filter) might reject a route, not use it for traffic forwarding, and not include it in an advertisement to other peers, the router retains these routes as hidden routes. These hidden routes are not available for policy or routing purposes. However, they do occupy memory space on the router. A service provider filtering routes to

control the amount of information being kept in memory and processed by a router might want the router to entirely drop the routes being rejected by the import policy.

Hidden routes can be viewed by using the **show route receive-protocol bgp neighbor-address hidden** command. The hidden routes can then be retained or dropped from the routing table by configuring the **keep all | none** statement at the **[edit protocols bgp]** or **[edit protocols bgp group group-name]** hierarchy level.

The rules of BGP route retention are as follows:

- By default, all routes learned from BGP are retained, except those where the AS path is looped. (The AS path includes the local AS.)
- By configuring the **keep all** statement, all routes learned from BGP are retained, even those with the local AS in the AS path.
- By configuring the **keep none** statement, all routes received are discarded. When this statement is configured and the inbound policy changes, Junos OS re-advertises all the routes advertised by the peer.

Options

policy-names—Name of one or more policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

virtual-switch and **layer2-control** options introduced in Junos OS Release 8.4.

Statement introduced in Junos OS Release 9.2 for EX Series switches.

Statement introduced in Junos OS Release 11.3 for the QFX Series.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

mpls-internet-multicast option introduced in Junos OS Release 11.1 for the EX Series, M Series, MX Series, and T Series.

evpn option introduced in Junos OS Release 13.2 for MX 3D Series routers.

evpn option introduced in Junos OS Release 17.3 for the QFX Series.

forwarding option introduced in Junos OS Release 14.2 for the PTX Series.

mpls-forwarding option introduced in Junos OS Release 16.1 for the MX Series.

evpn-vpws option introduced in Junos OS Release 17.1 for MX Series routers.

Support for logical systems on MX Series routers added in Junos OS Release 17.4R1.

Description

Define the type of routing instance.

Options

NOTE: On ACX Series routers, you can configure only the forwarding, virtual router, and VRF routing instances.

type—Can be one of the following:

- **evpn**—(MX 3D Series routers, QFX switches and EX9200 switches)—Enable an Ethernet VPN (EVPN) on the routing instance.
hierarchy level.
- **evpn-vpws**—Enable an Ethernet VPN (EVPN) Virtual Private Wire Service (VPWS) on the routing instance.

- **forwarding**—Provide support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance. Other instances are used for populating RPD learned routes. For this instance type, there is no one-to-one mapping between an interface and a routing instance. All interfaces belong to the default instance inet.0.
- **l2backhaul-vpn**—Provide support for Layer 2 wholesale VLAN packets with no existing corresponding logical interface. When using this instance, the router learns both the outer tag and inner tag of the incoming packets, when the **instance-role** statement is defined as **access**, or the outer VLAN tag only, when the **instance-role** statement is defined as **nni**.
- **l2vpn**—Enable a Layer 2 VPN on the routing instance. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **layer2-control**—(MX Series routers only) Provide support for RSTP or MSTP in customer edge interfaces of a VPLS routing instance. This instance type cannot be used if the customer edge interface is multihomed to two provider edge interfaces. If the customer edge interface is multihomed to two provider edge interfaces, use the default BPDU tunneling.
- **mpls-forwarding**—(MX Series routers only) Allow filtering and translation of route distinguisher (RD) values in IPv4 and IPv6 VPN address families on both routes received and routes sent for selected BGP sessions. In particular, for Inter-AS VPN Option-B networks, this option can prevent the malicious injection of VPN labels from one peer AS boundary router to another.
- **mpls-internet-multicast**—(EX Series, M Series, MX Series, and T Series routers only) Provide support for ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, using MBGP or next-generation MVPN.
- **no-forwarding**—This is the default routing instance. Do not create a corresponding forwarding instance. Use this routing instance type when a separation of routing table information is required. There is no corresponding forwarding table. All routes are installed into the default forwarding table. IS-IS instances are strictly nonforwarding instance types.
- **virtual-router**—Enable a virtual router routing instance. This instance type is similar to a VPN routing and forwarding instance type, but used for non-VPN-related applications. You must configure the **interface** statement for this type of routing instance. You do not need to configure the **route-distinguisher**, **vrf-import**, and **vrf-export** statements.
- **virtual-switch**—(MX Series routers, EX9200 switches, and QFX switches only) Provide support for Layer 2 bridging. Use this routing instance type to isolate a LAN segment with its Spanning Tree Protocol (STP) instance and to separate its VLAN identifier space.

- **vpls**—Enable VPLS on the routing instance. Use this routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **vrf**—VPN routing and forwarding (VRF) instance. Provides support for Layer 3 VPNs, where interface routes for each instance go into the corresponding forwarding table only. Required to create a Layer 3 VPN. Create a VRF table (**instance-name.inet.0**) that contains the routes originating from and destined for a particular Layer 3 VPN. For this instance type, there is a one-to-one mapping between an interface and a routing instance. Each VRF instance corresponds with a forwarding table. Routes on an interface go into the corresponding forwarding table. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for the **realm** statement introduced in Junos OS Release 9.2.

Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Specify how long the routing device waits to receive a link-state acknowledgment packet before retransmitting link-state advertisements (LSAs) to an interface's neighbors.

Options

seconds—Interval to wait.

Range: 1 through 65,535 seconds

Default: 5 seconds

NOTE: You must configure LSA retransmit intervals to be equal to or greater than 3 seconds to avoid triggering a retransmit trap, because Junos OS delays LSA acknowledgments by up to 2 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Support at **[edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]**

hierarchy level introduced in Junos OS Release 11.2.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Support at **[edit routing-instances *routing-instance-name* protocols l2vpn mesh-group *mesh-group-name*]**

hierarchy level introduced in Junos OS Release 13.2.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches.

Statement introduced in cRPD Release 19.4R1.

Description

Specify an identifier attached to a route, enabling you to distinguish to which VPN or virtual private LAN service (VPLS) the route belongs. Each routing instance must have a unique route distinguisher (RD) associated with it. The RD is used to place bounds around a VPN so that the same IP address prefixes can be used in different VPNs without having them overlap. If the instance type is **vrf**, the **route-distinguisher** statement is required.

For Layer 2 VPNs and VPLS, if you configure the **l2vpn-use-bgp-rules** statement, you must configure a unique RD for each PE router participating in the routing instance.

For other types of VPNs, we recommend that you use a unique RD for each provider edge (PE) router participating in specific routing instance. Although you can use the same RD on all PE routers for the same VPN routing instance, if you use a unique RD, you can determine the customer edge (CE) router from which a route originated within the VPN.

For Layer 2 VPNs and VPLSs, if you configure mesh groups, the RD in each mesh group must be unique.

CAUTION: We strongly recommend that if you change an RD that has already been configured, or change the routing-instance type from **virtual-router** to **vrf**, make the change during a maintenance window, as follows:

1. Deactivate the routing instance.
2. Change the RD.
3. Activate the routing instance.

This is not required if you are configuring the RD for the first time.

Options

as-number:number—as-number is an assigned AS number, and **number** is any 2-byte or 4-byte value. The AS number can be from 1 through 4,294,967,295. If the AS number is a 2-byte value, the administrative number is a 4-byte value. If the AS number is 4-byte value, the administrative number is a 2-byte value. An RD consisting of a 4-byte AS number and a 2-byte administrative number is defined as a type 2 RD in RFC 4364 *BGP/MPLS IP VPNs*.

NOTE: In Junos OS Release 9.1 and later, the numeric range for AS numbers is extended to provide BGP support for 4-byte AS numbers, as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*. All releases of Junos OS support 2-byte AS numbers. To configure an RD that includes a 4-byte AS number, append the letter “L” to the end of the AS number. For example, an RD with the 4-byte AS number 7,765,000 and an administrative number of 1,000 is represented as **77765000L:1000**.

In Junos OS Release 9.2 and later, you can also configure a 4-byte AS number using the AS dot notation format of two integer values joined by a period: *<16-bit high-order value in decimal>.<16-bit low-order value in decimal>*. For example, the 4-byte AS number of 65,546 in the plain-number format is represented as 1.10 in AS dot notation format.

ip-address:id—IP address (**ip-address** is a 4-byte value) within your assigned prefix range and a 2-byte value for the **id**. The IP address can be any globally unique unicast address.

Range: 0 through 4,294,967,295 ($2^{32} - 1$). If the router you are configuring is a BGP peer of a router that does not support 4-byte AS numbers, you need to configure a local AS number. For more information, see *Using 4-Byte Autonomous System Numbers in BGP Networks Technology Overview*.

NOTE: For Ethernet VPN (EVPN), an RD that includes zero as the **id** value is reserved for the default EVPN routing instance by default. Because the same RD cannot be assigned for two routing instances, using a **ip-address:id** RD for another routing instance (default-switch), where the **id** value is zero, throws a commit error.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

traceoptions (Protocols Link Management)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols link-management],
[edit protocols link-management]
```

Release Information

Statement introduced before Junos OS Release 7.4.

Support for **hello-packets**, **packets**, and **state** flags added in Junos OS Release 8.1.

Description

Trace options for the LMP protocol.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory `/var/log`.

files number—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000

Default: 2 files

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel
- **init**—Output from the initialization messages

- **packets**—Trace all packets other than hello packets on any LMP control channel
- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols
- **server**—Server processing operations
- **show**—**show** command servicing operations
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-world-readable—(Optional) Prevent all users from reading the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Enable log file access for all users.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for the **realm** statement introduced in Junos OS Release 9.2.

Support for the **realm** statement introduced in Junos OS Release 9.2 for EX Series switches.

Description

Set the estimated time required to transmit a link-state update on the interface. When calculating this time, make sure to account for transmission and propagation delays.

You should never have to modify the transit delay time.

Options

seconds—Estimated time, in seconds.

Range: 1 through 65,535 seconds

Default: 1 second

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

upstream-label

Syntax

```
upstream-label {  
  vlan-id vlan-id;  
}
```

Hierarchy Level

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
```

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Specify the upstream label for the bidirectional label-switched path (LSP).

Options

vlan-id *vlan-id*—VLAN ID to be used for the Generalized MPLS (GMPLS) VLAN LSP at the ingress provider edge (PE) to customer edge (CE) link.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 11.1 for EX Series switches.

Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches. **auto option** was also added at this time.

auto option added in Junos OS Release 19.1R1 for MX series.

Statement introduced in cRPD Release 19.4R1.

Description

Specify a virtual routing and forwarding (VRF) target community. If you configure the **community** option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. The purpose of the **vrf-target** statement is to simplify the configuration by allowing you to configure most statements at the **[edit routing-instances]** hierarchy level. In effect, this statement configures a single policy for import and a single policy for export to replace the per-VRF policies for every community.

You can still create more complex policies by explicitly configuring VRF import and export policies using the **import** and **export** options.

Options

community—Community name.

auto—Automatically derives the route target (RT). The auto-derived route targets have higher precedence over manually configured RT in vrf-target, vrf-export policies, and vrf-import policies.

NOTE: Auto-derived route targets are supported only in virtual switch and EVPN routing instances.

import community-name—Allowed communities accepted from neighbors.

export community-name—Allowed communities sent to neighbors.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

delegation-cleanup-timeout

Syntax

```
delegation-cleanup-timeout seconds;
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Specify the amount of time (in seconds) that a Path Computation Client (PCC) must wait before returning control of all LSPs to the routing protocol process after a PCEP session with the main active stateful Path Computation Element (PCE) is disconnected.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

Options

seconds—Time (in seconds) that a PCC must wait before returning control of all LSPs to the routing protocol process after a PCEP session with the main active stateful PCE is disconnected.

A value of 0 indicates immediate delegation cleanup.

Range: 0 through 2147483647 seconds Prior to Junos OS Release 18.4R1, the maximum range value is 600 seconds.

Default: 30 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

delegation-priority

Syntax

```
delegation-priority priority-number;
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Specify the priority number of the active stateful Path Computation Element (PCE). This value is used by the Path Computation Client (PCC) to elect a PCE to delegate LSPs. No two PCEs can have the same delegation-priority value. The PCC elects the PCE with a lower priority as the main active stateful PCE to delegate LSPs.

Options

priority-number—Priority number of the active stateful PCE.

Range: 1 through 65535

Default: 0 (no priority is set)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Syntax

```
lsp-cleanup-timer seconds;
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]  
[edit protocols pcep pce-group group-id]
```

Release Information

Statement introduced in Junos OS Release 13.3.

Description

Specify the amount of time (in seconds) that the Path Computation Client (PCC) must wait before deleting any non-delegated Path Computation Element (PCE)-initiated LSPs from the failed PCE after a PCEP session terminates.

NOTE: In compliance with *draft-ietf-pce-stateful-pce-09*, revoking of PCE-initiated LSP delegations by a PCC happens in a make-before-break fashion before the LSPs are redelegated to an alternate PCE. Starting in Junos OS Release 18.1R1, the **lsp-cleanup-timer** must be greater than or equal to the **delegation-cleanup-timeout** for the PCC to revoke the LSP delegations. If not, the redelegation timeout interval for the PCC can be set to infinity, where the LSP delegations to that PCE remain intact until specific action is taken by the PCC to change the parameters set by the PCE.

Options

seconds—Time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates. Non-delegated PCE-initiated LSPs are deleted immediately.

Range: 0 through 2147483647 seconds

Default: 60

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

lsp-cleanup-timer, **lsp-provisioning**, **max-unknown-requests**, **request-timer**, and **request-priority** options introduced in Junos OS Release 13.3.

authentication-key key, **authentication-key-chain key-chain**, and **p2mp-lsp-report-capability** options introduced in Junos OS Release 16.1.

max-sid-depth and **spring-capability** options introduced in Junos OS Release 17.2.

p2mp-lsp-init-capability and **p2mp-lsp-update-capability** options introduced in Junos OS Release 18.3R1 on all platforms.

pce_traffic_steering option introduced in Junos OS Release 19.4R1 on all platforms.

Description

Configure per-Path Computation Element (PCE) parameters.

Options

pce-id—IP address of the PCE.

authentication-key key—(Optional) Authentication password. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

It is recommended to define and bind an authentication key for securing a PCEP session, as opposed to binding an authentication keychain.

authentication-key-chain key-chain—(Optional) Authentication keychain password. It can be up to 126 characters. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks (" ").

local-address ip-address—(Optional) IP address of the local end of the PCEP session, the PCC.

lsp-retry-delegation—(Optional) Enable retry LSP delegation process.

lsp-retry-delegation-timer—(Optional) Specify the amount of time (in seconds) that the Path Computation Client (PCC) must wait before retrying delegation of Path Computation Element (PCE)-initiated LSPs in case of delegation failure or re-delegation.

Default: 3600 seconds

Range: 0 through 4294967294 seconds

max-sid-depth—(Optional) Specify the maximum value for service identifier (SID) depth.

Default: 5

Range: 1 through 5

p2mp-lsp-init-capability—(Optional) Capability to provision point-to-multipoint RSVP-TE LSPs by a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable PCE-initiated point-to-multipoint LSPs.

p2mp-lsp-report-capability—(Optional) Capability to report point-to-multipoint RSVP-TE LSPs to a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable reporting of point-to-multipoint LSPs to a PCE.

p2mp-lsp-update-capability—(Optional) Capability to update point-to-multipoint RSVP-TE LSP parameters by a PCE. By default, this capability is not supported on a PCC, and should be explicitly configured to enable updating of PCE-initiated point-to-multipoint LSPs.

pce_traffic_steering—(Optional) Configure the flow specification capability (also called traffic steering functionality) for enabling the mapping of PCE-initiated point-to-multipoint LSPs to an MVPN routing-instance.

spring-capability—(Optional) Enable SPRING-based provisioning for the PCE.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit protocols pcep pce pce-id]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Configure the path computation element (PCE) type:

- **active**—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegated control over their LSPs to the PCE.
- **stateful**—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update the LSP state. A PCC maintains synchronization with the PCE.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Release Information

Statement introduced in Junos OS Release 15.1.

Command introduced in Junos OS Release 16.1R3 for QFX Series switches.

Description

Configure querier options.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

RELATED DOCUMENTATION

traceoptions (PCE)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag (all | pcep);
  no-remote-trace;
}
```

Hierarchy Level

```
[edit protocols pcep pce pce-id]
```

Description

Configure the Path Computation Element Protocol (PCEP) tracing options.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory `/var/log`.

files number—(Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`, then `trace-file.1`, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000 files

Default: 2 files. If you specify a maximum number of files, you must also include the ***size*** statement to specify the maximum file size.

flag—Area of path computation client process (pccd) to enable debugging output.

- **all**—Trace all areas of PCD code.
- **pcep**—Trace Path Computation Element Protocol (PCEP) operations.

no-remote-trace—(Optional) Disable remote tracing options.

no-world-readable—(Optional) Allow only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named `trace-file` reaches this size, it is renamed `trace-file.0`. When the trace-file again reaches this size, `trace-file.0` is renamed `trace-file.1` and `trace-file` is renamed `trace-file.0`. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB.

Range: 10 KB through the maximum file size supported on your system.

Default: 1 MB. If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.

routing-control and trace-control—To add this statement to the configuration.

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
  no-remote-trace;
}
```

Hierarchy Level

[edit protocols pcep]

Description

Configure the Path Computation Element Protocol (PCEP) tracing options.

Options

filename—Name of the file to receive the output of the tracing operation. All files are placed in the directory `/var/log`.

files number—(Optional) Maximum number of trace files. When a trace file named `trace-file` reaches its maximum size, it is renamed `trace-file.0`, then `trace-file.1`, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Range: 2 through 1000 files

Default: 2 files. If you specify a maximum number of files, you must also include the ***size*** statement to specify the maximum file size.

flag—Area of path computation client process (pccd) to enable debugging output.

PCEP Tracing Flags

- ***all***—Trace all areas of PCCD code
- ***pccd-config***—All configuration parsing operations
- ***pccd-core***—PCCD core operations
- ***pccd-functions***—PCCD function entries and outs
- ***pccd-main***—PCCD main module
- ***pccd-rpd***—PCCD communication with RPD
- ***pccd-ui***—PCCD user interface handling

no-remote-trace—(Optional) Disable remote tracing options.

no-world-readable—(Optional) Allow only certain users to read the log file.

size size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches this size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Syntax: *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB.

Range: 10 KB through the maximum file size supported on your system.

Default: 1 MB. If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

world-readable—(Optional) Allow any user to read the log file.

update-rate-limit

Syntax

```
update-rate-limit updates-per-minute;
```

Hierarchy Level

```
[edit protocols pcep]
```

Release Information

Statement introduced in Junos OS Release 12.3.

Support for PTX Series added in Junos OS Release 14.2.

Support for QFX Series switches added in Junos OS Release 16.1R3.

Support for ACX Series added in Junos OS Release 17.1R1.

Description

Specify the number of updates per minute that the Path Computation Client (PCC) can receive at maximum. Updates above this limit are ignored by the PCC.

Options

updates-per-minute—Number of updates per minute that the PCC can receive at maximum.

Range: 1 through 16384

Default: 0 (disabled or no limit)

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

clear mpls lsp

List of Syntax

[Syntax on page 2221](#)

[Syntax \(EX and QFX Series Switches\) on page 2221](#)

Syntax

```
clear mpls lsp
<all>
<autobandwidth>
<counters>
<logical-system (all | logical-system-name)>
<name name>
<optimize | optimize-aggressive>
<path regular-expression>
<statistics>
```

Syntax (EX and QFX Series Switches)

```
clear mpls lsp
<all>
<autobandwidth>
<name name>
<optimize | optimize-aggressive>
<path regular-expression>
<statistics>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Release the routes and states associated with MPLS label-switched paths (LSPs), and start new LSPs.

CAUTION: This command disconnects existing Resource Reservation Protocol (RSVP) sessions on the ingress routing device. If there is a time lag between the old path being torn down and the new path being set up, this command might impact traffic traveling along the LSPs.

Options

all—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

autobandwidth—(Optional) Clear LSP autobandwidth counters.

counters—(Optional) Reset the flap and the MBB counters to zero.

logical-system (**all** | **logical-system-name**)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name **name**—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

optimize | **optimize-aggressive**—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

path **regular-expression**—(Optional) Clear the specific LSP path matching the specified regular expression.

statistics—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

Required Privilege Level

clear

<statistics>
```

Release Information

Statement introduced in Junos OS Release 14.2.

Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Release the routes and states associated with MPLS container label-switched paths (LSPs), and start new LSPs.

Options

none—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

autobandwidth—(Optional) Clear LSP autobandwidth counters.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *name*—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

optimize | optimize-aggressive—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

statistics—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

Required Privilege Level

clear

monitor mpls delay rsvp

Syntax

```
monitor mpls delay rsvp lsp-name
<detail>
<count count>
<interval seconds>
<padding-size padding-size>
<traffic-class traffic-class>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Perform an on-demand delay measurement and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the delay measurement is performed.

detail—(Optional) Display detailed output of the LSP delay measurement.

count count—(Optional) Specify the number of delay measurements to be carried out for the MPLS UHP LSP. For LSP delay measurement, the number of queries sent is the specified count number plus one additional query, because the LSP delay is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval seconds—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

padding-size padding-size— (Optional) Specify the length of padding TLV to be included in the query message.

Range: 0 through 1500

traffic-class traffic-class—(Optional) Specify the traffic class for the LSP delay measurement. When the traffic-class value is not specified, the default traffic-class code-point of 111 is used.

Range: 0 though 7

Required Privilege Level

Output Fields

[Table 37 on page 2227](#) describes the output fields for the **monitor mpls delay rsvp** command. Output fields are listed in the approximate order in which they appear.

Table 37: monitor mpls delay rsvp Output Fields

Field Name	Field Description	Level of Output
Current two-way channel delay	Sum of packet delays, excluding the processing time of the remote provider edge (PE) router.	All Levels
Current round-trip-time	Total time taken for completing round-trip of packet.	All Levels
Best two-way channel delay	Best available two-way channel delay count.	All Levels
Worst two-way channel delay	Worst available two-way channel delay count.	All Levels
Average two-way channel delay	Average of the available two-way channel delay counts.	All Levels
Best round-trip-time	Best available round-trip-time count.	All Levels
Worst round-trip-time	Worst available round-trip-time count.	All Levels
Average round-trip-time	Average of the available round-trip-time counts.	All Levels
Average forward delay variation	Average of the variation in forward delay.	All Levels
Average reverse delay variation	Average of the variation in reverse delay.	All Levels

Table 37: monitor mpls delay rsvp Output Fields (continued)

Field Name	Field Description	Level of Output
DM queries sent	Number of queries sent for delay measurement.	All Levels
DM responses received	Number of responses received for delay measurement queries.	All Levels
DM queries timedout	Number of timed out queries sent for delay measurement.	All Levels
DM responses dropped due to errors	Number of loss measurement responses dropped due to errors.	All Levels
Response code	Status of the messages used for delay measurement. Response code can be one of the following: <ul style="list-style-type: none"> • Success—Successful response code. • Failed—Failed response code. 	detail
Querier transmit timestamp	Timestamp on the query message when the message is sent out the ingress PE router (querier). This is done in the hardware before packet is sent out of an interface.	detail
Responder receive timestamp	Timestamp on the response message when the message is received by the egress PE router (responder). This is done in the hardware before packet is received by an interface.	detail
Responder transmit timestamp	Timestamp on the query message when the message is sent out the egress PE router (responder). This is done in the hardware before packet is sent out of an interface.	detail
Querier receive timestamp	Timestamp on the response message when the message is received by the ingress PE router (querier). This is done in the hardware before packet is received by an interface.	detail

monitor mpls loss rsvp

Syntax

```
monitor mpls loss rsvp lsp-name
<detail>
<bytes>
<count count>
<interval seconds>
<traffic-class traffic-class>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Perform an on-demand loss measurement and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the loss measurement is performed.

detail—(Optional) Display detailed output of the LSP loss measurement.

bytes—(Optional) Specify the measurement quantity for the LSP loss measurement as bytes. By default, LSP loss is measured in packets.

NOTE: The byte count of a packet sent or received over a channel counts only the payload, including the total length of that packet and excluding the headers, labels, and framing of the channel itself.

count count—(Optional) Specify the number of loss measurements to be carried out for the MPLS UHP LSP. For LSP loss measurement, the number of queries sent is the specified count number plus one additional query, because the LSP loss is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval seconds—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

traffic-class *traffic-class*—(Optional) Specify the traffic class and enable traffic-class-statistics for the LSP loss measurement.

Range: 0 though 7

Required Privilege Level

Output Fields

[Table 37 on page 2227](#) describes the output fields for the **monitor mpls loss rsvp** command. Output fields are listed in the approximate order in which they appear.

Table 38: monitor mpls loss rsvp Output Fields

Field Name	Field Description	Level of Output
Current forward loss	Difference between the current forward transmit count and the current forward receive count.	All Levels
Current forward loss ratio	Total packet loss (current forward loss divided by current forward transmit count).	All Levels
Current forward throughput	Current forward transmit count divided by 1000.	All Levels
Current reverse loss	Difference between the current reverse transmit count and the current reverse receive count.	All Levels
Current reverse loss ratio	Total packet loss (current reverse loss divided by current reverse transmit count).	All Levels
Current reverse throughput	Current reverse transmit count divided by 1000.	All Levels

Table 38: monitor mpls loss rsvp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Cumulative forward transmit count	Cumulative forward transmit counter value at the time the loss measurement message was originated.	All Levels
Cumulative forward loss	Cumulative forward loss counter value at the time the loss measurement message was originated.	All Levels
Average forward loss ratio	Average packet loss (current forward loss divided by current forward transmit count).	All Levels
Average forward throughput	Average forward transmit count divided by 1000.	All Levels
Cumulative reverse transmit count	Cumulative reverse transmit counter value at the time the loss measurement message was originated.	All Levels
Cumulative reverse loss	Difference between the cumulative reverse transmit count and the cumulative reverse receive count.	All Levels
Average reverse loss ratio	Average packet loss (average reverse loss divided by average reverse transmit count).	All Levels
Average reverse throughput	Average reverse transmit count divided by 1000.	All Levels
LM queries sent	Number of queries sent for loss measurement.	All Levels
LM responses received	Number of responses received for loss measurement queries.	All Levels
LM queries timedout	Number of timed out queries sent for loss measurement.	All Levels
LM responses dropped due to errors	Number of loss measurement responses dropped due to errors.	All Levels
Response code	Status of the messages used for loss measurement. Response code can be one of the following: <ul style="list-style-type: none"> ● Success—Successful response code. ● Failed—Failed response code. 	detail
Origin timestamp	Time and date the loss measurement message is originated without any specific format (NTP and PTP).	detail

Table 38: monitor mpls loss rsvp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Forward transmit count	Forward transmit counter value at the time the loss measurement message was originated.	detail
Forward receive count	Forward receive counter value at the time the loss measurement message was originated.	detail
Reverse transmit count	Reverse transmit counter value at the time the loss measurement message was originated.	detail
Reverse receive count	Reverse receive counter value at the time the loss measurement message was originated.	detail
Current forward transmit count	Difference between the current forward transit count and the previous forward transit count.	detail
Current forward receive count	Difference between the current forward receive count and the previous forward receive count.	detail
Current reverse transmit count	Difference between the current reverse transit count and the previous reverse transit count.	detail
Current reverse receive count	Difference between the current reverse receive count and the previous reverse receive count.	detail

monitor mpls loss-delay rsvp

Syntax

```
monitor mpls loss-delay rsvp lsp-name
<detail>
<bytes>
<count count>
<interval seconds>
<padding-size padding-size>
<traffic-class traffic-class>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Perform a simultaneous on-demand loss and delay measurement using combined loss and delay messages, and display the measured values for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs).

Options

lsp-name—Name of the associated bidirectional MPLS UHP LSP for which the delay measurement is performed.

detail—(Optional) Display detailed output of the LSP delay measurement.

bytes—(Optional) Specify the measurement quantity for the LSP loss measurement as bytes. By default, LSP loss is measured in packets.

NOTE: The byte count of a packet sent or received over a channel counts only the payload, including the total length of that packet and excluding the headers, labels, and framing of the channel itself.

count count—(Optional) Specify the number of delay measurements to be carried out for the MPLS UHP LSP. For LSP delay measurement, the number of queries sent is the specified count number plus one additional query, because the LSP delay is measured using successive messages.

Default: 10

Range: 1 through 1000000

interval seconds—(Optional) Specify in seconds the interval between two successive query messages.

Range: 1 through 255 seconds

padding-size *padding-size*—(Optional) Specify the length of padding TLV to be included in the query message.

Range: 0 through 1500

traffic-class *traffic-class*—(Optional) Specify the traffic class for the LSP delay measurement. When the traffic-class value is not specified, the default traffic-class code-point of 111 is used.

Range: 0 though 7

Required Privilege Level

ping mpls bgp

Syntax

```
ping mpls bgp fec
<bottom-label-ttl>
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced in Junos OS Release 11.1.

Description

Check the operability of MPLS BGP-signaled label-switched path (LSP) connections. Press Ctrl+c to interrupt a **ping mpls bgp** command.

NOTE: The **ping mpls bgp fec** command only supports single paths.

Options

bottom-label-ttl—(Optional) Time-to-live (TTL) value for the bottom label in the label stack. The range of values is 1 through 255. The default value is **255**.

count count—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

destination address—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp forwarding-class—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping a BGP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance routing-instance-name—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

size bytes—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only BGP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

[ping mpls bgp fec count on page 2245](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with

error codes are not counted in the received packets count. They are accounted for separately. To display the error codes, use the **detail** option (for example, **ping mpls bgp 10.255.245.222 detail**).

Sample Output

ping mpls bgp fec count

user@host> **ping mpls bgp 10.255.245.222 count 10**

```
!!!xxx...x--- 1sping statistics ---10 packets transmitted, 3 packets received, 70%  
packet loss 4 packets received with error status, not counted as received.
```

ping mpls lsp-end-point

Syntax

```
ping mpls lsp-end-point prefix-name
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **instance** option was introduced in Junos OS Release 10.0.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS label-switched path (LSP) endpoint connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

instance *routing-instance-name*—(Optional) Ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP connection.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

prefix-name—LDP forwarding equivalence class (FEC) prefix or RSVP LSP endpoint address.

size bytes—(Optional) Size of the LSP ping request packet. If the endpoint is LDP-based, the minimum size of the packet is **88** bytes. If the endpoint is RSVP-based, the minimum size of the packet is **100** bytes. The maximum size in either case is **65468** bytes.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

Description

Check the operability of the MPLS Layer 2 circuit connections. Type Ctrl+c to interrupt a **ping mpls l2circuit** command.

NOTE: This command is not supported on EX4500 and EX4550 switches.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

interface *interface-name*—Ping an interface configured for the Layer 2 circuit on the egress provider edge (PE) router.

logical-system (**all** | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

reply-mode—(Optional) Reply mode for the ping request. This option has the following suboptions:

application-level-control-channel—Reply using an application level control channel.

ip-udp—Reply using an IPv4 or IPv6 UDP packet.

no-reply—Do not reply to the ping request.

NOTE: The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

size bytes—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

v1—(Optional) Use the type 9 Layer 2 circuit type, length, and value (TLV).

virtual-circuit virtual-circuit-id neighbor address—Ping the virtual circuit identifier on the egress PE router or switch and the specified neighbor, testing the integrity of the Layer 2 circuit between the ingress and egress PE routers or switches.

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

Required Privilege Level

```
user@host> ping mpls l2circuit interface lt-1/2/0.21 reply-mode application-level-control-channel
```

```
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

ping mpls l2vpn

Syntax

```
ping mpls l2vpn (instance instance-name local-site-id local-site-id-number remote-site-id remote-site-id-number |
  interface interface-name)
<bottom-label-ttl>
<count count>
<destination address>
<detail>
<exp forwarding-class>
<logical-system (all | logical-system-name)>
reply-mode (application-level-control-channel | ip-udp | no-reply)
<size bytes>
<source source-address>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

Description

Check the operability of MPLS Layer 2 virtual private network (VPN) connections. Type Ctrl+c to interrupt a **ping mpls l2vpn** command.

Options

bottom-label-ttl—(Optional) Display the time-to-live value for the bottom label in the label stack.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

instance *instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number*—Ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, testing the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the ingress and egress provider edge (PE) routers or switches.

interface *interface-name*—Ping an interface configured for the Layer 2 VPN on the egress PE router or switch.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

reply-mode—(Optional) Reply mode for the ping request. This option has the following suboptions:

application-level-control-channel—Reply using an application level control channel.

ip-udp—Reply using an IPv4 or IPv6 UDP packet.

no-reply—Do not reply to the ping request.

The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (96 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Check the operability of a MPLS Layer 3 virtual private network (VPN) connection. Type Ctrl+c to interrupt a **ping mpls l3vpn** command.

Options

bottom-label-ttl—(Optional) Display the time-to-live value for the bottom label in the label stack.

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

l3vpn-name—(Optional) Layer 3 VPN name.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

prefix *prefix-name*—Ping to test whether a prefix is present in a provider edge (PE) router's or switch's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix. This option does not test the connection between a PE router or switch and a customer edge (CE) router or switch.

size *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (96 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

source *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

If the Layer 3 VPN traffic transits a route reflector within the network, the **ping mpls l3vpn** command does not work.

request mpls lsp adjust-autobandwidth

List of Syntax

[Syntax on page 2260](#)

[Syntax \(EX and QFX Series Switches\) on page 2260](#)

Syntax

```
request mpls lsp adjust-autobandwidth
<logical-system (all | logical-system-name)>
<name lsp-name>
```

Syntax (EX and QFX Series Switches)

```
request mpls lsp adjust-autobandwidth
<name lsp-name>
```

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.5 for EX Series switches.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

Description

Manually trigger a bandwidth allocation adjustment for active label-switched paths (LSPs).

Without running this command, the bandwidth adjustment is recomputed at a configurable interval. The default interval is 5 minutes. If you do not want to wait for the periodic adjustment (for example, during a software demonstration), this command is useful.

During bandwidth allocation adjustment, the LSP stays up to enable the bandwidth to be changed without dropping any traffic. This functionality is often referred to as *make-before-break*.

Options

none—Manually trigger a bandwidth allocation adjustment for all active LSP paths.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Manually trigger a bandwidth allocation adjustment on the specified LSP only.

Additional Information

For this command to work properly, the following conditions must exist:

- Automatic bandwidth allocation must be enabled on the LSP. The parameters for adjustment interval and maximum average bandwidth are not reset after you issue the **request mpls lsp adjust-autobandwidth** command.
- The difference between the adjusted bandwidth and the current LSP path bandwidth must be greater than the threshold limit.

Required Privilege Level

clear, maintenance

Output Fields

[Table 40 on page 2267](#) lists the output fields for the **show dynamic-tunnels database** command. Output fields are listed in the approximate order in which they appear.

Table 40: show dynamic-tunnels database Output Fields

Field Name	Field Description
Table	Name of the routing table (for example, inet.0).
Destination-network	Destination IP address and subnet.
Tunnel to	Destination IP address and prefix of the tunnel.
State	State of the tunnel: Up , Up (expires in <i>nn:nn:nn</i>seconds) , or Dn (down).
Reference count	Number of routes across the dynamic tunnel that are currently being resolved.
Next-hop type	Type of tunnel: GRE or UDP (BGP-Signal). <ul style="list-style-type: none"> • GRE or UDP (BGP signal) • SRTE—Segment routing traffic-engineered LSP.
Source address	Source IP address of the tunnel.
Next-hop	IP address of the destination interface.
VPN Label	The label provided by the peer device to identify the VPN through which the packet needs to go. This label is used to identify the VRF for route lookup.
Ingress Route	The IGP route along with the corresponding metric that has been selected for forwarding the tunnel-encapsulated packet.
Localized PFE	Packet Forwarding Engine interface which is the anchor Packet Forwarding Engine for the localized next-hop-based dynamic tunnels. When the anchor Packet Forwarding Engine of the tunnel goes down, it is represented by a # near the Packet Forwarding Engine name.
LSP template name	Name of the segment routing traffic-engineered template configured for dynamic creation of segment routing LSPs.
State	State of the destination interface: Up , Dn , or Dn (no tunnel pic) .
Status	Status of the dynamic segment routing LSP.

Sample Output

List of Sample Output

[show link-management on page 2273](#)

Output Fields

[Table 41 on page 2271](#) describes the output fields for the **show link-management** command. Output fields are listed in the approximate order in which they appear.

Table 41: show link-management Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is 0 through 64,000.
State	State of the peer: Up or Down.

Table 41: show link-management Output Fields (*continued*)

Field Name	Field Description
Control address	Address to which a control channel is established.
CC local ID	Identifier assigned to the control channel by the local peer. The range of values is 1 through 4,294,967,296 .
CC remote ID	Identifier assigned to the control channel by the remote peer. The range of values is 1 through 4,294,967,296 .
State	State of the control channel: Up or Down .
TxSeqNum	Sequence number of the hello message being sent to the peer. The range of values is 1 through 4,294,967,295 .
RcvSeqNum	Sequence number of the last hello message received from the peer. The range of values is 0 through 4,294,967,295 .
Flags	Code that provides information about the control channel. Currently supports only code value R , which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts.
TE links	Traffic-engineered links that are managed by their peer.
TE link name	Name of the traffic-engineered link.
State	State of the traffic-engineered link: Up , Down , or Init .
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include SDH/SONET , Ethernet , Packet , and PDH .
Switching	Type of switching that can be performed on the traffic-engineered link. Supported values are PSC-1 and Packet .

Table 41: show link-management Output Fields (*continued*)

Field Name	Field Description
Minimum bandwidth	Smallest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link (in bps).
Maximum bandwidth	Largest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).
Total bandwidth	Sum of the bandwidth, in bits per second (bps) and megabits per second (Mbps), of all interfaces that are members of the link.
Available bandwidth	Sum of the bandwidths of all interfaces that are members of the link and that are not yet allocated (in bps).
Name	Name of the interface.
State	State of the interface: Up or Down .
Local ID	Identifier of the local side of the interface.
Remote ID	Identifier of the remote side of the interface.
Bandwidth	Bandwidth, in bps or Mbps, of the member interface.
Used	Whether the resource is allocated to an LSP: Yes or No .
LSP-name	LSP name.

Sample Output

show link-management

user@host> **show link-management**

```

Peer name: PEER-A, System identifier: 11973
State: Up, Control address: 10.255.245.4
  CC local ID CC remote ID State      TxSeqNum  RcvSeqNum  Flags
      24547      24547 Up          1027      1026
TE links:
  pro4-ba

```

TE link name: pro4-ba, State: Init
Local identifier: 2662, Remote identifier: 0, Encoding: SDH/SONET, Switching:

[Table 42 on page 2275](#) describes the output fields for the **show link-management peer** command. Output fields are listed in the approximate order in which they appear.

Table 42: show link-management peer Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is 0 through 64,000.

Table 42: show link-management peer Output Fields (*continued*)

Field Name	Field Description
State	State of the peer: Up or Down .
Control address	Address to which a control channel is established.
Hello interval	How often the routing device sends Link Management Protocol (LMP) hello packets.
Hello dead interval	How long LMP waits before declaring the control channel to be dead. This is an interval during which the routing device receives no LMP hello packets from the neighbor on a control that is active or up.
CC local ID	Identifier assigned to the control channel by the local peer. The range of values is 1 through 4,294,967,296 .
CC remote ID	Identifier assigned to the control channel by the remote peer. The range of values is 1 through 4,294,967,296 .
State	State of the control channel: Up or Down .
TxSeqNum	Sequence number of the hello message being sent to the peer. The range of values is 1 through 4,294,967,295 .
RcvSeqNum	Sequence number of the last hello message received from the peer. The range of values is 0 through 4,294,967,295 .
Flags	Code that provides information about the control channel. Currently supports only code value R , which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts.
TE links	Traffic-engineered links that are managed by their peer.

Sample Output

show link-management peer

user@host> **show link-management peer**

```
Peer name: sonet, System identifier: 41448
  State: Up, Control address: 70.70.70.70

Output Fields

[Table 43 on page 2279](#) describes the output fields for the **show link-management routing** command. Output fields are listed in the approximate order in which they appear.

Table 43: show link-management routing Output Fields

Field Name	Field Description
Peer Name	Name of the peer.
System identifier	Internal identifier for the peer. The range of values is 0 through 64,000.
State	State of the peer: Up or Down .
Control address	Address to which a control channel is established.
Control channel	Interface over which control packets are sent.
State	State of the control channel.
TE link name	Traffic-engineered link name.
State	State of the traffic-engineered link: Up or Down .
Local identifier	Identifier of the local side of the link.
Remote identifier	Identifier of the remote side of the link.
Local address	Address of the local side of the link.
Remote address	Address of the remote side of the link.
Encoding	Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include SDH/SONET , Ethernet , and Packet .
Minimum bandwidth	Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link.
Maximum bandwidth	Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).
Total bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link.
Available bandwidth	Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.
Resource	Forwarding adjacency LSP information.

Table 43: show link-management routing Output Fields (*continued*)

Field Name	Field Description
Type	Type of resource. The type is always a forwarding adjacency LSP.
State	State of the LSP: Up or Down .
System Identifier	Internal identifier for the peer. The range of values is 0 through 64,000 .
Total bandwidth	Bandwidth resource, in bps or Mbps, on the TE-link learned from the routing process.
Traffic parameters	<ul style="list-style-type: none"> • Encoding—Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include SDH/SONET, Ethernet, and Packet. • Switching—Type of switching that can be performed on the traffic-engineered link: PSC-1 and Packet. • Granularity—Layer 2 data for switching Layer 2 LSPs for this resource. Not supported. This value is always unknown.

Output Fields

[Table 44 on page 2282](#) describes the output fields for the **show link-management statistics** command. Output fields are listed in the approximate order in which they appear.

Table 44: show link-management statistics Output Fields

Field Name	Field Description
Received packets	Number of received packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.

Table 44: show link-management statistics Output Fields (continued)

Field Name	Field Description
Received bad packets	Number of received bad packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Small packets	Number of packets that are too small.
Wrong protocol version	Number of packets specifying the wrong LMP version.
Messages for unknown peer	Number of packets destined for an unknown peer.
Messages for bad state	Number of packets indicating a state that does not match the recipient.
Stale acknowledgments	Number of configAck and LinkSummaryAck packets received that have a stale message ID.
Stale negative acknowledgments	Number of configNack and LinkSummaryNack packets received that have a stale message ID.
Sent packets	Number of sent packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Retransmitted packets	Number of retransmitted packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.
Dropped packets	Number of packets sent, by message type, that have been dropped by the receiver after the LMP retransmission interval has been exceeded. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.

show mpls association

Syntax

```
show mpls association (iif incoming-interface | oif outgoing-interface)
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 16.1 for the M Series, MX Series, and T Series.

Description

Display the Multiprotocol Label Switching (MPLS) label-switched paths (LSPs) based on the association with an incoming or outgoing LSP interface. The command output displays the list of RSVP-TE LSPs carrying traffic in and out of the same interface.

Options

iif *incoming-interface-name*—Display list of RSVP-TE LSPs that share the specified incoming interface to bring in traffic. This option works on transit label-switching routers (LSRs) and egress label edge routers (LERs).

oif *outgoing-interface-name*—Display list of RSVP-TE LSPs that share the specified outgoing interface to carry out traffic. This option works on ingress LERs and transit LSRs.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display Multiprotocol Label Switching (MPLS) label-switched path (LSP) call admission control (CAC) information.

Options

none—Display CAC information for all LSPs.

instance *instance-name*—(Optional) Display MPLS LSP CAC information for the specified instance. If *instance-name* is omitted, MPLS LSP CAC information for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-name—(Optional) Display CAC information for the specified LSP only.

Additional Information

The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by any Layer 2 connection at that class type.

List of Sample Output

[show mpls call-admission-control on page 2295](#)

Output Fields

[Table 49 on page 2295](#) describes the output fields for the **show mpls call-admission-control** command.

Output fields are listed in the approximate order in which they appear.

Table 49: show mpls call-admission-control Output Fields

Field Name	Field Description
Available bandwidth	Current available bandwidth on each LSP path. Depending on whether the LSP is an E-LSP or a regular LSP, either per-class bandwidth or a single bandwidth value (corresponding to best-effort bandwidth at ct0) is displayed. The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by some Layer 2 connections at that class type.
Layer2 connections	Different Layer 2 connections that had some bandwidth requirement and were admitted into an LSP path.
LSP name	LSP pathname.
Neighbor address	Neighbor address from which CAC and bandwidth booking are configured for Layer 2 circuits.
Circuit	Interface name and circuit information.
Primary	LSP's primary standby path.
Standby	LSP's secondary standby path.
VC bandwidth	Bandwidth constraints associated with a Layer 2 circuit route.

<ingress>
<logical-system (all | logical-system-name)>
<name name>
<statistics>
<transit>
<unidirectional>
```

Release Information

Command introduced in Junos OS Release 14.2.

Statement introduced for QFX Switches in Junos OS Release 15.1X53-D30.

Description

Display information about configured and active Multiprotocol Label Switching (MPLS) container label-switched paths (LSPs).

Options

none—Display standard information about all configured and active member LSPs of the container LSP.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

count-active-routes—(Optional) Show active routes for the container LSP.

defaults—(Optional) Display the default settings of the container LSP.

descriptions—(Optional) Display the container LSP descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls container-lsp]** hierarchy level. Only the LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

egress—(Optional) Display the LSPs ending at this device.

NOTE: The **egress** option displays all the LSPs including regular LSPs, members of container LSPs, and transit LSPs. This is an expected behavior for all platforms.

- ingress**—(Optional) Display the member LSPs originating from this device.
- logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.
- name *name***—(Optional) Display information about the specified LSP or group of LSPs.
- statistics**—(Optional) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.
- transit**—(Optional) Display LSPs transiting this routing device.
- unidirectional**—(Optional) Display unidirectional LSP information.

Output Fields

[Table 50 on page 2298](#) describes the output fields for the **show mpls container-lsp** command. Output fields are listed in the approximate order in which they appear.

Table 50: show mpls container-lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSP	Information about the member LSPs on the ingress routing device. Each LSP has one line of output.	All levels

Table 50: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Container LSP name	Name of the container LSP.	All levels
Member LSP count	Number of member LSPs in the container LSP.	All levels
To	Destination (egress routing device) of the session.	brief
From	Source (ingress routing device) of the session.	brief detail
State	State of the LSP handled by this RSVP session: <ul style="list-style-type: none"> • Up • Dn (down) • Restart 	brief detail
Rt	Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
P	Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.	brief
ActivePath	(Ingress LSP) Name of the active path: Primary or Secondary.	detail extensive
LSPname	Name of the member LSP.	brief detail
Egress LSP	Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output.	All levels
Transit LSP	Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
Min LSPs	Minimum number of member LSPs. Default: 1	extensive
Max LSPs	Number of member LSPs that the container LSP can have at maximum. Default: 64 (due to ECMP limit)	extensive

Table 50: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Aggregate bandwidth	Sum of the bandwidths of all member LSPs.	extensive
NormalizeTimer	Duration between two normalization events. When not configured, 21600 seconds (6 hours) is set as the default value.	extensive
NormalizeThreshold	Change in aggregate LSP utilization to trigger splitting or merging expressed in percentage.	extensive
Max Signaling BW	Maximum bandwidth used to signal LSPs after a normalization event. Default value is 0 bps. When not configured, the value is inherited from the splitting bandwidth configuration. NOTE: Between two normalization events, when auto-bandwidth adjustment happens, the per-LSP auto-bandwidth configuration and thresholds are used, instead of the maximum signaling bandwidth threshold.	extensive
Min Signaling BW	Minimum bandwidth used to signal LSPs after a normalization event. Default value is 0 bps. When not configured, the value is inherited from the merging bandwidth configuration. NOTE: Between two normalization events, when auto-bandwidth adjustment happens, the per-LSP auto-bandwidth configuration and thresholds are used, instead of the minimum signaling bandwidth threshold.	extensive
Splitting BW	Bandwidth used for LSP splitting and merging. Default value is 0 bps. When not configured, the value is inherited from the auto-bandwidth maximum bandwidth configuration.	extensive
Merging BW	Bandwidth used for LSP splitting and merging. Default value is 0 bps. When not configured, the value is inherited from the auto-bandwidth minimum bandwidth configuration.	extensive
LSPtype		extensive
LoadBalance		extensive
MinBW	Minimum LSP bandwidth in bps related to auto-bandwidth.	extensive

Table 50: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
AdjustTimer	Total amount of time in seconds allowed before LSP bandwidth adjustment take place. Range: 300 through 315360000 seconds	extensive
Max AvgBW util	Current value of the actual maximum average bandwidth utilization in bps.	extensive
Overflow limit	Threshold overflow limit.	extensive
Underflow limit	Threshold underflow limit.	extensive
Encoding type		extensive
Switching type		extensive
GPID		extensive
Priorities	Setup priority and hold priority values. For setup priority, 0 and 7 is the highest and lowest priority, respectively. When not explicitly configured, 7 and 0 are set as the default values for the setup priority and hold priority, respectively.	extensive
Bandwidth		extensive
SmartOptimizeTimer	Time in seconds allowed before path reoptimization.	extensive
Computed ERO	Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	extensive

Table 50: show mpls container-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Received RRO	<p>Received record route.</p> <p>RRO is a series of hops, each with an address followed by a flag. In most cases, the received RRO is the same as the computed ERO. If the received RRO is different from the computed ERO, there is a topology change in the network, and the route is taking a detour.</p> <p>The following flags identify the protection capability and status of the downstream node:</p> <ul style="list-style-type: none"> • 0x01—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding path message. • 0x02—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously). • 0x03—Combination of 0x01 and 0x02. • 0x04—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section. • 0x08—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the local protection available bit is set but the node protection bit is cleared. • 0x09—Detour is established. Combination of 0x01 and 0x08. • 0x10—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted. • 0x20—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently. • 0xb—Detour is in use. Combination of 0x01, 0x02, and 0x08. 	extensive
Make-before-break		extensive
Record Route		extensive

Table 50: show mpls container-lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Automatic Autobw adjustment succeeded		extensive
CSPF		extensive
Created	Date and time the LSP was created.	extensive

show mpls correlation label

Syntax

```
show mpls correlation label label-value  
<brief | detail | extensive | terse>  
<descriptions>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 15.2 for the M Series, MX Series, and T Series.

Description

Display the correlation information for the Multiprotocol Label Switching (MPLS) label-switched path (LSP) with the owner of the label.

Options

label-value—Display information about the specified label.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

descriptions—(Optional) Display the LSP descriptions. To view this information, you must configure the description statement at the [**edit protocol mpls lsp**] hierarchy level. Only the LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 53 on page 2313](#) describes the output fields for the **show mpls cspf** command. Output fields are listed in the approximate order in which they appear.

Table 53: show mpls cspf Output Fields

Field Name	Field Description
Queue length	Number of LSPs queued for automatic path computation.
current	Current queue length.
maximum	Maximum queue length (high-water mark).
dequeued	Number of aborted computation attempts.
Paths	Counters for label-switched path computations.
total	Sum of the next four fields.
successful	Number of path computations that were successfully completed.
no route	Number of path computations that failed because the destination is unreachable.
Sys Error	Number of path computations that failed because of lack of memory.
CSPFs	Total number of CSPF computations. A single path might require multiple CSPF computations.
Time	Time, in seconds, required to perform the label-switched path computation.
Total	Total amount of time consumed by the CSPF path computation algorithm.
CSPFs	Total number of CSPF computations.
Avg per CSPF	Average amount of time required for each CSPF computation.
% of rpd	Percentage of routing process CPU used in the CSPF computation.

Sample Output

show mpls cspf

user@host> **show mpls cspf**

CSPF statistics					
Queue length	current	maximum	dequeued		
	0	0	0		
Paths	total	successful	no route	sys error	CSPFs
	0	0	0	0	0

	0.000000	0.000000	0.000000	0.0000	

show mpls diffserv-te

List of Syntax

[Syntax on page 2315](#)

[Syntax \(EX Series Switches\) on page 2315](#)

Syntax

```
show mpls diffserve-te
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switches)

```
show mpls diffserve-te
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display Multiprotocol Label Switching (MPLS) label-switched path (LSP) Differentiated Services (DiffServ) class and preemption priority information.

Options

none—Display DiffServ classes and priorities used by MPLS LSPs.

instance *instance-name*—(Optional) Display DiffServ classes and priorities used by MPLS LSPs for the specified instance. If ***instance-name*** is omitted, DiffServ information for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

[show mpls diffserv-te on page 2316](#)

Output Fields

[Table 54 on page 2316](#) describes the output fields for the **show mpls diffserv-te** command. Output fields are listed in the approximate order in which they appear.

Table 54: show mpls diffserv-te Output Fields

Field Name	Field Description
Bandwidth model	Bandwidth constraint model supported. The maximum allocation model (MAM) for EXP-inferred LSPs (E-LSPs) is currently supported.
TE class	DiffServ traffic engineering class.
Traffic class	MPLS class type that corresponds to the DiffServ traffic engineering class: <ul style="list-style-type: none"> • ct0—Best effort • ct1—Assured forwarding • ct2—Expedited forwarding • ct3—Network control
Priority	MPLS preemption priority for this class type, a value from 0 through 7. Interior gateway protocols (IGPs) distribute information about the available bandwidth for each traffic engineering class.

Sample Output

show mpls diffserv-te

user@host> **show mpls diffserv-te**

```

Bandwidth model: Maximum Allocation Model with support for E-LSPs.
TE class      Traffic class      Priority
te0           ct0                   3
te1           ct1                   2

```

show mpls interface

Syntax

```
show mpls interface
```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about MPLS-enabled interfaces. MPLS is enabled on an interface when the interface is configured with both the **set protocols mpls interface *interface-name*** and **set interfaces *interface-name* unit 0 family mpls** commands.

Required Privilege Level

view

Table 55: show mpls interface Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: Up or Dn (down).
Administrative groups	Administratively assigned colors of the link.

Sample Output

show mpls interface

user@switch> **show mpls interface**

Interface	State	Administrative groups
so-1/0/0.0	Up	Blue Yellow Red

show mpls egress-protection

Syntax

```
show mpls egress-protection  
<brief | detail>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 11.4R3.

Description

Display information about egress protection.

NOTE: Use this command on the device configured as the protector PE router to display information about egress protection. If you use this command on the device configured as the primary PE router, no output is displayed.

Options

none—Display standard information about egress protection.

brief | detail—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

view

List of Sample Output

[show mpls interface on page 2324](#)

Output Fields

[Table 57 on page 2323](#) describes the output fields for the **show mpls interface** command. Output fields are listed in the approximate order in which they appear.

Table 57: show mpls interface Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: Up or Dn (down).
Administrative groups	Administratively assigned colors of the link.
Maximum labels	Maximum number of MPLS labels upon which MPLS can operate on a logical interface. This is configured using the maximum-labels statement at the [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] or the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] hierarchy levels.
Static protection revert time	Time (in seconds) that a static LSP must wait before traffic reverts from the bypass path to the original path. This is configured using the protection-revert-time statement at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels.
Always mark connection protection tlv	Enabled or Disabled : Enabled indicates that the always-mark-connection-protection-tlv statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. When this statement is configured, it marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, the switch-away-lsps statement must be configured.

Table 57: show mpls interface Output Fields (*continued*)

Field Name	Field Description
Switch away lsps	Enabled or Disabled : Enabled indicates that the switch-away-lsps statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. This enables you to switch an LSP away from a network node using a bypass LSP. This feature can be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.

Sample Output

show mpls interface

user@host> show mpls interface

```
Interface: ge-0/2/1.57
  State: Up
  Administrative group: <none>
  Maximum labels: 5
  Static protection revert time: 5 seconds
  Always mark connection protection tlv: Disabled
  Switch away lsps : Disabled
```

show mpls label usage

Syntax

```
show mpls label usage
<label label value>
<label-range range-start range-end>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 15.1.

Support for the **label** statement added in Junos OS Release 17.2.

Support for the **label-range** statement added in Junos OS Release 17.2.

Description

Show the available label space resource in RPD and also the applications that use the label space in RPD. There are four different label spaces currently used in MPLS—namely LSI, dynamic, block, and static. Each label space has a fixed number and cannot grow beyond the fixed value. Using this command, the administrator can monitor the available labels in each label space and the applications that are using the labels. Based on the availability of labels, the administrator can decide to stop any service and free some labels or use other service where the labels are available.

Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability.

When you set each member router's network services to **enhanced-ip**, only MPC or Modular Interface Cards (MICs) modules and Multiservices Dense Port Concentrator (MS-DPC) modules are powered on in the chassis. Non-service DPCs do not work with enhanced IP network services.

Options

none— Display the available labels in each label space and the applications using the labels.

label *label value*—(Optional) Display the information about which *label value* is used by which protocol, if any.

label-range *range-start range-end* —(Optional) Display the complete information about the **label-range** specified. With the **enhanced-ip** command enabled on the supported device, effective ranges and configured ranges along with details of different label spaces such as LSI, dynamic, block, and static types are displayed.

logical-system (*all* | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

Once the label space crosses the threshold, a new syslog message is added.

<label-space-name> label space usage crossed threshold limit of 90%.

For instance, LSI label space usage crossed threshold limit of 90%.

Required Privilege Level

view

List of Sample Output

[show mpls label usage on page 2326](#)

Output Fields

[Table 58 on page 2326](#) describes the output fields for the **show mpls label usage** command. Output fields are listed in the order in which they appear.

Table 58: show mpls label usage Fields

Field Name	Field Description
Label Space	Indicates the different types of labels currently used in MPLS.
Total	Indicates the total label space available.
Available	Indicates the number of freely available labels and also the percentage of the label space available.
Applications	Indicates the applications that use the MPLS label spaces.
Effective Ranges	Indicates actual ranges in use, which can be different from configured ranges, if conflicting with label already allocated.
Configured Ranges	Indicates the currently configured range assigned to different label spaces on the device.

Sample Output

show mpls label usage

user@host> **show mpls label usage**

```

Label space Total    Available      Applications
LSI           999984  999971 (100.00%) BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label

```

```

Block          999984  999971 (100.00%) BGP/LDP VPLS with tunnel-services, BGP L2VPN
Dynamic        999984  999971 (100.00%) RSVP, LDP, PW, L3VPN, RSVP-P2MP, LDP-P2MP,
MVPN, EVPN, BGP
Static         48576   48576  (100.00%) Static LSP, Static PW

```

With **enhanced-ip** enabled on the supported device, you get the following additional output.

user@host> **show mpls label usage**

```

Label space Total    Available      Applications
LSI           996983  996983 (100.00%) BGP/LDP VPLS with no-tunnel-services, BGP
L3VPN with vrf-table-label

SRGB        3000    4000    GLOBAL

```

user@host> **show mpls label usage label 101**

```

Label 101 is used by protocol BGP

```

user@host> **show mpls label usage label 102**

```

Label 102 is used by protocol LDP

```

user@host> **show mpls label usage label 103**

Label 103 is not allocated to any protocol

show mpls label usage label-range

Syntax

```
show mpls label usage label-range
<block-label-range range-start range-end>
<dynamic-label-range range-start range-end>
<label-limit label-limit value>
<lsi-label-range range-start range-end>
<static-label-range range-start range-end>
```

Release Information

Command introduced in Junos OS Release 17.2.

Description

There are four different label spaces currently used in MPLS—namely LSI, dynamic, block, and static. Each label space has a fixed number and cannot grow beyond the fixed value. Using **show mpls label usage label-range** command, the administrator can monitor the available labels in each label space and the applications that are using the labels. Based on the availability of labels, the administrator can decide to stop any service and free some labels or use other service where the labels are available.

Starting in Junos OS Release 17.2, you can configure the **enhanced-ip** command, which is supported on platforms using Modular Port Concentrators (MPCs) equipped with Junos Trio chipsets. You can also separate the MPLS labels used for different label spaces which provides more flexibility and scalability.

When you set each member router's network services to **enhanced-ip**, only MPC or Modular Interface Cards (MICs) modules and Multiservices Dense Port Concentrator (MS-DPC) modules are powered on in the chassis. Non-service DPCs do not work with enhanced IP network services.

Options

block-label-range range-start range-end—Display the details of block label type.

dynamic-label-range range-start range-end —Display the details of dynamic label type.

label-limit label-limit value—Limit for the number of concurrent active labels.

lsi-label-range range-start range-end—Display the details of LSI label type.

static-label-range range-start range-end—Display the details of static label type.

```

Release Information

Command introduced before Junos OS Release 7.4.

defaults option added in Junos OS Release 8.5.

Command introduced in Junos OS Release 9.5 for EX Series switches.

autobandwidth option added in Junos OS Release 11.4.

externally-controlled option added in Junos OS Release 12.3.

externally-provisioned option added in Junos OS Release 13.3.

Command introduced in Junos OS Release 13.2X51-D15 for QFX Series.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display information about configured and active dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all configured and active dynamic MPLS LSPs.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

In the extensive command output, the duplicate back-to-back messages are recorded as aggregated messages. An additional timestamp is included for these aggregated messages, where if the aggregated messages are five or less, timestamp deltas are recorded for each message, and if the aggregated messages are greater than five, the first and last timestamp is recorded.

For example:

- All timestamps

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route [3
times - 13:21:00, 13:22:01, 13:23:10]
```

- Timestamp deltas

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route [3
times - 13:21:00, +1:01, +2:10]
```

- First and last timestamp

```
9204 Jun 29 13:23:45.405 54.239.43.110: Explicit Route: bad strict route [6
times - 13:21:00, 13:23:10]
```

abstract-computation—(Optional) Display abstract computation preprocessing for LSPs.

See [show mpls lsp abstract-computation](#) for more details.

autobandwidth—(Optional) Display automatic bandwidth information. This option is explained separately (see [show mpls lsp autobandwidth](#)).

bidirectional | unidirectional—(Optional) Display bidirectional or unidirectional LSP information, respectively.

bypass—(Optional) Display LSPs used for protecting other LSPs.

count-active-routes—(Optional) Display active routes for LSPs.

defaults—(Optional) Display the MPLS LSP default settings.

descriptions—(Optional) Display the MPLS label-switched path (LSP) descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls lsp]** hierarchy level. Only LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

externally-controlled—(Optional) Display the LSPs that are under the control of an external Path Computation Element (PCE).

externally-provisioned—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

instance *instance-name*—(Optional) Display MPLS LSP information for the specified instance. If *instance-name* is omitted, MPLS LSP information is displayed for the master instance.

locally-provisioned—(Optional) Display LSPs that have been provisioned locally by the Path Computation Client (PCC).

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **egress**—Sessions that terminate on this routing device.
- **ingress**—Sessions that originate from this routing device.

- **pop-and-forward**—Sessions that originate from RSVP-TE pop-and-forward LSP tunnels.
- **transit**—Sessions that pass through this routing device.

name *name*—(Optional) Display information about the specified LSP or group of LSPs.

p2mp—(Optional) Display information about point-to-multipoint LSPs.

reverse-statistics—(Optional) Display packet statistics for reverse direction of LSPs.

segment—(Optional) Display segment identifier (SID) labels.

statistics—(Optional) (Ingress and transit routers only) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

NOTE: If a bypass LSP is configured for the primary static LSP, display cumulative statistics of packets traversing through the protected LSP and bypass LSP when traffic is re-optimized when the protected LSP link is restored. (Bypass LSPs are not supported on QFX Series switches.)

When used with the **bypass** option (**show mpls lsp bypass statistics**), display statistics for the traffic that flows only through the bypass LSP.

transit—(Optional) Display LSPs transiting this routing device.

Output Fields

Table 60 on page 2336 describes the output fields for the **show mpls lsp** command. Output fields are listed in the approximate order in which they appear.

Table 60: show mpls lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSP	Information about LSPs on the ingress routing device. Each session has one line of output.	All levels
Egress LSP	Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output.	All levels
Transit LSP	Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
P2MP name	Name of the point-to-multipoint LSP. Dynamically generated P2MP LSPs used for VPLS flooding use dynamically generated P2MP LSP names. The name uses the format <i>identifier:vppls:router-id:routing-instance-name</i> . The <i>identifier</i> is automatically generated by Junos OS.	All levels
P2MP branch count	Number of destination LSPs the point-to-multipoint LSP is transmitting to.	All levels
P	An asterisk (*) under this heading indicates that the LSP is a primary path.	All levels
address	(detail and extensive) Destination (egress routing device) of the LSP.	detail extensive
To	Destination (egress routing device) of the session.	brief
From	Source (ingress routing device) of the session.	brief detail
State	State of the LSP handled by this RSVP session: Up , Dn (down), or Restart .	brief detail

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Active Route	Number of active routes (prefixes) installed in the forwarding table. For ingress LSPs, the forwarding table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (mpls.0).	detail extensive
Rt	Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
P	Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.	brief
ActivePath	(Ingress LSP) Name of the active path: Primary or Secondary .	detail extensive
LSPname	Name of the LSP.	brief detail
Statistics	Displays the number of packets and the number of bytes transmitted over the LSP. These counters are reset to zero whenever the LSP path is optimized (for example, during an automatic bandwidth allocation).	extensive
Aggregate statistics	Displays the number of packets and the number of bytes transmitted over the LSP. These counters continue to iterate even if the LSP path is optimized. You can reset these counters to zero using the clear mpls lsp statistics command.	extensive
Packets	Displays the number of packets transmitted over the LSP.	brief extensive
Bytes	Displays the number of bytes transmitted over the LSP.	brief extensive
DiffServeInfo	Type of LSP: multiclass LSP (multiclass diffServ-TE LSP) or Differentiated-Services-aware traffic engineering LSP (diffServ-TE LSP).	detail
LSPtype	Type of LSP: <ul style="list-style-type: none"> • Static configured—Static • Dynamic configured—Dynamic • Externally controlled—External path computing entity Also indicates if the LSP is a Penultimate hop popping LSP or an Ultimate hop popping LSP.	detail extensive

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Bypass	(Bypass LSP) Destination address (egress routing device) for the bypass LSP.	All levels
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. LSPpath can be either primary or secondary and can be displayed on the ingress, egress, and transit routing devices.	detail
Bidir	(GMPLS) The LSP allows data to travel in both directions between GMPLS devices.	All levels
Bidirectional	(GMPLS) The LSP allows data to travel both ways between GMPLS devices.	All levels
FastReroute desired	Fast reroute has been requested by the ingress routing device.	detail
Link protection desired	Link protection has been requested by the ingress routing device.	detail
Node/Link protection desired	Link protection has been requested by the ingress routing device.	detail
LSP Control Status	<p>(Ingress LSP) LSP control mode:</p> <ul style="list-style-type: none"> • External—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP. • Local—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control. <p>A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.</p>	extensive

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
External Path CSPF status	(PCE-controlled LSPs) Status of the PCE-controlled LSP with per path attributes: <ul style="list-style-type: none"> • Local • External 	extensive
Externally Computed ERO	(PCE-controlled LSPs) Externally computed explicit route when the route object is not null or empty. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	extensive
EXTCTRL_LSP	(PCE-controlled LSPs) Display path history including the bandwidth, priority, and metric values received from the external controller.	extensive
flap counter	Counts the number of times a LSP flaps down or up.	extensive
LoadBalance	(Ingress LSP) CSPF load-balancing rule that was configured to select the LSP's path among equal-cost paths: Most-fill , Least-fill , or Random .	detail extensive
Signal type	Signal type for GMPLS LSPs. The signal type determines the peak data rate for the LSP: DS0 , DS3 , STS-1 , STM-1 , or STM-4 .	All levels
Encoding type	LSP encoding type: Packet , Ethernet , PDH , SDH/SONET , Lambda , or Fiber .	All levels
Switching type	Type of switching on the links needed for the LSP: Fiber , Lambda , Packet , TDM , or PSC-1 .	All levels
GPID	Generalized Payload Identifier (identifier of the payload carried by an LSP): HDLC , Ethernet , IPv4 , PPP , or Unknown .	All levels
Protection	Configured protection capability desired for the LSP: Extra , Enhanced , none , One plus one , One to one , or Shared .	All levels
Upstream label in	(Bidirectional LSPs) Incoming label for reverse direction traffic for this LSP.	All levels
Upstream label out	(Bidirectional LSPs) Outgoing label for reverse direction traffic for this LSP.	All levels
Suggested label received	(Bidirectional LSPs) Label the upstream interface suggests to use in the Resv message that is sent.	All levels

Table 60: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Suggested label sent	(Bidirectional LSPs) Label the downstream node suggests to use in the Resv message that is returned.	All levels
Autobandwidth	(Ingress LSP) The LSP is performing autobandwidth allocation.	detail extensive
Mbb counter	Counts the number of times a LSP incurs MBB.	extensive
MinBW	(Ingress LSP) Configured minimum value of the LSP, in bps.	detail extensive
MaxBW	(Ingress LSP) Configured maximum value of the LSP, in bps.	detail extensive
Dynamic MinBW	(Ingress LSP) Displays the current dynamically specified minimum bandwidth allocation for the LSP, in bps.	detail extensive
Dynamic MinBW	(Ingress LSP) Displays the current dynamically specified minimum bandwidth allocation for the LSP, in bps.	detail extensive
AdjustTimer	(Ingress LSP) Configured value for the adjust-timer statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.	detail extensive
Adjustment Threshold	(Ingress LSP) Configured value for the adjust-threshold statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization.	detail extensive
Time for Next Adjustment	(Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.	detail extensive
Time of Last Adjustment	(Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.	detail extensive
MaxAvgBW util	(Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps.	detail extensive
Overflow limit	(Ingress LSP) Configured value of the threshold overflow limit.	detail extensive
Overflow sample count	(Ingress LSP) Current value for the overflow sample count.	detail extensive

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Bandwidth Adjustment in <i>nnn</i> second(s)	(Ingress LSP) Current value of the bandwidth adjustment timer, indicating the amount of time remaining until the bandwidth adjustment will take place, in seconds.	detail extensive
Underflow limit	(Ingress LSP) Configured value of the threshold underflow limit.	detail extensive
Underflow sample count	(Ingress LSP) Current value for the underflow sample count.	detail extensive
Underflow Max AvgBW	(Ingress LSP) The highest sample bandwidth among the underflow samples recorded currently. This is the signaling bandwidth if an adjustment occurs because of an underflow.	detail extensive
Active path indicator	(Ingress LSP) A value of * indicates that the path is active. The absence of * indicates that the path is not active. In the following example, "long" is the active path. *Primary long Standby short	detail extensive
Primary	(Ingress LSP) Name of the primary path.	detail extensive
Secondary	(Ingress LSP) Name of the secondary path.	detail extensive
Standby	(Ingress LSP) Name of the path in standby mode.	detail extensive
State	(Ingress LSP) State of the path: Up or Dn (down).	detail extensive
COS	(Ingress LSP) Class-of-service value.	detail extensive
Bandwidth per class	(Ingress LSP) Active bandwidth for the LSP path for each MPLS class type, in bps.	detail extensive
Priorities	(Ingress LSP) Configured value of the setup priority and the hold priority respectively (the setup priority is displayed first), where 0 is the highest priority and 7 is the lowest priority. If you have not explicitly configured these values, the default values are displayed (7 for the setup priority and 0 for the hold priority).	detail extensive
OptimizeTimer	(Ingress LSP) Configured value of the optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.	detail extensive

Table 60: show mpls lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
SmartOptimizeTimer	(Ingress LSP) Configured value of the smart optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.	detail extensive
Reoptimization in xxx seconds	(Ingress LSP) Current value of the optimize timer, indicating the amount of time remaining until the path will be reoptimized, in seconds.	detail extensive
Computed ERO (S [L] denotes strict [loose] hops)	(Ingress LSP) Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).	detail extensive
CSPF metric	(Ingress LSP) Constrained Shortest Path First metric for this path.	detail extensive

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Received RRO	<p>(Ingress LSP) Received record route. A series of hops, each with an address followed by a flag. (In most cases, the received record route is the same as the computed explicit route. If Received RRO is different from Computed ERO, there is a topology change in the network, and the route is taking a detour.) The following flags identify the protection capability and status of the downstream node:</p> <ul style="list-style-type: none"> ● 0x01—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the Local protection flag was set in the SESSION_ATTRIBUTE object of the corresponding Path message. ● 0x02—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously). ● 0x03—Combination of 0x01 and 0x02. ● 0x04—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section. ● 0x08—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the Local protection available bit is set but the Node protection bit is cleared. ● 0x09—Detour is established. Combination of 0x01 and 0x08. ● 0x10—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted. ● 0x20—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently. ● 0xb—Detour is in use. Combination of 0x01, 0x02, and 0x08. 	detail extensive
Labels	<p>Labels of pop-and-forward LSP tunnel:</p> <ul style="list-style-type: none"> ● P—Pop labels. ● D—Delegation labels. 	extensive
Index number	(Ingress LSP) Log entry number of each LSP path event. The numbers are in chronological descending order, with a maximum of 50 index numbers displayed.	extensive

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Date	(Ingress LSP) Date of the LSP event.	extensive
Time	(Ingress LSP) Time of the LSP event.	extensive
Event	(Ingress LSP) Description of the LSP event.	extensive
Created	(Ingress LSP) Date and time the LSP was created.	extensive
Resv style	(Bypass) RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	brief detail extensive
Labelin	Incoming label for this LSP.	brief detail
Labelout	Outgoing label for this LSP.	brief detail
LSPname	Name of the LSP.	brief detail
Time left	Number of seconds remaining in the lifetime of the reservation.	detail
Since	Date and time when the RSVP session was initiated.	detail
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	detail
Port number	Protocol ID and sender or receiver port used in this RSVP session.	detail
PATH rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this router, and number of packets received from the upstream neighbor.	detail
PATH sentto	Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor, and number of packets sent to the downstream routing device.	detail
RESV rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor. The output in this field, which is consistent with that in the PATH rcvfrom field, indicates that the RSVP negotiation is complete.	detail

Table 60: show mpls lsp Output Fields (continued)

Field Name	Field Description	Level of Output
Record route	Recorded route for the session, taken from the record route object.	detail
Pop-and-forward	Attributes of the pop-and-forward LSP tunnel.	extensive
ETLD In	Number of transport labels that the LSP-Hop can potentially receive from its upstream hop. It is recorded as Effective Transport Label Depth (ETLD) at the transit and egress devices.	extensive
ETLD Out	Number of transport labels the LSP-Hop can potentially send to its downstream hop. It is recorded as ETLD at the transit and ingress devices.	extensive
Delegation hop	Specifies if the transit hop is selected as a delegation label: <ul style="list-style-type: none"> • Yes • No 	extensive
Soft preempt	Number of soft preemptions that occurred on a path and when the last soft preemption occurred. Only successful soft preemptions are counted (those that actually resulted in a new path being used).	detail
Soft preemption pending	Path is in the process of being soft preempted. This display is removed once the ingress router has calculated a new path.	detail
MPLS-TE LSP Defaults	Default settings for MPLS traffic engineered LSPs: <ul style="list-style-type: none"> • LSP Holding Priority—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. • LSP Setup Priority—Determines whether a new LSP that preempts an existing LSP can be established. • Hop Limit—Specifies the maximum number of routers the LSP can traverse (including the ingress and egress). • Bandwidth—Specifies the bandwidth in bits per second for the LSP. • LSP Retry Timer—Length of time in seconds that the ingress router waits between attempts to establish the primary path. 	defaults

The XML tag name of the **bandwidth** tag under the **auto-bandwidth** tag has been updated to **maximum-average-bandwidth**. You can see the new tag when you issue the **show mpls lsp extensive** command with the **| display xml** pipe option. If you have any scripts that use the **bandwidth** tag, ensure that they are updated to **maximum-average-bandwidth**.

show mpls lsp abstract-computation

Syntax

```
show mpls lsp abstract-computation
<brief | detail | extensive>;
<logical-system (all | logical-system-name)>;
<name lsp-name>;
```

Release Information

Command introduced in Junos OS Release 17.1 for all platforms.

Description

Display the ingress to egress abstract hop computation used by the constrained shortest path in the preprocessing for LSPs. The command output displays the various computation passes involved per LSP, and the qualifying exit devices for each pass. It also displays the affinity per pass, and the current start device chosen for the pass.

Options

brief | detail | extensive—(Optional) Display the desired level of output.

logical-system (all | *logical-system-name*)—(Optional) Display the abstract computation for abstract hop constraints on all logical systems or on a particular logical system.

lsp-name—(Optional) Name of the LSP for which the abstract hop computation is displayed.

Required Privilege Level

view

Output Fields

[Table 61 on page 2359](#) describes the output fields for the **show mpls lsp abstract-computation** command. Output fields are listed in the approximate order in which they appear.

Table 61: show mpls lsp abstract-computation Output Fields

Field Name	Field Description
Path computation using abstract hops for LSP	Name of the LSP for which the abstract hop computation is performed.
Path type	The type of the path can be primary or secondary.
Path name	Name of the path.
Credibility	Credibility value associated with the interior gateway protocol in use.
Total no of CSPF passes	Number of constrained shortest path passes for the abstract hop.
CSPF pass no	Constrained shortest path pass number for the abstract hop computation.
Start address of the pass	IP address where the pass starts.
Affinity	Name of the abstract hop.
Destination	Destination IP address for a node in the pass.
State	State of the backtracking: <ul style="list-style-type: none"> • Valid • Disqualified

show mpls lsp autobandwidth

Syntax

```
show mpls lsp autobandwidth
<brief | detail | extensive>
<logical-system (all | logical-system-name)>
<name lsp-name>
```

Release Information

Statement introduced in Junos OS Release 11.4.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 15.1X54-D60 for the ACX5000 Series.

Statement introduced in Junos OS Release 17.2R1 for QFX10000 Series switches.

name *lsp-name* option introduced in Junos OS Release 18.1R1 for all platforms.

Description

Display automatic bandwidth information for the LSP(s).

After a Routing Engine switchover, the output of the **show mpls autobandwidth** command might not be up-to-date, as the automatic bandwidth information for the LSP(s) is gathered by the new master Routing Engine during the first adjustment interval.

Options

brief | detail | extensive —(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

name *lsp-name*—(Optional) Specify name of the LSP for which the automatic bandwidth information should be displayed.

Required Privilege Level

Output Fields

Table 62 on page 2362 describes the output fields for the **show mpls lsp autobandwidth** command. Output fields are listed in the approximate order in which they appear.

Table 62: show mpls lsp autobandwidth Output Fields

Field Name	Field Description	Level of Output
To	Destination (egress routing device) of the session.	All Levels
From	Source (ingress routing device) of the session.	All Levels
LSPname	Name of the LSP.	All Levels
Min BW	(Ingress LSP) Configured minimum value of the LSP, in bps.	detail extensive
Max BW	(Ingress LSP) Configured maximum value of the LSP, in bps.	detail extensive
Max AvgBW util	(Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps. NOTE: In calculating this value, the sample collected during make before break (MBB) is ignored to prevent inaccurate results. The first sample after a bandwidth adjustment, or after a change in the LSP ID (regardless of path change), is also ignored.	detail extensive
Overflow limit	(Ingress LSP) Configured value of the threshold overflow limit.	detail extensive
Overflow sample count	(Ingress LSP) Current value for the overflow sample count.	detail extensive
Underflow limit	(Ingress LSP) Configured value of the threshold underflow limit.	detail extensive
Underflow sample count	(Ingress LSP) Current value for the underflow sample count.	detail extensive
Adjustment Timer	(Ingress LSP) Configured value for the adjust-timer statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.	detail extensive
Adjustment Threshold	(Ingress LSP) Configured value for the adjust-threshold statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization.	detail extensive
Time for Next Adjustment	(Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.	detail extensive

Table 62: show mpls lsp autobandwidth Output Fields (*continued*)

Field Name	Field Description	Level of Output
Time of Last Adjustment	(Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.	detail extensive
Last BW	Previous active bandwidth of the LSP.	detail extensive
Last Requested BW	Bandwidth requested in the previous automatic bandwidth adjustment.	detail extensive
Last Signaled BW	Bandwidth signaled in the previous automatic bandwidth adjustment.	detail extensive
Highest Watermark BW	Maximum bandwidth used by the LSP.	detail extensive
Total AutoBw Adjustments	Total number of attempts to adjust automatic bandwidth including failed and successful adjustments.	detail extensive
Successful Adjustments	Number of successful automatic bandwidth adjustments.	detail extensive
Failed Adjustments	Number of failed automatic bandwidth adjustments.	detail extensive

Sample Output

show mpls lsp autobandwidth

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all MPLS LSPs.

instance *instance-name*—(Optional) Display the dynamic MPLS LSP for the specified instance. If *instance-name* is omitted, dynamic MPLS LSP for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

path-name—(Optional) Display information about the specified LSP only.

Output Fields

Table 63 on page 2365 describes the output fields for the **show mpls path** command. Output fields are listed in the approximate order in which they appear.

Table 63: show mpls path Output Fields

Field Name	Field Description
Path name	Information about ingress LSPs. Each path has one line of output.
Address	Addresses of the routing devices that form the LSP.
Strict/loose address	Whether the address is a configured as a strict or loose address.

Sample Output

show mpls path

user@host> **show mpls path**

Path name	Address	Strict/loose address
p1	123.456.55.6	Strict
	123.456.1.6	Loose
p2	191.456.1.4	Strict

show mpls srlg

Syntax

```
show mpls srlg
<logical-systems (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 11.4.

Description

Display Shared Risk Link Group (SRLG) cost and value configuration information.

NOTE: If an SRLG is associated with a link that is used by an ingress LSP in the router, then on deleting the SRLG configuration from that router, the SRLG gets removed from the SRLG table only on the next reoptimization of the LSP. Until then, the output of the **run show mpls srlg** command displays **Unknown-XXX** instead of the SRLG name and a non zero srlg-cost for that SRLG.

Options

logical-system (all | *logical-system-name*)—(Optional) View SRLG configuration information for all logical systems or a particular logical system.

Required Privilege Level

view

Output Fields

[Table 64 on page 2366](#) lists the output fields for the **show mpls srlg** command. Output fields are listed in the approximate order in which they appear.

Table 64: show mpls srlg Output Fields

Field Name	Field Description
SRLG	Name of the SRLG.

Table 64: show mpls srlg Output Fields (continued)

Field Name	Field Description
Value	A group ID for the SRLG ranging from 1 through 4294967295 .
Cost	A cost for the Shared Risk Link Group (SRLG) ranging from 1 through 65535 .

Sample Output

user@host> show mpls srlg

SRLG	Value	Cost
srlg-a	101	10

show mpls static-lsp

Syntax

```
show mpls static-lsp
<brief | detail | extensive | terse>
<bypass>
<descriptions>
<down | up>
<ingress>
<instance instance-name>
<logical-system (all | logical-system-name)>
<lsp-type>
<name name>
<statistics>
<transit>
```

Release Information

Command introduced in Junos OS Release 10.1.

Command updated in Junos OS Release 14.1X53-D25 to accommodate the stitching feature of MPLS.

Statement introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Statement introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Display information about configured and active static Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

Options

none—Display standard information about all configured and active static MPLS LSPs.

brief | detail | extensive | terse—(Optional) Display the specified level of output. The **extensive** option displays the same information as the **detail** option, but covers the most recent 50 events.

bypass—(Optional) Display LSPs used for protecting other static LSPs.

descriptions—(Optional) Display the MPLS static LSP descriptions. To view this information, you must configure the description statement at the [edit protocols mpls static-label-switched-path *path-name* bypass], [edit protocols mpls static-label-switched-path *path-name* ingress], or [edit protocols mpls static-label-switched-path *path-name* transit *incoming-label*] hierarchy levels. Only static LSPs with a description are displayed.

down | up—(Optional) Display only static LSPs that are inactive or active, respectively.

instance *instance-name*—(Optional) Display information about all configured and active static MPLS LSPs for the specified routing instance. If ***instance-name*** is omitted, information about all configured and active static MPLS LSPs for the master instance is displayed.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that pass through this routing device.

name *name*—(Optional) Display information about the specified static LSP or group of LSPs.

statistics—(Optional) Display accounting information about static LSPs.

transit—(Optional) Display static LSPs transiting this routing device.

Required Privilege Level

Output Fields

[Table 50 on page 2298](#) describes the output fields for the **show mpls static-lsp** command. Output fields are listed in the approximate order in which they appear.

Table 65: show mpls static-lsp Output Fields

Field Name	Field Description	Level of Output
Ingress LSPs	Information about the static LSPs on the ingress routing device. Each session has one line of output.	All levels
Transit LSPs	Number of static LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.	All levels
Bypass LSPs	Information about the bypass LSPs configured on the routing device. Each session has one line of output.	All levels
LSPname	Name of the static LSP.	All levels

Table 65: show mpls static-lsp Output Fields (*continued*)

Field Name	Field Description	Level of Output
To	Destination (egress routing device) of the session.	All levels
State	State of the static LSP handled by this RSVP session: Up , Dn (down), or Restart .	All levels
Packets	Number of packet transiting the static LSP (statistics option only).	All levels
Bytes	Number of bytes transiting the static LSP (statistics option only).	All levels
Nexthop	IP address for the next-hop router for the static LSP.	detail, extensive
Bypass	(Bypass LSP) Destination address (egress routing device) for the bypass LSP.	All levels
Link protection desired	Link protection has been requested by the ingress routing device.	detail, extensive
LabelOperation	Label operation to perform: Push , Pop , Swap .	detail, extensive
Outgoing-label	Outgoing label to use for the MPLS packet in either push or swap label operations.	detail, extensive
Created	(Ingress LSP) Date and time the static LSP was created.	extensive
Bandwidth	Bandwidth configured for the static LSP.	detail, extensive
Resv style	(Bypass) RSVP reservation style. This field consists of two parts: the number of active reservations and the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	All levels

Sample Output

show mpls static-lsp extensive

user@host> show mpls static-lsp extensive

```
Ingress LSPs:
LSPname: alpha-to-beta, To: 192.168.14.1
State: Dn
```

```

Nexthop: 192.168.10.1
LabelOperation: Push, Outgoing-label: 1000001
Created: Thu Jan 14 16:44:43 2010
Bandwidth: 0 bps
Total 1, displayed 1, Up 0, Down 1

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

```

show mpls static-lsp statistics ingress

```
user@host> show mpls static-lsp statistics ingress
```

```

Ingress LSPs:
LSPname                To           State    Packets    Bytes
alpha-to-beta          192.168.14.1 Dn        NA         NA
Total 1, displayed 1, Up 0, Down 1

```

show mpls static-lsp (when MPLS stitching is used)

The show mpls static-lsp command was extended in Junos release 14.1X53-D25 to accommodate the stitching feature of MPLS. This example shows the LSP state as 'InProgress' because the LSP is waiting for protocol next-hop resolution. For more information, see

```
user@host> show mpls static-lsp
```

```

Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0

Transit LSPs: LSPname                Incoming-label  State
to-165                1000000        InProgress

```

show performance-monitoring mpls lsp

Syntax

```
show performance-monitoring mpls lsp  
<brief | detail | extensive>  
<name lsp name>
```

Release Information

Command introduced in Junos OS Release 15.1.

Description

Display the following performance monitoring data:

- Packet loss measurement
- Packet throughput measurement
- Two-way channel delay
- Round-trip delay
- Inter-packet delay variation (IPDV)

Options

none—Display standard information performance monitoring data.

brief | detail | extensive—(Optional) Display the specified level of output.

NOTE: The extensive option displays the same information as the detail option.

name *lsp name*—(Optional) Display information about the specified LSP.

Required Privilege Level

Output Fields

[Table 66 on page 2373](#) describes the output fields for the **show performance-monitoring mpls lsp** command.

Output fields are listed in the approximate order in which they appear.

Table 66: show performance-monitoring mpls lsp Output Fields

Field Name	Display Data	Field Description	Level of Output
Session	Total	Total number of performance monitoring sessions created.	All Levels
	Up	Number of performance monitoring sessions that are up and running.	All Levels
	Down	Number of performance monitoring sessions that are down.	All Levels
LSP name		Name of the LSP.	All Levels

Table 66: show performance-monitoring mpls lsp Output Fields (*continued*)

Field Name	Display Data		Field Description	Level of Output
Loss measurement Data	Traffic-class		Traffic class for which loss measurement is performed.	All Levels
	Queries sent		Total number of queries sent for loss measurement.	All Levels
	Responses received		Total number of responses received for loss measurement queries.	All Levels
	Responses dropped due to errors		Total number of loss measurement responses dropped due to errors.	All Levels
	Queries timeout		Number of timed out queries sent for loss measurement.	All Levels
	Forward loss measurement	Average packet loss	Average packet loss (total loss of packets divided by the total number of samples used since the session is up).	All Levels
		Average packet throughput	Total number of packets sent divided by the time considered for measurement.	All Levels
	Reverse loss measurement	Average packet loss	Average packet loss (total loss of packets divided by the total number of samples used since the session is up).	All Levels
		Average packet throughput	Total number of packets sent divided by the time considered for measurement.	All Levels

Table 66: show performance-monitoring mpls lsp Output Fields (*continued*)

Field Name	Display Data	Field Description	Level of Output
Delay measurement Data	Traffic-class	Traffic class for which delay measurement is performed.	All Levels
	Queries sent	Total number of queries sent for delay measurement.	All Levels
	Responses received	Total number of responses received for delay measurement queries.	All Levels
	Responses dropped due to errors	Total number of delay measurement responses dropped due to errors.	All Levels
	Queries timeout	Number of timed out queries sent for delay measurement.	All Levels
	Best 2-way channel delay	Best available two-way channel delay.	All Levels
	Worst 2-way channel delay	Worst available two-way channel delay.	All Levels
	Best round trip time	Best available round-trip time.	All Levels
	Worst round trip time	Worst available round-trip time.	All Levels
	Avg absolute fw delay variation	Average of the variation in forward delay.	All Levels
	Avg absolute rv delay variation	Average of the variation in reverse delay.	All Levels
	Two-way channel delay	Sum of packet delays, excluding the processing time of the remote provider edge (PE) router.	detail, extensive
	Two-way round trip delay	Total time taken for completing round-trip of packet.	detail, extensive

show route forwarding-table

Syntax

```
show route forwarding-table
<detail | extensive | summary>
<ccc ccc-interface-name>
<destination>
<family family-name>
<label label>
<matching ip_prefix>
<multicast>
<vpn vpn>
```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Command introduced in Junos OS Release 14.1X53-D30 for QFX Virtual Chassis and Virtual Chassis Fabric.

Description

Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

Options

none—Display the routes in the forwarding table.

detail | extensive | summary—(Optional) Display the specified level of output.

ccc—(Optional) Display the specified circuit cross-connect interface name for entries to match.

destination—(Optional) Display the destination prefix.

family family-name—(Optional) Display routing table entries for the specified family: **ethernet-switching**, **inet**, **inet6**, **iso**, **mpls**, **vlan classification**.

label label—(Optional) Display route entries for the specified label name.

matching ip_prefix—(Optional) Display route entries for the specified IP prefix.

multicast—(Optional) Display route entries for multicast routes.

vpn vpn—(Optional) Display route entries for the specified VPN.

Required Privilege Level

Output Fields

[Table 67 on page 2381](#) lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified or when the **detail** keyword is used instead of the **extensive** keyword.

Table 67: show route forwarding-table Output Fields

Field Name	Field Description	Level of Output
Routing table	Name of the routing table (for example, inet , inet6 , mpls).	All levels
Address family	Address family (for example, IP , IPv6 , ISO , MPLS).	All levels
Destination	Destination of the route.	detail , extensive

Table 67: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Route Type (Type)	<p>How the route was placed into the forwarding table. When the detail keyword is used, the route type might be abbreviated (as shown in parentheses):</p> <ul style="list-style-type: none"> • cloned (clon)—(TCP or multicast only) Cloned route. • destination (dest)—Remote addresses directly reachable through an interface. • destination down (iddn)—Destination route for which the interface is unreachable. • interface cloned (ifcl)—Cloned route for which the interface is unreachable. • route down (ifdn)—Interface route for which the interface is unreachable. • ignore (ignr)—Ignore this route. • interface (intf)—Installed as a result of configuring an interface. • permanent (perm)—Routes installed by the kernel when the routing table is initialized. • user—Routes installed by the routing protocol process or as a result of the configuration. 	All levels
Route reference (RtRef)	Number of routes to reference.	detail, extensive
Flags	<p>Route type flags:</p> <ul style="list-style-type: none"> • none—No flags are enabled. • accounting—Route has accounting enabled. • cached—Cache route. • incoming-iface interface-number —Check against incoming interface. • prefix load balance—Load balancing is enabled for this prefix. • sent to PFE—Route has been sent to the Packet Forwarding Engine. • static—Static route. 	extensive
Nexthop	IP address of the next hop to the destination.	detail, extensive

Table 67: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Next hop type (Type)	<p>Next-hop type. When the detail keyword is used, the next-hop type might be abbreviated (as indicated in parentheses):</p> <ul style="list-style-type: none"> • broadcast (bcst)—Broadcast. • deny—Deny. • hold—Next hop is waiting to be resolved into a unicast or multicast type. • indexed (idxd)—Indexed next hop. • indirect (indr)—Indirect next hop. • local (locl)—Local address on an interface. • routed multicast (mcrt)—Regular multicast next hop • multicast (mcst)—Wire multicast next hop (limited to the LAN). • multicast discard (mdsc)—Multicast discard. • multicast group (mgrp) —Multicast group member. • receive (recv)—Receive. • reject (rjct)—Discard. An ICMP unreachable message was sent. • resolve (rslv)—Resolving the next hop. • unicast (ucst)—Unicast. • unilist (ulst)—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list. 	detail, extensive
Index	Software index of the next hop that is used to route the traffic for a given prefix.	detail, extensive none
Route interface-index	Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.	extensive
Reference (NhRef)	Number of routes that refer to this next hop.	none detail, extensive
Next-hop interface (Netif)	Interface used to reach the next hop.	none detail, extensive
Alternate forward nh index	Index number of the alternate next hop interface. Seen with multicast option only.	extensive
Next-hop L3 Interface	The next hop layer 3 interface. This option can be expressed as a VLAN name and is only seen with the multicast option.	extensive

Table 67: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Next-hop L2 Interfaces	The next hop layer 2 interfaces. Seen with multicast option only.	extensive

List of Syntax

[Syntax on page 2391](#)

[Syntax \(EX Series Switches, QFX Series Switches\) on page 2391](#)

Syntax

```
show route table routing-table-name
<brief | detail | extensive | terse>
<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switches, QFX Series Switches)

```
show route table routing-table-name
<brief | detail | extensive | terse>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

Statement introduced in Junos OS Release 14.1X53-D15 for QFX Series switches.

Show route table evpn statement introduced in Junos OS Release 15.1X53-D30 for QFX Series switches.

Description

Display the route entries in a particular routing table.

Options

brief | detail | extensive | terse—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

routing-table-name—Display route entries for all routing tables whose names begin with this string (for example, inet.0 and inet6.0 are both displayed when you run the **show route table inet** command).

Required Privilege Level

Output Fields

Table 68 on page 2393 describes the output fields for the **show route table** command. Output fields are listed in the approximate order in which they appear.

Table 68: show route table Output Fields

Field Name	Field Description
<i>routing-table-name</i>	Name of the routing table (for example, inet.0).
Restart complete	<p>All protocols have restarted for this routing table.</p> <p>Restart state:</p> <ul style="list-style-type: none"> ● Pending:protocol-name—List of protocols that have not yet completed graceful restart for this routing table. ● Complete—All protocols have restarted for this routing table. <p>For example, if the output shows-</p> <ul style="list-style-type: none"> ● LDP.inet.0 : 5 routes (4 active, 1 holddown, 0 hidden) <p style="padding-left: 40px;">Restart Pending: OSPF LDP VPN</p> <p>This indicates that OSPF, LDP, and VPN protocols did not restart for the LDP.inet.0 routing table.</p> <ul style="list-style-type: none"> ● vpls_1.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden) <p style="padding-left: 40px;">Restart Complete</p> <p>This indicates that all protocols have restarted for the vpls_1.l2vpn.0 routing table.</p>
<i>number destinations</i>	Number of destinations for which there are routes in the routing table.
<i>number routes</i>	<p>Number of routes in the routing table and total number of routes in the following states:</p> <ul style="list-style-type: none"> ● active (routes that are active) ● holddown (routes that are in the pending state before being declared inactive) ● hidden (routes that are not used because of a routing policy)

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
<i>route-destination</i> (entry, announced)	<p>Route destination (for example:10.0.0.1/24). The entry value is the number of routes for this destination, and the announced value is the number of routes being announced for this destination. Sometimes the route destination is presented in another format, such as:</p> <ul style="list-style-type: none"> • MPLS-label (for example, 80001). • interface-name (for example, ge-1/0/2). • neighbor-address:control-word-status:encapsulation type:vc-id:source (Layer 2 circuit only; for example, 10.1.1.195:NoCtrlWord:1:1:Local/96). • neighbor-address—Address of the neighbor. • control-word-status—Whether the use of the control word has been negotiated for this virtual circuit: NoCtrlWord or CtrlWord. • encapsulation type—Type of encapsulation, represented by a number: (1) Frame Relay DLCI, (2) ATM AAL5 VCC transport, (3) ATM transparent cell transport, (4) Ethernet, (5) VLAN Ethernet, (6) HDLC, (7) PPP, (8) ATM VCC cell transport, (10) ATM VPC cell transport. • vc-id—Virtual circuit identifier. • source—Source of the advertisement: Local or Remote. • inclusive multicast Ethernet tag route—Type of route destination represented by (for example, 3:100.100.100.10:100::0::10::100.100.100.10/384): <ul style="list-style-type: none"> • route distinguisher—(8 octets) Route distinguisher (RD) must be the RD of the EVPN instance (EVI) that is advertising the NLRI. • Ethernet tag ID—(4 octets) Identifier of the Ethernet tag. Can set to 0 or to a valid Ethernet tag value. • IP address length—(1 octet) Length of IP address in bits. • originating router's IP address—(4 or 16 octets) Must set to the provider edge (PE) device's IP address. This address should be common for all EVIs on the PE device, and may be the PE device's loopback address.
label stacking	<p>(Next-to-the-last-hop routing device for MPLS only) Depth of the MPLS label stack, where the label-popping operation is needed to remove one or more labels from the top of the stack. A pair of routes is displayed, because the pop operation is performed only when the stack depth is two or more labels.</p> <ul style="list-style-type: none"> • S=0 route indicates that a packet with an incoming label stack depth of 2 or more exits this routing device with one fewer label (the label-popping operation is performed). • If there is no S= information, the route is a normal MPLS route, which has a stack depth of 1 (the label-popping operation is not performed).

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
[<i>protocol, preference</i>]	<p>Protocol from which the route was learned and the preference value for the route.</p> <ul style="list-style-type: none"> • +—A plus sign indicates the active route, which is the route installed from the routing table into the forwarding table. • - —A hyphen indicates the last active route. • *—An asterisk indicates that the route is both the active and the last active route. An asterisk before a to line indicates the best subpath to the route. <p>In every routing metric except for the BGP LocalPref attribute, a lesser value is preferred. In order to use common comparison routines, Junos OS stores the 1's complement of the LocalPref value in the Preference2 field. For example, if the LocalPref value for Route 1 is 100, the Preference2 value is -101. If the LocalPref value for Route 2 is 155, the Preference2 value is -156. Route 2 is preferred because it has a higher LocalPref value and a lower Preference2 value.</p>
Level	(IS-IS only). In IS-IS, a single AS can be divided into smaller groups called areas. Routing between areas is organized hierarchically, allowing a domain to be administratively divided into smaller areas. This organization is accomplished by configuring Level 1 and Level 2 intermediate systems. Level 1 systems route within an area. When the destination is outside an area, they route toward a Level 2 system. Level 2 intermediate systems route between areas and toward other ASs.
Route Distinguisher	IP subnet augmented with a 64-bit prefix.
PMSI	Provider multicast service interface (MVPN routing table).
Next-hop type	Type of next hop. For a description of possible values for this field, see Table 69 on page 2400 .
Next-hop reference count	Number of references made to the next hop.
Flood nexthop branches exceed maximum message	Indicates that the number of flood next-hop branches exceeded the system limit of 32 branches, and only a subset of the flood next-hop branches were installed in the kernel.
Source	IP address of the route source.
Next hop	Network layer address of the directly reachable neighboring system.

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
via	<p>Interface used to reach the next hop. If there is more than one interface available to the next hop, the name of the interface that is actually used is followed by the word Selected. This field can also contain the following information:</p> <ul style="list-style-type: none"> • Weight—Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible. • Balance—Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a routing device is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.
Label-switched-path <i>lsp-path-name</i>	Name of the LSP used to reach the next hop.
Label operation	MPLS label and operation occurring at this routing device. The operation can be pop (where a label is removed from the top of the stack), push (where another label is added to the label stack), or swap (where a label is replaced by another label).
Interface	(Local only) Local interface name.
Protocol next hop	Network layer address of the remote routing device that advertised the prefix. This address is used to derive a forwarding next hop.
Indirect next hop	Index designation used to specify the mapping between protocol next hops, tags, kernel export policy, and the forwarding next hops.
State	State of the route (a route can be in more than one state). See Table 70 on page 2401 .
Local AS	AS number of the local routing devices.
Age	How long the route has been known.
AIGP	Accumulated interior gateway protocol (AIGP) BGP attribute.
Metricn	Cost value of the indicated route. For routes within an AS, the cost is determined by IGP and the individual protocol metrics. For external routes, destinations, or routing domains, the cost is determined by a preference value.
MED-plus-IGP	Metric value for BGP path selection to which the IGP cost to the next-hop destination has been added.

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
TTL-Action	For MPLS LSPs, state of the TTL propagation attribute. Can be enabled or disabled for all RSVP-signaled and LDP-signaled LSPs or for specific VRF routing instances.
Task	Name of the protocol that has added the route.
Announcement bits	<p>The number of BGP peers or protocols to which Junos OS has announced this route, followed by the list of the recipients of the announcement. Junos OS can also announce the route to the kernel routing table (KRT) for installing the route into the Packet Forwarding Engine, to a resolve tree, a Layer 2 VC, or even a VPN. For example, n-Resolve inet indicates that the specified route is used for route resolution for next hops found in the routing table.</p> <ul style="list-style-type: none"> • n—An index used by Juniper Networks customer support only.
AS path	<p>AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated:</p> <ul style="list-style-type: none"> • I—IGP. • E—EGP. • Recorded—The AS path is recorded by the sample process (sampled). • ?—Incomplete; typically, the AS path was aggregated. <p>When AS path numbers are included in the route, the format is as follows:</p> <ul style="list-style-type: none"> • []—Brackets enclose the number that precedes the AS path. This number represents the number of ASs present in the AS path, when calculated as defined in RFC 4271. This value is used in the AS-path merge process, as defined in RFC 4893. • []—If more than one AS number is configured on the routing device, or if AS path prepending is configured, brackets enclose the local AS number associated with the AS path. • { }—Braces enclose AS sets, which are groups of AS numbers in which the order does not matter. A set commonly results from route aggregation. The numbers in each AS set are displayed in ascending order. • ()—Parentheses enclose a confederation. • ([])—Parentheses and brackets enclose a confederation set. <p>NOTE: In Junos OS Release 10.3 and later, the AS path field displays an unrecognized attribute and associated hexadecimal value if BGP receives attribute 128 (attribute set) and you have not configured an independent domain in any routing instance.</p>

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
validation-state	<p>(BGP-learned routes) Validation status of the route:</p> <ul style="list-style-type: none"> • Invalid—Indicates that the prefix is found, but either the corresponding AS received from the EBGP peer is not the AS that appears in the database, or the prefix length in the BGP update message is longer than the maximum length permitted in the database. • Unknown—Indicates that the prefix is not among the prefixes or prefix ranges in the database. • Unverified—Indicates that the origin of the prefix is not verified against the database. This is because the database got populated and the validation is not called for in the BGP import policy, although origin validation is enabled, or the origin validation is not enabled for the BGP peers. • Valid—Indicates that the prefix and autonomous system pair are found in the database.
FECs bound to route	Indicates point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.
Primary Upstream	When multipoint LDP with multicast-only fast reroute (MoFRR) is configured, indicates the primary upstream path. MoFRR transmits a multicast join message from a receiver toward a source on a primary path, while also transmitting a secondary multicast join message from the receiver toward the source on a backup path.
RPF Nexthops	When multipoint LDP with MoFRR is configured, indicates the reverse-path forwarding (RPF) next-hop information. Data packets are received from both the primary path and the secondary paths. The redundant packets are discarded at topology merge points due to the RPF checks.
Label	Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.
weight	Value used to distinguish MoFRR primary and backup routes. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.
VC Label	MPLS label assigned to the Layer 2 circuit virtual connection.
MTU	Maximum transmission unit (MTU) of the Layer 2 circuit.
VLAN ID	VLAN identifier of the Layer 2 circuit.
Prefixes bound to route	Forwarding equivalent class (FEC) bound to this route. Applicable only to routes installed by LDP.

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
Communities	Community path attribute for the route. See Table 71 on page 2404 for all possible values for this field.
Layer2-info: encaps	Layer 2 encapsulation (for example, VPLS).
control flags	Control flags: none or Site Down .
mtu	Maximum transmission unit (MTU) information.
Label-Base, range	First label in a block of labels and label block size. A remote PE routing device uses this first label when sending traffic toward the advertising PE routing device.
status vector	Layer 2 VPN and VPLS network layer reachability information (NLRI).
Accepted Multipath	Current active path when BGP multipath is configured.
Accepted LongLivedStale	The LongLivedStale flag indicates that the route was marked LLGR-stale by this router, as part of the operation of LLGR receiver mode. Either this flag or the LongLivedStaleImport flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.
Accepted LongLivedStaleImport	<p>The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy. Either this flag or the LongLivedStale flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.</p> <p>Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and import into the inet.0 routing table</p>
ImportAccepted LongLivedStaleImport	<p>Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and imported into the inet.0 routing table</p> <p>The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy.</p>
Accepted MultipathContrib	Path currently contributing to BGP multipath.
Localpref	Local preference value included in the route.
Router ID	BGP router ID as advertised by the neighbor in the open message.

Table 68: show route table Output Fields (*continued*)

Field Name	Field Description
Primary Routing Table	In a routing table group, the name of the primary routing table in which the route resides.
Secondary Tables	In a routing table group, the name of one or more secondary tables in which the route resides.

Table 69 on page 2400 describes all possible values for the Next-hop Types output field.

Table 69: Next-hop Types Output Field Values

Next-Hop Type	Description
Broadcast (bcast)	Broadcast next hop.
Deny	Deny next hop.
Discard	Discard next hop.
Flood	Flood next hop. Consists of components called branches, up to a maximum of 32 branches. Each flood next-hop branch sends a copy of the traffic to the forwarding interface. Used by point-to-multipoint RSVP, point-to-multipoint LDP, point-to-multipoint CCC, and multicast.
Hold	Next hop is waiting to be resolved into a unicast or multicast type.
Indexed (idxd)	Indexed next hop.
Indirect (indr)	Used with applications that have a protocol next hop address that is remote. You are likely to see this next-hop type for internal BGP (IBGP) routes when the BGP next hop is a BGP neighbor that is not directly connected.
Interface	Used for a network address assigned to an interface. Unlike the router next hop, the interface next hop does not reference any specific node on the network.
Local (locl)	Local address on an interface. This next-hop type causes packets with this destination address to be received locally.
Multicast (mcst)	Wire multicast next hop (limited to the LAN).
Multicast discard (mdsc)	Multicast discard.

Table 69: Next-hop Types Output Field Values (*continued*)

Next-Hop Type	Description
Multicast group (mgrp)	Multicast group member.
Receive (recv)	Receive.
Reject (rjct)	Discard. An ICMP unreachable message was sent.
Resolve (rslv)	Resolving next hop.
Routed multicast (mcrt)	Regular multicast next hop.
Router	<p>A specific node or set of nodes to which the routing device forwards packets that match the route prefix.</p> <p>To qualify as a next-hop type router, the route must meet the following criteria:</p> <ul style="list-style-type: none"> • Must not be a direct or local subnet for the routing device. • Must have a next hop that is directly connected to the routing device.
Table	Routing table next hop.
Unicast (ucst)	Unicast.
Unilist (ulst)	List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.

Table 70 on page 2401 describes all possible values for the State output field. A route can be in more than one state (for example, <Active NoReadvrt Int Ext>).

Table 70: State Output Field Values

Value	Description
Accounting	Route needs accounting.
Active	Route is active.
Always Compare MED	Path with a lower multiple exit discriminator (MED) is available.
AS path	Shorter AS path is available.

Table 70: State Output Field Values (*continued*)

Value	Description
Cisco Non-deterministic MED selection	Cisco nondeterministic MED is enabled, and a path with a lower MED is available.
Clone	Route is a clone.
Cluster list length	Length of cluster list sent by the route reflector.
Delete	Route has been deleted.
Ex	Exterior route.
Ext	BGP route received from an external BGP neighbor.
FlashAll	Forces all protocols to be notified of a change to any route, active or inactive, for a prefix. When not set, protocols are informed of a prefix only when the active route changes.
Hidden	Route not used because of routing policy.
IfCheck	Route needs forwarding RPF check.
IGP metric	Path through next hop with lower IGP metric is available.
Inactive reason	Flags for this route, which was not selected as best for a particular destination.
Initial	Route being added.
Int	Interior route.
Int Ext	BGP route received from an internal BGP peer or a BGP confederation peer.
Interior > Exterior > Exterior via Interior	Direct, static, IGP, or EBGp path is available.
Local Preference	Path with a higher local preference value is available.
Martian	Route is a martian (ignored because it is obviously invalid).
MartianOK	Route exempt from martian filtering.

Table 70: State Output Field Values (*continued*)

Value	Description
Next hop address	Path with lower metric next hop is available.
No difference	Path from neighbor with lower IP address is available.
NoReadvrt	Route not to be advertised.
NotBest	Route not chosen because it does not have the lowest MED.
Not Best in its group	Incoming BGP AS is not the best of a group (only one AS can be the best).
NotInstall	Route not to be installed in the forwarding table.
Number of gateways	Path with a greater number of next hops is available.
Origin	Path with a lower origin code is available.
Pending	Route pending because of a hold-down configured on another route.
Release	Route scheduled for release.
RIB preference	Route from a higher-numbered routing table is available.
Route Distinguisher	64-bit prefix added to IP subnets to make them unique.
Route Metric or MED comparison	Route with a lower metric or MED is available.
Route Preference	Route with lower preference value is available.
Router ID	Path through a neighbor with lower ID is available.
Secondary	Route not a primary route.
Unusable path	Path is not usable because of one of the following conditions: <ul style="list-style-type: none"> • The route is damped. • The route is rejected by an import policy. • The route is unresolved.
Update source	Last tiebreaker is the lowest IP address value.

Table 71 on page 2404 describes the possible values for the Communities output field.

Table 71: Communities Output Field Values

Value	Description
<i>area-number</i>	4 bytes, encoding a 32-bit area number. For AS-external routes, the value is 0 . A nonzero value identifies the route as internal to the OSPF domain, and as within the identified area. Area numbers are relative to a particular OSPF domain.
bandwidth: local AS number:link-bandwidth-number	Link-bandwidth community value used for unequal-cost load balancing. When BGP has several candidate paths available for multipath purposes, it does not perform unequal-cost load balancing according to the link-bandwidth community unless all candidate paths have this attribute.
domain-id	Unique configurable number that identifies the OSPF domain.
domain-id-vendor	Unique configurable number that further identifies the OSPF domain.
<i>link-bandwidth-number</i>	Link-bandwidth number: from 0 through 4,294,967,295 (bytes per second).
<i>local AS number</i>	Local AS number: from 1 through 65,535 .
<i>options</i>	1 byte. Currently this is only used if the route type is 5 or 7 . Setting the least significant bit in the field indicates that the route carries a type 2 metric.
origin	(Used with VPNs) Identifies where the route came from.
<i>ospf-route-type</i>	1 byte, encoded as 1 or 2 for intra-area routes (depending on whether the route came from a type 1 or a type 2 LSA); 3 for summary routes; 5 for external routes (area number must be 0); 7 for NSSA routes; or 129 for sham link endpoint addresses.
route-type-vendor	Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute 0x8000 . The format is area-number:ospf-route-type:options .
rte-type	Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute 0x0306 . The format is area-number:ospf-route-type:options .
target	Defines which VPN the route participates in; target has the format 32-bit IP address:16-bit number . For example, 10.19.0.0:100.
unknown IANA	Incoming IANA codes with a value between 0x1 and 0x7fff . This code of the BGP extended community attribute is accepted, but it is not recognized.

Table 71: Communities Output Field Values (*continued*)

Value	Description
unknown OSPF vendor community	Incoming IANA codes with a value above 0x8000 . This code of the BGP extended community attribute is accepted, but it is not recognized.
evpn-mcast-flags	Identifies the value in the multicast flags extended community and whether snooping is enabled. A value of 0x1 indicates that the route supports IGMP proxy.
evpn-l2-info	Identifies whether Multihomed Proxy MAC and IP Address Route Advertisement is enabled. A value of 0x20 indicates that the proxy bit is set. . Use the show bridge mac-ip-table extensive statement to determine whether the MAC and IP address route was learned locally or from a PE device.

List of Syntax

[Syntax on page 2447](#)

[Syntax \(EX Series Switches\) on page 2447](#)

Syntax

```
show ted database
<brief | detail | extensive>
<instance instance-name>
<logical-system (all | logical-system-name)>
<system-name>
<topology-id topology bgp-ls-epe>
```

Syntax (EX Series Switches)

```
show ted database
<brief | detail | extensive>
<system-name>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

topology-id *topology* option added in Junos OS Release 17.4R1 for MX Series and PTX Series.

Description

Display the entries in the Multiprotocol Label Switching (MPLS) traffic engineering database.

Options

none—Display standard information about all entries in the traffic engineering database.

brief | detail | extensive—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

system-name—(Optional) Display traffic engineering database information for a particular system.

topology-id *topology*— Display the topology information. By default, traffic engineering topology information is displayed.

Required Privilege Level

Output Fields

[Table 72 on page 2448](#) describes the output fields for the **show ted database** command. Output fields are listed in the approximate order in which they appear.

Table 72: show ted database Output Fields

Field Name	Field Description	Level of Output
TED database	Number of nodes and pseudonodes participating in IS-IS and OSPF domain routing.	All levels
ID	Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode. If the node contains a router ID, it is displayed in parentheses.	brief
NodeID	Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.	extensive
Type	Type of node. It can be either Rtr (router) or Net (pseudonode).	All levels
Age(s)	How long since the node was last refreshed, in seconds.	All levels
LnkIn	Number of nodes pointing toward this node.	All levels
LnkOut	Number of nodes to which this node points.	All levels
Protocol	Protocol that reported the node information: <ul style="list-style-type: none"> • IS-IS(1)—IS-IS Level 1. • IS-IS(2)—IS-IS Level 2. • OSPF (area-number)—OSPF from the specified area. 	All levels
To	Address on the far end of a link.	detail extensive

Table 72: show ted database Output Fields (*continued*)

Field Name	Field Description	Level of Output
Local	Address of the local interface being used to reach the remote node.	detail extensive
Remote	Address of the interface on the remote node.	detail extensive
Local interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	detail extensive
Remote interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	detail extensive
Metric	Configured traffic engineering metric.	extensive
IGP metric	Configured interior gateway protocol metric.	extensive
Static BW	Total interface bandwidth in bps.	extensive
Reservable bandwidth	Subscription factor for the interface, which is the percentage of the link bandwidth that can be used for the RSVP reservation process. You configure this by including the subscription statement when configuring RSVP.	extensive
Available BW [priority]	(Must include diffserv-te statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each priority level. The bandwidth shown is for the entire interface, not for each individual LSP.	extensive
Diffserv-TE BW Model	Bandwidth constraint model used by the LSPs.	extensive
Available BW [TE-class]	(Must include the diffserv-te statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each traffic engineering class.	extensive
Static BW [CT-class]	Total interface bandwidth used by an MPLS traffic class, in bps.	extensive

Table 72: show ted database Output Fields (*continued*)

Field Name	Field Description	Level of Output
Interface Switching Capability Descriptor (n)	<p>Information about the interface switching capability descriptor, which is a subtype length value (TLV) of the link TLV. <i>n</i> is the index number.</p> <ul style="list-style-type: none"> • Switching type—Type of switching to be performed on a particular link: <ul style="list-style-type: none"> • PSC-1—Packet switch-capable 1 • PSC-2—Packet switch-capable 2 • PSC-3—Packet switch-capable 3 • PSC-4—Packet switch-capable 4 • L2SC—Layer-2-switch-capable • TDM—Time-division-multiplexing-capable • LSC—Lambda switch-capable • FSC—Fiber switch-capable • Encoding type—Encoding of the LSP being requested: <ul style="list-style-type: none"> • Packet • Ethernet • ANSI/ETSI PDH • Reserved • SDH /SONET • Digital Wrapper • Lambda (photonic) • Fiber • FiberSDH/SONET • Maximum LSP BW [priority] bps—Maximum LSP bandwidth information. Amount of bandwidth actually reserved for each priority level. The bandwidth shown is for the entire interface. <ul style="list-style-type: none"> • [n]—Priority level. The range is from 0 (high) through 7 (low). • n Mbps—Amount of the maximum bandwidth. • Minimum LSP BW—Minimum LSP bandwidth in Mbps. Amount of bandwidth actually reserved for each priority level. The bandwidth shown is for the entire interface. Minimum LSP BW is displayed only when switching type is PSC-1 or TDM. • Interface MTU—Displayed only when switching type is TDM. • Interface supports standard SONET/SDH—Displayed only when switching type is TDM. 	extensive

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display Multiprotocol Label Switching (MPLS) traffic engineering database link information.

Options

none—Display standard information about traffic engineering database link information.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 73 on page 2460 describes the output fields for the **show ted link** command. Output fields are listed in the approximate order in which they appear.

Table 73: show ted link Output Fields

Field Name	Field Description	Level of Output
ID	Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.	brief
-->ID	Hostname and address of the node that the link is going to. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.	brief
<i>hostname</i>	Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.	detail
<i>hostname</i>	Hostname and address of the node that the link is going to. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.	detail
Local Path	Number of paths CSPF on the local routing device has placed on the link.	All levels
Metric	Configured traffic engineering metric.	extensive
IGP metric	Configured interior gateway protocol metric.	detail
Local BW	Amount of bandwidth the local routing device has placed on the link.	All levels
Local	Address of the local interface being used to reach the remote node.	detail extensive
Remote	Address of the interface on the remote node.	detail extensive
Local interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	detail
Remote interface index	The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.	detail

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance *instance-name* option added in Junos OS Release 15.1.

Description

Display information about the protocols from which the Multiprotocol Label Switching (MPLS) traffic engineering database learned about its nodes.

Options

none—Display standard information about the protocols from which the traffic engineering database learned about its nodes.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 74 on page 2465 describes the output fields for the **show ted protocol** command. Output fields are listed in the approximate order in which they appear.

Table 74: show ted protocol Output Fields

Field Name	Field Description
Protocol name	Protocol that reported the node information: <ul style="list-style-type: none"> • IS-IS(1)—IS-IS Level 1. • IS-IS(2)—IS-IS Level 2. • OSPF (<i>area-number</i>)—OSPF from the specified area.
Credibility	If the protocols provide conflicting information about a node, the protocol with the highest credibility value is the one that the traffic engineering database uses.
Self node	Address the protocol uses as the local address.

Sample Output

show ted protocol

```
user@host> show ted protocol
```

Protocol name	Credibility	Self node
IS-IS(2)	2 (highest)	corriedale.00(123.456.1.11)
IS-IS(1)	1	corriedale.00(123.456.1.11)

traceroute mpls bgp

Syntax

```
traceroute mpls bgp fec
<destination destination-address>
<detail>
<exp exp>
<fanout fanout-number>
<logical-system logical system-name>
<no-resolve>
<paths paths-number>
<pipe-mode>
<retries retries-number>
<routing-instance routing-instance-name>
<source source-address>
<ttl value>
<wait seconds>
```

Release Information

Command introduced in Junos OS Release 14.2.

Description

Trace route to a remote host for an MPLS label-switched path (LSP) signaled by the Border Gateway Protocol (BGP). Use **traceroute mpls bgp** as a debugging tool to locate MPLS BGP forwarding issues in a network. (Currently supported for IPv4 packets only.)

To use the **traceroute mpls bgp** command, make sure you have BGP routes with MPLS labels.

NOTE: The **traceroute mpls bgp fec** command only supports single paths.

Options

fec—Specify the IP address and optional prefix of the forwarding equivalence class (FEC). Suppose you are at PE1, use would want to use the IP address of PE2 to trace the BGP path to that router.

destination *destination-address*—(Optional) Specify the destination address to use when sending probes.

detail—(Optional) Display detailed output.

exp *exp*—(Optional) Specify the class of service to use when sending probes.

Range: 0 through 7

Default: 7

fanout *fanout-number*—(Optional) Specify the maximum number of next hops to search per node.

Range: 1 through 16

Default: 16

logical-system *logical-system-name*—(Optional) Specify the name of the logical system for the traceroute attempt.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

paths *paths-number*—(Optional) Specify the number of paths to search.

Range: 1 through 255

Default: 16

pipe-mode—(Optional) Specify to trace only the outermost FEC.

retries *retries-number*—(Optional) Specify the number of times to resend probe values.

Range: 1 through 9

Default: 3

routing-instance *routing-instance-name*—(Optional) Specify the name of the routing instance for the trace route attempt.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl *value*—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds.

Range: 1 through 125

Default: 64

wait *seconds*—(Optional) Specify the number of seconds to wait before resending a probe.

Range: 5 through 15

Default: 10

Required Privilege Level

Output Fields

Table 75 on page 2468 describes the output fields for the **traceroute mpls bgp fec** command and the **traceroute mpls bgp fec detail** command. Output fields are listed in the approximate order in which they appear.

Table 75: traceroute mpls bgp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the traceroute mpls bgp fec command.	All levels
ttl	Time to live value of the labeled packet.	None
Label	Outgoing label used for forwarding the packet along the label-switched paths.	None
Protocol	Signaling protocol used. For this command, it is BGP.	None
Address	Address of the next hop.	None
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null .	None
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).	None
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	detail
Parent	Address of the previous hop. Parent value for the first hop is null .	detail
Return Code	Return code for reporting the result of processing the echo request by the receiver.	detail
Response time	Time for the echo request to reach the receiver.	detail
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none .	detail
Label Stack	Label stack used to forward the packet.	detail

Sample Output

traceroute mpls bgp

user@host> **traceroute mpls bgp fec**

```

    Probe options: retries 3, exp 7

transit (Chained Composite Next Hops)

Syntax

```
transit {
  (all | no-all);
  (l2vpn | no-l2vpn);
  (l3vpn | no-l3vpn);
  (labeled-bgp | no-labeled-bgp);
  (ldp | no-ldp);
  (ldp-p2mp | no-ldp-p2mp);
  lsp-statistics-from-route;
  (rsvp | no-rsvp);
  (rsvp-p2mp | no-rsvp-p2mp);
  (static | no-static);
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options forwarding-table chained-composite-next-hop],
[edit routing-options forwarding-table chained-composite-next-hop]
```

NOTE: The [edit logical-systems] hierarchy level is not supported on the QFX10000 switches.

Release Information

Statement introduced in Junos OS Release 12.1.

Statement introduced in Junos OS Release 15.1 for QFX10000 Series switches.

Description

Allows you to configure the chained composite next hops transit configuration options for devices handling transit traffic in the network. This statement and the associated functionality is available only on PTX Packet Transport Routers and QFX10000 switches.

Default

All of the **transit** statement options are enabled on PTX transport routers and QFX10000 switches. However, you can disable any of the statements with a **no** option.

Starting in Junos OS Release 14.1, the **transit l3vpn** statement is enabled by default on PTX Series Packet Transport Routers only.

Options

all | no-all—Enable or disable chained composite next-hops for all of the possible packet transit protocols and applications. The **all | no-all** statements do not apply to the **lsp-statistics-from-route** statement.

l2vpn | no-l2vpn—Enable or disable chained composite next-hops for Layer 2 VPNs.

l3vpn | no-l3vpn—Enable or disable chained composite next-hops for Layer 3 VPNs.

labeled-bgp | no-labeled-bgp—Enable or disable chained composite next-hops for labeled BGP.

ldp | no-ldp—Enable or disable chained composite next-hops for LDP.

ldp-p2mp | no-ldp-p2mp—Enable or disable chained composite next-hops for LDP-signaled P2MP LSPs.

NOTE: The **ldp-p2mp** and **rsvp-p2mp** statements are not supported on MX series routers.

On an MX series router with redundant Routing Engines and enhanced-ip mode configuration, enabling the **ldp-p2mp** and **rsvp-p2mp** statements under the **[edit routing-options forwarding-table chained-composite-next-hop transit]** hierarchy level causes ping from the current master logical system to fail at the time of a Routing Engine switchover.

lsp-statistics-from-route—Enable LSP statistics collection from the route.

rsvp | no-rsvp—Enable or disable chained composite next-hops for RSVP.

rsvp-p2mp | no-rsvp-p2mp—Enable or disable chained composite next-hops for RSVP-signaled P2MP LSPs.

NOTE: The **ldp-p2mp** and **rsvp-p2mp** statements are not supported on MX series routers.

On an MX series router with redundant Routing Engines and enhanced-ip mode configuration, enabling the **rsvp-p2mp** and **ldp-p2mp** statements under the **[edit routing-options forwarding-table chained-composite-next-hop transit]** hierarchy level causes ping from the current master logical system to fail at the time of a Routing Engine switchover.

static | no-static—Chained composite next hops are enabled for transit static LSPs by default. You can also disable this functionality for transit static LSPs.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Syntax (EX and QFX Series Switches)

```
clear rsvp session
<connection-destination address>
<connection-source address>
<gracefully>
<lsp-id identifier>
<name name>
<optimize-fast-reroute>
<tunnel-id identifier>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Reset and restart Resource Reservation Protocol (RSVP) sessions.

Options

all—Clear all RSVP sessions for which this routing device is the ingress, transit, or egress routing device.

connection-source *address*—(Optional) Source address for GMPLS and MPLS LSPs from the RSVP sender template.

connection-destination *address*—(Optional) Destination address for GMPLS and MPLS LSPs from the RSVP sender template.

gracefully—(Optional) Gracefully reset an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin-Status object is signaled along the path to the other endpoint of the RSVP session. In the second pass, the path used by the RSVP session is torn down. This option can only be used on the ingress or egress routing device of the RSVP session and is only valid for nonpacket LSPs.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-id *identifier*—(Optional) LSP identifier (source port) for the RSVP sender template.

name *name*—(Optional) Reset and restart the specified RSVP session.

optimize-fast-reroute—(Optional) Begin fast reroute optimization.

tunnel-id *identifier*—(Optional) Tunnel identifier (destination port) for the RSVP session.

monitor label-switched-path

Syntax

```
monitor label-switched-path lsp-name
<logical-system (logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Logical system support introduced in Junos OS Release 9.4.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Display the real-time status of the specified RSVP label-switched path (LSP). You can also use this command to monitor LSPs configured within logical systems.

Options

logical-system (*logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-name—Name of the LSP.

Additional Information

You can track the amount of traffic traversing an RSVP LSP and observe its essential parameters, such as uptime, ingress and egress addresses, labels, routes, and ports. Values are typically sampled every second. The display also allows you to scroll to other currently running LSPs. You cannot use this command to display information about static LSPs or LDP-signaled LSPs.

The output of this command shows how much each field has changed since you started the command or since you cleared the counters by using the **c** key. To control the output of the **monitor label-switched-path** command while it is running, use the keys listed in [Table 76 on page 2478](#). The keys are not case-sensitive.

Table 76: Output Control Keys for the monitor label-switched-path Command

Key	Action
c	Clears the screen and refreshes the display for this LSP.
f	Freezes the display, preventing new information from being displayed.
l	Monitors a different LSP. After you type l, you can type the new LSP name.
n	Displays information about the next LSP (whose name is alphabetically higher than the current LSP name) configured on the router.

Table 76: Output Control Keys for the monitor label-switched-path Command (*continued*)

Key	Action
p	Goes to the previous LSP (whose name is alphabetically lower than the current LSP name) configured on the router.
q or Esc	Quits the command and returns to the command prompt.
t	Thaws, or restarts, the data display for this LSP.

Required Privilege Level

trace

List of Sample Output[monitor label-switched-path on page 2480](#)**Output Fields**

[Table 77 on page 2479](#) describes the output fields for the **monitor label-switched-path** command. Output fields are listed in the approximate order in which they appear.

Table 77: monitor label-switched-path Output Fields

Field Name	Field Description
(1)	<p>Displays the following information:</p> <ul style="list-style-type: none"> • hostname—Name of the router. • Seconds—Time elapsed since this display was started. • Time—Current local time.
(2)	<p>Delay—Length of the time delay, in milliseconds, required to obtain the information in the monitor display. The first number shows the current sampling delay. The second number shows the shortest delay recorded to date. The third number shows the worst delay recorded to date. This delay can vary substantially depending on the system load.</p>
(3)	<p>Displays the following:</p> <ul style="list-style-type: none"> • To—Destination address of the LSP. • From—Originating address of the LSP. • State—Current state of the LSP: Up or Down.
(4)	<p>Displays the following:</p> <ul style="list-style-type: none"> • LSPName—Name of the LSP. • Type—Type of LSP: Ingress, Egress, or Transit.

Sample Output

ping mpls rsvp

Syntax

```
ping mpls rsvp  
  <lsp-name>  
  <count count>  
  <destination address>  
  <detail>  
  <dynamic-bypass>  
  <egress egress-address>  
  <exp forwarding-class>  
  <interface interface-name>  
  <logical-system (all | logical-system-name)>  
  <manual-bypass>  
  <multipoint>  
  <size bytes>  
  <source source-address>  
  <standby standby-path-name>  
  <sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

The **egress** and **multipoint** options were introduced in Junos OS Release 9.2.

The **size** and **sweep** options were introduced in Junos OS Release 9.6.

The **dynamic-bypass** and **manual-bypass** options were introduced in Junos OS Release 10.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS RSVP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count count—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination address—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

NOTE: When using the **detail** option, the reported time is based on the system time configured on the local and remote routers. Differences in these system times can result in inaccurate one way ping trip times being reported.

In practice, it is difficult to synchronize the system times of independent Juniper Networks routers with sufficient accuracy to provide a meaningful time value for the **detail** option (even when synchronized using NTP).

dynamic-bypass—(Optional) Ping dynamically generated bypass LSPs, used for protecting other LSPs.

egress egress-address—(Optional) Only the specified egress router or switch responds to the ping request.

exp forwarding-class—(Optional) Value of the forwarding class for the MPLS ping packets.

interface—(Optional) Specify the name of the interface protected by the manual bypass LSP. This option is only available when you have also used the **manual-bypass** option.

logical-system (all | logical-system-name)—(Optional) Perform this operation on all logical systems or on the specified logical system.

lsp-name—Ping an RSVP-signaled LSP using an LSP name.

manual-bypass—(Optional) Ping manually configured bypass LSPs, used for protecting other LSPs. For this option, you must also specify the interface protected by the manual bypass LSP using the **interface** option.

multipoint—(Optional) Send ping requests to each of the egress routers or switches participating in a point-to-multipoint LSP. You can also include the **egress** option to ping a specific egress router or switch participating in a point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (**100** through **65468** bytes). Packets are 4-byte aligned. For example, if you enter a size of 101, 102, 103, or 104, the router or switch uses a size value of 104 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 100-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface.

standby standby-path-name—(Optional) Name of the standby path.

sweep —(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

[ping mpls rsvp \(Echo Reply Received\) on page 2484](#)
[ping mpls rsvp \(Echo Reply with Error Code\) on page 2485](#)
[ping mpls rsvp detail on page 2485](#)

[ping mpls rsvp destination detail count size on page 2486](#)
[ping mpls rsvp destination detail sweep size on page 2487](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

Sample Output

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display the status of Resource Reservation Protocol (RSVP)-enabled interfaces and packet statistics. The RSVP input/input module collects statistics for certain events on a per-interface basis. Most of these events were tracked on a routing-instance basis in Junos OS releases earlier than Release 17.2. The **show rsvp interface detail** command displays these event counters under the **Events** section of the output only when the values of these fields are higher than zero. These statistics are also maintained at the global level (per routing-instance) and are also displayed in the output of the **show rsvp statistics** command.

Options

none—Display standard information about the status of RSVP-enabled interfaces and packet statistics.

brief | detail | extensive | link-management—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display RSVP status information for the specified instance. If **instance-name** is omitted, RSVP status information is displayed for the master instance.

link-management—(Optional) Use the link-management option to display the control peers and corresponding TE-link information created by the Link Management Protocol (LMP).

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 78 on page 2490](#) lists the output fields for the **show rsvp interface** command. Output fields are listed in the approximate order in which they appear.

Table 78: show rsvp interface Output Fields

Field Name	Field Description	Level of Output
RSVP interface	Number of interfaces on which RSVP is active. Each interface has one line of output.	All levels
Interface	Name of the interface.	All levels
Index	Index of the interface.	detail
State	State of the interface. <ul style="list-style-type: none"> • Disabled—No traffic engineering information is displayed. • Down—Interface is not operational. • Enabled—Displays traffic engineering information. • Up—Interface is operational. 	All levels
NoAuthentication	Interface does not support RSVP authentication.	detail
NoAggregate	Interface does not support refresh reduction.	detail
NoReliable	Interface does not support refresh reduction message ID extension.	detail
NoLinkProtection	Interface does not support link protection.	detail

Table 78: show rsvp interface Output Fields (continued)

Field Name	Field Description	Level of Output
HelloInterval	Frequency at which RSVP hellos are sent on this interface (in seconds). Prior to Junos OS Release 18.2R2, when the no-interface-hello statement is configured under the [edit protocols rsvp] hierarchy, and there is no interface-specific configuration for the hello interval, the HelloInterval output field displayed the default hello interval time of 9 seconds. Starting in Junos OS Release 18.2R2, with a similar configuration, the HelloInterval output field displays 0 as the hello interval.	detail
Address	IP address of the local interface.	detail
Active control channel	Next-hop link address to transmit messages.	None specified
TElink	Traffic-engineered links that are managed by the peer they are associated with.	None specified
Active resv	Number of reservations that are actively reserving bandwidth on the interface.	All levels
PreemptionCnt	Number of times an RSVP session was preempted on this interface.	detail
Update threshold	Percentage change in reserved bandwidth to trigger an IGP update.	detail
Subscription	User-configured subscription factor.	All levels
Actual	Available RSVP bandwidth that is recalculated after considering SPRING bandwidth utilization.	extensive
bc number	Bandwidth allocated for the specified bandwidth constraint.	extensive
ct number	Bandwidth allocated for the specified class type.	extensive
Static BW	Total interface bandwidth, in bps.	All levels
Available BW	Amount of bandwidth that RSVP is allowed to reserve, in bps. It is equal to (static bandwidth * subscription factor).	al levels
Reserved BW	Currently reserved bandwidth, in bps.	All levels
SoftPreemptionCnt	Number of times a soft preemption occurred on this interface. This number is not included in the PreemptionCnt value.	detail

Table 78: show rsvp interface Output Fields (*continued*)

Field Name	Field Description	Level of Output
Overbooked BW	Currently overbooked bandwidth, in bps, by class type (ct0 through ct3).	detail
Highwater mark	Highest bandwidth that has ever been reserved on this interface, in bps.	brief
PacketType	Type of RSVP packet.	detail
Total Sent	Total number of packets sent.	detail
Total Received	Total number of packets received since RSVP was enabled.	detail
Last 5 seconds Sent	Number of packets sent in the last 5 seconds.	detail
Last 5 seconds Received	Number of packets received in the last 5 seconds.	detail
Path	Statistics about Path messages, which are sent from the RSVP sender along the data paths and store path state information in each node along the path.	detail
PathErr	Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.	detail
PathTear	Statistics about PathTear messages, which remove path states and dependent reservation states in any routers along a path.	detail
Resv	Statistics about Resv messages, which are sent from the RSVP receiver along the data paths and store reservation state information in each node along the path.	detail
ResvErr	Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.	detail
ResvTear	Statistics about ResvTear messages, which remove reservation states along a path.	detail
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.	detail
Ack	Acknowledge message for refresh reductions.	detail

Table 78: show rsvp interface Output Fields (*continued*)

Field Name	Field Description	Level of Output
Srefresh	Summary refresh messages.	detail
EndtoEnd RSVP	Statistics for the number of end-to-end RSVP messages sent.	detail
Queue	CoS transmit queue number and its associated forwarding class designation.	extensive
TxRate	Configured bandwidth in Mbps and configured bandwidth as a percentage of the specified queue.	extensive
Priority	Weight of the queue relative to other configured queues, in percentage.	extensive
queue-priority-value	Low, High, None, or Exact. None indicates no rate limiting. Exact indicates the queue transmits at the configured rate only.	extensive

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display Resource Reservation Protocol (RSVP) neighbors that were discovered dynamically during the exchange of RSVP packets.

Options

none—Display standard information about RSVP neighbors.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display the RSVP neighbor information for the specified instance. If **instance-name** is omitted, RSVP neighbor information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

[show rsvp neighbor detail on page 2502](#)

Output Fields

Table 79 on page 2498 lists the output fields for the **show rsvp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 79: show rsvp neighbor Output Fields

Field Name	Field Description	Level of Output
RSVP neighbor	Number of neighbors that the routing device has learned of. Each neighbor has one line of output.	All levels
via	Name of the interface where the neighbor has been detected. In the case of generalized MPLS (GMPLS) LSPs, the name of the peer where the neighbor has been detected.	detail
Address	Address of a learned neighbor.	All levels
Idle	Length of time the neighbor has been idle, in seconds. NOTE: Until Junos OS Release 15.1, in the output of the show rsvp neighbor command, the value under the Idle field immediately reflects the changed idle time when a link in the neighboring router is brought down. Starting with Junos OS Release 15.2, a router does not declare a neighbor as idle when a hello adjacency exists and has not timed out. When an interface is brought down, RSVP brings down the neighbor because of the notification it receives from IGP. The reason for considering the IGP-down notification is to support BFD-triggered fast reroute (FRR) and RSVP-TE is not directly a client for BFD notifications. When RSVP brings down the neighbor, the input/output process is not impacted. As a result, the idle time in the output of the show command is not immediately updated.	All levels
Up/Dn	Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.	All levels
Up cnt and Down cnt	Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.	detail

Table 79: show rsvp neighbor Output Fields (continued)

Field Name	Field Description	Level of Output
status	<p>State of the RSVP neighbor:</p> <ul style="list-style-type: none"> • Up—Routing device can detect RSVP Hello messages from the neighbor. • Down—Routing device has received one of the following indications: <ul style="list-style-type: none"> • Communication failure from the neighbor. • Communication from IGP that the neighbor is unavailable. • Change in the sequence numbers in the RSVP Hello messages sent by the neighbor. • Restarting—RSVP neighbor is unavailable and might be restarting. The neighbor remains in this state until it has restarted or is declared dead. This state is possible only when graceful restart is enabled. • Restarted—RSVP neighbor has restarted and is undergoing state recovery (graceful restart) procedures. • Dead—Routing device has lost all communication with the RSVP neighbor. Any RSVP sessions with that neighbor are torn down. 	detail
LastChange	Time elapsed since the neighbor state changed either from up to down or from down to up. The format is hh:mm:ss .	All levels
Last changed time	Time elapsed since the neighbor state changed either from up to down or from down to up.	detail
HelloInt	Frequency at which RSVP hellos are sent on this interface (in seconds).	All levels
HelloTx/Rx	Number of hello packets sent to and received from the neighbor.	All levels
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.	detail
Message received	Number of Path and Resv messages that this routing device has received from the neighbor.	detail
Remote Instance	Identification provided by the remote routing device during Hello message exchange.	detail
Local Instance	Identification sent to the remote routing device during Hello message exchange.	detail

Table 79: show rsvp neighbor Output Fields (continued)

Field Name	Field Description	Level of Output
Refresh reduction	<p>Measure of processing overhead requests of refresh messages. Refresh reduction extensions improve routing device performance by reducing the process overhead, thus increasing the number of LSPs a routing device can support. Refresh reduction can have the following values:</p> <ul style="list-style-type: none"> • operational—All four RSVP refresh reduction extensions—message ack, bundling, summary refresh, and staged refresh timer—are functional between the two neighboring routing devices. For a detailed explanation of these extensions, see RFC 2961. • incomplete—Some RSVP refresh reduction extensions are functional between the two neighboring routing devices. • not operational—Either the refresh reduction feature has been turned off, or the remote routing device cannot support the refresh reduction extensions. 	detail
Remote end	<p>Neighboring routing device's status with regard to refresh reduction:</p> <ul style="list-style-type: none"> • enabled—Remote routing device has requested refresh reduction during RSVP message exchanges. • disabled—Remote routing device does not require refresh reduction. 	detail
Pop label	Pop labels of the RSVP-TE pop-and-forward LSP tunnels.	detail
Ack-extension	<p>An RSVP refresh reduction extension:</p> <ul style="list-style-type: none"> • enabled—Both local and remote routing devices support the ack-extension (RFC 2961). • disabled—Remote routing device does not support the ack-extension. 	detail
Link protection	<p>Status of the MPLS fast reroute mechanism that protects traffic from link failure:</p> <ul style="list-style-type: none"> • enabled—Link protection feature has been turned on, protecting the neighbor with a bypass LSP. • disabled—No link protection feature has been enabled for this neighbor. 	detail
LSP name	Name of the bypass LSP.	detail

Table 79: show rsvp neighbor Output Fields (*continued*)

Field Name	Field Description	Level of Output
Bypass LSP	Status of the bypass LSP. It can have the following values: <ul style="list-style-type: none"> • does not exist—Bypass LSP is not available. • connecting—Routing device is in the process of establishing a bypass LSP, and the LSP is not available for link protection at the moment. • operational—Bypass LSP is up and running. • down—Bypass LSP has gone down, with the most probable cause a node or a link failure on the bypass path. 	detail
Backup routes	Number of user LSPs (or routes) that are being protected by a bypass LSP (before link failure).	detail
Backup LSPs	Number of LSPs that have been temporarily established to maintain traffic by refreshing the downstream LSPs during link failure (not a one-to-one correspondence).	detail
Bypass explicit route	Explicit route object's (ERO) path that is taken by the bypass LSP.	detail
Restart time	Length of time a neighbor waits to receive a Hello from the restarting node before declaring the node dead and deleting the states (in milliseconds).	detail
Recovery time	Length of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds). Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.	detail

Sample Output

show rsvp neighbor

user@host> **show rsvp neighbor**

```

RSVP neighbor: 2 learned
Address          Idle Up/Dn LastChange HelloInt HelloTx/Rx

```

show rsvp route-session-id

Syntax

```
show rsvp route-session-id
```

Release Information

Command introduced in Junos OS Release 16.1 for the MX Series.

Description

Display the session ID and the version information associated with the ingress route added by the Resource Reservation Protocol (RSVP) in the inet.3 table.

Session ID is a pre-populated identifier used for indirect next hops in BGP Prefix Independent Convergence (PIC) enabled router. Session ID is used to identify the session or path.

NOTE: **protect core** configuration is not required to display the **route-session-id**.

Options

none—Validate and display RSVP route session details.

Required Privilege Level

Output Fields

[Table 80 on page 2503](#) describes the output fields for the **show rsvp route-session-id** command. Output fields are listed in the approximate order in which they appear.

Table 80: show rsvp route-session-id Output Fields

Field Name	Field Description
Ingress Route Destination	Destination (egress routing device) of the session.
Ingress Route Preference	RSVP preference value of the ingress session.
Ingress Route Metric 1	Metric 1 associated with the RSVP ingress route.

Table 80: show rsvp route-session-id Output Fields (*continued*)

Field Name	Field Description
Ingress Route Metric 2	Metric 2 associated with the RSVP ingress route.
Ingress Route Session ID	Session ID associated with the RSVP ingress route.
Version	Version number associated with the RSVP ingress route.

Sample Output

show rsvp route-session-id

user@host> **show rsvp route-session-id**

```
RSVP Ingress Route Session ID Database:
=====
Ingress Route Destination: 1.1.1.5/32
Ingress Route Preference: 7
Ingress Route Metric 1:    20,          Metric 2: 0
Ingress Route Session ID: 0x146,       Version: 0
```

show rsvp pop-and-forward

Syntax

```
show rsvp pop-and-forward
<brief | detail | extensive>
<instance routing-instance-name>
<label label>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced in Junos OS Release 18.1R1 on MX Series routers, PTX Series routers, and vMX series routers.

Description

Display RSVP-TE pop-and-forward LSP tunnel information. This information includes the set of in-labels (one-hop pop label or a delegation label), the number of session using each label and the next segment-label (if there is another delegation hop downstream), and whether the in-label is used for unprotected or protected LSPs.

Options

none—Display the standard level of information for the RSVP-TE pop-and-forward LSP tunnels.

brief | detail | extensive—(Optional) Display the desired level of output. The brief option is the default level of output.

The detail option provides more information about the hops in a delegation segment (whether its one-hop or multi-hop).

The extensive option lists the set of LSPs that are using a given pop or delegation label.

instance *routing-instance-name*—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for the specified routing instance.

label *label*—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for the specified label.

logical-system (all | *logical-system-name*)—(Optional) Display the RSVP-TE pop-and-forward LSP tunnel information for all or the specified logical system.

Required Privilege Level

<te-link te-link>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

externally-provisioned option added in Junos OS Release 13.3.

Command introduced in Junos OS Release 13.2X51-D15 for QFX Series.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display information about RSVP sessions.

Options

none—Display standard information about all RSVP sessions.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

bidirectional | unidirectional—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.

bypass—(Optional) Display RSVP sessions for bypass LSPs.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

externally-provisioned—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

instance *instance-name*—(Optional) Display RSVP sessions for the specified instance. If **instance-name** is omitted, RSVP session information is displayed for the master instance.

interface *interface-name*—(Optional) Display RSVP sessions for the specified interface only.

RSVP reserves resources only for outgoing LSPs of an interface. Because resources are not reserved for incoming LSPs, the **show rsvp sessions interface *interface-name*** command output displays only those RSVP sessions whose next hops correspond to the specified interface.

To identify the number of RSVP sessions formed over the uplink interface on the egress label-switching router (LSR), you can use the following command:

```
user@host> show rsvp session egress extensive | match "PATH rcvfrom:" | match interface-name | count
```

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

lsp-type—(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

name *session-name*—(Optional) Display information about the named session.

p2mp—(Optional) Display point-to-multipoint information.

session-type—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this routing device.

To identify the number of RSVP sessions formed over the uplink interface on the egress label-switching router (LSR), you can use the following command:

```
user@host> show rsvp session egress extensive | match "PATH rcvfrom:" | match interface-name
| count
```

- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that transit through this routing device.

statistics—(Optional) Display packet statistics.

te-link te-link—(Optional) Display sessions with reservations on the specified TE link.

Required Privilege Level

Output Fields

[Table 81 on page 2511](#) describes the output fields for the **show rsvp session** command. Output fields are listed in the approximate order in which they appear.

Table 81: show rsvp session Output Fields

Field Name	Field Description	Level of Output
Ingress RSVP	Information about ingress RSVP sessions.	detail
Ingress RSVP	Information about ingress RSVP sessions. Each session has one line of output.	All levels
Egress RSVP	Information about egress RSVP sessions.	All levels
Transit RSVP	Information about the transit RSVP sessions.	All levels
P2MP name	(Appears only when the p2mp option is specified). Name of the point-to-multipoint LSP path.	All levels
P2MP branch count	(Appears only when the p2mp option is specified). Number of LSPs receiving packets from the point-to-multipoint LSP.	All levels
To	Destination (egress routing device) of the session.	All levels
From	Source (ingress routing device) of the session.	All levels
State	State of the path: Up , Down , or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	All levels
Address	Destination (egress routing device) of the LSP.	detail
From	Source (ingress routing device) of the session.	detail
LSPstate	State of the LSP that is being handled by this RSVP session. It can be either Up , Dn (down), or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	brief detail
Rt	Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
Active Route	Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (mpls.0).	detail
LSPname	Name of the LSP.	brief detail

Table 81: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. LSPpath can be either primary or secondary and can be displayed on the ingress, egress, and transit routing devices. LSPpath can also indicate when a graceful LSP deletion has been triggered.	detail
Bypass	(Egress routing device) Destination address for the bypass LSP.	detail
Bidir	(When LSP is bidirectional) LSP will allow data to travel in both directions between GMPLS devices.	detail
Bidirectional	(When LSP is bidirectional) LSP will allow data to travel both ways between GMPLS devices.	detail
Upstream label in	(When LSP is bidirectional) Incoming label for reverse direction traffic for this LSP.	detail
Upstream label out	(When LSP is bidirectional) Outgoing label for reverse direction traffic for this LSP.	detail
Recovery label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Recovery label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.	detail
Suggested label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Suggested label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.	detail
Resv style or Style	RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	brief detail
Label in	Incoming label for this LSP.	brief detail
Label out	Outgoing label for this LSP.	brief detail
Time left	Number of seconds remaining in the lifetime of the reservation.	brief detail

Table 81: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Since	Date and time when the RSVP session was initiated.	detail
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	detail
DiffServ info	Indicates whether the LSP is a multiclass LSP (multiclass diffServ-TE LSP) or a Differentiated-Services-aware traffic engineering LSP (diffServ-TE LSP).	detail
bandwidth	Bandwidth for each class type (ct0 , ct1 , ct2 , or ct3).	detail
Port number	Protocol ID and sender/receiver port used in this RSVP session.	detail
Attrib flags	Non-PHP indicates that ultimate hop popping has been requested by the LSP using this RSVP session	extensive
FastReroute desired	Fast reroute has been requested by the ingress routing device.	detail
Soft preemption desired	Soft preemption has been requested by the ingress routing device.	detail
FastReroute desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Fast reroute (one-to-one backup) has been requested by the ingress routing device.	detail extensive
Link protection desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Link protection (many-to-one backup) has been requested by the ingress routing device.	detail extensive
Node/Link protection desired	(Data [not a bypass or backup] LSP when the protection scheme has been requested) Node and link protection (many-to-one backup) has been requested by the ingress routing device.	detail extensive

Table 81: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Type	<p>LSP type:</p> <ul style="list-style-type: none"> • Link protected LSP—LSP has been protected by link protection at the outgoing interface. The name of the bypass used is also listed here (extensive). • Node/Link protected LSP—LSP has been protected by node and link protection at the outgoing interface. The name of the bypass used is also listed here (extensive). • Protection down—LSP is not currently protected. • Bypass LSP—LSP that is used to protected one or more user LSPs in case of link failure. • Backup LSP at Point-of-Local-Repair (PLR)—LSP that has been temporarily established to protected a user LSP at the ingress of a failed link. • Backup LSP at Merge Point (MP)—LSP that has been temporarily established to protected a user LSP at the egress of a failed link. 	detail extensive
New bypass	New bypass (the bypass name is also displayed) has been activated to protect the LSP.	extensive
Link protection up, using <i>bypass-name</i>	Link protection (the bypass name is also displayed) has been activated for the LSP.	extensive
Creating backup LSP, link down	A link down event occurred, and traffic is being switched over to the bypass LSP.	extensive
Deleting backup LSP, protected LSP restored	Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.	extensive
Path mtu	Displays the value of the path MTU received from the network (through signaling) and the value used for forwarding. This value is only displayed on ingress routing devices with the allow-fragmentation statement configured at the [edit protocols mpls path-mtu] hierarchy level. If there is a detour LSP, the path MTU for the detour is also displayed.	detail

Table 81: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Egress protection PLR as protector	RSVP state on the Protector or the point-of-local-repair (PLR) routing device: <ul style="list-style-type: none"> • Active— Egress protection is available at the Protector or the PLR routing device. • In Use— Local repair has been completed. 	detail
PATH rcvfrom	Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor.	detail
Adspec	MTU signaled from the ingress routing device to the egress routing device by means of the adspec object.	detail
PATH sentto	Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor (or peer-name in the GMPLS LSP case), and number of packets sent to the downstream routing device.	detail
Explt route	Explicit route for the session. Normally this value will be the same as that of record route. Differences indicate that path rerouting has occurred, typically during fast reroute.	detail
Record route	Recorded route for the session, taken from the record route object. Normally this value will be the same as that of explct route. Differences indicate that path rerouting has occurred, typically during fast reroute.	detail

<name session-name>
<session-type>
<statistics>
<te-link te-link>
```

Release Information

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about Resource Reservation Protocol (RSVP) sessions.

Options

none—Display standard information about all RSVP sessions.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

bidirectional | unidirectional—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.

down | up—(Optional) Display only LSPs that are inactive or active, respectively.

interface *interface-name*—(Optional) Display RSVP sessions for the specified interface only.

lsp-type —(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

name *session-name*—(Optional) Display information about the named session.

session-type—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this switch.
- **ingress**—Sessions that originate from this switch.

- **transit**—Sessions that transit through this switch.

statistics—(Optional) Display packet statistics.

te-link *te-link*—(Optional) Display sessions with reservations on the specified traffic-engineered link name.

Output Fields

[Table 82 on page 2524](#) describes the output fields for the **show rsvp session** command. Output fields are listed in the approximate order in which they appear.

Table 82: show rsvp session Output Fields

Field Name	Field Description	Level of Output
Ingress RSVP	Information about ingress RSVP sessions.	detail
Ingress RSVP	Information about ingress RSVP sessions. Each session has one line of output.	All levels
Egress RSVP	Information about egress RSVP sessions.	All levels
Transit RSVP	Information about the transit RSVP sessions.	All levels
To	Destination (egress switch) of the session.	All levels
From	Source (ingress switch) of the session.	All levels

Table 82: show rsvp session Output Fields (continued)

Field Name	Field Description	Level of Output
State	State of the path: Up , Down , or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	All levels
Address	Destination (egress switch) of the LSP.	detail
LSPstate	State of the LSP that is being handled by this RSVP session. It can be either Up , Dn (down), or AdminDn . AdminDn indicates that the LSP is being taken down gracefully.	brief, detail
Rt	Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the routing table is the primary MPLS table (mpls.0).	brief
ActiveRoute	Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table (inet.0). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table (mpls.0).	detail
LSPname	Name of the LSP.	brief, detail
LSPpath	Indicates whether the RSVP session is for the primary or secondary LSP path. LSPpath can be either primary or secondary and can be displayed on the ingress, egress, and transit switches. LSPpath can also indicate when a graceful LSP deletion has been triggered.	detail
Recovery label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Recovery label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.	detail
Suggested label received	(When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.	detail
Suggested label sent	(When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.	detail
Resv style or Style	RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be FF (fixed filter), SE (shared explicit), or WF (wildcard filter).	brief detail

Table 82: show rsvp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Label in	Incoming label for this LSP.	brief, detail
Label out	Outgoing label for this LSP.	brief, detail
Time left	Number of seconds remaining in the lifetime of the reservation.	brief, detail
Since	Date and time when the RSVP session was initiated.	detail
Tspec	Sender's traffic specification, which describes the sender's traffic parameters.	detail
Port number	Protocol ID and sender/receiver port used in this RSVP session.	detail
Creating backup LSP, link down	A link down event occurred, and traffic is being switched over to the bypass LSP.	extensive
Deleting backup LSP, protected LSP restored	Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.	extensive
PATH rcvfrom	Address of the previous-hop (upstream) switch or client, interface the neighbor used to reach this switch, and number of packets received from the upstream neighbor.	detail

Syntax

```
show rsvp statistics
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switches)

```
show rsvp statistics
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

instance option added in Junos OS Release 15.1 for the MX Series.

Description

Display Resource Reservation Protocol (RSVP) packet and error statistics. The RSVP input/output module collects statistics for certain events on a per-interface basis. Most of these events were tracked on a routing-instance basis in Junos OS releases earlier than Release 17.2. The "show rsvp interface detail" command displays these event counters under the Events section of the output only when the values of these fields are higher than zero. These statistics are also maintained at the global level (per routing-instance) and are also displayed in the output of the "show rsvp statistics" command.

Options

none—Display RSVP packet and error statistics.

instance *instance-name*—(Optional) Display RSVP packet and error statistics for the specified instance. If **instance-name** is omitted, RSVP statistics are displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

[show rsvp statistics on page 2534](#)

Output Fields

[Table 83 on page 2530](#) describes the output fields for the **show rsvp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 83: show rsvp statistics Output Fields

Field Name	Field Description
Packet Type	Statistics about different RSVP messages.
Total Sent	Total number of packets sent since RSVP was enabled.
Total Received	Total number of packets received since RSVP was enabled.
Last 5 seconds Sent	Total number of packets sent in the last 5 seconds.
Last 5 seconds Received	Number of packets received in the last 5 seconds.
Path	Statistics about Path messages, which are sent from the RSVP sender along the data paths and which store path state information in each node along the path.
PathErr	Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.
PathTear	Statistics about PathTear messages, which remove path states and dependent reservation states in any routing devices along a path.
Resv FF	Statistics about fixed-filter reservation style messages, which consist of distinct reservations among explicit senders.
Resv WF	Statistics about wildcard-filter reservation style messages, which consist of shared reservations among wildcard senders.
Res SE	Statistics about shared-explicit reservation style messages, which consist of shared reservations among explicit senders.
ResvErr	Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.

Table 83: show rsvp statistics Output Fields (*continued*)

Field Name	Field Description
ResvTear	Statistics about ResvTear messages, which remove reservation states along a path.
ResvConf	Statistics about ResvConfirm messages, which are responses to confirm a reservation request.
Ack	Acknowledge message for refresh reductions.
SRefresh	Summary refresh messages.
Hello	Number of RSVP hello packets that have been sent to and received from the neighbor.
EndtoEnd RSVP	Statistics for the number of End-to-end RSVP messages.
Errors	Statistics about errored RSVP packets.
Rcv pkt bad length	The packet was not processed because its length is inappropriate.
Rcv pkt unknown type	The packet is not one of the well-known RSVP types, as defined in RFC 2205, <i>Resource ReSerVation Protocol (RSVP)</i> .
Rcv pkt bad version	The packet is not an RSVP version 1 packet.
Rcv pkt auth fail	The packet failed authentication checks.
Rcv pkt bad checksum	The RSVP checksum check failed.
Rcv pkt bad format	General packet processing failed because the packet was badly formed.
Memory allocation fail	An internal resource failure occurred.
No path information	A reservation was received, but no sender is active.
Resv style conflict	The same session contains inconsistent reservation styles.
Port conflict	There were inconsistent port numbers for the same session.
Resv no interface	An interface for the receive reservation packets cannot be located.
PathErr to client	Number of PathErr packets delivered to the local client.

Table 83: show rsvp statistics Output Fields (*continued*)

Field Name	Field Description
ResvErr to client	Number of ResvErr packets delivered to the local client.
Path timeout	Number of times the sender timed out because the path was removed.
Resv timeout	Number of times the receiver timed out because the reservation was removed.
Message out-of-order	Records the number of RSVP incoming messages that are considered out of order. This is detected from the message ID object's sequence number.
Unknown ack msg	A neighboring routing device replies with an ACK object that contains an unknown message ID. This can indicate a message ID handshake problem. For example, a router receives an ACK for message IDs 1, 2, and 3. However, it only has state for message IDs 1 and 3. The router increments the unknown ack counter by 1.
Recv nack	If a neighboring router receives an unknown message ID in an RSVP refresh message, the router sends a Resv nack message back to the sender. This can happen if that neighbor has been rebooted. For this case, the router sends a regular RSVP refresh message to recover the state and start the message-ID handshake process again.
Recv duplicated msg-id	Number of times the same message ID is used by two different RSVP messages. This duplication is usually caused when a neighboring routing device restarts.
No TE-link to recv Hop	Counter of packets discarded because a TE link was not found.
Rcv pkt disabled interface	Number of RSVP packets received on an interface that is not enabled for RSVP.
Transmit buffer full	Number of times the buffer for assembling an outgoing RSVP message was not large enough.
Transmit failure	Number of times the RSVP task failed to send out a packet.
Receive failure	Number of times the RSVP task failed to read an incoming packet.
P2MP RESV discarded by appl	Number of Resv messages discarded because the MPLS label is not valid for the P2MP LSP application.
Rate limit	Number of RSVP packets dropped due to rate limiting.
Err msg loop detected	Number of RSVP error messages that have looped back to their originator. This is detected by checking the error node address in the ERROR_SPEC object.

Sample Output

show rsvp statistics

Starting in Junos OS Release 16.1, this command also shows conditional PathTear statistics and the number of times an LSP state has been retained because of Link Protecting Merge Point (LP-MP) or Node Protecting Merge Point (NP-MP) determination.

```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about the Resource Reservation Protocol (RSVP) protocol settings, such as the version of the RSVP software, the refresh timer and keep multiplier, and local RSVP graceful restart capabilities on a routing device.

Options

none—Display RSVP protocol settings.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

List of Sample Output

[show rsvp version on page 2540](#)

Output Fields

[Table 84 on page 2538](#) describes the output fields for the **show rsvp version** command. Output fields are listed in the approximate order in which they appear.

Table 84: show rsvp version Output Fields

Field Name	Field Description
Resource ReSerVation Protocol, version	RSVP software version.
RSVP protocol	Status of RSVP: Enabled or Disabled .
R(refresh timer)	Configured time interval used to generate periodic RSVP messages.
K(keep multiplier)	Number of RSVP messages that can be lost before an RSVP state is declared stale.
Preemption	Currently configured preemption capability: Aggressive , Disabled , or Normal . The default is Normal .
Soft-preemption cleanup	Time, in seconds, that an LSP is kept after it has been soft preempted. This is a global property of the RSVP protocol.
Graceful deleting timeout	Currently configured value for the graceful-deletion-timeout statement. The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.
NSR Mode	Status of the nonstop active routing feature for RSVP on the restarting device: Disabled , Enabled/Master , or Enabled/Standby .
NSR State	<p>State of the nonstop active routing feature for RSVP on the restarting device.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> • Idle • TE-link sync complete • Neighbor sync complete • Path state sync complete • Resv state sync complete • Bypass sync complete • Init sync complete
Setup protection	Status of point-to-point and point-to-multipoint LSP setup protection configuration on the device: Enabled or Disabled .

Table 84: show rsvp version Output Fields (continued)

Field Name	Field Description
Route Session-Id count	<p>Total count of session IDs associated with the combination of all the RSVP ingress routes.</p> <p>NOTE: Starting in Junos OS Release 16.1, the show rsvp version command output displays the Route Session-Id count output field by default, irrespective of the presence of associated session IDs.</p> <p>When there are no session IDs associated with any RSVP ingress route, the <i>Route Session-Id count</i> value is zero (0).</p>
Graceful restart	Status of the graceful restart feature for RSVP on the restarting routing device: Enabled or Disabled .
Restart helper mode	Status of the helper mode feature: Enabled or Disabled . When this feature is enabled, the restarting routing device can help the neighbor with its RSVP restart procedures.
Maximum helper restart time	Number of milliseconds (ms) configured for the maximum helper restart time. The maximum helper restart time is the length of time the routing device waits before declaring that an RSVP neighbor attempting to restart gracefully is down.
Maximum helper recovery time	Number of milliseconds configured for the maximum helper recovery time. The maximum helper recovery time is the amount of time the routing device maintains the state of an RSVP neighbor attempting to restart gracefully.
Restart time	Number of milliseconds that a neighbor waits to receive a Hello message from the restarting node before declaring the node dead and deleting the states.
Recovery time	Number of milliseconds during which the restarting node attempts to recover its lost states with help from its neighbors. Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.
P2p transit LSP nexthop mode	Point-to-point transit LSP next-hop mode on PTX Series devices. The possible values are Chained or Unchained .
P2mp transit LSP nexthop mode	Point-to-multipoint transit LSP next-hop mode on PTX Series devices. The possible values are Chained or Unchained .

Sample Output

show rsvp version

Starting with Junos OS Release 16.1, this command also shows whether enhanced FRR procurers are enabled on the router.

```
user@host> show rsvp version
```

```

```

traceroute mpls rsvp

Syntax

```
traceroute mpls <rsvp> lsp-name  
<detail>  
<egress>  
<exp>  
<logical-system>  
<multipoint>  
<no-resolve>  
<retries>  
<source source-address>  
<ttl>
```

Release Information

Command introduced in Junos OS Release 9.2.

egress, **multipoint**, and **ttl** options added in Junos OS Release 11.2.

Description

Trace route to a remote host for an MPLS LSP signaled by RSVP. Use **traceroute mpls rsvp** as a debugging tool to locate MPLS label-switched path (LSP) forwarding issues in a network. (Currently supported for IPv4 packets only.)

Options

lsp-name—Specify the name of the LSP to be traced.

detail—(Optional) Display detailed output.

egress—(Optional) Request that a specific point-to-multipoint egress node reply to the trace route. The trace route would follow the associated sub-LSP to the egress node.

exp—(Optional) Specify the class of service to use when sending probes. The range of values is 0 through 7. The default value is 7.

logical-system—(Optional) Specify the name of the logical system for the traceroute attempt.

multipoint—(Optional) Perform a trace route on a point-to-multipoint LSP.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

retries—(Optional) Specify the number of times to resend probe. The range of values is 1 through 9. The default value is 3.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl—(Optional) Specify the number of hops to follow before forcing the trace route to quit.

Required Privilege Level

network

List of Sample Output[traceroute mpls rsvp on page 2543](#)[traceroute mpls rsvp detail on page 2543](#)[traceroute mpls rsvp multipoint \(branch node for sub-LSPs\) on page 2544](#)[traceroute mpls rsvp multipoint \(single-hop sub-LSPs\) on page 2545](#)**Output Fields**

[Table 85 on page 2542](#) describes the output fields for the **traceroute mpls rsvp *lsp-name*** and **traceroute mpls rsvp *lsp-name* detail** commands. Output fields are listed in the approximate order in which they appear.

Table 85: traceroute mpls rsvp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the traceroute mpls rsvp <i>lsp-name</i> command.	all levels
ttl	Time-to-live value of the labeled packet.	none specified
Label	MPLS label used to forward the packets along the LSP.	none specified
Protocol	Signaling protocol used. For this command, it is RSVP-TE.	none specified
Address	Address of the next hop.	none specified
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null.	none specified
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths). Displays Success if the trace to a hop is successful or Egress if the trace has reached the last router on the path.	none specified
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	detail
Parent	Address of the previous hop. Parent value for the first hop is null.	detail
Return Code	Return code for reporting the result of processing the echo request by the receiver.	detail

Table 85: traceroute mpls rsvp Output Fields (*continued*)

Field Name	Field Description	Level of Output
Sender timestamp	Displays the timestamp when the MPLS echo request is sent to the next hop.	detail
Receiver timestamp	Timestamp when the echo request from the previous hop is received and acknowledged with an echo response by the next hop.	detail
Response time	Time for the echo request to reach the receiver.	detail
MTU	Size of the largest packet that includes the label stack forwarded to the next hop.	detail
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none.	detail
Label stack	Label stack used to forward the packet.	detail
Path	Displays the sub-lsp path number for this traceroute, the interface used, and the destination address.	all levels

- `traceroute mpls segment-routing isis` | 2628

clear ldp neighbor

Syntax

```
clear ldp neighbor  
<instance instance-name>  
<logical-system (all | logical-system-name)>  
<neighbor>
```

Description

Tear down Label Distribution Protocol (LDP) neighbor connections.

Options

none—Tear down connections with all LDP neighbors for all routing instances.

instance *instance name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

neighbor—(Optional) Clear an LDP session for the specified neighbor (IP address) only.

Required Privilege Level

clear

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

clear ldp neighbor

user@host> clear ldp neighbor

clear ldp session

Syntax

```
clear ldp session  
<all>  
<destination>  
<instance instance-name>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Clear Label Distribution Protocol (LDP) sessions.

Options

all—Clear LDP sessions for all destinations for all routing instances.

destination—(Optional) Clear an LDP session for the specified destination (IP address).

instance *instance-name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

clear ldap session

```
user@host> clear ldap session all
```

clear ldp statistics

Syntax

```
clear ldp statistics  
<instance instance-name>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Set all Label Distribution Protocol (LDP) statistics to zero.

Options

none—Set all LDP statistics to zero for all routing instances.

instance *instance-name*—(Optional) Clear the LDP session for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

clear

Sample Output

clear ldp statistics

```
user@host> clear ldp statistics
```

ping mpls ldp

Syntax

```
ping mpls ldp fec
<count count>
<destination address>
<detail>
<exp forwarding-class>
<instance routing-instance-name>
<logical-system (all | logical-system-name)>
<p2mp root-addr ip-address lsp-id identifier>
<size bytes>
<source source-address>
<stitched-protocol>
<sweep>
```

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.0 for EX Series switches.

size and **sweep** options introduced in Junos OS Release 9.6.

instance option introduced in Junos OS Release 10.0.

p2mp, **root-address**, and **lsp-id** options introduced in Junos OS Release 11.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Check the operability of MPLS LDP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (**all** | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr ip-address lsp-id identifier—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (**88** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

stitched-protocol—(Optional) Protocol stitched on intermediate node.

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Additional Information

If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

You can configure the ping interval for the **ping mpls ldp** command by specifying a new time in seconds using the **lsp-ping-interval** statement at the **[edit protocols ldp oam]** hierarchy level. For more information, see the *MPLS Applications User Guide*.

In asymmetric MTU scenarios, the echo response may be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

NOTE: In a Juniper-Cisco interoperation network scenario, a point-to-multipoint LSP ping echo reply message from a Cisco device in a different IGP area is dropped on the Juniper device when the source address of the reply message is an interface address other than the loopback address or router ID. Starting in Junos OS Release 13.3X8, 14.2R6, 15.1R4, 15.1F6, 15.1F5-S8, 16.1R1, and later releases, such point-to-multipoint LSP ping echo reply messages are accepted by the Juniper device and the messages get logged as uncorrelated responses.

Required Privilege Level

network

List of Sample Output

[ping mpls ldp fec count on page 2553](#)

[ping mpls ldp p2mp root-addr lsp-id on page 2553](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls ldp fec count

```
user@host> ping mpls ldp 10.255.245.222 count 10
```

```
!!!xxx...x--- lsping statistics ---10 packets transmitted, 3 packets received, 70%
packet loss 4 packets received with error status, not counted as received.
```

<stitched-protocol>
<sweep>
```

Release Information

Command introduced in Junos OS Release 19.1R1

Description

Check the operability of MPLS segment routing label-switched path (LSP) connections added by ospf protocol. Type Ctrl+c to interrupt a **ping mpls segment routing ospf** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr *ip-address* *lsp-id identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

stitched-protocol—(Optional) Protocol stitched on intermediate node.

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Release Information

Command introduced in Junos OS Release 19.1R1

Description

Check the operability of MPLS segment routing label-switched path (LSP) connections added by ISIS protocol. Type Ctrl+c to interrupt a **ping mpls segment routing isis** command.

Options

count *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is **1** through **1,000,000**. The default value is **5**.

destination *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

detail—(Optional) Display detailed information about the echo requests sent and received.

exp *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

fec—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

instance *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

logical-system (*all* | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

p2mp root-addr *ip-address* *lsp-id identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

size bytes—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

source source-address—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

stitched-protocol—(Optional) Protocol stitched on intermediate node.

sweep—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

Required Privilege Level

network

List of Sample Output

[ping mpls segment-routing isis on page 2558](#)

[ping mpls segment-routing isis on page 2558](#)

Output Fields

When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

Sample Output

ping mpls segment-routing isis

```
user@host>ping mpls segment-routing isis 6.6.6.6
```

```
!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

ping mpls segment-routing isis

show ldp database

Syntax

```
show ldp database
<brief | detail | extensive>
<inet | l2circuit>
<instance instance-name>
<logical-system (all | logical-system-name)>
<p2mp>
<session session>
<summary>
```

Release Information

Command introduced before Junos OS Release 7.4.

summary option introduced in Junos OS Release 14.2.

Description

Display entries in the LDP database.

Options

none—Display standard information about all entries in the LDP database for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

inet | l2circuit—(Optional) Display only IPv4 or Layer 2 circuit bindings.

instance *instance-name*—(Optional) Display routing instance information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

p2mp—(Optional) Display point-to-multipoint binding information.

session *session*—(Optional) Display database for the specified session only. ***session*** is the destination address of the LDP session.

summary—(Optional)—Display summary output. This option displays the number of labels received and advertised for each LDP session.

Output Fields

Table 86 on page 2561 describes the output fields for the **show ldp database** command. Output fields are listed in the approximate order in which they appear.

Table 86: show ldp database Output Fields

Field Name	Field Description	Level of Output
Input label database	Label received from the other router.	All levels
Output label database	Label advertised to the other router.	All levels
<i>session-identifier</i>	Session identifier, which includes the local and remote label space identifiers.	All levels
Labels received	Number of labels received from the other router.	All levels
Labels advertised	Number of labels advertised to the other router.	All levels.
Label	Label binding to a route prefix.	All levels

Table 86: show ldp database Output Fields (*continued*)

Field Name	Field Description	Level of Output
Prefix	<p>Route prefix.</p> <p>It can be one of the following values:</p> <ul style="list-style-type: none"> • IP prefix. • Point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured. • Layer 2 encapsulation type. <p>Layer 2 encapsulation types are displayed in the format L2CKT control word status encapsulation-type vc-number, for example, L2CKT CtlfWord FRAME RELAY VC 2</p> <ul style="list-style-type: none"> • control-word-status—Displays whether the use of the control word has been negotiated for this virtual circuit: <ul style="list-style-type: none"> • NoCtrlWord • CtrlWord • encapsulation-type—Encapsulation type: <ul style="list-style-type: none"> • FRAME RELAY • ATM AAL5 • ATM CELL • VLAN • ETHERNET • CISCO_HDLC • PPP • VC number—Virtual circuit number. It can have any numeric value. • (Stale)—When you display the LDP database for the neighbor of a restarting router, the bindings learned from the restarting neighbor are displayed as (Stale). Stale bindings are deleted if they are not refreshed within the recovery time. 	All levels
MTU	MTU of the Layer 2 circuit. MTU is displayed for all encapsulation types except ATM cell encapsulations.	detail
VCCV Control Channel types	<p>Virtual Circuit Connection Verification (VCCV) control channel types.</p> <ul style="list-style-type: none"> • MPLS router alert label • MPLS PW label with TTL=1 	extensive

Table 86: show ldp database Output Fields (*continued*)

Field Name	Field Description	Level of Output
VCCV Control Verification types	The only valid VCCV control verification type is LSP ping .	extensive
TDM payload size	Size of the Time Division Multiplex (TDM) payload.	All levels
TDM bitrate	Bit rate for the TDM traffic.	All levels
Requested VLAN ID	(VLANs) VLAN identifier of the Layer 2 circuit.	detail
Cell bundle size	(ATM cell encapsulations) Maximum number of cells that the Layer 2 circuit can receive in a packet.	detail
State	State of the label binding: <ul style="list-style-type: none"> • Active—Label binding has been installed and distributed appropriately. A label binding is almost always in this state. • New—New label that has not yet been distributed. <ul style="list-style-type: none"> • MapRcv—Waiting to receive a label mapping message. • MapSend—Waiting to send a label mapping message. • RelRcv—Waiting to receive a label release message. • RelRsnd—Waiting to receive a label release message before resending label mapping message. • RelSend—Waiting to send a label release message. • ReqSend—Waiting to send a label request message. • W/dSend—Waiting to send a label withdrawal message. 	detail
Age	Time elapsed since the binding was created.	detail

show ldp fec-filters

Syntax

```
show ldp fec-filters
<fec>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display information about configured Label Distribution Protocol (LDP) forwarding equivalence class (FEC) filters.

Options

- fec**—(Optional) Display FEC filter information for the specified FEC.
- instance *instance-name***—(Optional) Display FEC filter information for the specified instance.
- logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 87 on page 2571](#) lists the output fields for the **show ldp fec-filters** command. Output fields are listed in the approximate order in which they appear.

Table 87: show ldp fec-filters Output Fields

Field Name	Field Description
Ingress	Names of the FEC filters on the ingress routers.
Transit	Names of the FEC filters on the transit routers.

Sample Output

show ldp fec-filters

user@host> **show ldp fec-filters 10/8**

```
10.22.1.2/32
  Ingress: f1-10.22.1.2/32 (index: 3)
  Transit: (null) (index: 0)
```

show ldp interface

Syntax

```
show ldp interface
<brief | detail | extensive>
<interface-name>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display the status of Label Distribution Protocol (LDP)-enabled interfaces.

Options

- none**—Display standard status information about all LDP-enabled interface for all routing instances.
- interface-name**—(Optional) Display information for the specified interface.
- brief | detail | extensive**—(Optional) Display the specified level of output.
- instance instance-name**—(Optional) Display information for the specified routing instance.
- logical-system (all | logical-system-name)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 88 on page 2573](#) describes the output fields for the **show ldp interface** command. Output fields are listed in the approximate order in which they appear.

Table 88: show ldp interface Output Fields

Field Name	Field Description	Level of Output
Interface	Interface name.	All levels

Table 88: show ldp interface Output Fields (*continued*)

Field Name	Field Description	Level of Output
Label space ID	Label space identifier that the router is advertising on the interface.	All levels
Nbr count	Number of neighbors on the interface.	All levels
Next hello	How long until the next hello packet is sent on this interface, in seconds.	All levels
Hello interval	One-third of the negotiated hold time (in seconds). If the user-configured value for the hello interval is smaller than the computed value, the user-configured value is used.	detail extensive
Hold time	Configured hold time, in seconds.	detail extensive
Transport address	Address to which the neighbor wants the local route to establish the LDP session.	extensive
Local hello interval	Locally configured hello interval.	extensive

Sample Output

show ldp interface extensive

user@host> **show ldp interface extensive**

```

Interface          Label space ID      Nbr count  Next hello
fe-0/0/3.0         10.255.245.6:0      2           0
  Hello interval: 1, Hold time: 15, Transport address: 10.255.245.6
  Local hello interval: 2, Index: 69

```

show ldp neighbor

Syntax

```
show ldp neighbor
<brief | detail | extensive>
<auto-targeted>
<instance instance-name>
<logical-system (all | logical-system-name)>
<neighbor-address>
```

Release Information

Command introduced before Junos OS Release 7.4.

neighbor-address option added in Junos OS Release 8.5.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

auto-targeted option added in Junos OS Release 14.2.

Description

Display Label Distribution Protocol (LDP) neighbor information.

Options

none—Display standard information about LDP neighbors for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

auto-targeted—(Optional) Display information about LDP neighbors that are automatically targeted using the loopback addresses.

instance *instance-name*—(Optional) Display information for the specified routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

neighbor-address—(Optional) Display information about the specified LDP neighbor.

Output Fields

[Table 89 on page 2576](#) describes the output fields for the **show ldp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 89: show ldp neighbor Output Fields

Field Name	Field Description	Level of Output
Address	IP address of the neighbor.	All levels
Interface	Interface over which the neighbor was discovered.	All levels
Label space ID	Label space identifier advertised by the neighbor.	All levels
Hold time	Remaining hold time before the neighbor expires, in seconds.	All levels
Transport address	Address to which the neighbor wants the local route to establish the LDP session.	detail
Configuration sequence	Counter that increments whenever the neighbor changes its configuration.	detail
Up for	Length of time the LDP neighbor has been in operation.	detail extensive
Reference count	Reference count for the LDP neighbor.	extensive
Hold time	Displays the neighbor's hold time. The hold time is the proposed hold times for the local and peer routers.	extensive
Proposed local/peer	Hold time value proposed by the local router and the peer router.	extensive

Sample Output

show ldp neighbor extensive

```
user@host> show ldp neighbor extensive
```

```

```

Syntax (EX Series Switch and QFX Series)

```
show ldp overview
<instance instance-name>
```

Release Information

Command introduced in Junos OS Release 11.2.

Description

Display LDP overview information.

Options

none— Display standard overview information about LDP for all routing instances.

instance *instance-name*— (Optional) Display LDP overview information for the specified routing instance.

logical-system (all | *logical-system-name*)— (Optional) Display LDP information from systems or a particular logical system on the devices.

Output Fields

[Table 90 on page 2578](#) lists the output fields for the **show ldp overview** command. Output fields are listed in the approximate order in which they appear.

Table 90: show ldp overview Output Fields

Field Name	Field description	Level of Output
Instance	LDP routing instance.	All Levels
Router ID	Router ID of the routing device.	All Levels

Table 90: show ldp overview Output Fields (*continued*)

Field Name	Field description	Level of Output
Message ID	Unique identifier of message.	All Levels
Configuration sequence	Value of configuration sequence.	All Levels
Deaggregate	Status of control forwarding equivalence class (FEC) deaggregation on the router. By default it is disabled on the router.	All Levels
Explicit null	Advertise label 0 to the egress routing device of an LSP. Explicit null: enabled or disabled . NOTE: If you do not include the explicit-null statement in the configuration, label 3 (implicit null) is advertised.	All Levels
IPv6 tunneling	Internet Protocol version 6 tunneling: enabled or disabled .	All Levels
Strict targeted hellos	Prevent LDP sessions from being established with remote neighbors that have not been specifically configured. Strict targeted hellos: enabled or disabled . NOTE: LDP peers will not respond to targeted hellos coming from a source that is not one of the configured remote neighbors.	All Levels
Loopback if added	Loopback interface is added: yes or no .	All Levels
Route preference	Default preference value (also known as an administrative distance) assigned to each route that the routing table receives. LDP preference is: 9	All Levels
Unicast transit LSP chaining	Unicast transit LSP chaining: enabled or disabled .	All Levels
P2MP transit LSP chaining	P2MP transit LSP chaining: enabled or disabled .	All Levels
Transit LSP statistics based on route statistics	Transit LSP statistics based on route statistics: enabled or disabled .	All Levels
Longest match	Longest match for label mapping: enabled or disabled .	All Levels
Capabilities enabled	Enabled capabilities: none	All Levels

Table 90: show ldp overview Output Fields (*continued*)

Field Name	Field description	Level of Output
Timers	<ul style="list-style-type: none"> • Keepalive interval: Keepalive interval value. • Keepalive timeout: Time interval for which the neighbor LDP node waits before determining session failure. • Link hello interval: Specify how often the router sends Link Management Protocol (LMP) hello packets. • Link hello hold time: Time interval for which an LDP node waits for a hello message before declaring a neighbor is down. • Targeted hello interval: Specify how often LDP sends targeted hello messages. • Targeted hello hold time: Time interval for which a sending LSR maintains a record of targeted hello messages from the receiving LSR without receipt of another targeted hello message from that LSR. • Label withdraw delay: Time interval for withdrawing labels to reduce router workload during IGP convergence. 	All Levels
Graceful restart	<p>Graceful restart attributes.</p> <ul style="list-style-type: none"> • Restart– Graceful restart capability: enabled or disabled. • Helper– Standard graceful restart helper capability: enabled or disabled. • Restart in process– Graceful restart in process. • Reconnect time– Period of time that a restarting LSR (label switched router) designates to LDP neighbors to wait until the former reestablishes the session after restarting. • Max neighbor reconnect time– Maximum reconnect time. • Recovery time– Period of time that an LSR preserves its state across the restart. • Max neighbor recovery time– Maximum recovery time designated to LDP neighbors by a restarting LSR. 	All Levels
Traffic Engineering	<ul style="list-style-type: none"> • Bgp igp– BGP and IGP destinations: enabled or disabled. When enabled, IGP's use MPLS paths for forwarding traffic. • Both ribs– BGP and IGP destinations with routes in both RIBs: enabled or disabled. • Mpls forwarding– MPLS routes used for forwarding: enabled or disabled. 	All Levels

Table 90: show ldp overview Output Fields (*continued*)

Field Name	Field description	Level of Output
IGP	<ul style="list-style-type: none"> ● Tracking igp metric—Cause the IGP route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1). ● Sync session up delay— Time interval to synchronize LDP session. 	All Levels
Session protection	<ul style="list-style-type: none"> ● Session protection— Remote neighbor added to LDP configuration which enables protection for all sessions in the corresponding LDP instance: enabled or disabled. ● Session protection timeout— Period of time until which the remote neighbor is connected to LSR in the absence of link neighbors. 	All Levels
Interface addresses advertising	Advertises interface address.	All Levels
Label allocation	<p>Label accounting information.</p> <ul style="list-style-type: none"> ● Current number of LDP labels allocated—Number of labels currently in use. ● Total number of LDP labels allocated—Cumulative number of labels being allocated. ● Total number of LDP labels freed—Cumulative number of labels being freed. ● Total number of LDP label allocation failures—Cumulative number of failures for allocating a label. ● Current number of labels allocated by all protocols—Number of labels currently being used by routing protocols. 	All Levels

<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) label-switched paths (LSPs).

Options

- none**—Display standard information about all LDP LSPs for all routing instances.
- brief | detail | extensive**—(Optional) Display the specified level of output.
- destination**—(Optional) Restrict the output to entries that match the specified destination prefix.
- instance instance-name**—(Optional) Display information for the specified routing instance only.
- logical-system (all | logical-system-name)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

[Table 91 on page 2584](#) describes the output fields for the **show ldp path** command. Output fields are listed in the approximate order in which they appear.

Table 91: show ldp path Output Fields

Field Name	Field Description
Output Session (label)	Session ID and labels that this system has sent using LDP. These correspond to MPLS packets received.

Table 91: show ldp path Output Fields (*continued*)

Field Name	Field Description
Input Session (label)	Session ID and labels that this system has received using LDP. These correspond to MPLS packets transmitted.
route	MPLS route.
Attached route	Route corresponding to the LSP.
Ingress route	The router acts as the ingress for the LSP.
Reference count	Reference count for the LDP neighbor.
Transit route	Names of the forwarding equivalence class (FEC) filters on the transit routers.
Global label	MPLS label that is used globally.

Sample Output

show ldp path extensive

user@host> **show ldp path extensive**

```

Output Session (label)      Input Session (label)
10.255.14.220:0(3)          ( )
    Attached route: 10.255.14.221/32
    Reference count: 3, Global label: 3
10.255.14.220:0(100000)      10.255.14.220:0(3)
    Attached route: 10.255.14.220/32, Ingress route
    Reference count: 2, Transit route, Global label: 100000
10.255.14.220:0(100001)      10.255.14.220:0(100001)
    Attached route: 10.255.14.214/32, Ingress route
    Reference count: 2, Transit route, Global label: 100001

```

show ldp route

Syntax

```
show ldp route
<brief | detail | extensive>
<destination>
<fec-and-route>
<fec-only>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display the entries in the Label Distribution Protocol (LDP) internal topology table. The internal topology table contains routes from inet.0 and inet.3 and is used when binding a label to a forwarding equivalence class (FEC).

Options

none—Display standard information about all entries in the LDP internal topology table for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

destination—(Optional) Restrict the output to entries that are longer than the specified destination prefix and prefix length.

fec-and-route—Display the show routes and the FECs.

fec-only—Display only LDP FECs.

instance *instance-name*—(Optional) Display entries for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 92 on page 2587 describes the output fields for the **show ldp route** command. Output fields are listed in the approximate order in which they appear.

Table 92: show ldp route Output Fields

Field Name	Field Description
Destination	Destination prefix.
Next-hop intf/lsp/table	Interface that is the next hop to the destination prefix.
Next-hop address	IP address of the next hop.
Session ID	LDP session ID.
Route flags	Information about the route. For example, the Ingress TTL propagate flag indicates that the time-to-live (TTL) value is being propagated with the route.
Bound to outgoing label	The route has been bound to LSPs with the label being distributed for that LSP.
Topology entry	The topology that the route is bound to.
Ingress route status	Status of the ingress route. For example, it could be Active or Inactive .
Last modified	The length of time since the ingress route status last changed.
Last event(s)	The last event that occurred.

show ldp session

Syntax

```
show ldp session
<brief | detail | extensive>
<auto-targeted>
<destination>
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

auto-targeted option added in Junos OS Release 14.2.

Description

Display information about Label Distribution Protocol (LDP) sessions.

Options

none—Display standard information about all LDP sessions for all routing instances.

brief | detail | extensive—(Optional) Display the specified level of output.

auto-targeted—(Optional) Display information about LDP sessions that are automatically targeted using loopback addresses.

destination—(Optional) Restrict LDP session display to the specified address.

instance *instance-name*—(Optional) Display routing instance information for the specified instance. If *instance-name* is omitted, information is displayed for the master instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 93 on page 2598 describes the output fields for the **show ldp session** command. Output fields are listed in the approximate order in which they appear.

Table 93: show ldp session Output Fields

Field Name	Field Description	Level of Output
Address	Transport address of the session.	any
State	State of the session: Nonexistent , Connecting , Initialized , OpenRec , OpenSent , Operational , or Closing . The states correspond to the state diagram specified in Internet Draft LDP Specification draft-ietf-mpls-rfc3036bis-01.txt.	any
Connection	TCP connection state: Closed , Opening , or Open .	any
Hold time	Time remaining until the session will be closed, in seconds.	any
Session ID	LDP identifiers of the peers of this session.	detail extensive
Next keepalive	Time until next keepalive is sent, in seconds.	detail extensive
Active	Whether the local router is playing the active role in the session and during session establishment.	detail extensive
Passive	Whether the local router is playing the passive role in the session and during session establishment.	detail extensive
Maximum PDU	Maximum protocol data unit (PDU) size (packet size) for the session.	detail extensive
Hold time	Time remaining until the session will be closed, in seconds. This value corresponds to the one configured using the keepalive-timeout statement configured at the [edit protocols ldp] hierarchy level.	detail extensive
Neighbor count	Number of neighbors that are contributing to the session.	detail extensive
Neighbor types	Category of LDP session: discovered or auto-targeted .	any
Keepalive interval	Keepalive interval, in seconds.	detail extensive

Table 93: show ldp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Connect retry interval	TCP connection retry interval, in seconds.	detail extensive
Local address	Local transport address.	detail extensive
Remote address	Remote transport address.	detail extensive
Up for	Time that this session has been up.	detail extensive
Last down	Time since the session last went down.	detail extensive
Reason	Reason the session went down: <ul style="list-style-type: none"> • Aborted graceful restart • Authentication key was changed • Bad type length value (TLV) • Bad protocol data unit (PDU) packets • Command-line interface (CLI) command • Connect time expired • Connection error • Connection reset • Error during initialization • Hold time expired • No adjacency or all adjacencies down • Notification received • Received notification from peer • Unexpected End of File (EOF) • Unknown reason 	detail extensive
Number of session flaps	Number of times the session changes from up to down.	detail extensive
Restarting	LDP is in the process of gracefully restarting.	detail extensive
Capabilities advertised	LDP capabilities advertised to a peer.	detail extensive
Capabilities received	LDP capabilities received from a peer.	detail extensive

Table 93: show ldp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Protection	Information about the status of MPLS LDP session protection.	detail extensive
restart complete in <i>nnn</i> msec	Amount of time (in milliseconds) remaining until graceful restart is declared complete.	detail extensive
Authentication type	Shows the longest match MD5 authentication	detail extensive
Local	<p>Information about graceful restart for the local end of an LDP session. Graceful restart and helper mode are independent.</p> <ul style="list-style-type: none"> • Restart—Status of the graceful restart feature at the local end of the LDP session: enabled or disabled. • Helper mode—Status of the helper mode feature at the local end of the LDP session: enabled or disabled. When this feature is enabled, the local end of the LDP session can help the restarting router with its LDP restart procedures. • Reconnect time—Amount of time to wait from when a restart is initiated until the router can exchange LDP messages with its neighbors. The default is 60000 msec and is not configurable. (Reconnect timeout refers to "FT Reconnect timeout" in draft-ietf-mpls-ldp-restart-06, <i>Internet Draft Graceful Restart Mechanism for LDP</i>.) 	detail extensive
Remote	<p>Information about graceful restart at the remote end of an LDP session. Graceful restart and helper mode are independent.</p> <ul style="list-style-type: none"> • Restart—Status of the graceful restart feature at the remote end of the LDP session: enabled or disabled. • Helper mode—Status of the helper mode feature at the remote end of the LDP session: enabled or disabled. When this feature is enabled, the remote end of the LDP session can help the restarting router with its LDP restart procedures. • Reconnect time—Amount of time in milliseconds from when a restart is initiated until the remote router can exchange LDP messages with its neighbors. 	detail extensive
Local maximum recovery time	Amount of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds).	detail extensive
Next-hop addresses received	Next-hop addresses received on the session.	detail extensive

Table 93: show ldp session Output Fields (*continued*)

Field Name	Field Description	Level of Output
Queue depth	Number of messages that are queued for sending to the peers in the group.	extensive
Message type	<p>Type of message being sent:</p> <ul style="list-style-type: none"> • Initialization—Session initialization negotiation messages sent by an LSR to an LDP peer when the transport connection is established. • Keepalive—Keepalive timer messages sent by an LSR to an LDP peer to keep the session active when there is no information or PDU exchanged between them. • Notification—Notification messages (such as state of the LDP session) or error information (such as bad PDU length) sent by an LSR to an LDP peer. • Address—Message sent by an LSR to an LDP peer to advertise interface addresses. • Address withdraw—Message sent by an LSR to an LDP peer to withdraw a previously advertised interface address. • Label mapping—Message sent by an LSR to an LDP peer to advertise label mapping for a forwarding equivalence class (FEC). • Label request—Message sent by an LSR to an LDP peer to request a label mapping for an FEC. • Label withdraw—Message sent by an LSR to an LDP peer to withdraw a previously advertised FEC-label mapping. • Label release—Message sent by an LSR to an LDP peer to notify the peer that a specific FEC-label mapping has been released. • Label abort—Message sent by an LSR to an LDP peer to abort a label request message. • Total—Messages sent and received during the lifetime of the session. • Last 5 seconds—Messages sent and received during the current session. 	extensive

List of Sample Output

[show ldp statistics on page 2609](#)

Output Fields

[Table 94 on page 2605](#) lists the output fields for the **show ldp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 94: show ldp statistics Output Fields

Field Name	Field Description
Total Sent, Received	Total number of each message type sent and received.

Table 94: show ldp statistics Output Fields (*continued*)

Field Name	Field Description
Last 5 seconds Sent, Received	Number of each message type sent and received in the last 5 seconds.
Message type	<p>LDP message types:</p> <ul style="list-style-type: none"> • Hello—Messages that enable LDP nodes to discover one another and to detect the failure of a neighbor or of the link to the neighbor. • Initialization—Messages that indicate an LDP session has started. • Keepalive—Messages that ensure that the keepalive timeout is not exceeded. • Notification—Advisory information and signal error information. • Address—Messages with address information. • Address withdrawal—Messages regarding address withdrawal. • Label mapping—Messages with label mapping information. • Label request—Request for a label mapping from a neighboring router. • Label withdrawal—Withdrawal message sent by the downstream LSR to recall a label that it previously mapped. If an LSR that has received a label mapping subsequently determines that it no longer needs that label, it can send a label release message that frees the label for use. • Label release—Message sent by the downstream LSR to recall a label that it previously mapped. If an LSR that has received a label mapping subsequently determines that it no longer needs that label, it can send a label release message that frees the label for use. • Label abort—Messages about label interruptions. • All UDP—All hello messages sent by LSRs to the well-known UDP port, 646. • All TCP—All LDP session messages.

Table 94: show ldp statistics Output Fields *(continued)*

Field Name	Field Description
Event type	

Table 94: show ldp statistics Output Fields (*continued*)

Field Name	Field Description
	<p>LDP events and errors:</p> <ul style="list-style-type: none"> • Sessions opened—Number of LDP sessions that have been opened. • Sessions closed—Number of LDP sessions that have been closed. • Topology changes—Number of changes to the known LDP topology. • No interface—Number of missing interface address messages. When a new LDP session is initialized and before sending label lapping or label request messages, the LSR advertises its interface addresses with one or more address messages. • No session—Number of missing session messages. Session messages are used to establish, maintain, and terminate sessions between LDP peers. • No adjacency—The exchange of hello adjacency messages results in the creation of an adjacency. The LDP identifier, together with the sender's LDP identifier in the PDU header, enables the receiver to match the initialization message with one of its hello adjacencies. If there is no matching hello adjacency, the LSR sends a session the initialization message is rejected. • Unknown version—The LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment. • Malformed PDU—An LDP PDU received on a TCP connection for an LDP session is malformed if the LDP identifier in the PDU header is unknown to the receiver, or if it is known but is not the LDP identifier associated by the receiver with the LDP peer for this LDP session. <p>An LDP PDU is considered to be malformed if the LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment.</p> <p>An LDP PDU is considered malformed if the PDU length field is too small (less than 14) or too large (greater than maximum PDU length).</p> • Malformed message—Malformed LDP messages that are part of the LDP discovery mechanism are handled by silently discarding them. <p>An LDP message is malformed if the message type is unknown. If the message type is less than 0x8000 (high order bit = 0), it is an error signaled by the unknown message type status code.</p> <p>An LDP message is considered to be malformed If the message length is too large, meaning that the message extends beyond the end of the containing LDP PDU.</p> <p>The LDP message is considered to be malformed if the message length is too small, meaning that it is smaller than the smallest possible value component.</p> <p>The LDP message is considered to be malformed if the message is missing one or more mandatory parameters.</p> • Unknown message type—If the message type is less than 0x8000 (high order bit = 0) or greater than or equal to 0x8000 (high order bit = 1) it is considered to be an unknown message. • Inappropriate message—The message is not of the type that the receiver expects to receive. • Malformed TLV—The TLV ILength is too large or the receiver cannot decode the TLV value. This can indicate an issue in either the sending or receiving LSR.

Table 94: show ldp statistics Output Fields (*continued*)

Field Name	Field Description
	<ul style="list-style-type: none"> • Bad TLV value—The TLV Length is too large. • Missing TLV—The TLV is missing one or more mandatory parameters. • PDU too large—The PDF is greater than the maximum PDU length. Section "Initialization Message" in RFC 5036 describes how the maximum PDU length for a session is determined.
Total	Total number of each event or error.
Last 5 seconds	Number of each event or error in the last 5 seconds.

show ldp traffic-statistics

Syntax

```
show ldp traffic-statistics  
<instance instance-name>  
<logical-system (all | logical-system-name)>  
<p2mp>
```

Release Information

Command introduced before Junos OS Release 7.4.

p2mp option added in Junos OS Release 11.2.

Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

Description

Display Label Distribution Protocol (LDP) traffic statistics.

NOTE: If nonstop active routing features is configured, **show ldp traffic-statistics** command is not supported on backup Routing Engines.

Options

none—Display LDP traffic statistics for all routing instances.

instance *instance-name*—(Optional) Display LDP traffic statistics for the specified routing instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

p2mp—(Optional) Display only the data traffic statistics for a point-to-multipoint LSP.

Additional Information

To collect output from this command on a periodic basis, configure the [traffic-statistics](#) statement for the LDP protocol. For more information, see the *Junos MPLS Applications Configuration Guide*.

Output Fields

Table 95 on page 2612 lists the output fields for the **show ldp traffic-statistics** command. Output fields are listed in the approximate order in which they appear.

Table 95: show ldp traffic-statistics Output Fields

Field Name	Field Description
Message type	LDP message types.
FEC	Forwarding equivalence class (FEC) for which LDP traffic statistics are collected. For P2MP LSPs, FEC appears as a combination of root address and the LSP ID (root_addr:lsp_id). For M-LDP P2MP LSPs, FEC appears as a combination of root address multicast source address, and multicast group address (root_addr:lsp_id/grp,src).
Type	Type of traffic originating from a router, either Ingress (originating from this router) or Transit (forwarded through this router).
Packets	Number of packets passed by the FEC since its LSP came up.
Bytes	Number of bytes of data passed by the FEC since its LSP came up.
Shared	Whether a label is shared by prefixes: Yes or No . A Yes value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
Nexthop	The next hop address for P2MP LSPs. (This is the downstream LDP Session ID.)

Table 95: show ldp traffic-statistics Output Fields (*continued*)

Field Name	Field Description
Label	<p>For multipoint LDP with multicast-only fast reroute (MoFRR), the multipoint LDP node selects two separate upstream peers and sends two separate labels, one to each upstream peer. The same algorithm described in RFC 6388 is used to select the primary upstream path. The backup upstream path selection again uses the same algorithm but excludes the primary upstream LSR as a candidate. Two streams of MPLS traffic are sent to the egress node from the two different upstream peers. The MPLS traffic from only one of the upstream neighbors is selected as the primary path to accept the traffic, and the other becomes the backup path. The traffic on the backup path is dropped. When the primary upstream path fails, the traffic from the backup path is then accepted. The multipoint LDP node selects the two upstream paths based on the interior gateway protocol (IGP) root node next hop.</p> <p>Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.</p>
Backup route	For multipoint LDP with MoFRR, the route that is used if the primary route becomes unavailable.

show security keychain

Syntax

```
show security keychain  
<brief | detail>
```

Release Information

Command introduced in Junos OS Release 11.2.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Display information about authentication keychains configured for the Border Gateway Protocol (BGP), the Label Distribution Protocol (LDP) routing protocols, the Bidirectional Forwarding Detection (BFD) protocol, and the Intermediate System-to-Intermediate System (IS-IS) protocol.

Options

none—Display information about authentication keychains.

brief | detail—(Optional) Display the specified level of output.

Required Privilege Level

[show security keychain detail on page 2618](#)

Output Fields

[Table 96 on page 2616](#) describes the output fields for the **show security keychain** command. Output fields are listed in the approximate order in which they appear.

Table 96: show security keychain Output Fields

Field Name	Field Description	Level of Output
keychain	The name of the keychain in operation.	All levels
Active-ID Send	Number of routing protocols packets sent with the active key.	All levels
Active-ID Receive	Number of routing protocols packets received with the active key.	All levels
Next-ID Send	Number of routing protocols packets sent with the next key.	All levels

Table 96: show security keychain Output Fields (*continued*)

Field Name	Field Description	Level of Output
Next-ID Receive	Number of routing protocols packets received with the next key.	All levels
Transition	Amount of time until the current key will be replaced with the next key in the keychain.	All levels
Tolerance	Configured clock-skew tolerance, in seconds, for accepting keys for a key chain.	All levels
Id	Identification number configured for the current key.	detail
Algorithm	Authentication algorithm configured for the current key.	detail
State	<p>State of the current key.</p> <p>The value can be:</p> <ul style="list-style-type: none"> • receive • send • send-receive <p>For the active key, the State can be send-receive, send, or receive. For keys that have a future start time, the State is inactive. Compare the State field to the Mode field.</p>	detail
Option	<p>For IS-IS only, the option determines how Junos OS encodes the message authentication code in routing protocol packets.</p> <p>The values can be:</p> <ul style="list-style-type: none"> • basic—Based on RFC 5304. • isis-enhanced—Based on RFC 5310. <p>The default value is basic. When you configure the isis-enhanced option, Junos OS sends RFC 5310-encoded routing protocol packets and accepts both RFC 5304-encoded and RFC 5310-encoded routing protocol packets that are received from other devices.</p> <p>When you configure basic (or do not include the options statement in the key configuration) Junos OS sends and receives RFC 5304-encoded routing protocols packets, and drops 5310-encoded routing protocol packets that are received from other devices.</p> <p>Because this setting is for IS-IS only, the TCP and the BFD protocol ignore the encoding option configured in the key.</p>	detail

Table 96: show security keychain Output Fields (continued)

Field Name	Field Description	Level of Output
Start-time	Time that the current key became active.	detail
Mode	<p>Mode of each key (Informational only.)</p> <p>The value can be</p> <ul style="list-style-type: none"> ● receive ● send ● send-receive <p>The mode of the key is based on the configuration. Suppose you configure two keys, one with a start-time of today and the other with a start-time of next week. For both keys, the Mode can be send-receive, send, or receive, regardless of the configured start-time. Compare the Mode field to the State field.</p>	detail

traceroute mpls ldp

Syntax

```
traceroute mpls <ldp> fec
<destination ip-address>
<detail>
<exp exp>
<fanout fanout-number>
<logical-system logical-system-name>
<no-resolve>
<paths maximum-paths>
<pipe-mode>
<retries retries-number>
<routing-instance routing-instance-name>
<source ip-address>
<ttl value>
<update>
<wait seconds>
```

Release Information

Command introduced in Junos OS Release 8.4.

Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

Description

Trace route to a remote host for an MPLS label-switched path signaled by the LDP. Use **traceroute mpls ldp** as a debugging tool to locate MPLS label-switched path forwarding issues in a network. (Currently supported for IPv4 packets only.)

Options

fec—Specify the IP address and optional prefix of the forwarding equivalence class (FEC).

destination *ip-address*—(Optional) Specify the destination address to use when sending probes.

Values: The destination IP address must be within the 127.0.0.0/8 IP address space for Operation, Administration, and Maintenance (OAM) packets.

detail—(Optional) Display detailed output.

exp *exp*—(Optional) Specify the class-of-service to use when sending probes.

Range: 0 through 7

Default: 7

fanout *fanout-number*—(Optional) Specify the maximum number of nexthops to search per node.

Range: 1 through 16

Default: 16

logical-system—(Optional) Specify the name of the logical system for the traceroute attempt.

no-resolve—(Optional) Specify not to resolve the hostname that corresponds to the IP address.

paths *maximum-paths*—(Optional) Specify the maximum number of paths to search.

Range: 1 through 255

Default: 16

pipe-mode—(Optional) Specify to trace only nodes that understand LDP FEC.

In an interoperation with other vendor devices or devices running Junos OS Release that do not support tracing of hierarchical LSPs as described in RFC 6424, continuous non-complaint probe status is displayed in the **traceroute mpls ldp** command output. To avoid this LDP loop creation, use the **pipe-mode** option with the **traceroute mpls ldp fec** command.

NOTE: Even after using the **traceroute mpls ldp fec pipe-mode** command, one or more intermediate transit nodes that do not understand LDP FEC can return non-complaint probe status in the command output.

retries *retries-number*—(Optional) Specify the number of times to resend probe values.

Range: 1 through 9

Default: 3

routing-instance *routing-instance-name*—(Optional) Specify the name of the routing instance for the traceroute attempt.

source *source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

ttl *value*—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds.

Range: 1 through 125

Default: 64

update—(Optional) Update database contents with traceroute results.

wait *seconds*—(Optional) Specify the number of seconds to wait before resending a probe.

Range: 5 through 15

Default: 10

Required Privilege Level

[traceroute mpls ldp detail on page 2622](#)

Output Fields

[Table 75 on page 2468](#) describes the output fields for the **traceroute mpls ldp fec** command and the **traceroute mpls ldp fec detail** commands. Output fields are listed in the approximate order in which they appear.

Table 97: traceroute mpls ldp Output Fields

Field Name	Field Description	Level of Output
Probe options	Probe options specified in the traceroute mpls ldp fec command.	all levels
ttl	Time to live value of the labeled packet.	none specified
Label	Outgoing label used for forwarding the packet along the label-switched paths.	none specified
Protocol	Signaling protocol used. For this command, it is LDP.	none specified
Address	Address of the next hop.	none specified
Previous Hop	Address of the previous hop. Previous hop address of the first hop is null .	none specified
Probe status	Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).	none specified
Hop	Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.	detail
Parent	Address of the previous hop. Parent value for the first hop is null .	detail
Return Code	Return code for reporting the result of processing the echo request by the receiver.	detail
Response time	Time for the echo request to reach the receiver.	detail
Multipath type	Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none .	detail
Label Stack	Label stack used to forward the packet.	detail

Release Information

Command introduced before Junos OS Release 7.4.

Command introduced in Junos OS Release 9.5 for EX Series switches.

Description

Display information about the configured circuit cross-connect (CCC) connections.

Options

none—Display the standard level of output for all configured CCC connections.

all—(Optional) Display all connections.

brief | extensive—(Optional) Display the specified level of output. Use history to display information about connection history. Use labels to display labels used for transmit and receive LSPs. Use status to display information about the connection and interface status.

- interface-switch**—(Optional) Display interface switch connections only.
- lsp-switch**—(Optional) Display LSP switch connections only.
- p2mp-receive-switch**—(Optional) Display point-to-multipoint LSP to local interfaces switch connections only.
- p2mp-transmit-switch**—(Optional) Display local interface to point-to-multipoint LSP switch connections only.
- remote-interface-switch**—(Optional) Display remote interface switch connections only.
- down | up | up-down**—(Optional) Display nonoperational, operational, or both kinds of connections.
- history**—(Optional) Display information about connection history.
- labels**—(Optional) Display labels used for transmit and receive.
- logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.
- name**—(Optional) Display information about the specified connection only.
- status**—(Optional) Display information about the connection and interface status.

Output Fields

[Table 39 on page 2263](#) describes the output fields for the **show connections** command. Output fields are listed in the approximate order in which they appear.

Table 100: show connections Output Fields

Field Name	Field Description
CCC and TCC connections [Link Monitoring On Off]	Whether link monitoring is enabled: On or Off .
Legend for Status (St)	Connection or circuit status. See the output's legend for an explanation of the status field values.

Table 100: show connections Output Fields (*continued*)

Field Name	Field Description
Legend for connection types	Type of connection: <ul style="list-style-type: none"> • if-sw—Layer 2 switching cross-connect. • rmt-if—Remote interface switch. While graceful restart is in progress, rmt-if will display a state (St) of Restart. • lsp-sw—LSP stitching cross-connect. While graceful restart is in progress, lsp-sw will display a state (St) of Restart.
Legend for circuit types	Type of circuits: <ul style="list-style-type: none"> • intf—Interface circuit. • tlsp—Transmit LSP circuit. • rlsp—Receive LSP circuit.
Connection/Circuit	Name of the configured CCC connection.
Type	Type of connection.
St	State of the connection.
Time last up	Time that the connection or circuit last transitioned to the Up (operational) state.
# Up trans	Number of times that the connection or circuit has transitioned to the Up (operational) state.

Sample Output

show connections

user@switch> **show connections**

```

CCC and TCC connections [Link Monitoring On]
  Legend for status (St)           Legend for connection types
  UN -- uninitialized             if-sw:  interface switching
  NP -- not present               rmt-if: remote interface switching
  WE -- wrong encapsulation       lsp-sw: LSP switching
  DS -- disabled
  Dn -- down
  -> -- only outbound conn is up
  Legend for circuit types
  intf -- interface

```

```
<- -- only inbound conn is up      tlsp -- transmit LSP
Up -- operational                    rlsp -- receive LSP
RmtDn -- remote CCC down
Restart -- restarting
```

CCC Graceful restart : Restarting

Connection/Circuit	Type	St	Time last up	# Up trans
IFSW-ed	if-sw	Up	Aug 5 15:39:15	1

show route ccc

Syntax

```
show route ccc ccc  
<brief | detail | extensive | terse>  
<logical-system (all | logical-system-name)>
```

Release Information

Command introduced before Junos OS Release 7.4.

Description

Display circuit cross-connect (CCC) entries in the Multiprotocol Link Switching (MPLS) routing table.

Options

ccc—Name of an entry with a circuit cross-connect interface.

brief | detail | extensive | terse—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

```

Release Information

Command introduced before Junos OS Release 7.4.

Option **bridge-domain** introduced in Junos OS Release 7.5

Option **learning-vlan-id** introduced in Junos OS Release 8.4

Options **all** and **vlan** introduced in Junos OS Release 9.6.

Command introduced in Junos OS Release 11.3 for the QFX Series.

Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

NOTE: The Routing Engine copies the forwarding table to the Packet Forwarding Engine, the part of the router that is responsible for forwarding packets. To display the entries in the Packet Forwarding Engine's forwarding table, use the **show pfe route** command.

Options

none—Display the routes in the forwarding tables. By default, the **show route forwarding-table** command does not display information about private, or internal, forwarding tables.

detail | extensive | summary—(Optional) Display the specified level of output.

all—(Optional) Display routing table entries for all forwarding tables, including private, or internal, tables.

bridge-domain (**all** | **bridge-domain-name**)—(MX Series routers only) (Optional) Display route entries for all bridge domains or the specified bridge domain.

ccc interface-name—(Optional) Display route entries for the specified circuit cross-connect interface.

destination destination-prefix—(Optional) Destination prefix.

family family—(Optional) Display routing table entries for the specified family: **bridge** (**ccc** | **destination** | **detail** | **extensive** | **interface-name** | **label** | **learning-vlan-id** | **matching** | **multicast** | **summary** | **table** | **vlan** | **vpn**), **ethernet-switching**, **evpn**, **fibre-channel**, **fmembers**, **inet**, **inet6**, **iso**, **mcsnoop-inet**, **mcsnoop-inet6**, **mpls**, **satellite-inet**, **satellite-inet6**, **satellite-vpls**, **tnp**, **unix**, **vpls**, or **vlan-classification**.

interface-name interface-name—(Optional) Display routing table entries for the specified interface.

label name—(Optional) Display route entries for the specified label.

lcc number—(TX Matrix and TX matrix Plus routers only) (Optional) On a routing matrix composed of a TX Matrix router and T640 routers, display information for the specified T640 router (or line-card chassis) connected to the TX Matrix router. On a routing matrix composed of the TX Matrix Plus router and T1600 or T4000 routers, display information for the specified router (line-card chassis) connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

learning-vlan-id learning-vlan-id—(MX Series routers only) (Optional) Display learned information for all VLANs or for the specified VLAN.

matching matching—(Optional) Display routing table entries matching the specified prefix or prefix length.

multicast—(Optional) Display routing table entries for multicast routes.

table —(Optional) Display route entries for all the routing tables in the main routing instance or for the specified routing instance. If your device supports logical systems, you can also display route entries for the specified logical system and routing instance. To view the routing instances on your device, use the **show route instance** command.

vlan (all | vlan-name)—(Optional) Display information for all VLANs or for the specified VLAN.

vpn vpn—(Optional) Display routing table entries for a specified VPN.

Output Fields

[Table 67 on page 2381](#) lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified, or when the **detail** keyword is used instead of the **extensive** keyword.

Table 101: show route forwarding-table Output Fields

Field Name	Field Description	Level of Output
Logical system	Name of the logical system. This field is displayed if you specify the table logical-system-name/routing-instance-name option on a device that is configured for and supports logical systems.	All levels
Routing table	Name of the routing table (for example, inet, inet6, mpls).	All levels

Table 101: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
Enabled protocols		All levels

Table 101: show route forwarding-table Output Fields (continued)

Field Name	Field Description	Level of Output
	<p>The features and protocols that have been enabled for a given routing table. This field can contain the following values:</p> <ul style="list-style-type: none"> • BUM hashing—BUM hashing is enabled. • MAC Stats—Mac Statistics is enabled. • Bridging—Routing instance is a normal layer 2 bridge. • No VLAN—No VLANs are associated with the bridge domain. • All VLANs—The vlan-id all statement has been enabled for this bridge domain. • Single VLAN—Single VLAN ID is associated with the bridge domain. • MAC action drop—New MACs will be dropped when the MAC address limit is reached. • Dual VLAN—Dual VLAN tags are associated with the bridge domain • No local switching—No local switching is enabled for this routing instance.. • Learning disabled—Layer 2 learning is disabled for this routing instance. • MAC limit reached—The maximum number of MAC addresses that was configured for this routing instance has been reached. • VPLS—The VPLS protocol is enabled. • No IRB I2-copy—The no-irb-layer-2-copy feature is enabled for this routing instance. • ACKed by all peers—All peers have acknowledged this routing instance. • BUM Pruning—BUM pruning is enabled on the VPLS instance. • Def BD VXLAN—VXLAN is enabled for the default bridge domain. • EVPN—EVPN protocol is enabled for this routing instance. • Def BD OVSDb—Open vSwitch Database (OVSDb) is enabled on the default bridge domain. • Def BD Ingress replication—VXLAN ingress node replication is enabled on the default bridge domain. • L2 backhaul—Layer 2 backhaul is enabled. • FRR optimize—Fast reroute optimization • MAC pinning—MAC pinning is enabled for this bridge domain. • MAC Aging Timer—The MAC table aging time is set per routing instance. • EVPN VXLAN—This routing instance supports EVPN with VXLAN encapsulation. • PBBN—This routing instance is configured as a provider backbone bridged network. 	

Table 101: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
	<ul style="list-style-type: none"> • PBN—This routing instance is configured as a provider bridge network. • ETREE—The ETREE protocol is enabled on this EVPN routing instance. • ARP/NDP suppression—EVPN ARP NDP suppression is enabled in this routing instance. • Def BD EVPN VXLAN—EVPN VXLAN is enabled for the default bridge domain. • MPLS control word—Control word is enabled for this MPLS routing instance. 	
Address family	Address family (for example, IP , IPv6 , ISO , MPLS , and VPLS).	All levels
Destination	Destination of the route.	detail extensive
Route Type (Type)	<p>How the route was placed into the forwarding table. When the detail keyword is used, the route type might be abbreviated (as shown in parentheses):</p> <ul style="list-style-type: none"> • cloned (clon)—(TCP or multicast only) Cloned route. • destination (dest)—Remote addresses directly reachable through an interface. • destination down (iddn)—Destination route for which the interface is unreachable. • interface cloned (ifcl)—Cloned route for which the interface is unreachable. • route down (ifdn)—Interface route for which the interface is unreachable. • ignore (ignr)—Ignore this route. • interface (intf)—Installed as a result of configuring an interface. • permanent (perm)—Routes installed by the kernel when the routing table is initialized. • user—Routes installed by the routing protocol process or as a result of the configuration. 	All levels
Route Reference (RtRef)	Number of routes to reference.	detail extensive

Table 101: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Flags	<p>Route type flags:</p> <ul style="list-style-type: none"> • none—No flags are enabled. • accounting—Route has accounting enabled. • cached—Cache route. • incoming-iface <i>interface-number</i>—Check against incoming interface. • prefix load balance—Load balancing is enabled for this prefix. • rt nh decoupled—Route has been decoupled from the next hop to the destination. • sent to PFE—Route has been sent to the Packet Forwarding Engine. • static—Static route. 	extensive
Next hop	<p>IP address of the next hop to the destination.</p> <p>NOTE: For static routes that use point-to-point (P2P) outgoing interfaces, the next-hop address is not displayed in the output.</p>	detail extensive
Next hop Type (Type)	<p>Next-hop type. When the detail keyword is used, the next-hop type might be abbreviated (as indicated in parentheses):</p> <ul style="list-style-type: none"> • broadcast (bcst)—Broadcast. • deny—Deny. • discard (dscd)—Discard. • hold—Next hop is waiting to be resolved into a unicast or multicast type. • indexed (idxd)—Indexed next hop. • indirect (indr)—Indirect next hop. • local (loc)—Local address on an interface. • routed multicast (mcrt)—Regular multicast next hop. • multicast (mcst)—Wire multicast next hop (limited to the LAN). • multicast discard (mdsc)—Multicast discard. • multicast group (mgrp)—Multicast group member. • receive (rcv)—Receive. • reject (rjct)—Discard. An ICMP unreachable message was sent. • resolve (rslv)—Resolving the next hop. • unicast (ucst)—Unicast. • unilist (ulst)—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list. 	detail extensive

Table 101: show route forwarding-table Output Fields (*continued*)

Field Name	Field Description	Level of Output
Index	Software index of the next hop that is used to route the traffic for a given prefix.	detail extensive none
Route interface-index	Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.	extensive
Reference (NhRef)	Number of routes that refer to this next hop.	detail extensive none
Next-hop interface (Netif)	Interface used to reach the next hop.	detail extensive none
Weight	Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible (see the Balance field description).	extensive
Balance	Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a router is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.	extensive
RPF interface	List of interfaces from which the prefix can be accepted. Reverse path forwarding (RPF) information is displayed only when rpf-check is configured on the interface.	extensive

show route forwarding-table extensive (RPF)

The next example is based on the following configuration, which enables an RPF check on all routes that are learned from this interface, including the interface route:

```
so-1/1/0 {
  unit 0 {
    family inet {
      rpf-check;
      address 192.0.2.2/30;
    }
  }
}
```

user@host> **show route forwarding-table extensive**

```
Routing table: inet [Index 0]
Internet:
...
...
Destination: 192.0.2.3/32
  Route type: destination
  Route reference: 0                      Route interface-index: 67
  Flags: sent to PFE
  Nexthop: 192.0.2.3
  Next-hop type: broadcast                Index: 328      Reference: 1
  Next-hop interface: so-1/1/0.0
  RPF interface: so-1/1/0.0
```

show route forwarding-table extensive (PIM using point-to-multipoint mode)

user@host> **show route forwarding-table extensive**

```
Destination: 198.51.100.0/24
  Route type: user
  Route reference: 0                      Route interface-index: 335
  Multicast RPF nh index: 0
  P2mpidx: 0
  Flags: cached, check incoming interface , accounting, sent to PFE, rt nh
decoupled
  Next-hop type: indirect                Index: 1048575  Reference: 4
  Nexthop:

Next-hop interface: st0.1, 192.0.2.0

```

show route forwarding-table (dynamic list next hop)

The **show route forwarding table** output shows the two next hop elements for a multihomed EVPN destination.

```
user@host> show route forwarding-table label 299952 extensive
```

```

MPLS:

Destination: 299952
Route type: user
Route reference: 0          Route interface-index: 0
Multicast RPF nh index: 0
P2mpidx: 0
Flags: sent to PFE, rt nh decoupled
Next-hop type: indirect          Index: 1048575  Reference: 2
Nexthop:
Next-hop type: composite          Index: 601      Reference: 2
Next-hop type: indirect          Index: 1048574  Reference: 3
Nexthop: 1.0.0.4
Next-hop type: Push 301632, Push 299776(top) Index: 600 Reference: 2
Load Balance Label: None
Next-hop interface: ge-0/0/1.0
Next-hop type: indirect          Index: 1048577  Reference: 3

clear path-computation-client statistics

Syntax

```
clear path-computation-client statistics  
<pce-id | all>
```

Release Information

Statement introduced in Junos OS Release 12.3.

Statement introduced in Junos OS Release 16.1R3 for QFX Series switches.

Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Clear Path Computation Element (PCE) statistics.

Options

pce-id—(Optional) Clear statistics of the specified PCE.

all—(Optional) Clear statistics of all available PCEs configured on the path computation client (PCC).

Required Privilege Level

clear

RELATED DOCUMENTATION

List of Sample Output

[clear path-computation-client statistics pce-id on page 2664](#)

[clear path-computation-client statistics all on page 2665](#)

Output Fields

When you enter this command, you are not provided feedback on the status of your request.

Sample Output

```
clear path-computation-client statistics pce-id
```

```
user@host> clear path-computation-client statistics pce1
```

clear path-computation-client statistics all

user@host> clear path-computation-client statistics all

request path-computation-client active-pce

Syntax

```
request path-computation-client active-pce pce-id
```

Release Information

Command introduced in Junos OS Release 12.3.

Command introduced in Junos OS Release 16.1R3 for QFX Series switches.

Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Request a new active Path Computation Element (PCE).

Options

pce-id—Unique user defined ID for this PCE.

retry-delegation—Retry label-switched path (LSP) delegation

Required Privilege Level

request

RELATED DOCUMENTATION

| [show path-computation-client active-pce](#) | 2670

Output Fields

This command produces no output. To verify the operation of the command, run the [show path-computation-client active-pce](#) before and after running the **request path-computation-client active-pce** command.

show isis spring sensor info

Syntax

```
show isis spring sensor info
logical-system (all | logical-system-name)
```

Release Information

Command introduced in 19.1R1 on MX Series routers with MPC and MIC interfaces, and PTX series routers.

Description

Displays a list of sensors associated with the label IS-IS route and next hops for segment routing traffic. The command only displays the information related to the sensors and not the traffic statistics.

Options

none— Display the sensor information of an IS-IS SPRING route.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

view

RELATED DOCUMENTATION

Output Fields

[Table 103 on page 2670](#) describes the output fields for the **show path-computation-client active-pce** command. Output fields are listed in the approximate order in which they appear.

Table 103: show path-computation-client active-pce Output Fields

Field Name	Field Description	Level of Output
IP address	IP address of the current active PCE.	All levels
Priority	Active PCE priority.	All levels

Table 103: show path-computation-client active-pce Output Fields (*continued*)

Field Name	Field Description	Level of Output
PCE status	<p>Active PCE state:</p> <ul style="list-style-type: none"> • PCE_STATE_NEW—Initial PCEP session state. • PCE_STATE_RECONNECT—Trying to re-establish TCP connection with the PCEP peer. • PCE_STATE_CONNECTING—Establishing TCP connection with the PCEP peer. • PCE_STATE_CONNECTED—TCP connection established with the PCEP peer. • PCE_STATE_SYNC—Open messages exchanged with the PCEP peer and entering SYNC state. • PCE_STATE_UP—PCEP session established. 	All levels
Session type	<p>Active PCE type:</p> <ul style="list-style-type: none"> • PCE_TYPE_STATELESS—Does not learn LSP state information from PCC. • PCE_TYPE_STATEFUL—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update LSP state. A PCC maintains synchronization with the PCE. • PCE_TYPE_STATEFULACTIVE—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegate control of their LSPs to the PCE. 	All levels
PCE-mastership	<p>PCE mastership state:</p> <ul style="list-style-type: none"> • main—Current active PCE. • backup—Backup PCE. 	All levels
PCRpts	Number of PC report (PCRpt) messages sent by PCC to a stateful PCE to report current state of LSP(s).	All levels
PCUpdates	Number of PC update (PCUpd) messages sent by a PCE to a PCC to update LSP parameters.	All levels
Local Keepalive timer	Keepalive timer used by or for the PCC.	All levels
Local Dead timer	Dead timer used by or for the PCC.	All levels
Remote Keepalive timer	Keepalive timer used by or for the PCE.	All levels

Table 103: show path-computation-client active-pce Output Fields (*continued*)

Field Name	Field Description	Level of Output
Remote Dead timer	Dead timer used by or for the PCE.	All levels
PCErr-recv	Information about type, value, and number of PC Error messages received.	All levels
Max unknown messages	Maximum number of unknown messages received for a PCEP session. Recommended value is 5. If the number of unknown messages received by a PCC or PCE is greater than or equal to the maximum number, the PCEP session is closed.	detail
Keepalives received	Number of Keepalive messages received by a PCC from a PCE.	detail
Keepalives sent	Number of Keepalive messages sent by a PCC to a PCE.	detail
Dead timer	Dead timer used by the current active PCE.	detail
Elapsed as main current	Time (in seconds) the PCE is in the main mastership state.	detail
Elapsed as main total	Time (in seconds) the PCE became main from the last PCCD restart.	detail
Unknown msgs/min rate	Number of unknown messages received per minute.	detail
Session failures	Number of PCEP session failures with the PCE.	detail
Delegation timeout in	Time (in seconds) left for LSP delegation to timeout.	detail
Delegation failures	Number of LSP delegation failures.	detail
Connection down	Time (in seconds) since the PCEP session is down.	detail
PCErr-sent	Information about type, value, and number of PC Error messages sent.	All levels

Syntax

```
show path-computation-client lsp
<extensive>
<p2mp>
```

Release Information

Command introduced in Junos OS Release 17.2R1 on MX Series routers.

extensive and **p2mp** options introduced in Junos OS Release 18.3R1 on MX Series routers.

Description

Display the state of label-switched paths (LSPs) known to the Path Computation Client (PCC).

Options

none—Display information about LSPs known to the PCC.

extensive—(Optional) Display extensive level of output about each known LSP - point-to-point and point-to-multipoint LSPs.

p2mp—(Optional) Display information about known point-to-multipoint Path Computation Element (PCE)-initiated LSPs.

Output Fields

[Table 104 on page 2676](#) describes the output fields for the **show path-computation-client lsp** command. Output fields are listed in the approximate order in which they appear.

Table 104: show path-computation-client lsp Output Fields

Field Name	Field Description
LSP Name	Name of the LSP.
Status	LSP status: <ul style="list-style-type: none"> • Primary(Act)—Primary LSP. • Bypass—PCE-initiated bypass LSP.
PLSP-Id	PCEP-specific unique identifier for each LSP. The ID is created by the PCC for the lifetime of a PCEP session.
LSP-Type	Type of LSP: <ul style="list-style-type: none"> • External provisioned • Local
Controller	Name of the external path computing entity.
Path-Setup-Type	Protocol used to set up the LSP: <ul style="list-style-type: none"> • RSVP-TE • SPRING-TE
Template	Name of template used.
P2MP name	Name of the point-to-multipoint tree that includes the sub-LSPs of the PCE-initiated LSP.
P2MP Branch Name	Name of the branch sub-LSP that makes up the point-to-multipoint tree of the PCE-initiated LSP.
PathName	Name of LSP path.
From	Ingress IP address of LSP.
To	Egress IP address of LSP.
State	LSP state: up, down.
Active Path	Name of active path.
Link Protection	LSP Link protection.

Table 104: show path-computation-client lsp Output Fields (*continued*)

Field Name	Field Description
P2mp tree	Name of the point-to-multipoint tree that includes the sub-LSPs of the PCE-initiated LSP.
Path cspf status	CSPF computation done by an external controller or local router.
LSP-ID	LSP identifier.
RSVP Error	RSVP error ID.
Priorities	Setup and hold priorities.
Bandwidth	LSP bandwidth.
Requested AutoBw	Requested bandwidth to controller for auto-bandwidth.
Controller	Name of external controller.
Record Route	LSP record route object.
From PCE ERO (received)	Explicit Route Object (ERO) received by controller from the routing protocol process.
From RPD ERO (reported)	ERO reported from the routing protocol process.
Configured ERO on PCC	ERO configured on router.
PCE Traffic Steering	MVPN flow specification capability.
FS-ID	Flow specification ID.
Route Distinguisher	Route Distinguisher of MVPN instance.
Source Prefix	Matching source address of MVPN flow specification.
Multicast Group Prefix	Matching group address of MVPN flow specification.
State	Flow specification state of specific flow specification ID.
Last Rpt/Pcreqest received from RPD at	Time the last PC report or PE request message was received.
Last Update sent to PCE at	Time the last update was sent to PCE.

Table 104: show path-computation-client lsp Output Fields (*continued*)

Field Name	Field Description
Last PcUpdate/PcCreate received from PCE at	Time the last PC update message was received from the controller.
Last error sent to PCE at	Time the last PC error was sent to the controller.
Last 5 reasons to send Report/Pcrequest	<ul style="list-style-type: none"> • Reconfig • Down • Get_info • Up • Active

Release Information

Command introduced in Junos OS Release 12.3.

Command introduced in Junos OS Release 16.1R3 for QFX Series switches.

Command introduced in Junos OS Release 17.1R1 for ACX Series routers.

Description

Display statistics about the Path Computation Element (PCE).

Options

none—Display statistics about the primary PCE.

brief | detail—(Optional) Display the specific level of output.

all—(Optional) Display the statistics about all PCEs configured on the PCC.

Required Privilege Level

Output Fields

[Table 105 on page 2682](#) describes the output fields for the **show path-computation-client statistics** command. Output fields are listed in the approximate order in which they appear.

Table 105: show path-computation-client statistics Output Fields

Field Name	Field Description	Level of Output
IP address	IP address of the PCE.	All levels
Priority	PCE priority.	All levels
PCE status	PCE state: <ul style="list-style-type: none"> • PCE_STATE_NEW—Initial PCEP session state. • PCE_STATE_RECONNECT—Trying to re-establish TCP connection with the PCEP peer. • PCE_STATE_CONNECTING—Establishing TCP connection with the PCEP peer. • PCE_STATE_CONNECTED—TCP connection established with the PCEP peer. • PCE_STATE_SYNC—Open messages exchanged with the PCEP peer and entering SYNC state. • PCE_STATE_UP—PCEP session established. 	All levels
Session type	Active PCE type: <ul style="list-style-type: none"> • PCE_TYPE_STATELESS—Does not learn LSP state information from PCC. • PCE_TYPE_STATEFUL—Uses LSP state information learned from PCCs to optimize path computations, but does not actively update LSP state. A PCC maintains synchronization with the PCE. • PCE_TYPE_STATEFULACTIVE—Uses LSP state information learned from PCCs to optimize path computations, and actively updates LSP parameters in those PCCs that delegate control of their LSPs to the PCE. 	All levels
PCE-mastership	PCE mastership state: <ul style="list-style-type: none"> • main • primary • backup 	All levels

Table 105: show path-computation-client statistics Output Fields (*continued*)

Field Name	Field Description	Level of Output
PCRpts	Number of PC report (PCRpt) messages sent by PCC to a stateful PCE to report current state of LSP(s).	All levels
PCUpdates	Number of PC update (PCUpd) messages sent by a PCE to a PCC to update LSP parameters.	All levels
Local Keepalive timer	Keepalive timer used by or for the PCC.	All levels
Local Dead timer	Dead timer used by or for the PCC.	All levels
Remote Keepalive timer	Keepalive timer used by or for the PCE.	All levels
Remote Dead timer	Dead timer used by or for the PCE.	All levels
PCErr-recv	Information about type, value, and number of PC Error messages received.	All levels
PCErr-sent	Information about type, value, and number of PC Error messages sent.	All levels
Max unknown messages	Maximum number of unknown messages received for a PCEP session. Recommended value is 5. If the number of unknown messages received by a PCC or PCE is greater than or equal to the maximum number, the PCEP session is closed.	detail
Keepalives received	Number of Keepalive messages received by a PCC from a PCE.	detail
Keepalives sent	Number of Keepalive messages sent by a PCC to a PCE.	detail
Elapsed as main current	Time (in seconds) the PCE is in the main mastership state.	detail
Elapsed as main total	Time (in seconds) the PCE became main from the last PCCD restart.	detail

Table 105: show path-computation-client statistics Output Fields (*continued*)

Field Name	Field Description	Level of Output
Unknown msgs/min rate	Number of unknown messages received per minute.	detail
Session failures	Number of PCEP session failures with the PCE.	detail
Delegation timeout in	Time (in seconds) left for LSP delegation to timeout.	detail
Delegation failures	Number of LSP delegation failures.	detail
Connection down	Time (in seconds) since the PCEP session is down.	detail
Local IP address	IP address of the PCC.	detail
LSP provisioning allowed	LSP provisioning capability.	detail
P2MP LSP report allowed	Report capability of point-to-multipoint LSP.	detail
P2MP LSP update allowed	Update capability of point-to-multipoint LSP.	detail
P2MP LSP init allowed	Initiate capability of point-to-multipoint LSP.	detail
PCE Traffic Steering	Traffic steering capability of the PCE.	detail

show path-computation-client status

Syntax

```
show path-computation-client status  
<extensive>
```

Release Information

Command introduced in Junos OS Release 17.2R1 on MX Series routers.

extensive option introduced in Junos OS Release 18.3R1 on MX Series routers.

Description

Display the status of the Path Computation Client (PCC).

Options

none—Display the status of the PCC.

extensive—(Optional) Display extensive information about the PCC including point-to-point and point-to-multipoint PCE-initiated LSPs.

For point-to-multipoint PCE-initiated LSPs, the extensive output displays the point-to-multipoint LSP tree and branches separately for a PCEP session.

[Table 106 on page 2690](#) describes the output fields for the **show path-computation-client status** command. Output fields are listed in the approximate order in which they appear.

Table 106: show path-computation-client status Output Fields

Field Name	Field Description
Session	Name of the PCE with which the PCEP session is established.
Type	Type of PCE.
Provisioning	Provisioning status of the PCE.
Status	PCEP session status.
Total number of LSPs	Number of LSPs in total.
Static LSPs	Status of point-to-point and point-to-multipoint static LSPs.
Externally controlled LSPs	Status of point-to-point and point-to-multipoint LSPs that are controlled by a PCE.
Externally provisioned LSPs	Status of point-to-point and point-to-multipoint LSPs that are provisioned by a PCE.
Orphaned LSPs	Status of LSPs that are in the orphaned state because of PCEP session failure.
Delegated	Status of point-to-point and point-to-multipoint LSPs that are delegated to the PCE by the PCC.

Sample Output

Output Fields

Table 107 on page 2693 describes the output fields for the **show spring-traffic-engineering** command. Output fields are listed in the approximate order in which they appear.

Table 107: show spring-traffic-engineering Output Fields

Field Name	Field Description
To	IP address of the SR-TE LSP destination.
State	State of the SR-TE LSP: <ul style="list-style-type: none"> • Up • Down
LSP Name	Name of the SR-TE LSP.
S-ERO	Source Explicit Route Object (ERO), or LSP path.
Bandwidth	Bandwidth allocated for the SR-TE LSP.
Delegation info	LSP control and routing status: <ul style="list-style-type: none"> • Control-status: <ul style="list-style-type: none"> • Externally controlled—PCE has control of the source-routing-path. This can happen when: <ul style="list-style-type: none"> • The lsp-external-controller pccd statement is configured either under the source-routing-path or under the primary segment list. • The request path-computation-client retry-delegation lsp-name command is issued for a delegated LSP which was not previously controlled by the PCE. • Locally controlled—PCC has control of the source-routing-path. This can happen when: <ul style="list-style-type: none"> • The PCE has returned the control of the source-routing-path. • Delegation timer with the PCE has expired. • Routing-status: Applicable to delegated source-routing-paths only. <ul style="list-style-type: none"> • Externally routed—PCE provided the ERO for the source-routing-path for a delegated LSP through PCUpdate. • Locally routed—PCE does not provide ERO for the source-routing-path.
Route preference	Route preference of the SR-TE LSP.
Number of LSPs	Statistics of the total number of SR-TE LSPs and the LSP state.

Table 107: show spring-traffic-engineering Output Fields (continued)

Field Name	Field Description
External controllers	Name of the LSP external controller. By default the only supported external controller is pccd .
BFD name	Name of the BFD session. The name is auto-generated in the V4-srte_bfd_session-id for IPv6. The name is based on the Explicit Route Object (ERO) stack of the LSP path, that is, if multiple LSPs have same path they share the same BFD session name.
BFD status	Status of the BFD session: UP, DOWN.
Referencing LSPs	Name of referencing LSP. If the LSP does not have a path name, then the referencing LSP is displayed as unnamed path .
SR-ERO hop count	Number of hops in the segment routing ERO.
Hop 1	Represents the path of the BFD session. If any other LSP is on same path, it has the same BFD session.
Total displayed BFD sessions	Total count of all the BFD sessions.
Tunnel source	Source of the tunnel configuration; for example, static configuration .
Ingress telemetry statistics	Ingress telemetry statistics including the sensor name and ID.
Transit telemetry statistics	Transit telemetry statistics including the sensor name and ID.
